Anti-van der Waerden numbers of 3-term arithmetic progressions.

Zhanar Berikkyzy, Alex Schulte, and Michael Young

September 15, 2018

#### Abstract

The anti-van der Waerden number, denoted by  $\operatorname{aw}([n],k)$ , is the smallest r such that every exact r-coloring of [n] contains a rainbow k-term arithmetic progression. Butler et. al. showed that  $\lceil \log_3 n \rceil + 2 \le \operatorname{aw}([n],3) \le \lceil \log_2 n \rceil + 1$ , and conjectured that there exists a constant C such that  $\operatorname{aw}([n],3) \le \lceil \log_3 n \rceil + C$ . In this paper, we show this conjecture is true by determining  $\operatorname{aw}([n],3)$  for all n. We prove that for  $7 \cdot 3^{m-2} + 1 \le n \le 21 \cdot 3^{m-2}$ ,

$$\operatorname{aw}([n],3) = \left\{ \begin{array}{ll} m+2, & \text{if } n=3^m \\ m+3, & \text{otherwise.} \end{array} \right.$$

**Keywords.** arithmetic progression; rainbow coloring; unitary coloring; Behrend construction.

## 1 Introduction

Let n be a positive integer and let  $G \in \{[n], \mathbb{Z}_n\}$ , where  $[n] = \{1, ..., n\}$ . A k-term arithmetic progression (k-AP) of G is a sequence in G of the form

$$a, a + d, a + 2d, \dots, a + (k-1)d,$$

where  $d \ge 1$ . For the purposes of this paper, an arithmetic progression is referred to as a set of the form  $\{a, a+d, a+2d, \ldots, a+(k-1)d\}$ . An r-coloring of G is a function  $c: G \to [r]$ , and such a coloring is called exact if c is surjective. Given  $c: G \to [r]$ , an arithmetic progression is called exact if exact if

The anti-van der Waerden number, denoted by aw(G, k), is the smallest r such that every exact r-coloring of G contains a rainbow k-AP. If G contains no k-AP, then aw(G, k) = |G| + 1; this is consistent with the property that there is a coloring of G with aw(G, k) - 1 colors that has no rainbow k-AP.

An r-coloring of G is unitary if there is an element of G that is uniquely colored. The smallest r such that every exact unitary r-coloring of G contains a rainbow k-AP is denoted by  $aw_u(G, k)$ . Similar to the anti-van der Waerden number,  $aw_u(G, k) = |G| + 1$  if G has no k-AP.

Problems involving counting and the existence of rainbow arithmetic progressions have been well-studied. The main results of Axenovich and Fon-Der-Flaass [1] and Axenovich and Martin [2] deal with the existence of 3-APs in colorings that have uniformly sized color classes. Fox,

Jungić, Mahdian, Nešetril, and Radoičić also studied anti-Ramsey results of arithmetic progressions in [6]. In particular, they showed that every 3-coloring of [n] for which each color class has density more than 1/6, contains a rainbow 3-AP. Fox et. al. also determined all values of n for which aw( $\mathbb{Z}_n$ , 3) = 3.

The specific problem of determining anti-van der Waerden numbers for [n] and  $\mathbb{Z}_n$  was studied by Butler et. al. in [4]. It is proved in [4] that for  $k \geq 4$ , aw([n], k) =  $n^{1-o(1)}$  and aw( $\mathbb{Z}_n, k$ ) =  $n^{1-o(1)}$ . These results are obtained using results of Behrend [3] and Gowers [5] on the size of a subset of [n] with no k-AP. Butler et. al. also expand upon the results of [6] by determining aw( $\mathbb{Z}_n, 3$ ) for all values of n. These results were generalized to all finite abelian groups in [7]. Butler et. al. also provides bounds for aw([n], 3), as well as many exact values (see Table 1).

Table 1: Values of aw([n], k) for  $3 \le k \le \frac{n+3}{2}$ .

In this paper, we determine the exact value of aw([n], 3), which answers questions posed in [4] and confirms the following conjecture:

Conjecture 1. [4] There exists a constant C such that  $aw([n], 3) \leq \lceil \log_3 n \rceil + C$ , for all  $n \geq 3$ .

