# THE LAW OF THE ITERATED LOGARITHM FOR A CLASS OF SPDES

PARISA FATHEDDIN

Abstract. After establishing the moderate deviation principle by the Classical Azencott method, we prove the Strassen's compact law of the iterated logarithm (LIL) for a class of stochastic partial differential equations (SPDEs). As an application, we obtain this type of LIL for two population models known as super-Brownian motion and Fleming-Viot process. In addition, the classical LIL is shown for the class of SPDEs and the two population models.

### 1. INTRODUCTION

Large deviations has noticeably become an active area of research with applications in queues, communication theory, exit problems and statistical mechanics. It is the study of very rare events that have probability tending to zero exponentially fast and its goal is to determine the exact form of this rate of convergence. Another closely related area of study is moderate deviations, which is proved for events that have probability going to zero at a rate slower than that of large deviations but faster than the rate for central limit theorem. An important application of large and moderate deviations is the law of the iterated logarithm (LIL). Beginning with J. Deuschel, D. Stroock [\[19\]](#page-20-0) (Lemma 1.4.3), a notable number of authors have used this connection. For instance, P. Baldi [\[3\]](#page-19-0), G. Divanji, K. Vidyalaxmi [\[20\]](#page-20-1), B. Jing, Q. Shao, Q. Wang [\[32\]](#page-21-0), and A. Mogul'skii [\[34\]](#page-21-1) applied their large deviation principle (LDP) to prove LIL; whereas, Y. Chen, L. Liu [\[11\]](#page-20-2) and R. Wang, L. Xu [\[43\]](#page-21-2) applied their result on moderate deviation principle (MDP).

LIL has useful applications in fields such as finance (see for example [\[30,](#page-21-3) [49\]](#page-21-4)). There are different forms of LIL in the literature: Classical LIL, Strassen's Compact LIL, Chover's type, and Chung's type, which inherited names from the authors who introduced them; namely, A. Khintchine [\[33\]](#page-21-5), V. Strassen [\[41\]](#page-21-6), J. Chover [\[12\]](#page-20-3), and K. Chung [\[13\]](#page-20-4), respectively. In section two, we provide a description of each type of LIL. For a more detailed introduction and history on each type we recommend [\[5\]](#page-20-5). As one may observe from the literature, every type of LIL may be derived from large and moderate deviations by the use of the Borel-Cantelli lemma. The most common form for this application is the Stassen's

Key words and phrases. Law of iterated logarithm, large deviation principle, moderate deviation principle, stochastic partial differential equation, Fleming-Viot process, super-Brownian motion.

compact LIL. Here we prove the MDP by Azencott method and as an application establish the Strassen's compact LIL. We note that LDP and MDP for the class of SPDEs and the population models considered here were achieved in [\[27\]](#page-20-6) and [\[28\]](#page-20-7), respectively by the weak convergence approach introduced by  $[6, 8]$  $[6, 8]$ . Here the MDP by the Azencott method provides us the Freidlin-Wentzell inequality, which plays a major role in proving the Strassen's compact LIL.

To achieve the Strassen's compact LIL, one needs to show that the centered process multiplied by  $1/\sqrt{2\log\log t}$  is relatively compact and then specify the set of limit points. Since our process is real-valued, we obtain that it is relative compact by proving its tightness property by a classical method. Moreover, to determine the set of limit points, we apply the result introduced by P. Baldi [\[2\]](#page-19-1) and implemented in [\[23,](#page-20-10)[36,](#page-21-7) [37\]](#page-21-8). Other methods have also been applied by some authors to establish that their process is relatively compact. A. Dembo, T. Zajic [\[17\]](#page-20-11) and L. Wu [\[44\]](#page-21-9) prove this condition by showing that their process is totally bounded. A. Schied [\[40\]](#page-21-10), attains the Strassen's compact LIL for super-Brownian motion (SBM) in all dimensions,  $d \geq 1$ , as a corollary to its moderate deviation result also given in [\[40\]](#page-21-10). Similar to many other results in LIL derived from LDP or MDP, A. Schied uses the rate function in MDP to form the set of limit points. Since his rate function is a good rate function, he applies the compactness property of its level sets and Lemma 1.4.3 in [\[19\]](#page-20-0). Different from results in [\[40\]](#page-21-10), here our proof of LIL for SBM relies on the more recent presentation of SBM by a stochastic PDE given by [\[45\]](#page-21-11). To the best of our knowledge, LIL has not been proven for Fleming-Viot Process (FVP) in the literature. Also the Classical LIL for SBM and FVP would be new contributions.

