

Pathwidth, trees, and random embeddings

James R. Lee[†]

Anastasios Sidiropoulos[‡]

Abstract

We prove that, for every integer $k \geq 1$, every shortest-path metric on a graph of pathwidth k embeds into a distribution over random trees with distortion at most $c = c(k)$, independent of the graph size. A well-known conjecture of Gupta, Newman, Rabinovich, and Sinclair [GNRS04] states that for every minor-closed family of graphs \mathcal{F} , there is a constant $c(\mathcal{F})$ such that the multi-commodity max-flow/min-cut gap for every flow instance on a graph from \mathcal{F} is at most $c(\mathcal{F})$. The preceding embedding theorem is used to prove this conjecture whenever the family \mathcal{F} does not contain all trees.

1 Introduction

We view an undirected graph $G = (V, E)$ as a topological template that supports a number of different geometries. Such a geometry is specified by a non-negative length function $\text{len} : E \rightarrow [0, \infty)$ on edges, which induces a shortest-path pseudometric d_{len} on V , with

$$d_{\text{len}}(u, v) = \text{length of the shortest path between } u \text{ and } v \text{ in } G,$$

where a pseudometric might have $d_{\text{len}}(u, v) = 0$ for some pairs $u, v \in V$ with $u \neq v$. A pseudometric d is *supported on* G if $d = d_{\text{len}}$ for some such $\text{len} : E \rightarrow [0, \infty)$. From this point of view, we are interested in properties which hold simultaneously for all geometries supported on G , or even for all geometries supported on a family of graphs \mathcal{F} . In what follows, we will deal exclusively with *finite* graphs and families of finite graphs unless explicitly stated otherwise.

In the seminal works of Linial-London-Rabinovich [LLR95] and Aumann-Rabani [AR98], and later Gupta-Newman-Rabinovich-Sinclair [GNRS04], the geometry of graphs is related to the classical study of the relationship between flows and cuts.

Multi-commodity flows and L_1 embeddings. For a metric space (X, d) , we use $c_1(X, d)$ to denote the L_1 *distortion* of (X, d) , i.e. the infimum over all numbers D such that X admits an embedding $f : X \rightarrow L_1$ with

$$d(x, y) \leq \|f(x) - f(y)\|_1 \leq D \cdot d(x, y)$$

for all $x, y \in X$. Here, we have $L_1 = L_1([0, 1])$, which can be replaced by the sequence space ℓ_1 when X is finite.

*A portion of the results in this paper were announced at the 41st Annual Symposium on the Theory of Computing [LS09].

Corresponding to the preceding discussion, for a graph $G = (V, E)$ we write $c_1(G) = \sup c_1(V, d)$ where d ranges over all metrics supported on G . For a family \mathcal{F} of graphs, we write $c_1(\mathcal{F}) = \sup_{G \in \mathcal{F}} c_1(G)$. Thus for a family \mathcal{F} of finite graphs, $c_1(\mathcal{F}) \leq D$ if and only if every geometry supported on a graph in \mathcal{F} embeds into L_1 with distortion at most D .

A *multi-commodity flow instance in G* is specified by a pair of non-negative mappings $\text{cap} : E \rightarrow \mathbb{R}$ and $\text{dem} : V \times V \rightarrow \mathbb{R}$. We write $\text{maxflow}(G; \text{cap}, \text{dem})$ for the value of the *maximum concurrent flow* in this instance, which is the maximal value ε such that a flow of value $\varepsilon \cdot \text{dem}(u, v)$ can be simultaneously routed between every pair $u, v \in V$ while not violating the given edge capacities.

A natural upper bound on $\text{maxflow}(G; \text{cap}, \text{dem})$ is given by the *sparsity* of any cut $S \subseteq V$:

$$\Phi(S; \text{cap}, \text{dem}) = \frac{\sum_{uv \in E} \text{cap}(u, v) |\mathbf{1}_S(u) - \mathbf{1}_S(v)|}{\sum_{u, v \in V} \text{dem}(u, v) |\mathbf{1}_S(u) - \mathbf{1}_S(v)|}, \quad (1)$$

where $\mathbf{1}_S : V \rightarrow \{0, 1\}$ is the indicator function for membership in S . In the case where $\text{dem}(u, v) > 0$ for exactly one pair u, v , also known as *single-commodity flow* [FF56], minimizing the upper bound (1) over all cuts $S \subseteq V$ computes the minimum u - v cut in G , and the max-flow/min-cut theorem states that this upper bound is achieved by the corresponding maximum flow.

In general, we write

$$\text{gap}(G) = \sup_{\text{cap}, \text{dem}} \frac{\min_{S \subseteq V} \Phi(S; \text{cap}, \text{dem})}{\text{maxflow}(G; \text{cap}, \text{dem})}.$$

for the maximum ratio between the best upper bound given by (1) and the value of the flow, over all multi-commodity flow instances on G . This is the *multi-commodity max-flow/min-cut gap* for G . Now we can state the fundamental relationship between the geometry of graphs and the flows they support:

Theorem 1.1 ([LLR95, GNRS04]). *For every graph G , $c_1(G) = \text{gap}(G)$.*

In the general Sparsest Cut problem (also known as Sparsest Cut with general demands), given G , cap , and dem , we want to find a cut in G of minimum sparsity. Combined with the techniques of [LR99, LLR95], Theorem 1.1 implies that there exists a $c_1(G)$ -approximation for the general Sparsest Cut problem on a graph G . Motivated by this connection, Gupta, Newman, Rabinovich, and Sinclair sought to *characterize* the graph families \mathcal{F} such that $c_1(\mathcal{F}) < \infty$, and they posed the following conjecture. We will say that a family of graphs \mathcal{F} *forbids some minor* if there exists a graph G that is not a minor of any graph in \mathcal{F} .

Conjecture 1 ([GNRS04]). *For every family of finite graphs \mathcal{F} , one has $c_1(\mathcal{F}) < \infty$ if and only if \mathcal{F} forbids some minor.*

We refer to Section 1.3 for a review of graph minors. Progress on the preceding conjecture has been limited. Classical work of Okamura and Seymour [OS81] implies that $c_1(\text{Outerplanar}) = 1$, where *Outerplanar* denotes the class of outerplanar graphs (planar graphs where all vertices lie on a single face). Gupta, Newman, Rabinovich, and Sinclair [GNRS04] proved that $c_1(\text{Treewidth}(2)) = O(1)$, where *Treewidth*(k) denotes the family of all graphs of treewidth at most k (see, e.g. [Die05] for a discussion of treewidth, or Section 1.3 for the relevant definitions). This was improved to $c_1(\text{Treewidth}(2)) = 2$ in [LR10, CJLV08]. Finally, in [CGN⁺06], it is shown that $c_1(\text{Outerplanar}(k)) < 2^{O(k)}$ for all $k \in \mathbb{N}$, where *Outerplanar*(k) denotes the class of k -outerplanar graphs. We remark that a strengthening of Conjecture 1, regarding integer multi-commodity flows, has been investigated by Chekuri, Shepherd, and Weibel [CSW10]. The present paper is devoted to proving the following special case of Conjecture 1.

Theorem 1.2. *Every minor-closed family of finite graphs \mathcal{F} which does not contain every possible tree satisfies $c_1(\mathcal{F}) < \infty$. Equivalently, the multi-commodity max-flow/min-cut gap for \mathcal{F} is uniformly bounded, i.e. $\text{gap}(\mathcal{F}) < \infty$, whenever \mathcal{F} has bounded pathwidth.*

We remark that Theorem 1.2 implies a polynomial-time $O(1)$ -approximation algorithm for the general Sparsest Cut problem on graphs of bounded pathwidth. Recently, an $O(1)$ -approximation algorithm for graphs of bounded treewidth has been obtained by Chlamtac, Krauthgamer, and Raghavendra [CKR10]. We also note that [CKR10] uses a different approach, and does not establish an analogous bound on the multi-commodity max-flow/min-cut gap for graphs of bounded treewidth (which remains an important open problem).

1.1 Simplifying the topology with random embeddings

A basic question is whether one can embed a graph metric G into a graph metric H with a simpler topology (for example, perhaps G is planar and H is a tree), where the embedding is required to have small distortion, i.e. such that every pairwise distance changes by only a bounded amount. The viability of this approach as a general method was ruled out by Rabinovich and Raz [RR98]. For instance, $\Omega(n)$ distortion is required to embed an n -cycle into a tree. In general (see [CG04]), if all metrics supported on a subdivision of some graph G can be embedded with distortion $O(1)$ into metrics supported on a family \mathcal{F} , then G is a minor of some graph in \mathcal{F} , implying that we have not obtained a reduction in topological complexity.

On the other hand, a classical example attributed to Karp [Kar89] shows that random reductions might still be effective: If one removes a uniformly random edge from the n -cycle, this gives an embedding into a random tree which has distortion at most 2 “in expectation.” More formally, if (X, d) is any finite metric space, and \mathcal{Y} is a family of finite metric spaces, we say that (X, d) *admits a stochastic D -embedding into \mathcal{Y}* if there exists a randomly chosen metric space $(Y, d_Y) \in \mathcal{Y}$ and a randomly chosen mapping $F : X \rightarrow Y$ such that the following two properties hold.

Non-contracting. With probability one, for every $x, y \in X$, we have $d_Y(F(x), F(y)) \geq d(x, y)$.