Our main result, Theorem 2, also determines  $aw_u([n],3)$  which shows the existence of extremal colorings of [n] that are unitary.

Theorem 2. For all integers  $n \geq 2$ ,

$$aw_u([n],3) = aw([n],3) = \begin{cases} m+2, & \text{if } n = 3^m \\ m+3, & \text{if } n \neq 3^m \text{ and } 7 \cdot 3^{m-2} + 1 \le n \le 21 \cdot 3^{m-2}. \end{cases}$$

In section 2, we provide lemmas that are useful in proving Theorem 2 and section 3 contains the proof of Theorem 2.

## 2 Lemmas

In [4, Theorem 1.6] it is shown that  $3 \leq \operatorname{aw}(\mathbb{Z}_p, 3) \leq 4$  for every prime number p and that if  $\operatorname{aw}(\mathbb{Z}_p, 3) = 4$  then  $p \geq 17$ . Furthermore, it is shown that the value of  $aw(\mathbb{Z}_n, 3)$  is determined by the values of  $aw(\mathbb{Z}_p, 3)$  for the prime factors p of n. We have included this theorem below with some notation change.

**Theorem 3.** [4] Let n be a positive integer with prime decomposition  $n = 2^{e_0} p_1^{e_1} p_2^{e_2} \cdots p_s^{e_s}$  for  $e_i \geq 0$ ,  $i = 0, \ldots, s$ , where primes are ordered so that  $\operatorname{aw}(\mathbb{Z}_{p_i}, 3) = 3$  for  $1 \leq i \leq \ell$  and  $\operatorname{aw}(\mathbb{Z}_{p_i}, 3) = 4$  for  $\ell + 1 \leq i \leq s$ . Then

$$aw(\mathbb{Z}_n, 3) = \begin{cases} 2 + \sum_{j=1}^{\ell} e_j + \sum_{j=\ell+1}^{s} 2e_j, & \text{if } n \text{ is odd} \\ \ell & 3 + \sum_{j=1}^{s} e_j + \sum_{j=\ell+1}^{s} 2e_j, & \text{if } n \text{ is even.} \end{cases}$$

We use Theorem 3 to prove the following lemma.

**Lemma 4.** Let  $n \geq 3$ , then  $\operatorname{aw}(\mathbb{Z}_n, 3) \leq \lceil \log_3 n \rceil + 2$  with equality if and only if  $n = 3^j$  or  $2 \cdot 3^j$  for  $j \geq 1$ .

*Proof.* Suppose  $n = 2^{e_0} p_1^{e_1} p_2^{e_2} \dots p_s^{e_s}$  with  $e_i \ge 0$  for  $i = 0, \dots, s$ , where primes  $p_1, p_2, \dots, p_s$  are ordered so that  $\operatorname{aw}(\mathbb{Z}_{p_i}, 3) = 3$  for  $1 \le i \le \ell$  and  $\operatorname{aw}(\mathbb{Z}_{p_i}, 3) = 4$  for  $\ell + 1 \le i \le s$ . We consider two cases depending on parity of n.

Case 1. Suppose n is odd, that is  $e_0 = 0$ . Then  $\operatorname{aw}(\mathbb{Z}_n, 3) = 2 + \sum_{j=1}^{\ell} e_j + \sum_{j=\ell+1}^{s} 2e_j$  by

Theorem 3. Since  $\operatorname{aw}(\mathbb{Z}_p,3)=3$  for odd primes  $p\leq 13$ , we have  $p_i\geq 17$  for  $i\geq \ell+1$ , and clearly  $p_i\geq 3$  for  $i\leq \ell$ , therefore

$$3^{\mathrm{aw}(\mathbb{Z}_n,3)} = 3^{2+\sum\limits_{j=1}^{\ell} e_j + \sum\limits_{j=\ell+1}^{s} 2e_j} = 9 \cdot 3^{e_1} \cdots 3^{e_\ell} \cdot 9^{e_{\ell+1}} \cdots 9^{e_s} \le 9 \cdot p_1^{e_1} \cdots p_s^{e_s} = 9n.$$

Note that the equality holds if and only if n is a power of 3, that is  $e_j = 0$  for  $2 \le j \le s$ . Therefore,  $\operatorname{aw}(\mathbb{Z}_n, 3) \le \lceil \log_3 n \rceil + 2$  for odd n, with equality if and only if  $n = p_1^{e_1}$ .