We begin in section two with notations and spaces used throughout the paper and provide the main results. Also we offer some definitions and background on the Azencott method, LIL and the two population models. Section three is devoted to achieving the LDP, Strassen's compact LIL and Classical LIL for the class of SPDEs and in section four the results are applied to obtain the LDP and the two types of LIL for SBM and FVP.

## 2. NOTATION AND MAIN RESULTS

Following the notation given in [\[27,](#page-20-6) [28\]](#page-20-7), we introduce the space used here as follows. Suppose  $(\Omega, \mathcal{F}, P)$  is a probability space and  $\{\mathcal{F}_t\}_{t>0}$  is a family of non-decreasing, right continuous sub-σ-fields of F such that  $\mathcal{F}_0$  contains all P-null subsets of  $\Omega$ . We denote  $\mathcal{C}_b(\mathbb{R})$  to be the space of continuous bounded functions on  $\mathbb{R}$  and  $\mathcal{C}_c(\mathbb{R})$  to be composed of continuous functions in R with compact support. For  $0 < \beta \in \mathbb{R}$ , let  $\mathcal{M}_{\beta}(\mathbb{R})$  denote the set of  $\sigma$ -finite measures  $\mu$  on  $\mathbb R$  such that,

<span id="page-1-0"></span>
$$
\int e^{-\beta|x|} d\mu(x) < \infty,\tag{1}
$$

and let  $\mathcal{P}_{\beta}(\mathbb{R})$  be the set of probability measures satisfying [\(1\)](#page-1-0). We endow these spaces with the topology defined by a modification of the usual weak topology:  $\mu^n \to \mu$  in  $\mathcal{M}_\beta(\mathbb{R})$  (respectively in  $\mathcal{P}_{\beta}(\mathbb{R})$ ) iff for every  $f \in \mathcal{C}_b(\mathbb{R}),$ 

$$
\int_{\mathbb{R}} f(x)e^{-\beta|x|} \mu^{n}(dx) \to \int_{\mathbb{R}} f(x)e^{-\beta|x|} \mu(dx).
$$

For  $\alpha \in (0,1)$ , consider the space  $\mathbb{B}_{\alpha,\beta}$  composed of all functions  $f : \mathbb{R} \to \mathbb{R}$  such that for all  $m \in \mathbb{N}$ , there exist  $K_1, K_2 > 0$  with the following conditions:

<span id="page-2-0"></span>
$$
|f(y_1) - f(y_2)| \le K_1 e^{\beta m} |y_1 - y_2|^\alpha, \quad \forall |y_1|, |y_2| \le m \tag{2}
$$

$$
|f(y)| \leq K_2 e^{\beta |y|}, \quad \forall y \in \mathbb{R}, \tag{3}
$$

and with the metric,

$$
d_{\alpha,\beta}(u,v) = \sum_{m=1}^{\infty} 2^{-m} (||u-v||_{m,\alpha,\beta} \wedge 1), \qquad u, v \in \mathbb{B}_{\alpha,\beta},
$$

where

$$
||u||_{m,\alpha,\beta} = \sup_{x \in \mathbb{R}} e^{-\beta |x|} |u(x)| + \sup_{y_1 \neq y_2 |y_1|, |y_2| \le m} \frac{|u(y_1) - u(y_2)|}{|y_1 - y_2|^{\alpha}} e^{-\beta m}.
$$

We refer to the collection of continuous functions on R satisfying [\(3\)](#page-2-0) as  $\mathbb{B}_{\beta}$ , which is a Banach space with norm,

$$
||f||_{\beta} = \sup_{x \in \mathbb{R}} e^{-\beta |x|} |f(x)|.
$$

The above space was used to match the setup in [\[8\]](#page-20-9), where weak convergence approach was introduced to prove the large deviation principle and the technical difficulties in time discretization in classical Azencott method were avoided.