Low-expansion. For every $x, y \in X$,

$$\mathbb{E} \left[d_Y(F(x), F(y)) \right] \leq D \cdot d(x, y).$$

For two graph families \mathcal{F} and \mathcal{G} , we write $\mathcal{F} \rightsquigarrow \mathcal{G}$ if there exists a $D < \infty$ such that every metric supported on \mathcal{F} admits a stochastic D -embedding into the family of metrics supported on \mathcal{G} . We will write $\mathcal{F} \overset{D}{\rightsquigarrow} \mathcal{G}$ if we wish to emphasize the particular constant. Finally, we write $\mathcal{F} \not\rightsquigarrow \mathcal{G}$ if no such D exists. The relationship with Conjecture 1 is given by the following simple lemma (see, e.g. [GNRS04]).

Lemma 1.3. *If $\mathcal{F} \overset{D}{\rightsquigarrow} \mathcal{G}$, then $c_1(\mathcal{F}) \leq D \cdot c_1(\mathcal{G})$.*

At first glance, \rightsquigarrow seems like a powerful operation; indeed, in [GNRS04] it is proved that $\text{OuterPlanar} \rightsquigarrow \text{Trees}$, where OuterPlanar and Trees are the families of outerplanar graphs and connected, acyclic graphs, respectively. In general, if L is a finite list of graphs, we will write $\mathcal{E}L$ for the family of all graphs which do not have a member of L as a minor. The preceding result can be restated as $\mathcal{E}\{K_{2,3}\} \rightsquigarrow \mathcal{E}\{K_3\}$, where K_n and $K_{m,n}$ denote the complete and complete

bipartite graphs, respectively. Unfortunately, [GNRS04] also showed that this cannot be pushed much further: $\mathcal{E}\{K_4\} \not\rightsquigarrow \mathcal{E}\{K_3\}$. Restated, this means that even graphs of treewidth 2 cannot be stochastically embedded into trees.

These lower bounds were extended in [CG04] to show that $\text{Treewidth}(k+3) \not\rightsquigarrow \text{Treewidth}(k)$ for any $k \geq 1$. Finally, in [CJLV08], these results are extended to any family with a weak closure property, which we describe next.

Sums of graphs. We now introduce a graph operation which will be useful in stating our results. Suppose that H and G are two graphs and C_H, C_G are k -cliques in H and G respectively, for some $k \geq 1$. One defines the k -sum of H and G as the graph $H \oplus_k G$ which results from taking the disjoint union of H and G and then identifying the two cliques C_H and C_G , and possibly removing a subset of the clique edges. We remark that the notation is somewhat ambiguous, as both the cliques and their identifications are implicit. For a family of graphs \mathcal{F} , we write $\oplus_k \mathcal{F}$ for the closure of \mathcal{F} under i -sums for every $i = 1, 2, \dots, k$. With this notation in hand, we can state the following theorem.

Theorem 1.4 ([CJLV08]). *If \mathcal{F} and \mathcal{G} are families of graphs and \mathcal{G} is minor-closed, then $\oplus_2 \mathcal{F} \rightsquigarrow \mathcal{G}$ implies $\mathcal{F} \subseteq \mathcal{G}$.*

In fact, one case of this theorem relies on Theorem 1.7 proved in the present paper, which states that for every $k = 1, 2, \dots$, we have $\text{Trees} \cap \text{Pathwidth}(k+1) \not\rightsquigarrow \text{Pathwidth}(k)$, where $\text{Pathwidth}(k)$ denotes the class of pathwidth- k graphs (see Section 1.3 for the relevant definitions).

Theorem 1.4 implies, for example, that $\text{Planar} \cap \text{Treewidth}(k+1) \not\rightsquigarrow \text{Treewidth}(k)$ for any $k \geq 1$, where Planar is the family of planar graphs, since planar graphs and bounded treewidth graphs are both closed under 2-sums. The assumptions of the preceding theorem imply that even random embeddings are not particularly useful for reducing the topology when $\oplus_2 \mathcal{F} = \mathcal{F}$. However, some recent reductions suggest that when $\oplus_2 \mathcal{F} \neq \mathcal{F}$, the situation is more hopeful.

In [CGN⁺06], it is proved that $\text{Outerplanar}(k) \rightsquigarrow \text{Trees}$. Perhaps more surprisingly, it is shown in [IS07] that $\text{Genus}(g) \rightsquigarrow \text{Planar}$, where $\text{Genus}(g)$ is the family of graphs embedded on an orientable surface of genus g , and $\text{Genus}(0) = \text{Planar}$. Note that while trees and planar graphs are closed under 2-sums, neither $\text{Outerplanar}(k)$ nor $\text{Genus}(g)$ are for $k \geq 1$ and $g \geq 1$.

It should be noted that an extensive amount of work has been done on embedding finite metric spaces into distributions over trees, where the distortion is allowed to depend on n , the number of points in the metric space; see, e.g. [Bar96, Bar98, FRT04]. These results are not particularly useful for us since we desire bounds that are independent of n .

1.2 Results and techniques

We now discuss the main results of the paper, along with the techniques that go into proving them.

In [GNRS04], it is proved that $c_1(\text{Treewidth}(2)) < \infty$, and later works [LR10, CJLV08] nailed down the precise dependence $c_1(\text{Treewidth}(2)) = 2$. Resolving whether $c_1(\text{Treewidth}(3))$ is finite seems quite difficult, and is a well-known open problem. In fact, perhaps the simplest “width 3” problem (which was open until the present work) involves the family $\text{Pathwidth}(3)$ (recall that $\text{Pathwidth}(k) \subseteq \text{Treewidth}(k)$ denotes the family of graphs of pathwidth at most k ; see Section 1.3). These families are fundamental in the graph minor theory (see e.g. [RS83, Lov06]); see Lemma 1.9 for an inductive definition.

Our main technical theorem shows that graphs of bounded pathwidth can be randomly embedded into trees. In fact, the theorem shows something slightly stronger, that the target trees themselves can be taken to have bounded pathwidth.

Theorem 1.5. *For every $k \in \mathbb{N}$, $\text{Pathwidth}(k) \rightsquigarrow \text{Trees} \cap \text{Pathwidth}(k)$. Quantitatively,*

$$\text{Pathwidth}(k) \stackrel{D}{\rightsquigarrow} \text{Trees} \cap \text{Pathwidth}(k),$$

for some $D \leq (4k)^{k^3+1}$.

In particular, this verifies Conjecture 1 for graphs of bounded pathwidth. The quantitative bound of Theorem 1.5 is likely far from tight. Naively, one might hope that for $D \leq O(\log k)$, one has $\text{Pathwidth}(k) \stackrel{D}{\rightsquigarrow} \text{Trees}$. But, in fact, known results imply that the distortion must satisfy $D \geq \Omega(k)$. The k -th level diamond graph (see [GNRS04]) has pathwidth $O(k)$ but it is shown in [GNRS04] that every stochastic embedding of this graph into a distribution over trees incurs distortion $\Omega(k)$.

Robertson and Seymour [RS83] showed that a minor-closed family \mathcal{F} excludes a forest if and only if $\mathcal{F} \subseteq \text{Pathwidth}(k)$ for some $k \in \mathbb{N}$.

Corollary 1.6. *If T is any tree, then $\mathcal{E}\{T\} \rightsquigarrow \text{Trees}$.*

As a consequence of this, together with Lemma 1.3, and the elementary fact that $c_1(\text{Trees}) = 1$, we resolve Conjecture 1 whenever \mathcal{F} forbids some tree, yielding Theorem 1.2. We remark that Theorem 1.2 was unknown even for $\mathcal{F} = \text{Pathwidth}(3)$.

In Section 4, we complement our upper bound by proving the following theorem.

Theorem 1.7. *For every $k \in \mathbb{N}$, $\text{Pathwidth}(k+1) \cap \text{Trees} \not\rightsquigarrow \text{Pathwidth}(k)$.*

This result serves two purposes. First, it shows that our proof of Theorem 1.5, which embeds $\text{Pathwidth}(k)$ directly into trees cannot proceed by inductively reducing the pathwidth by one. Secondly, it is needed in the proof of Theorem 1.4 in the case when \mathcal{F} contains only trees (the techniques of [CJLV08] handle the case when \mathcal{F} contains at least one cycle). We remark that, perhaps surprisingly, the proof our non-embeddability result (Theorem 1.7) uses our embedding result (Theorem 1.5).

1.3 Preliminaries

We now review some basic definitions and notions which appear throughout the paper.

Graphs and metrics. We deal exclusively with finite graphs $G = (V, E)$ which are free of loops and parallel edges. We will also write $V(G)$ and $E(G)$ for the vertex and edge sets of G , respectively. A *metric graph* is a graph G equipped with a non-negative length function on edges $\text{len} : E \rightarrow \mathbb{R}_+$. We will denote the pseudometric space associated with a graph G as (V, d_G) , where d_G is the shortest path metric according to the edge lengths. Note that $d_G(x, y) = 0$ may occur even when $x \neq y$, and also if G is disconnected, there will be pairs $x, y \in V$ with $d_G(x, y) = \infty$. We allow both possibilities throughout the paper. An important point is that *all length functions in the paper are assumed to be reduced*, i.e. they satisfy the property that for every $e = (u, v) \in E$, $\text{len}(e) = d_G(u, v)$.

Given a metric graph G , we extend the length function to paths $P \subseteq E$ by setting $\text{len}(P) = \sum_{e \in P} \text{len}(e)$. For a pair of vertices $a, b \in P$, we use the notation $P[a, b]$ to denote the sub-path

of P from a to b . We recall that for a subset $S \subseteq V$, $G[S]$ represents the induced graph on S . For a pair of subsets $S, T \subseteq V$, we use the notations $E(S, T) = \{(u, v) \in E : u \in S, v \in T\}$ and $E(S) = E(S, S)$. For a vertex $u \in V$, we write $N(u) = \{v \in V : (u, v) \in E\}$.