Case 2. Suppose n is even, that is  $e_0 \geq 1$ . Then  $\operatorname{aw}(\mathbb{Z}_n,3) = 3 + \sum_{j=1}^{\ell} e_j + \sum_{j=\ell+1}^{s} 2e_j$  by

Theorem 3. If  $n = 2^{e_0} \cdot 3^j$  for  $j \ge 1$ , then by direct computation  $\operatorname{aw}(\mathbb{Z}_n, 3) = 3 + j \le 2 + \lceil \log_3 n \rceil$ , with equality if and only if  $e_0 = 1$ . So suppose there is i such that  $p_i \ne 3$ , and let  $h = \frac{n}{2^{e_0} p_i^{e_i}}$ .

If  $i \leq \ell$  then  $p_i \geq 5$ , and so  $3 \cdot 3^{e_i} < 2^{e_0} p_i^{e_i}$  for all  $e_0 \geq 1$  and  $e_i \geq 1$ . Therefore, since h is odd, by the previous case

$$3^{\mathrm{aw}(\mathbb{Z}_n,3)} = 3 \cdot 3^{e_i} \cdot 3^{\mathrm{aw}(\mathbb{Z}_h,3)} \le 3 \cdot 3^{e_i} \cdot 9h < 2^{e_0} p_i^{e_i} \cdot 9h = 9n.$$

If  $i \ge \ell + 1$  then  $p_i \ge 17$ , and so  $3 \cdot 9^{e_i} < 2^{e_0} p_i^{e_i}$  for all  $e_0 \ge 1$  and  $e_i \ge 1$ . Then by the previous case

$$3^{\mathrm{aw}(\mathbb{Z}_n,3)} = 3 \cdot 9^{e_i} \cdot 3^{\mathrm{aw}(\mathbb{Z}_h,3)} \le 3 \cdot 9^{e_i} \cdot 9h < 2^{e_0} p_i^{e_i} \cdot 9h = 9n.$$

A set of consecutive integer I in [n] is called an *interval* and  $\ell(I)$  is the number of integers in I. Given a coloring c of some finite nonempty subset S of [n], a color class of a color i under c in S is denoted  $c_i(S) := \{x \in S : c(x) = i\}$ . A coloring c of [n] is special if n = 7q + 1 for some positive integer q, c(1) and c(n) are both uniquely colored, and there are two colors  $\alpha$  and  $\beta$  such that  $c_{\alpha}([n]) = \{q + 1, 2q + 1, 4q + 1\}$  and  $c_{\beta}([n]) = \{3q + 1, 5q + 1, 6q + 1\}$ .

**Lemma 5.** Let N be an integer and c be an exact r-coloring of [N] with no rainbow 3-AP, where 1 and N are colored uniquely. Then either the coloring c is special or  $|\{c(x): x \equiv i \pmod{3} \text{ and } x \in [N]\}| \geq r-1$  for i=1 or i=N.

Proof. Observe that N is even, otherwise  $\{1, (N+1)/2, N\}$  is a rainbow 3-AP. We partition the interval [N] into four subintervals  $I_1 = \{1, \ldots, \lceil N/4 \rceil\}$ ,  $I_2 = \{\lceil N/4 \rceil + 1, \ldots, N/2 \}$ ,  $I_3 = \{N/2+1, \ldots, \lfloor 3N/4 \rfloor\}$ , and  $I_4 = \{\lfloor 3N/4 \rfloor + 1, \ldots, N\}$ . Notice that every color other than c(1) and c(N) must be used in the subinterval  $I_2$ . To see this, assume i is the missing color in  $I_2$  distinct from c(1) and c(N). Let x be the largest integer in  $c_i(I_1)$ . Since N is even, we have  $2x-1 \leq 2\lceil N/4 \rceil - 1 \leq N/2$ , and so  $2x-1 \in I_2$  and  $c(2x-1) \neq i$ . Therefore the 3-AP  $\{1,x,2x-1\}$  is a rainbow. If there is no such integer x in  $I_1$ , then the integers colored with i must be in the second half of the interval [N], so we choose the smallest such integer y in  $c_i(I_3 \cup I_4)$ . Then  $\{2y-N,y,N\}$  is a rainbow 3-AP since  $c(2y-N) \neq i$ , because  $2y-N \in I_1 \cup I_2$ . Similarly, every color other than c(1) and c(N) must be used in the subinterval  $I_3$ .