We now give a short introduction on the two population models under study. For more information we refer the reader to  $[15, 22, 24, 46]$  $[15, 22, 24, 46]$  $[15, 22, 24, 46]$  $[15, 22, 24, 46]$  $[15, 22, 24, 46]$  $[15, 22, 24, 46]$ . SBM is the continuous version of branching Brownian motion, the most classical and best known branching process where individuals reproduce according to Galton-Watson process. Since the population is set to evolve as a cloud in  $\mathbb{R}^d$ , it is a measure-valued process and because of its branching property, we associate a branching rate, denoted as  $\varepsilon$ . One of the common ways used to characterize SBM, denoted as  $\{\mu_\ell^\varepsilon\}_{\varepsilon>0}$ , is by the unique solution to the martingale problem given as: for all  $f \in C_b^2(\mathbb{R}),$ 

$$
M_t(f) := \langle \mu_t^{\varepsilon}, f \rangle - \langle \mu_0^{\varepsilon}, f \rangle - \int_0^t \left\langle \mu_s^{\varepsilon}, \frac{1}{2} \Delta f \right\rangle ds,
$$

is a square-integrable martingale with quadratic variation,

$$
\langle M(f) \rangle_t = \varepsilon \int_0^t \langle \mu_s^\varepsilon, f^2 \rangle \, ds,
$$

(see [\[24\]](#page-20-14) Section 1.5 for this formulation). Recently, [\[45\]](#page-21-11) offered the following SPDE to characterize SBM,

<span id="page-2-1"></span>
$$
u_t^{\varepsilon}(y) = F(y) + \int_0^t \int_0^{u_s^{\varepsilon}(y)} W(dads) + \int_0^t \frac{1}{2} \Delta u_s^{\varepsilon}(y) ds,
$$
\n(4)

where,

<span id="page-3-3"></span>
$$
u_t^{\varepsilon}(y) = \int_0^y \mu_t^{\varepsilon}(dx), \qquad \forall y \in \mathbb{R}, \tag{5}
$$

 $F(y) = \int_0^y \mu_0(dx)$ , and W is an  $\mathcal{F}_t$ -adapted space-time white noise random measure on  $\mathbb{R}^+ \times \mathbb{R}$  with intensity measure *dsda*.

The other model studied here is FVP, which observes the evolution of the population based on the genetic type of individuals. It is the continuous version of the step-wise mutation model, in which individuals move in  $\mathbb{Z}^d$  according to a continuous time sample random walk. In FVP, the population is fixed throughout time with each individual having a gene type and every time a mutation occurs the individual changes gene type and moves to a new location. Therefore, the distribution of gene types is observed, making FVP a probability-measure valued process with mutation rate given by  $\varepsilon$ . More background on FVP can be found in [\[24](#page-20-14)[–26\]](#page-20-15). Similar to SBM, FVP can be given by the unique solution to the following martingale problem: for  $f \in C_c^2(\mathbb{R})$ ,

$$
M_t(f) = \langle \mu_t^{\varepsilon}, f \rangle - \langle \mu_0^{\varepsilon}, f \rangle - \int_0^t \left\langle \mu_s^{\varepsilon}, \frac{1}{2} \Delta f \right\rangle ds,
$$

is a continuous square-integrable martingale with quadratic variation,

$$
\langle M_t(f) \rangle = \varepsilon \int_0^t \left( \langle \mu_s^{\varepsilon}, f^2 \rangle - \langle \mu_s^{\varepsilon}, f \rangle^2 \right) ds,
$$

(see [\[24\]](#page-20-14) Section 1.11 for more details on this formulation). An SPDE characterization of FVP was also made in [\[45\]](#page-21-11). There by using,

<span id="page-3-4"></span>
$$
u_t^{\varepsilon}(y) = \mu_t^{\varepsilon}((-\infty, y]), \tag{6}
$$