Graph minors. If H and G are two graphs, one says that H is a *minor* of G if H can be obtained from G by a sequence of zero or more of the three operations: edge deletion, vertex deletion, and edge contraction. G is said to be *H -minor-free* if H is not a minor of G . We refer to [Lov06, Die05] for a more extensive discussion of the vast graph minor theory.

Equivalently, H is a minor of G if there exists a collection of disjoint sets $\{A_v\}_{v \in V(H)}$ with $A_v \subseteq V(G)$ for each $v \in V(H)$, such that each A_v is connected in G , and there is an edge between A_u and A_v whenever $(u, v) \in E(H)$. A metric space (X, d) is said to be *H -minor-free* if it is supported on some H -minor-free graph.

Treewidth. The notion of *treewidth* involves a representation of a graph as a tree, called a tree decomposition. More precisely, a *tree decomposition* of a graph $G = (V, E)$ is a pair (T, χ) in which $T = (I, F)$ is a tree and $\chi = \{\chi_i \mid i \in I\}$ is a family of subsets of $V(G)$ such that (1) $\bigcup_{i \in I} \chi_i = V$; (2) for each edge $e = \{u, v\} \in E$, there exists an $i \in I$ such that both u and v belong to χ_i ; and (3) for all $v \in V$, the set of nodes $\{i \in I \mid v \in \chi_i\}$ forms a connected subtree of T . To distinguish between vertices of the original graph G and vertices of T in the tree decomposition, we call vertices of T *nodes* and their corresponding χ_i 's *bags*. The maximum size of a bag in χ minus one is called the *width* of the tree decomposition. The *treewidth* of a graph G is the minimum width over all possible tree decompositions of G .

Pathwidth. A tree decomposition is called a *path decomposition* if $T = (I, F)$ is a path. The *pathwidth* of a graph G is the minimum width over all possible path decompositions of G . We will use the following alternate characterization.

Definition 1.8 (Linear composition sequence). *Let k be a positive integer. A sequence of pairs $(G_0, V_0), (G_1, V_1), \dots, (G_t, V_t)$ is a linear width- k composition sequence for G if $G_t = G$, G_0 is a k -clique with vertex set V_0 , and (G_{i+1}, V_{i+1}) arises from (G_i, V_i) as follows: Attach a new vertex v_{i+1} to all the vertices of V_i and choose $V_{i+1} \subseteq V_i \cup \{v_{i+1}\}$ so that $|V_{i+1}| = k$. Observe that it is possible to have $V_{i+1} = V_i$. We further note that for any $j \in \{1, \dots, t\}$, we have $V(G_j) = V_0 \cup \{v_1, \dots, v_j\}$.*

The following lemma is straightforward to prove.

Lemma 1.9. *A graph has pathwidth- k if and only if it is a subgraph of some graph possessing a linear width- k composition sequence.*

Proof sketch. A path decomposition of width k can be obtained from a width- k composition sequence $(G_0, V_0), \dots, (G_t, V_t)$ by setting for every $i \in \{1, \dots, t\}$, the i -th bag to be $V_{i-1} \cup \{v_i\}$. For the other direction, one can always assume that a pathwidth- k graph admits a path decomposition of width k such that every bag has size exactly $k + 1$, and every two bags differ in exactly one vertex. This immediately yields a linear width- k composition sequence. \square

Asymptotic notation. For two expressions E and F , we sometimes use the notation $E \lesssim F$ to denote $E = O(F)$. We use $E \approx F$ to denote the conjunction of $E \lesssim F$ and $E \gtrsim F$.

2 Warm-up: Embedding pathwidth-2 graphs into trees

In this section, we prove that $\text{Pathwidth}(2) \rightsquigarrow \text{Trees}$, as a warmup for the general case in Section 3. The pathwidth-2 case does not possess many of the difficulties of the general case; in particular, it does not require us to bound the stretch in multiple phases (for which we introduce a rank parameter in the next section). But it does show the importance of using an inflation factor to blowup small edges, in order for a certain geometric sum to converge.

Let $G = (V, E)$ be a metric graph of pathwidth 2. By Lemma 1.9, it suffices to give a probabilistic embedding for a graph G possessing a linear width-2 composition sequence $(G_0, e_0), \dots, (G_t, e_t)$, where e_i plays the role of V_i in Definition 1.8. We will inductively embed G into a distribution over its spanning trees. First, we put $T_0 = e_0$. Now, let T_i be a spanning tree of G_i , with $e_i \in E(T_i)$. We will produce a random spanning tree T_{i+1} of G_{i+1} with $e_{i+1} \in E(T_{i+1})$ as follows. Let $e_i = \{u, v\}$, and let w^* be the newly attached vertex. We also add the edges $\{u, w^*\}$, and $\{v, w^*\}$, so the resulting graph is not a tree. We obtain a tree by randomly deleting either $\{u, w^*\}$, or $\{v, w^*\}$ as follows. Let $\tau = 12$; we refer to this constant as an ‘‘inflation factor.’’

There are two cases.

1. If $e_i = e_{i+1}$, we delete $\{u, w^*\}$ with probability $\frac{\text{len}(u, w^*)}{\text{len}(u, w^*) + \text{len}(v, w^*)}$, and otherwise we delete $\{w^*, v\}$.
2. If $e_i \neq e_{i+1}$, assume (without loss of generality) that $e_{i+1} = \{v, w^*\}$. In that case, we delete $\{u, w^*\}$ with probability

$$\min \left\{ \frac{\tau \text{len}(u, w^*)}{\text{len}(u, w^*) + \text{len}(u, v)}, 1 \right\}, \quad (2)$$

and otherwise we delete $\{u, v\}$.

It is easy to see that if T_i was a spanning tree, then so is T_{i+1} . Furthermore, by construction $e_{i+1} \in E(T_{i+1})$. Let $T = T_t$ be the final tree, and set $T_i = T$ for $i > t$. It remains to bound the expected stretch in T .

For every edge $\{x, y\} \in E(G_i)$ and $i \geq 0$, define the value,

$$K_i^{x,y} = \max \left\{ \mathbb{E} \left[\frac{d_T(x, y)}{d_{T_i}(x, y)} \mid T_i = \Gamma \right] : \mathbb{P}(T_i = \Gamma) > 0 \right\}.$$

This is the maximum expected stretch between x and y incurred over all stages later than i , conditioned on the worst possible configuration for T_i .

For each $x \in V$, define $s(x) = -1$ for $x \in V(G_0)$, and otherwise it is the unique value $s \geq 0$ such that $x \in V(G_{s+1}) \setminus V(G_s)$. Also define $s(x, y) = \max(s(x), s(y))$. The next two lemmas form the core of our analysis.

Lemma 2.1. *If $\{x, y\} \in E$ and $s(x, y) = i$, then*

$$\mathbb{E}[d_T(x, y)] \leq 3\tau \cdot K_{i+1}^{x,y} \cdot \text{len}(x, y). \quad (3)$$

Proof. If $x, y \in V(G_0)$, then $s(x, y) = -1$ and $\mathbb{E}[d_T(x, y)] = K_0^{x,y} \cdot \text{len}(x, y)$ by definition. Otherwise, assume without loss of generality that $s(x) < s(y)$. In this case, it must be that $x \in e_i = \{u, v\}$ and $y = w^*$. Suppose that $x = u$.

If $e_{i+1} = e_i$, an elementary calculation based on case (1) of our algorithm yields,

$$\mathbb{E} \left[\frac{d_{T_{i+1}}(u, w^*)}{\text{len}(u, w^*)} \mid T_i \right] \leq \frac{3 \text{len}(v, w^*) + \text{len}(u, w^*)}{\text{len}(v, w^*) + \text{len}(u, w^*)} \leq 3,$$

from which $\mathbb{E}[d_T(u, w^*)] \leq 3 K_{i+1}^{u, w^*} \cdot \text{len}(u, w^*)$ immediately follows.

Similarly, if $e_{i+1} = \{v, w^*\}$, then the expected stretch is inflated by at most a factor of τ , and therefore (3) again follows by a similar calculation. Finally, if $e_{i+1} = \{u, w^*\}$, then $\{u, w^*\} \in E(T_{i+1})$, and therefore $\mathbb{E}[d_T(u, w^*)] \leq K_{i+1}^{u, w^*} \cdot \text{len}(u, w^*)$. \square

Lemma 2.2. *For any $\{x, y\} \in E(G_i)$, we have $K_i^{x, y} \leq \max\{3, K_{i+1}^{a, b}\}$ for some $\{a, b\} \in E(G_i)$.*

Proof. Let Γ be a tree on $V(G_i)$ which is a maximizer for $K_i^{x, y}$. Let Γ_u and Γ_v be the subtrees of $\Gamma \setminus e_i$ rooted at u and v respectively, where we recall that $e_i = \{u, v\}$. If x and y are both either in Γ_u , or in Γ_v , then $K_i^{x, y} = 1$, since Γ_u and Γ_v remain intact in the final tree T , conditioned on $T_i = \Gamma$.