Throughout the proof we mostly drop (mod 3) and just say congruent even though we mean congruent modulo 3. We consider the following three cases.

Case 1:  $N \equiv 0 \pmod{3}$ . Assume  $|\{c(x) : x \equiv i \pmod{3} \text{ and } x \in [N]\}| < r-1 \text{ for both } i = 1$  and i = N. So there are two colors, say red and blue, such that no integer in [N] colored with red is congruent to 1, and no integer in [N] colored with blue is congruent to 0. We further partition the interval  $I_2$  into subintervals  $I_{2(i)}$  and  $I_{2(ii)}$  so that  $\ell(I_{2(i)}) \leq \ell(I_{2(ii)}) \leq \ell(I_{2(i)}) + 1$ , and partition the interval  $I_3$  into subintervals  $I_{3(i)}$  and  $I_{3(ii)}$  so that  $\ell(I_{3(ii)}) \leq \ell(I_{3(ii)}) \leq \ell(I_{3(ii)}) + 1$ . Then we have the following observations:

- (i)  $x \equiv 0$  for all  $x \in c_{red}(I_3 \cup I_4)$  and  $y \equiv 1$  for all  $y \in c_{blue}(I_1 \cup I_2)$ . If there is an integer r in  $I_3 \cup I_4$  colored with red and congruent to 2, then  $2r - N \equiv 1$ , and so c(2r - N) is not red by our assumption. Therefore the 3-AP  $\{2r - N, r, N\}$  is rainbow. Similarly, if there is an integer b in  $I_1 \cup I_2$  colored with blue and congruent to 2, then  $2b - 1 \equiv 0$ , and so c(2b - 1) is not blue, forming a rainbow 3-AP  $\{1, b, 2b - 1\}$ .
- (ii)  $x \equiv 2$  for all  $x \in c_{red}(I_2)$  and  $y \equiv 2$  for all  $y \in c_{blue}(I_3)$ . If there is an integer r in  $c_{red}(I_2)$  congruent to 0, then  $2r - 1 \equiv 2$  and  $2r - 1 \in I_3 \cup I_4$  since  $2r - 1 \geq N/2 + 1$ . Therefore, 2r - 1 is not colored with red by the previous observation, and so the 3-AP  $\{1, r, 2r - 1\}$  is a rainbow. Similarly, if there is an integer b in  $c_{blue}(I_3)$  congruent to 1, then using N we obtain the rainbow 3-AP  $\{2b - N, b, N\}$ , because  $2b - N \equiv 2$  and  $2b - N \leq N/2$ .
- (iii)  $c_{red}(I_{3(ii)}) = c_{blue}(I_{2(i)}) = \emptyset$ . If there is an integer r in  $I_{3(ii)}$  colored with red, then  $2r - N \equiv 0$ , by observation (i). Furthermore,  $2r - N \leq N/2$  and  $2r - N \geq 2(N/2 + \ell(I_{3(i)}) + 1) - N \geq (2\ell(I_{3(i)}) + 1) + 1 \geq \lceil N/4 \rceil + 1$ . So

 $2r - N \in I_2$  and hence it is not colored with red by observation (ii). Therefore,  $\{2r - N, r, N\}$  is a rainbow 3-AP. Similarly, if there is an integer b in  $I_{2(i)}$  colored with blue, then  $2b - 1 \equiv 1$  and  $N/2 + 1 \leq 2b - 1 \leq \lfloor 3N/4 \rfloor$ . So  $2b - 1 \in I_3$  and hence it is not colored with blue by observation (ii). Therefore,  $\{1, b, 2b - 1\}$  is a rainbow 3-AP.