FVP was proved to be given by,

<span id="page-3-0"></span>
$$
u_t^{\varepsilon}(y) = F(y) + \int_0^t \int_0^1 \left(1_{a \le u_s^{\varepsilon}(y)} - u_s^{\varepsilon}(y)\right) W(dsda) + \int_0^t \frac{1}{2} \Delta u_s^{\varepsilon}(y)ds,\tag{7}
$$

with the same description for  $F(y)$  and noise as for SBM in [\(4\)](#page-2-1). Note that the main difference between  $(4)$  and  $(7)$  is in the second term. Hence, as in [\[27,](#page-20-6) [28\]](#page-20-7), we consider the following class of SPDEs and have SBM and FVP as special cases,

<span id="page-3-1"></span>
$$
u_t^{\varepsilon}(y) = F(y) + \sqrt{\varepsilon} \int_0^t \int_U G(a, y, u_s^{\varepsilon}(y)) W(dads) + \int_0^t \frac{1}{2} \Delta u_s^{\varepsilon}(y) ds,
$$
 (8)

where  $(U, U, \lambda)$  is a measure space such that  $L^2(U, U, \lambda)$  is separable, F is a function of R and  $u_1, u_2, u, y \in \mathbb{R}$ . In addition,  $G: U \times \mathbb{R}^2 \to \mathbb{R}$  satisfies the following conditions,

<span id="page-3-2"></span>
$$
\int_{U} |G(a, y, u_1) - G(a, y, u_2)|^2 \lambda(da) \leq K|u_1 - u_2|,
$$
\n(9)

$$
\int_{U} |G(a, y, u)|^2 \,\lambda(da) \leq K \left(1 + |u|^2\right). \tag{10}
$$

We note that since the well-posedness of [\(8\)](#page-3-1) achieved in [\[45\]](#page-21-11) was in dimension one, our results are limited to dimension one only. For moderate deviation principle, we consider the centered process,

<span id="page-4-0"></span>
$$
v_t^{\varepsilon}(y) = \frac{a(\varepsilon)}{\sqrt{\varepsilon}} \left( u_t^{\varepsilon}(y) - u_t^0(y) \right), \tag{11}
$$

where  $a(\varepsilon)$  satisfies,

<span id="page-4-5"></span>
$$
0 \le a(\varepsilon) \to 0, \quad \frac{a(\varepsilon)}{\sqrt{\varepsilon}} \to \infty \text{ as } \varepsilon \to 0.
$$
 (12)

One may observe that the speed,  $a(\varepsilon)$  of moderate deviations is less than  $\sqrt{\varepsilon}$ , the speed for large deviations; hence, the term moderate is used. For the rate of decay we need the following controlled PDE version of [\(11\)](#page-4-0), also referred to as the skeleton equation given by,

<span id="page-4-1"></span>
$$
S_t(h, y) = \int_0^t \int_U G(a, y, u_s^0(y)) h_s(a) \lambda(da) ds + \frac{1}{2} \int_0^t \Delta S_s(h, y) ds,
$$
 (13)

where  $h_s \in L^2([0,1] \times U, ds\lambda(da))$ . It is not difficult to show that for every  $h_s(\cdot)$  there is a unique solution to [\(13\)](#page-4-1). For MDP, the first term of SPDE  $(8)$ ,  $F(y)$ , is assumed to be in space,  $\mathbb{B}_{\alpha,\beta_0}$  where  $\beta_0 \in (0,\beta)$ . By the classical Azencott method, we prove the following MDP result.

<span id="page-4-3"></span>**Theorem 1.** *If*  $F \in \mathbb{B}_{\alpha,\beta_0}$  for  $\alpha \in (0, \frac{1}{2})$  $\frac{1}{2}$ ), then family  $\{v_t^{\varepsilon}(y)\}_{{\varepsilon}>0}$  satisfies the LDP in  $\mathcal{C}([0,1];\mathbb{B}_{\beta})$  *with speed*  $a(\varepsilon)$  *and rate function,* 

<span id="page-4-4"></span>
$$
I(g) = \frac{1}{2} \inf \left\{ \int_0^1 \int_U |h_s(a)|^2 \lambda(da) ds : g = S_t(h, y) \right\},\tag{14}
$$

*which implies that family*  $\{u_t^{\varepsilon}(y)\}_{{\varepsilon}>0}$  *obeys the MDP*.