So, it suffices to consider the case $x \in \Gamma_u$ and $y \in \Gamma_v$. Observe further that since the unique path between x and y in Γ passes through $\{u, v\}$, and the x - u and y - v paths will both remain in T , we have

$$\mathbb{E} \left[\frac{d_T(x, y)}{d_{T_i}(x, y)} \mid T_i = \Gamma \right] \leq \mathbb{E} \left[\frac{d_T(u, v)}{d_{T_i}(u, v)} \mid T_i = \Gamma \right] \leq K_i^{u, v}.$$

Thus to prove the lemma, it suffices to show that $K_i^{u, v} \leq \max\{3, K_{i+1}^{u, v}\}$. To this end, let Γ be the maximizer for $K_i^{u, v}$, and suppose that $T_i = \Gamma$. If $e_{i+1} = e_i$, then the edge $\{u, v\}$ remains intact (i.e. $\{u, v\} \in E(T_{i+1})$), and therefore $K_i^{u, v} \leq K_{i+1}^{u, v}$. Assume now that $e_{i+1} \neq e_i$, which means that we are in case (2) of the algorithm. Assume further, without loss of generality, that $e_{i+1} = \{v, w^*\}$. Recall that either $\{u, v\}$ or $\{u, w^*\}$ is deleted.

Let $A = \text{len}(u, w^*)$, $B = \text{len}(u, v)$, $C = \text{len}(v, w^*)$. With probability $p = \min\{1, \frac{\tau A}{A+B}\}$, the edge $\{u, w^*\}$ is deleted, in which case $d_T(u, v) = d_{T_i}(u, v)$. With probability $1 - p$, the edge $\{u, v\}$ is deleted, and the new path between u and v in T_{i+1} is u - w^* - v , so the distance between u and v is stretched to $A + C \leq 2A + B$, and is eligible to be stretched by at most a factor $K_{i+1}^{u, v}$ in the future.

Thus, if $A \geq B/(\tau - 1)$, we have $K_i^{u, v} = 1$. We can therefore assume $A < B/(\tau - 1)$. Thus we can bound,

$$\begin{aligned} K_i^{u, v} &\leq \frac{\tau A}{A+B} + K_{i+1}^{u, v} \left(1 - \frac{\tau A}{A+B}\right) \frac{2A+B}{B} \\ &\leq \tau \frac{A}{B} + K_{i+1}^{u, v} \left(1 - \frac{\tau A}{2B}\right) \left(1 + 2\frac{A}{B}\right) \\ &\leq \tau \frac{A}{B} + K_{i+1}^{u, v} \left(1 - \frac{\tau A}{3B}\right), \end{aligned}$$

where we have used $1 - \frac{\tau A}{2B} + 2\frac{A}{B} \leq 1 - \frac{\tau A}{3B}$ since $\tau = 12$. But now one sees that,

$$K_i^{u, v} \leq 3\frac{\tau A}{3B} + K_{i+1}^{u, v} \left(1 - \frac{\tau A}{3B}\right) \leq \max\{3, K_{i+1}^{u, v}\}.$$

\square

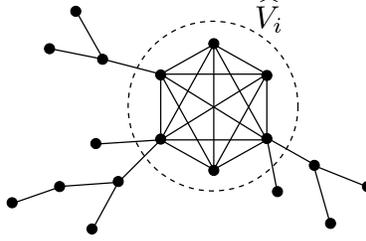

Figure 1: The graph H_i with $k = 5$.

Finally, the next lemma completes our analysis.

Lemma 2.3. *For any $x, y \in V$, we have $\mathbb{E}[d_T(x, y)] \leq 9\tau \cdot d_G(x, y)$.*

Proof. By the triangle inequality and linearity of expectation, it suffices to prove the lemma for edges $\{x, y\} \in E$. We will prove the following by reverse induction on i : For every $\{x, y\} \in E$ and $i \geq s(x, y) + 1$, we have $K_i^{x, y} \leq 3$. Combining this with Lemma 2.1 will complete the proof.

The claim is trivial for $i = t$ since $K_t^{x, y} = 1$ for all $\{x, y\} \in E$. If $t > i \geq s(x, y) + 1$, then $\{x, y\} \in E(G_i)$, and Lemma 2.2 immediately implies that $K_i^{x, y} \leq \max\{3, K_{i+1}^{a, b}\}$ for some a, b with $i + 1 \geq s(a, b) + 1$. By induction, $K_{i+1}^{a, b} \leq 3$, hence $K_i^{x, y} \leq 3$ as well. \square

3 Embedding pathwidth- k graphs into trees

We now turn to graphs of pathwidth k for some $k \in \mathbb{N}$. Let G be such a graph. By Lemma 1.9, we may assume that G has a linear width- k composition sequence, $(G_0, V_0), \dots, (G_t, V_t)$. For $i \geq 1$, we define $\widehat{V}_i = V_{i-1} \cup \{v_i\}$. Our algorithm for embedding G into a random tree proceeds inductively along the composition sequence. For each $i \in \{1, \dots, t\}$ we compute a subgraph H_i of G_i , whose only non-trivial 2-connected component is a $(k + 1)$ -clique on \widehat{V}_i (see Figure 1). More specifically, H_1 is just a clique on \widehat{V}_1 . Given H_i , we derive H_{i+1} by adding all the edges between v_{i+1} and V_i , and removing all the edges, except for one, between V_i and the unique vertex in $\widehat{V}_i \setminus V_i$.

The main part of the algorithm involves determining which edge in $(\widehat{V}_i \setminus V_i) \times V_i$ we keep in H_{i+1} . The high-level idea behind our approach is as follows. On one hand, we want to keep short edges so that the distance between $\widehat{V}_i \setminus V_i$ and V_i is small. On the other hand, keeping always the shortest edge leads to accumulation of the stretch for certain pairs (whose shortest-path keeps getting longer, through a sequence of “short” edges). We avoid this obstacle via a randomized process that assigns a *rank* to each edge, which intuitively means that edges of lower rank are more likely to be deleted. More specifically, at each step i , we pick a random threshold L and keep the highest ranked edge of length at most L , deleting the rest. We also update the ranks of the edges in the new graph appropriately.

Formally, let $\text{rank}_i : V(G) \times V(G) \rightarrow \mathbb{Z}_{\geq 0}$ be an arbitrary symmetric function, with $\text{rank}_1(u, v) = 0$, for each $u, v \in V(G)$. Let $E(\widehat{V}_i) = \binom{\widehat{V}_i}{2}$, i.e. the set of edges internal to \widehat{V}_i . For $u, v \in V(H_i)$, let $P_i^{u, v}$ be the unique path between u and v in H_i that contains at most one edge in $E(\widehat{V}_i)$. Observe that $P_i^{u, v}$ is well-defined since \widehat{V}_i forms a clique. For an edge $e \in E(\widehat{V}_i)$ we set

$$\text{edge-rank}_i(e) = \max_{u, v \in V(H_i): e \in P_i^{u, v}} \text{rank}_i(u, v)$$

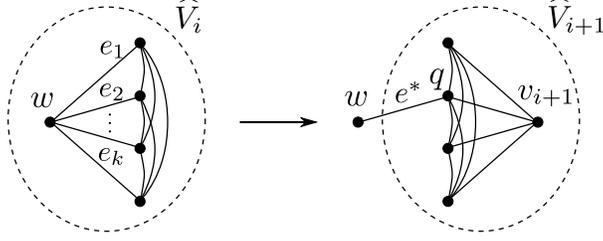

Figure 2: Transitioning from H_i to H_{i+1} . Here, w is the unique vertex in $\widehat{V}_i \setminus V_i$.

The randomized process for generating H_{i+1} and rank_{i+1} from H_i and rank_i is as follows. Let $\tau = 4k$ be our new “inflation factor.”

Let w be the unique vertex in $\widehat{V}_i \setminus V_i$, and enumerate $E(w, V_i) = \{e_1, e_2, \dots, e_k\}$ so that $\text{len}(e_1) \leq \text{len}(e_2) \leq \dots \leq \text{len}(e_k)$.

Now, let $\{\sigma_j\}_{j=1}^{k-1}$ be a family of independent $\{0, 1\}$ random variables with

$$\mathbb{P}[\sigma_j = 1] = \min \left\{ 1, \tau \frac{\text{len}(e_j)}{\text{len}(e_{j+1})} \right\},$$

and define the set of eligible edges by

$$\mathcal{E} = \left\{ e_j : \prod_{i=1}^{j-1} \sigma_i = 1 \right\}.$$

In particular, $e_1 \in \mathcal{E}$ always. Let $e^* \in \mathcal{E}$ be any edge satisfying $\text{edge-rank}_i(e^*) = \max_{e \in \mathcal{E}} \text{edge-rank}_i(e)$.

Finally, we define H_{i+1} as the graph with vertex set $V(G_{i+1})$ and edge set (see Figure 2),

$$E(H_{i+1}) = \{e^*\} \cup \{\{v_{i+1}, u\} : u \in V_i\} \cup (E(H_i) \setminus E(w, V_i)).$$

We also define rank_{i+1} as follows. For any $u, v \in V(G)$

$$\text{rank}_{i+1}(u, v) = \begin{cases} \text{rank}_i(u, v) & \text{if } E(P_i^{u,v}) \cap \mathcal{E} = \emptyset \\ \text{rank}_i(u, v) + 1 & \text{otherwise.} \end{cases}$$

Intuitively, $\text{rank}_i(u, v)$ counts how many times the path between u and v was under risk to be *significantly* stretched until step i . If $P_i^{u,v}$ does not use an edge of \mathcal{E} then the edge $\{u, v\}$ will be stretched, but the alternative path will, on average, be “short enough” that we need not increase its rank (this is how the set \mathcal{E} is defined). It remains to analyze the expected stretch incurred by the above process. First, we observe that the maximum rank of an edge is $O(k^2)$.