(iv)  $c_{red}(I_{2(ii)}) = c_{blue}(I_{3(i)}) = \emptyset.$ 

Suppose there is an integer r in  $I_{2(ii)}$  colored with red. Since the coloring of  $I_2$  contains both red and blue and there is no integer in  $I_{2(i)}$  colored with blue, by (iii), there must be an integer b in  $I_{2(ii)}$  colored with blue. By (i) and (ii),  $b \equiv 1$  and  $r \equiv 2$ . Wlog, suppose b > r. Then  $2r - b \equiv 0$  and  $2r - b \in I_2$  since  $\ell(I_{2(ii)}) \leq \ell(I_{2(i)}) + 1$ . So 2r - b is not colored red or blue and hence the 3-AP  $\{2r - b, r, b\}$  is rainbow. Therefore, there is no integer in  $I_{2(ii)}$  that is colored with red. Similarly, there is no integer in  $I_{3(i)}$  that is colored with blue.

Recall that every color other than c(1) and c(N) is used in both intervals  $I_2$  and  $I_3$ . Therefore, sets  $c_{red}(I_{2(i)})$ ,  $c_{blue}(I_{2(ii)})$ ,  $c_{red}(I_{3(i)})$ , and  $c_{blue}(I_{3(ii)})$  are nonempty. Using above observations we next show that in fact these integers colored with blue and red in each subinterval are unique. Let  $B = \{b_1, \ldots, b_2\}$  be the shortest interval in  $I_{2(ii)}$  which contains all integers colored with blue and let  $R = \{r_1, \ldots, r_2\}$  be the shortest interval in  $I_{3(i)}$  which contains all integers colored with red. Choose the largest integer x in  $c_{red}(I_{2(i)})$  and consider two 3-APs  $\{x, b_1, 2b_1 - x\}$  and  $\{x, b_2, 2b_2 - x\}$ . Since x is congruent to 2 and both  $b_1$  and  $b_2$  are congruent to 1, we have that both  $2b_1 - x$  and  $2b_2 - x$  are congruent to 0 and are contained in  $I_3$ , otherwise the 3-APs are rainbow. Since all integers colored with blue in  $I_3$  are congruent to 2 by (ii), we have that  $2b_1 - x$  and  $2b_2 - x$  are both colored with red and so contained in R. Therefore,  $2\ell(B) - 1 \le \ell(R)$ . Now using the smallest integer in  $c_{blue}(I_{3(ii)})$ , we similarly have that  $2\ell(R) - 1 \le \ell(R)$ . Since  $\ell(B) \ge 1$  and  $\ell(R) \ge 1$ , we have that  $\ell(R) = \ell(B) = 1$ , i.e. there are unique integers b in  $c_{blue}(I_{2(ii)})$  and r in  $c_{red}(I_{3(i)})$ .

Now for any integer  $\tilde{r}$  from  $c_{red}(I_{2(i)})$  the integer  $2\tilde{r}-1$  must be colored with red, otherwise the 3-AP  $\{1,\tilde{r},2\tilde{r}-1\}$  is rainbow. Since  $2\tilde{r}-1\in I_3$ , it must be equal to the unique red colored integer r of  $I_3$ . Therefore, there is exactly one such  $\tilde{r}$  in  $I_{2(i)}$ , i.e.  $c_{red}(I_{2(i)})=\{\tilde{r}\}$ . Similarly, using N there is a unique integer  $\tilde{b}$  in  $I_{3(ii)}$  colored with blue. Since  $\{1,\tilde{r},r\}$ ,  $\{\tilde{r},b,r\}$ ,  $\{b,r,\tilde{b}\}$ , and  $\{b,\tilde{b},N\}$  are all 3-APs,  $N=7(\ell(\{b,\ldots,r\})-1)+1=7(r-b)+1$ .

Observe that if  $\tilde{r}$  is even, the integer  $(\tilde{r}+N)/2$  in 3-AP  $\{\tilde{r},(\tilde{r}+N)/2,N\}$  must be red and congruent to 1 since  $\tilde{r}\equiv 2$  by (ii), contradicting our assumption. So  $\tilde{r}$  is odd, and hence the integer  $r'=(\tilde{r}+1)/2$  in  $I_1$  must be colored with red. Notice that there cannot be another integer x larger than r' in  $c_{red}(I_1)$ , otherwise 2x-1 will be another integer colored with red in  $I_2$  distinct from  $\tilde{r}$ . Now, since  $\ell(\{r',\ldots,\tilde{r}\})=\ell(\{b,\ldots,r\})$  we have that  $\{r',r,N\}$  is a 3-AP, and so r' must be even. Suppose there are integers smaller than r' in  $c_{red}(I_1)$ , and let z be the largest of them. Then 2z-1 is also in  $c_{red}(I_1)$  and must be equal to or larger than r' in  $I_1$ . However, that is impossible because r' is even and there is no integer in  $c_{red}(I_1)$  larger than r'. So r' is a unique integer in  $I_1$  colored with red. Similarly, there is a unique integer r0 in r2 colored with r3 blue. Therefore the 8-AP can be formed using integers r4, r5, r7, r7, r7, r7, r7, r8, r7, r8, r8, r9 can be r9. Therefore the 8-AP can be r9 can be formed using integers r9 can be r9. Therefore the 8-AP can be r9 can be r9 can be r9. Therefore the 8-AP can be r9 can be r9 can be r9 can be r9. Therefore the 8-AP can be r9 can be r9 can be r9. Therefore the 8-AP can be r9 can be r9 can be r9. Therefore the 8-AP can be r9 can be r9.

In order for this coloring to be special, it remains to show that  $c_{blue}(I_1) = c_{red}(I_4) = \emptyset$ . If  $c_{blue}(I_1) \neq \emptyset$ , then choose the largest integer y in it and consider the 3-AP  $\{1, y, 2y - 1\}$ . Since 2y - 1 must be in  $c_{blue}(I_2)$  and the only integer in this set is b, we have 2y - 1 = b. However, we know that b is even because  $b = 2\tilde{b} - N$ , a contradiction. Similarly, if  $c_{red}(I_4) \neq \emptyset$  choose the

smallest integer x in it and consider the 3-AP  $\{2x - N, x, N\}$ . Since 2x - N must be in  $c_{red}(I_3)$  and the only integer in this set is r, we have 2x - N = r. However, we know that r is odd because  $r = 2\tilde{r} - 1$ , a contradiction. This implies that  $c_{red}([N]) = \{r', \tilde{r}, r\}$  and  $c_{blue}([N]) = \{b, \tilde{b}, b'\}$ , so the coloring is special.

Case 2:  $N \equiv 2 \pmod{3}$ . This case is analogous to Case 1.

Case 3:  $N \equiv 1 \pmod{3}$ . Assume  $|\{c(x) : x \equiv i \pmod{3}\}$  and  $x \in [N]\}| < r-1$  i.e. there are two colors, say red and blue, such that no integer in [N] colored with red or blue is congruent to 1. Recall that every color other than c(1) and c(N) appears in  $I_2$  and  $I_3$ . First, notice that all integers colored with red or blue in  $I_2$  must be congruent modulo 3. Otherwise, choosing a red colored integer and a blue colored integer, we obtain a 3-AP whose third term is colored with red or blue and is congruent to 1 contradicting our assumption. Similarly, this is also the case for  $I_3$ . So suppose all integers in  $c_{red}(I_2) \cup c_{blue}(I_2)$  and  $c_{red}(I_3) \cup c_{blue}(I_3)$  are congruent modulo 3 to integers  $p \not\equiv 1$  and  $q \not\equiv 1$ , respectively. Pick the largest integers from  $c_{red}(I_2)$  and  $c_{blue}(I_2)$  and form a 3-AP whose third term is in  $I_3$ . Then the third term is colored with red or blue and is congruent to p. Therefore,  $p \equiv q \not\equiv 1$ .

We further partition the interval  $I_2$  into subintervals  $I_{2(i)}$  and  $I_{2(ii)}$ , so that  $\ell(I_{2(i)}) \leq \ell(I_{2(ii)}) \leq \ell(I_{2(i)}) + 1$ . If there exists  $x \in c_{red}(I_{2(i)}) \cup c_{blue}(I_{2(i)})$ , the integer 2x - 1 must be colored with c(x) and contained in  $I_3$ , so  $2x - 1 \equiv p$  while  $x \equiv p \not\equiv 1$ , a contradiction. So  $c_{red}(I_{2(i)}) \cup c_{blue}(I_{2(i)}) = \emptyset$ . However, then the smallest integers of  $c_{red}(I_{2(ii)})$  and  $c_{blue}(I_{2(ii)})$  form a 3-AP whose first term is contained in  $I_{2(i)}$  and is colored with red or blue, a contradiction. This completes the proof of the lemma.