Lemma 3.1. *For every $i = 1, 2, \dots, t$ and every edge $e \in E(\widehat{V}_i)$, $\text{edge-rank}_i(e) \leq \binom{k+1}{2}$.*

Proof. For each $i = 1, 2, \dots, t$, and each $j = 1, 2, \dots, \binom{k+1}{2}$, let $R_{i,j}$ be the j -th largest edge-rank of the edges in $E(\widehat{V}_i)$. That is, for each $i = 1, 2, \dots, t$, $R_{i,1} \leq R_{i,2} \leq \dots \leq R_{i,\binom{k+1}{2}}$.

We will prove by induction on i that for each $i = 1, 2, \dots, t$, for each $1 \leq j \leq \binom{k+1}{2}$, we have $R_{i,j} \leq j$. For $i = 1$, all the ranks are equal to 0, and the assertion holds trivially.

Assume now that the assertion holds for $i - 1$. It is convenient to analyze the transition from step $i - 1$ to step i in three phases. We need to remove the edges in $E(w, V_i) \setminus \{e^*\}$ and add the edges in $E(v_{i+1}, V_i)$, while updating the ranks accordingly. For notational simplicity, we assume that the rank of an edge that is removed is set to zero. Let e^* be the maximum-rank edge in \mathcal{E} . In the first phase, we set the rank of e^* to zero, and we increase the rank of all remaining edges in \mathcal{E} by one. Clearly, the resulting edge ranks satisfy the inductive invariant.

In the second phase, for any edge $e \in E(w, V_i) \setminus \{e^*\}$, we update the rank of an edge $e' = e'(e) \in E(\widehat{V}_i) \cap E(\widehat{V}_{i+1})$ to be $\text{edge-rank}(e') = \max\{\text{edge-rank}(e'), \text{edge-rank}(e)\}$, and we set the rank of e to zero. The point here is that for any $e \in E(w, V_i)$, there is a unique edge $e' \in E(\widehat{V}_i) \cap E(\widehat{V}_{i+1})$ such that, for any $u, v \in V(H_i)$, if $e \in P_i^{u,v}$ then $e' \in P_{i+1}^{u,v}$. In other words, the paths that use e will have to be rerouted through a new path that uses e' . This explains how the edge-rank of e is “transferred” to e' .

Clearly, after the second phase the ranks still satisfy the inductive invariant. Finally, in the third phase we remove the edges in $E(w, V_i)$, and we add the edges in $E(v_{i+1}, V_i)$. All the removed edges have at this point rank zero, and all new edges also have rank zero. Thus, the inductive invariant is satisfied. \square

For any $i \in \{1, \dots, t\}$, $r \in \{0, \dots, \binom{k+1}{2}\}$, and any edge $\{u, v\} \in E(G_i)$, we put

$$K_i^{u,v}(r) = \max \left\{ \mathbb{E} \left[\frac{d_{H_i}(u, v)}{d_{H_i}(u, v)} \mid H_i = \Gamma, \text{rank}_i(u, v) = \rho \right] : (\Gamma, \rho) \in \Omega_i(u, v; r) \right\}, \quad (4)$$

where we define

$$\Omega_i(u, v; r) = \{(\Gamma, \rho) : \mathbb{P}(H_i = \Gamma, \text{rank}_i(u, v) = \rho) > 0 \text{ and } \rho \geq r\}.$$

In other words, $K_i^{u,v}(r)$ is the maximum expected stretch for all stages after i , conditioned on the worst possible configuration over subgraphs H_i and rank functions satisfying $\text{rank}_i(u, v) \geq r$. We further define $K_i^{u,v} \left(\binom{k+1}{2} + 1 \right) = 1$.

For the next three lemmas and the corollary that follows, we fix an edge $\{u, v\} \in E(G_i)$, and a number $r \in \{0, \dots, \binom{k+1}{2}\}$. Let $(\Gamma, \rho) \in \Omega_i(u, v; r)$ be a maximizer in (4), and write $\mathbb{P}^*[\cdot] = \mathbb{P}[\cdot \mid H_i = \Gamma, \text{rank}_i = \rho]$ and $\mathbb{E}^*[\cdot] = \mathbb{E}[\cdot \mid H_i = \Gamma, \text{rank}_i = \rho]$. A major point is that the following calculations are oblivious to the conditioning, aside from the assumption that $\text{rank}_i(u, v) \geq r$.

Lemma 3.2. *Suppose that $e_j \in E(P_i^{u,v})$ for some $j \in \{1, 2, \dots, k\}$. Then,*

$$\begin{aligned} K_i^{u,v}(r) &\leq \mathbb{P}^*[e_j \in \mathcal{E}] \left(1 + 2 \frac{\mathbb{E}^*[\text{len}(e^*) \mid e_j \in \mathcal{E}]}{\text{len}(e_j)} \right) K_{i+1}^{u,v}(r+1) \\ &\quad + \mathbb{P}^*[e_j \notin \mathcal{E}] \left(1 + 2 \frac{\mathbb{E}^*[\text{len}(e^*) \mid e_j \notin \mathcal{E}]}{\text{len}(e_j)} \right) K_{i+1}^{u,v}(r) \end{aligned}$$

Proof. We have, $\frac{d_{H_{i+1}}(u,v)}{d_{H_i}(u,v)} \leq \frac{2\text{len}(e^*) + \text{len}(e_j)}{\text{len}(e_j)}$. There are two possibilities: (1) $e_j \in \mathcal{E}$ occurs, and the rank of $\{u, v\}$ is increased by 1, (2) $e_j \notin \mathcal{E}$ and the rank of $\{u, v\}$ remains the same. This verifies the claimed inequality for $r < \binom{k+1}{2}$.

Note that, by Lemma 3.1, $\text{rank}_i(u, v) \leq \binom{k+1}{2}$. Thus the lemma holds true even for $r = \binom{k+1}{2}$, in which case $e_j \in \mathcal{E} \implies e_j = e^*$ (since the rank of the pair u, v cannot increase anymore). If this happens, then $d_{H_i}(u, v) = d_{H_i}(u, v)$, again verifying the claimed inequality, since $K_{i+1}^{u,v} \left(\binom{k+1}{2} + 1 \right) = 1$ by definition. \square

Lemma 3.3. *For any $j \in [k]$, $\mathbb{P}^* [e_j \in \mathcal{E}] \left(1 + 2 \frac{\mathbb{E}^*[\text{len}(e^*) | e_j \in \mathcal{E}]}{\text{len}(e_j)} \right) \leq 3(4k)^{k-1} \frac{\text{len}(e_1)}{\text{len}(e_j)}$.*

Proof. We have

$$\begin{aligned}
\mathbb{P}^* [e_j \in \mathcal{E}] \mathbb{E}^*[\text{len}(e^*) | e_j \in \mathcal{E}] &\leq \mathbb{E}^*[\text{len}(e^*)] \\
&= \sum_{h=1}^k \text{len}(e_h) \mathbb{P}^*[e^* = e_h] \\
&\leq \sum_{h=1}^k \text{len}(e_h) \mathbb{P}^*[e_h \in \mathcal{E}] \\
&\leq \sum_{h=1}^k \text{len}(e_h) \frac{\text{len}(e_1)}{\text{len}(e_h)} \tau^{h-1} \\
&\leq 2 \text{len}(e_1) \tau^{k-1}.
\end{aligned}$$

Also, we have $\mathbb{P}^* [e_j \in \mathcal{E}] \leq \tau^{j-1} \frac{\text{len}(e_1)}{\text{len}(e_j)} \leq \tau^{k-1} \frac{\text{len}(e_1)}{\text{len}(e_j)}$. Combining these estimates yields the claim, recalling that $\tau = 4k$. \square

Lemma 3.4. *For any $j \in [k]$, $\mathbb{P}^* [e_j \notin \mathcal{E}] \left(1 + 2 \frac{\mathbb{E}^*[\text{len}(e^*) | e_j \notin \mathcal{E}]}{\text{len}(e_j)} \right) \leq 1 - \frac{\text{len}(e_1)}{\text{len}(e_j)}$.*

Proof. Let

$$I = \{h \in \{1, 2, \dots, j-1\} : \text{len}(e_{h+1}) > \tau \cdot \text{len}(e_h)\}.$$

Observe that if $h \in \{1, 2, \dots, j-1\} \setminus I$, then whenever $e_h \in \mathcal{E}$, we have also $e_{h+1} \in \mathcal{E}$. For each

$h \in I$, let $k_h = |I \cap \{1, 2, \dots, h\}|$.