## 3 Proof of Theorem 2

Given a positive integer n, define the function f as follows:

$$f(n) = \begin{cases} m+2, & \text{if } n = 3^m \\ m+3, & \text{if } n \neq 3^m \text{ and } 7 \cdot 3^{m-2} + 1 \le n \le 21 \cdot 3^{m-2}. \end{cases}$$

In this section, we prove Theorem 2 by showing that aw([n],3) = f(n) for all n.

First, we show that  $f(n) \leq \operatorname{aw}_u([n], 3)$  by inductively constructing a unitary coloring of [n] with f(n) - 1 colors and no rainbow 3-AP. The result is true for n = 1, 2, 3, by inspection. Suppose n > 3 and that the result holds for all positive integers less than n. Let n = 3h - s, where  $s \in \{0, 1, 2\}$  and  $2 \leq h < n$ .

Let  $r = \operatorname{aw}_u([h], 3)$ . So there is an exact unitary (r-1)-coloring c of [h] with no rainbow 3-AP. Let red be a color not used in c. Define the coloring  $c_1$  of [n] such that if  $x \equiv 1 \pmod{3}$ , then  $c_1(x) = c((x+2)/3)$ , otherwise color x with red. When  $s \neq 0$ , define the coloring  $c_2$  of [n] as follows: if  $x \not\equiv 0 \pmod{3}$  then color x with red; if  $x \equiv 0 \pmod{3}$  then  $c_2(x) = c(x/3+1)$  when c(h) is the only unique color in c and  $c_2(x) = c(x/3)$  otherwise. Notice that  $c_2$  is a unitary  $\operatorname{aw}_u([h-1],3)$ -coloring when  $s \neq 0$  and  $c_1$  is a unitary r-coloring of [n]. Now consider a 3-AP  $\{a,b,2b-a\}$  in [n]. If  $a \equiv b \not\equiv 1$ , then a and a are colored with a and so the 3-AP is not a rainbow. If  $a \equiv b \equiv 1$ , then  $a \equiv b \equiv 1$ , then  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colored with  $a \equiv b \equiv 1$  and  $a \equiv b \equiv 1$  are colorings of  $a \equiv b \equiv 1$ . Similarly, this 3-AP is not rainbow under  $a \equiv 1$ . Similarly, this 3-AP is not rainbow under  $a \equiv 1$ .

3-AP. Also note that  $aw_u([n], 3) \ge aw_u([h], 3) + 1$  under  $c_1$  and  $aw_u([n], 3) \ge aw_u([h-1], 3) + 1$  under  $c_2$ . We proceed with three cases determined by  $\frac{n}{3}$ .

Case 1. First suppose  $7 \cdot 3^{m-2} + 1 \le n \le 3^m - 3$  or  $3^m \le n \le 21 \cdot 3^{m-2}$ . By the induction hypothesis and using the coloring  $c_1$ ,

$$aw_u([n], 3) \ge aw_u([h], 3) + 1 \ge f(h) + 1 = f(n).$$

Case 2. Suppose  $n = 3^m - t$  where  $t \in \{1, 2\}$ . Notice that  $h = 3^{m-1}$ , so by induction and using coloring  $c_2$ ,

$$aw_u([n], 3) \ge aw_u([h-1], 3) + 1 \ge f(h-1) + 1 = f(3^{m-1} - 1) + 1 = (m+2) + 1 = f(n).$$

The upper bound,  $\operatorname{aw}([n],3) \leq f(n)$ , is also proved by induction on n. For small n, the result follows from Table 1. Assume the statement is true for all value less than n, and let  $7 \cdot 3^{m-2} + 1 \leq n \leq 21 \cdot 3^{m-2}$  for some m. Let aw([n]) = r + 1, so there is an exact r-coloring  $\hat{c}$  of [n] with no rainbow 3-AP. We need to show that  $r \leq f(n) - 1$ . Let  $[n_1, n_2, \ldots, n_N]$  be the shortest interval in [n] containing all r colors under  $\hat{c}$ . Define c to be an r-coloring of [N] so that  $c(j) = \hat{c}(n_j)$  for  $j \in \{1, \ldots, N\}$ . By minimality of N the colors of 1 and N are unique. If [N] has at least r - 1 colors congruent to 1 or N, then [n] has at least r - 1 colors congruent to  $n_1$  or  $n_N$ , respectively, so  $r \leq aw(\lfloor n/3 \rfloor)$  and by induction  $r \leq f(\lfloor n/3 \rfloor) \leq f(n) - 1$ . So suppose that is not the case, then by Lemma 5 we have that the coloring c is special.

Let N = 7q + 1 for some  $q \ge 1$ , and let the 8-AP in this special coloring be  $\{1, r_1, r_2, b_1, r_3, b_2, b_3, N\}$ , where  $r_1, r_2, r_3$  are the only integers colored red,  $b_1, b_2, b_3$  are the only integers colored blue and  $q = r_1 - 1$ . If  $n \ge 9q$ , then the 8-AP can be extended to a 9-AP in n by adding the 9th element to either the beginning or the ending. Wlog, suppose  $\{1, r_1, r_2, b_1, r_3, b_2, b_3, N, 2N - b_3\}$  correspond to a 9-AP in [n]. Since the coloring has no rainbow 3-AP, the color of  $2N - b_3$  is blue or c(N), so we have a 4-coloring of this 9-AP. However, aw([9], 3) = 4 and hence there is a rainbow 3-AP in this 9-AP which is in turn a rainbow 3-AP in [n]. Therefore,  $n \le 9q - 1$ .

By uniqueness of red colored integer  $r_1$  in interval  $\{1, \ldots, r_2 - 1\}$ , the colors of integers in interval  $\{r_1 + 1, \ldots, r_2 - 1\}$  is the same as the reversed colors of integers in  $\{2, \ldots, r_1 - 1\}$ , i.e.  $c(r_1+i) = c(r_1-i)$  for  $i = 1, \ldots, q-1$ . Similarly, coloring of integers in interval  $\{r_2+1, \ldots, b_1-1\}$  is the reversed of the coloring of integers in interval  $\{r_1 + 1, \ldots, r_2 - 1\}$ , and so on. This gives a rainbow 3-AP-free (r-2)-coloring of  $\mathbb{Z}_{2q}$ . Therefore,  $r-2 \leq aw(\mathbb{Z}_{2q}, 3) - 1$ .

If  $q = 3^i$  for some i, then n can not be a power of 3 because  $7 \cdot 3^i + 1 \le n \le 9 \cdot 3^i - 1$ . Suppose  $n = 3^m$ , then 2q is not twice a power of 3 and clearly 2q is not a power of 3. Therefore, by Lemma 4 we have

$$r \le aw(\mathbb{Z}_{2q}, 3) + 1 \le \lceil \log_3(2q) \rceil + 2 \le \lceil \log_3(2n/7) \rceil + 2 = \lceil \log_3(2 \cdot 3^m/7) \rceil + 2 = m + 1 \le f(n) - 1.$$

Suppose now that  $n \neq 3^m$ . If  $q = 3^i$  for some i then  $i \leq m-2$ . Otherwise, if  $i \geq m-1$  then  $q \geq 3^{m-1} \geq 1/7n$  which contradicts the fact that q < 1/7n. Therefore,  $2q \leq 2 \cdot 3^{m-2} = 18 \cdot 3^{m-4}$  and so by induction and Lemma 4,  $r \leq aw(\mathbb{Z}_{2q},3) + 1 = aw([2q],3) + 1 \leq m+2 \leq f(n)-1$ . If q is not a power of 3, then again using Lemma 4,  $r \leq aw(\mathbb{Z}_{2q},3) + 1 \leq aw([2q],3)$ . Notice that  $6 \cdot 3^{m-3} + 2/7 \leq 2n/7 \leq 18 \cdot 3^{m-3}$ , and so  $aw([2q],3) \leq m+2$  by induction. Therefore,  $r \leq m+2 \leq f(n)-1$ .