$$\begin{aligned}
\mathbb{P}^*[e_j \notin \mathcal{E}] \left(1 + 2 \frac{\mathbb{E}^*[\text{len}(e^*) | e_j \notin \mathcal{E}]}{\text{len}(e_j)}\right) &\leq \sum_{h=1}^{j-1} \mathbb{P}^*[e_h \in \mathcal{E} \text{ and } e_{h+1} \notin \mathcal{E}] \left(1 + \frac{2\text{len}(e_h)}{\text{len}(e_j)}\right) \\
&= \sum_{h \in I} \mathbb{P}^*[e_h \in \mathcal{E} \text{ and } e_{h+1} \notin \mathcal{E}] \left(1 + \frac{2\text{len}(e_h)}{\text{len}(e_j)}\right) \\
&\leq \sum_{h \in I} \tau^{k_h-1} \frac{\text{len}(e_1)}{\text{len}(e_h)} \left(1 - \tau \frac{\text{len}(e_h)}{\text{len}(e_{h+1})}\right) \left(1 + \frac{2\text{len}(e_h)}{\text{len}(e_j)}\right) \\
&\leq \sum_{h \in I} \tau^{k_h-1} \frac{\text{len}(e_1)}{\text{len}(e_h)} \left(1 - \tau \frac{\text{len}(e_h)}{\text{len}(e_{h+1})} + \frac{2\text{len}(e_h)}{\text{len}(e_j)}\right) \\
&= \sum_{h \in I} \tau^{k_h-1} \frac{\text{len}(e_1)}{\text{len}(e_h)} \left(1 - \tau \frac{\text{len}(e_h)}{\text{len}(e_{h+1})}\right) + \frac{\text{len}(e_1)}{\text{len}(e_j)} \sum_{h \in I} 2\tau^{k_h-1} \\
&\leq 1 - \tau^{|I|} \frac{\text{len}(e_1)}{\text{len}(e_j)} + \frac{\text{len}(e_1)}{\text{len}(e_j)} (2k\tau^{|I|-1}) \\
&= 1 + \frac{\text{len}(e_1)}{\text{len}(e_j)} \left(2k\tau^{|I|-1} - \tau^{|I|}\right) \\
&\leq 1 - \frac{\text{len}(e_1)}{\text{len}(e_j)}.
\end{aligned}$$

□

Corollary 3.5. *For every $\{u, v\} \in E(G_i)$ and $r \in \{0, \dots, \binom{k+1}{2}\}$, we have*

$$K_i^{u,v}(r) \leq \max \left\{ 3(4k)^{k-1} K_{i+1}^{u,v}(r+1), K_{i+1}^{u,v}(r) \right\}.$$

Proof. Suppose that $H_i = \Gamma$ and $\text{rank}_i = \rho$. If $E(P_i^{u,v}) \cap E(\hat{V}_i)$ is empty, then $K_i^{u,v}(r) = 1$ because the current u - v path in H_i will be preserved in H_t . Otherwise, we have $E(P_i^{u,v}) \cap E(\hat{V}_i) = \{e_j\}$ for some $j \in [k]$. Apply Lemmas 3.2, 3.3, and 3.4 to conclude that

$$\begin{aligned}
K_i^{u,v}(r) &\leq \frac{\text{len}(e_1)}{\text{len}(e_j)} 3(4k)^{k-1} K_{i+1}^{u,v}(r+1) + \left(1 - \frac{\text{len}(e_1)}{\text{len}(e_j)}\right) K_{i+1}^{u,v}(r) \\
&\leq \max \left\{ 3(4k)^{k-1} K_{i+1}^{u,v}(r+1), K_{i+1}^{u,v}(r) \right\},
\end{aligned}$$

completing the proof. □

We can now state and prove our main theorem.

Theorem 3.6. *For every $k \geq 1$, every metric graph of pathwidth k admits a stochastic D -embedding into a distribution over trees with $D \leq (4k)^{k^3}$.*

Proof. We may assume that $k \geq 2$ as the statement is trivial for $k = 1$. Let H_t be the random subgraph of G . Fix $\{u, v\} \in E(G)$, and suppose that i_0 is the smallest number for which $u, v \in V(G_{i_0})$. In this case, since $\{u, v\}$ is an edge, we have $d_{G_{i_0}}(u, v) = d_G(u, v)$, thus

$$\mathbb{E}[d_{H_t}(u, v)] \leq K_{i_0}^{u,v}(0) \cdot \text{len}(u, v).$$

Now applying Corollary 3.5 inductively immediately yields the bound,

$$K_{i_0}^{u,v}(0) \leq \left(3(4k)^{k-1}\right)^{\binom{k+1}{2}+1},$$

recalling that $K_i^{u,v}\left(\binom{k+1}{2}+1\right) = 1$ for all i , and $K_t^{u,v}(r) = 1$ for all r .

Finally, observe that the only non-trivial 2-connected component of H_t is a $(k+1)$ -clique on \widehat{V}_t . Replacing \widehat{V}_t by a minimum spanning tree yields a tree T with $d_T(u,v) \leq (k+1) \cdot d_{H_t}(u,v)$. This completes the proof. \square

4 Pathwidth($k+1$) $\not\sim$ Pathwidth(k)

We now show that for any fixed $k \geq 1$, and for any $n \geq 1$, there exists an n -vertex graph of pathwidth $k+1$ for which any stochastic D -embedding into graphs of pathwidth k has $D \geq \Omega(n^{2-k})$, where the $\Omega(\cdot)$ notation hides a multiplicative constant depending on k . In fact, our lower bound holds even for trees of pathwidth $k+1$. We begin by giving two structural lemmas that allow us to decompose a tree of pathwidth ℓ into a path and a collection of trees of pathwidth at most $\ell-1$.

Lemma 4.1. *Let G_1, G_2, G_3 be connected graphs of pathwidth k with disjoint vertex sets, and for $i \in [3]$, let $v_i \in V(G_i)$. Let G be the graph obtained by introducing a new vertex v^* , and connecting it to v_1, v_2 , and v_3 . Formally, $V(G) = \{v^*\} \cup \bigcup_{i=1}^3 V(G_i)$, and $E(G) = \bigcup_{i=1}^3 E(G_i) \cup \{\{v^*, v_i\}\}$. Then G has pathwidth $k+1$.*

Proof. It is easy to see that G has pathwidth at most $k+1$: For each $i \in [3]$ take a path decomposition of G_i with bags $C_{i,1}, \dots, C_{i,\ell_i}$. For each $i \in [3]$, $j \in [\ell_i]$, let $C'_{i,j} = C_{i,j} \cup \{v^*\}$. The bags $C'_{1,1}, \dots, C'_{1,\ell_1}, C'_{2,1}, \dots, C'_{2,\ell_2}, C'_{3,1}, \dots, C'_{3,\ell_3}$ induce a path decomposition of G with width at most $k+1$.

Assume now for the sake of contradiction that the pathwidth of G is at most k . That is, there exists a path decomposition of G with bags C_1, \dots, C_ℓ , such that: (i) for each $i \in [\ell]$, $|C_i| \leq k+1$, (ii) for each $\{u, v\} \in E(G)$ there exists $i \in [\ell]$ with $u, v \in C_i$, and (iii) for each $v \in V(G)$ there exists a subinterval $I \subseteq [\ell]$ such that $v \in C_i$ iff $i \in I$. For each $i \in [3]$, let G'_i be the subgraph of G induced by $V(G_i) \cup \{v^*\}$. Let also

$$A_i = \{j \in [\ell] : C_j \cap V(G'_i) \neq \emptyset\}.$$

Note that since G'_i is connected, it follows that A_i is a subinterval of $[\ell]$. Pick $i_1, i_2 \in [3]$, such that $1 \in A_{i_1}$, and $\ell \in A_{i_2}$. Note that we might have $i_1 = i_2$. Since $V(G'_{i_1}) \cap V(G'_{i_2}) \neq \emptyset$, we have that $A_{i_1} \cap A_{i_2} \neq \emptyset$. In particular, $A_{i_1} \cup A_{i_2} = [\ell]$. Therefore, each bag C_i contains at least one vertex either from G'_{i_1} , or G'_{i_2} . Let i_3 be an element in $[3] \setminus \{i_1, i_2\}$. Removing $V(G'_{i_1}) \cup V(G'_{i_2})$ from all the bags C_i , we get a decomposition of $G \setminus (G'_{i_1} \cup G'_{i_2}) = G_{i_3}$ with width at most $k-1$, a contradiction since G_{i_3} has pathwidth k . \square

The following lemma is straightforward.

Lemma 4.2. *If H is a minor of G , then the pathwidth of H is at most the pathwidth of G .*

Lemma 4.3. *Let T be a tree of pathwidth $\ell \geq 2$. Then, there exists a simple path P in T such that deleting the vertices of P from T leaves a forest with each tree having pathwidth at most $\ell-1$.*

Proof. For every $v \in V(T)$, let $\alpha(v)$ denote the number of connected components of $T \setminus \{v\}$ of pathwidth ℓ . We first argue that for any $v \in V(T)$, we have $\alpha(v) \leq 2$. To see that, assume for the sake of contradiction that there exists $v \in V(T)$, such that $T \setminus \{v\}$ contains connected components C_1, C_2, C_3 , each of pathwidth at least ℓ . Then, by Lemma 4.1 it follows that T must have pathwidth $\ell + 1$, a contradiction.

First, observe that if there exists $v \in V(T)$ with $\alpha(v) = 0$, then the path containing only v satisfies the assertion. Next, we consider the case where for every $v \in V(T)$, $\alpha(v) = 1$. We construct a path $Q = x_1, \dots, x_s$ as follows. We set x_1 to be an arbitrary leaf of T . Given x_i , let y_i be the unique neighbor of x_i in T , such that y_i is contained in the unique connected component of $T \setminus \{x_i\}$ of pathwidth ℓ . If there exists $j < i$, such that $x_j = y_i$, then we terminate the path Q at x_i , and we set $s = i$. Otherwise, we set $x_{i+1} = y_i$, and continue at x_{i+1} . We now argue that Q satisfies the assertion. For the sake of contradiction suppose that $T \setminus V(Q)$ contains a connected component C of pathwidth ℓ . The component C must be attached to Q via some edge $\{y, x_r\}$, with $y \in V(C)$. This implies however that y is chosen as y_r when examining x_r , and therefore y must be in Q , a contradiction.

Finally, it remains to consider the case where there exists at least one $v \in V(T)$, with $\alpha(v) = 2$. Let $X = \{v \in V(T) : \alpha(v) = 2\}$. Let $H = T[X]$ be the subgraph of T induced on X . We first argue that H is connected. To see this, let $x, y \in X$, and let L be the unique path between x and y in T . Since $\alpha(x) = \alpha(y) = 2$, it follows that there exist connected components C_x, C_y of $T \setminus V(L)$ with C_x attached to x , and C_y attached to y , such that both C_x and C_y have pathwidth ℓ . Let $z \in V(L)$. It follows that there exist components C'_x, C'_y of $T \setminus \{z\}$, such that $C_x \subseteq C'_x$, and $C_y \subseteq C'_y$, which implies that $\alpha(z) = 2$. Thus, $z \in X$. This implies that $L \subseteq H$, and therefore H must be connected.

We next show that H is a path. To see this suppose for the sake of contradiction that there exists $v \in V(H)$ with distinct neighbors $v_1, v_2, v_3 \in V(H)$. Since $\alpha(v_1) = \alpha(v_2) = \alpha(v_3) = 2$, it follows that there exist components C_1, C_2, C_3 of $T \setminus \{v, v_1, v_2, v_3\}$, with each C_i adjacent to v_i , and such that each C_i has pathwidth ℓ , for all $i \in \{1, 2, 3\}$. By Lemma 4.2 we have that for any $i \in \{1, 2, 3\}$, the connected component of $T \setminus \{v\}$ containing v_i has pathwidth at least ℓ . Applying Lemma 4.1, we obtain that T has pathwidth at least $\ell + 1$, a contradiction. Therefore, H is a path.

Let w_1, w_2 be the two endpoints of the path H . We remark that we might have $w_1 = w_2$, if there is only one vertex in H . Since $\alpha(w_1) = 2$, it follows that there exists a connected component of C_{w_1} of $T \setminus V(H)$ of pathwidth ℓ which is attached to w_1 . Similarly, there exists a connected component C_{w_2} of $T \setminus V(H)$ of pathwidth ℓ which is attached to w_2 . Note that even if $w_1 = w_2$, since $\alpha(w_1) = 2$, the components C_{w_1}, C_{w_2} can be chosen to be distinct. Let w'_1, w'_2 be the neighbors of w_1 , and w_2 in C_{w_1} , and C_{w_2} respectively. Let H' be the path obtained by adding w'_1 , and w'_2 to H .

We will show that $Q = H'$ satisfies the assertion of the lemma. To that end, it remains to show that any connected component of $T \setminus V(H')$ has pathwidth at most $\ell - 1$. Let C be a component of $T \setminus V(H')$, and suppose for the sake of contradiction that it has pathwidth ℓ . Suppose first that C is attached to a vertex $v \in V(H)$. Since $v \in V(H)$, it follows that $\alpha(v) = 2$. By applying Lemma 4.1 on the clusters C, C_{w_1} , and C_{w_2} , we obtain that T contains a minor of pathwidth at least $\ell + 1$, which combined with Lemma 4.2 leads to a contradiction.

Finally, suppose that C is attached to a vertex $w \in \{w'_1, w'_2\}$, and assume, without loss of generality, that $w = w'_1$. Then it follows that $T \setminus \{w\}$ contains at least two components of pathwidth ℓ (one containing C , and another containing C_{w_2}), and thus $\alpha(w) = 2$, a contradiction since $w \notin X$. This concludes the proof. \square

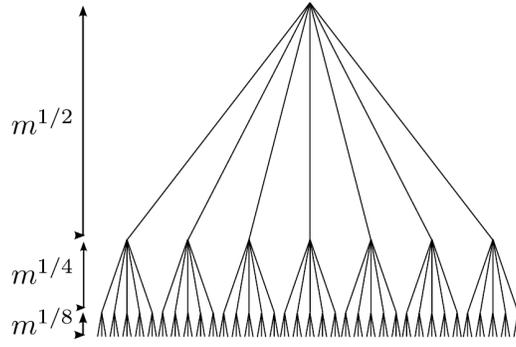

Figure 3: The tree $\Psi_{3,m}$.

We now state the main result of this Section.

Theorem 4.4. *For any $k \geq 1$, and for any $n \geq 1$, there exists an n -vertex tree G of pathwidth $k+1$, such that any stochastic D -embedding of G into metric graphs of pathwidth k , has $D \geq \Omega(n^{2^{-k}})$. In particular, $\text{Pathwidth}(k+1) \cap \text{Trees} \not\rightsquigarrow \text{Pathwidth}(k)$.*

The remainder of this Section is devoted to proving Theorem 4.4. We first construct a graph that will be used for the lower bound. For each $i \geq 1$, let Φ_i be the unit-weighted graph consisting of a vertex v connected to i disjoint paths of length i . Observe that Φ_i is a tree with i leaves. We consider Φ_i as being rooted at the vertex v .

For each $i \geq 1$, and for each $m \geq 1$, we define the graph $\Psi_{i,m}$ as follows. For $i = 1$, we set $\Psi_{1,m} = \Phi_{\lceil \sqrt{m} \rceil}$. For $i \geq 2$, let $\Psi_{i,m}$ be the graph obtained by identifying the root of a copy of $\Psi_{i-1,\sqrt{m}}$, with each leaf of $\Phi_{\lceil \sqrt{m} \rceil}$. For $\ell \leq \lceil \sqrt{m} \rceil$, let $\Psi_{i,m,\ell}$ be the tree obtained from $\Psi_{i,m}$ by deleting $\lceil \sqrt{m} \rceil - \ell$ children of the root of $\Psi_{i,m}$, along with everything underneath those children. In particular, $\Psi_{i,m,\sqrt{m}} = \Psi_{i,m}$.

Lemma 4.5. *For each $i \geq 1$ and $m \geq 3^{2^i}$, $\Psi_{i,m}$ has pathwidth $i+1$.*

Proof. Note that for $m \geq 3^{2^i}$, $\Psi_{i,m}$ contains, as a minor, a full ternary tree T of depth i . Using Lemma 4.1 inductively shows that the pathwidth of the depth i ternary tree is $i+1$, hence Lemma 4.2 implies that the pathwidth of $\Psi_{i,m}$ is at least $i+1$. It is also easy to check by hand that the pathwidth of $\Psi_{i,m}$ is at most $i+1$, for every $m \geq 1$. \square

Fix $k \geq 1$, and let $G = \Psi_{k,m}$. By Lemma 4.5, for $m \geq 3^{2^k}$, G has pathwidth $k+1$. We will show that for m large enough, any stochastic c -embedding of $(V(G), d_G)$ into a distribution over metric graphs of pathwidth k , has distortion $c \geq \Omega(n^{2^{-k}})$, where $n = |V(G)|$.

Assume there exists a stochastic c -embedding of $(V(G), d_G)$ into a distribution over metric graphs of pathwidth k . By composing this with the result of Theorem 3.6, we get a stochastic c' -embedding of $(V(G), d_G)$ into the family of metrics supported on $\text{Pathwidth}(k) \cap \text{Trees}$, with $c' = O(c)$ (where the $O(\cdot)$ notation hides a constant depending on the fixed parameter k).

By averaging, there exists a metric tree T of pathwidth k and a single non-contractive mapping $f : V(G) \rightarrow V(T)$ which satisfies,

$$\frac{1}{|E(G)|} \sum_{\{u,v\} \in E(G)} d_T(f(u), f(v)) \leq c'.$$

Thus it suffices to prove a lower bound on this quantity. In fact we will prove a somewhat stronger statement; we will give a lower bound on the average stretch of any non-contractive embedding of $\Psi_{k,m,\sqrt{m}/2}$. We first prove an auxiliary lemma.

Lemma 4.6. *Let S be an unweighted tree with $r \in V(S)$, and let $L \geq 0$. Let $\ell \geq 0$, and let S_1, \dots, S_ℓ be vertex-disjoint subtrees of S such that for each $i \in [\ell]$, S_i is attached to r via a path Q_i of length at least L , and for each $i \neq j \in [\ell]$, the paths Q_i and Q_j intersect only at r . We remark that each S_i might contain only a single vertex. Let $g : V(S) \rightarrow V(T)$ be a non-contractive embedding of S into a metric tree T , and let P be a simple path in T . If $I = \{i \in [\ell] : d_T(g(S_i), P) < L/2\}$, then*

$$\sum_{\{u,v\} \in E(S)} d_T(g(u), g(v)) \geq \frac{|I|^2 L}{16}.$$

Proof. For each $i \in I$, let $z_i = \operatorname{argmin}_{v \in P} d_T(v, g(S_i))$, and

$$B_i = \{x \in V(P) : d_T(z_i, x) \leq L/2\}.$$

Since g is non-contractive, we have that for each $i, j \in I$ with $i \neq j$, $d_T(g(S_i), g(S_j)) \geq 2L$, and therefore

$$d_T(z_i, z_j) \geq d_T(g(S_i), g(S_j)) - d_T(g(S_i), z_i) - d_T(g(S_j), z_j) = 2L - d_T(S_i, P) - d_T(S_j, P) > L,$$

which implies $B_i \cap B_j = \emptyset$.

By reordering, we assume that $I = \{1, 2, \dots, |I|\}$, and that for each $i, j \in I$ with $i < j$, B_i appears to the left of B_j in P , after fixing some orientation of P . Furthermore, by choosing the proper orientation, we may assume that there is a vertex $u_0 \in P$ such that u_0 is contained in, or appears to the left of $B_{\lceil |I|/2 \rceil}$ in P , and $g(r)$ and u_0 are in the same subtree of $T \setminus E(P)$.

For each $i \in \{1, \dots, |I|\}$, let $w_i = \operatorname{argmin}_{v \in V(S_i)} d_S(v, r)$. It follows that for each $i \in \{\lceil |I|/2 \rceil + 1, \dots, |I|\}$,

$$d_T(g(r), g(w_i)) \geq (i - \lceil |I|/2 \rceil) L.$$

Furthermore, for every $i \in [\ell]$, clearly $d_T(g(r), g(w_i)) \geq L$ by non-contractiveness. Therefore,

$$\begin{aligned} \sum_{\{u,v\} \in E(S)} d_T(g(u), g(v)) &\geq \sum_{i \in \{1, \dots, |I|\}} \sum_{\{u,v\} \in E(Q_i)} d_T(g(u), g(v)) \\ &\geq \sum_{i \in \{1, \dots, |I|\}} d_T(g(r), g(w_i)) \\ &\geq \left\lceil \frac{|I|}{2} \right\rceil L + \sum_{i \in \{\lceil |I|/2 \rceil + 1, \dots, |I|\}} \left(i - \left\lceil \frac{|I|}{2} \right\rceil \right) L > \frac{|I|^2 L}{16}. \end{aligned}$$

□

The proof of the lower bound proceeds by induction on k . We first prove the base case for embedding into trees of pathwidth one.

Lemma 4.7. *Let $g : V(\Psi_{1,m,\sqrt{m}/2}) \rightarrow V(T)$ be a non-contracting embedding into a metric tree T of pathwidth one. Then,*

$$\frac{1}{|E(\Psi_{1,m,\sqrt{m}/2})|} \sum_{\{u,v\} \in E(\Psi_{1,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{\sqrt{m}}{2^{10}}.$$

Proof. Since the tree T has pathwidth one, it consists of a path $P = \{v_1, \dots, v_t\}$, and a collection of vertex-disjoint stars T_1, \dots, T_t , with each T_i being rooted at v_i . Note that T_i might contain only the vertex v_i .

Recall that $\Psi_{1,m,\sqrt{m}/2}$ consists of $\lfloor \sqrt{m}/2 \rfloor$ disjoint paths $Q_1, \dots, Q_{\lfloor \sqrt{m}/2 \rfloor}$, with

$$Q_i = \{r, q_{i,1}, \dots, q_{i,\lceil \sqrt{m} \rceil}\},$$

where r is the root of $\Psi_{1,m,\sqrt{m}/2}$. For each $i \in [\lfloor \sqrt{m}/2 \rfloor]$ let Q'_i be the subpath of Q_i of length $\lfloor \sqrt{m}/2 \rfloor$ with $Q'_i = \{q_{i,\lceil \sqrt{m}/2 \rceil}, \dots, q_{i,\lceil \sqrt{m} \rceil}\}$.

Let $I_1 = \{i \in [\lfloor \sqrt{m}/2 \rfloor] : d_T(g(Q'_i), P) \geq \sqrt{m}/4\}$, and let $I_2 = [\lfloor \sqrt{m}/2 \rfloor] \setminus I_1$. By Lemma 4.6,

$$\sum_{\{u,v\} \in E(\Psi_{1,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{|I_2|^2 \sqrt{m}}{32}.$$

Since $|E(\Psi_{1,m})| \leq 2m$, we are done if $|I_2| \geq \sqrt{m}/4$.

It remains to consider the case $|I_1| \geq \lfloor \sqrt{m}/4 \rfloor$. Observe that for each $i \in I_1$, all the edges of Q'_i have their endpoints mapped to distinct leaves of the stars T_1, \dots, T_t , with the edge adjacent to each such leaf having length at least $\sqrt{m}/4$, by non-contractiveness of g . Therefore, each edge of such a Q'_i is stretched by a factor of $\sqrt{m}/2$ in T . In other words,

$$\begin{aligned} \frac{1}{|E(\Psi_{1,m,\sqrt{m}/2})|} \sum_{\{u,v\} \in E(\Psi_{1,m,\sqrt{m}/2})} d_T(g(u), g(v)) &\geq \frac{1}{2m} \cdot |I_1| \cdot \left\lfloor \frac{\sqrt{m}}{2} \right\rfloor \frac{\sqrt{m}}{2} \\ &= \frac{\sqrt{m}}{4} \left\lfloor \frac{\sqrt{m}}{4} \right\rfloor \left\lfloor \frac{\sqrt{m}}{2} \right\rfloor \geq \frac{\sqrt{m}}{32}, \end{aligned}$$

with the latter bound holding for $m \geq 4$. Observe that the LHS is always at least 1, yielding the desired result for $m \leq 4$ as well, and completing the proof. \square

We are now ready to prove the main inductive step.

Lemma 4.8. *Let $k \geq 1$, $a \in \mathbb{N}$, $m = (2a)^{2^k}$, and let $g : V(\Psi_{k,m,\sqrt{m}/2}) \rightarrow V(T)$ be a non-contractive embedding of $\Psi_{k,m,\sqrt{m}/2}$ into a metric tree T of pathwidth k . Then,*

$$\frac{1}{|E(\Psi_{k,m,\sqrt{m}/2})|} \sum_{\{u,v\} \in E(\Psi_{k,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{m^{2^{-k}}}{2^{7+3k}}.$$

Proof. We proceed by induction on k . The base case $k = 1$ is given by Lemma 4.7, so we can assume that $k \geq 2$, and that the assertion is true for $k - 1$.

Since the tree T has pathwidth $k \geq 2$, by Lemma 4.3 it follows that it consists of a path P , and a collection of trees T_1, \dots, T_t of pathwidth at most $k - 1$, with each T_i being rooted at some vertex v_i , and v_i being attached to P via an edge. Recall that $\Psi_{k,m,\sqrt{m}/2}$ consists of a root r and $\sqrt{m}/2$ subtrees $Q_1, \dots, Q_{\sqrt{m}/2}$, with each Q_i having a copy Q'_i of $\Psi_{k-1,\sqrt{m}}$ that is connected to r via a path of length \sqrt{m} .

Let $I_1 = \{i \in [\sqrt{m}/2] : d_T(g(Q'_i), P) \geq \sqrt{m}/2\}$, and let $I_2 = [\sqrt{m}/2] \setminus I_1$. By Lemma 4.6,

$$\sum_{\{u,v\} \in E(\Psi_{k,m,\sqrt{m}/2})} d_T(g(u), g(v)) \geq \frac{|I_2|^2 \sqrt{m}}{16}.$$

Since $|E(\Psi_{k,m})| \leq km$, this yields the desired result for $|I_2| \geq \sqrt{m}/4$.

It remains to consider the case $|I_1| \geq \sqrt{m}/4$. Let $I_{1,1}$ be the subset of I_1 containing all indices $i \in I_1$ such that for some $j \in [t]$, T_j contains the image of a copy of $\Psi_{k-1,m^{1/2},m^{1/4}/2}$ from Q'_i . Let also $I_{1,2} = I_1 \setminus I_{1,1}$.

By the induction hypothesis it follows that for any $i \in I_{1,1}$,

$$\sum_{\{u,v\} \in E(Q'_i)} d_T(g(u), g(v)) \geq m^{1/2} \cdot (k-1) \cdot \frac{(m^{1/2})^{2^{1-k}}}{2^{7+3(k-1)}} = m^{1/2} \cdot (k-1) \cdot \frac{m^{2-k}}{2^{4+3k}}. \quad (5)$$

Consider now $i \in I_{1,2}$. Let r_i be the root of Q'_i and let $W_{i,1}, \dots, W_{i,m^{1/4}}$ be the copies of $\Psi_{k-1,m^{1/2},1}$ in Q'_i , intersecting only at r_i . By the definition of $I_{1,2}$ we have that for any $J \subset [m^{1/4}]$ with $|J| = m^{1/4}/2$, and for any $i' \in [t]$, $\bigcup_{j \in J} g(W_{i,j}) \not\subseteq T_{i'}$. Assume that the image of r_i is contained in T_τ , for some $\tau \in [t]$. It follows that there exists $R \subseteq [m^{1/4}]$, with $|R| \geq m^{1/4}/2$, such that for each $j \in R$, the image of $W_{i,j}$ intersects some tree T_{σ_j} , with $\sigma_j \neq \tau$. Since $r_i \in V(W_{i,j})$ it follows that there exists an edge $e_{i,j} \in E(W_{i,j}) \cup E(Z_{i,j})$ that is stretched by a factor of at least $m^{1/2}$. It follows that for any $i \in I_{1,2}$,

$$\sum_{\{u,v\} \in E(Q'_i)} d_T(g(u), g(v)) \geq \frac{m^{1/4}}{2} \cdot m^{1/2}. \quad (6)$$

By (5) we get a lower bound for the average stretch of the edges of every Q'_i , with $i \in I_{1,1}$. Similarly, by (6) we get a lower bound for the average stretch of the edges of every Q'_i , with $i \in I_{1,2}$. Thus, combining (5) and (6) we get

$$\begin{aligned} \frac{1}{|E(\Psi_{k,m,\sqrt{m}/2})|} \sum_{\{u,v\} \in E(\Psi_{k,m,\sqrt{m}/2})} d_T(g(u), g(v)) &\geq \frac{1}{k \cdot m} \cdot |I_1| \cdot m^{1/2} \cdot (k-1) \cdot \frac{m^{2-k}}{2^{4+3k}} \\ &> \frac{m^{2-k}}{2^{7+3k}}, \end{aligned}$$

as desired. \square

This concludes the proof of Theorem 4.4.