LDP by Azencott method was first introduced by [\[1,](#page-19-2)[39\]](#page-21-13) and it may be described as follows. Suppose a family of random variables,  $\{X_1^{\varepsilon}\}_{\varepsilon>0}$ , on a Polish space,  $E_1$ , satisfies the LDP with rate function,  $I_1: E_1 \to [0, \infty]$ . Then family  $\{X_2^{\varepsilon}\}_{\varepsilon>0}$  on another Polish space,  $E_2$ , satisfies the LDP with rate function,  $I_2(g) := \inf\{I_1(f) : \Phi(f) = g\}$ , if for any  $R, \rho, a > 0$ , there exist  $\eta > 0$ , and  $\varepsilon_0 > 0$ , such that for any  $f \in E_1$  with  $I_1(f) \le a$  and any  $\varepsilon \le \varepsilon_0$ ,

<span id="page-4-2"></span>
$$
P\left(\|X_2^{\varepsilon} - \Phi(f)\|_2 \ge \rho, \|X_1^{\varepsilon} - f\|_1 < \eta\right) \le \exp\left(-\frac{R}{\varepsilon^2}\right),\tag{15}
$$

where  $\Phi: \{I_1 \leq a\} \to E_2$  is continuous with respect to the topology of  $E_1$  when restricted to sets  $\{I_1 \leq a\}$  for any  $a > 0$ . Inequality [\(15\)](#page-4-2) is referred to as the Freidlin-Wentzell inequality and in the setting of SPDEs,  $\Phi(f)$  is the unique solution to the controlled PDE. For some examples of results on LDP for SPDEs by this method we refer the reader to [\[9,](#page-20-16) [35\]](#page-21-14). Below is the general definition of LDP. For more background on the large deviations theory we recommend [\[7,](#page-20-17) [18,](#page-20-18) [21\]](#page-20-19).

**Definition 1** (Large Deviation Principle (LDP)). *The sequence*  $\{X^{\varepsilon}\}_{\varepsilon>0}$  *satisfies the LDP on* E *with rate function* I *if the following two conditions hold. a. LDP lower bound: for every open set*  $U \subset \mathcal{E}$ ,

$$
-\inf_{x\in U} I(x) \le \liminf_{\varepsilon \to 0} \varepsilon \log P(X^{\varepsilon} \in U),
$$

*b. LDP upper bound: for every closed set*  $C \subset \mathcal{E}$ ,

$$
\limsup_{\varepsilon \to 0} \varepsilon \log P(X^{\varepsilon} \in C) \leq - \inf_{x \in C} I(x).
$$

As for SBM and FVP, each model being a measure-valued process is denoted as  $\{\mu_t^{\varepsilon}\}_{\varepsilon>0}$ with  $\varepsilon$  being the branching rate or mutation rate based on context and is set to go to zero. For SBM, the Cameron-Martin space,  $H$  is used and for FVP we use  $H$ , the space for which conditions for H hold with  $M_{\beta}(\mathbb{R})$  replaced by the space of probability measures  $\mathcal{P}(\mathbb{R})$ , and with the additional assumption,

$$
\left\langle \mu_t^0, \frac{d\left(\dot{\omega}_t - \frac{1}{2}\Delta^*\omega_t\right)}{d\mu_t^0} \right\rangle = 0,
$$

where for both population models the centered process for MDP is given by,

<span id="page-5-2"></span>
$$
\omega_t^{\varepsilon}(dy) := \frac{a(\varepsilon)}{\sqrt{\varepsilon}} \left( \mu_t^{\varepsilon}(dy) - \mu_t^0(dy) \right). \tag{16}
$$

With the above notation, we obtain the following theorems.

**Theorem 2.** If  $\omega_0 \in M_\beta(\mathbb{R})$  such that  $F \in \mathbb{B}_{\alpha,\beta_0}$  then super-Brownian motion,  $\{\mu_t^{\varepsilon}\}_{\varepsilon > 0}$ , *obeys the MDP in*  $\mathcal{C}([0,1];\mathcal{M}_{\beta}(\mathbb{R}))$  *with speed*  $a(\varepsilon)$  *and rate function,* 

<span id="page-5-0"></span>
$$
I(\omega) = \begin{cases} \frac{1}{2} \int_0^1 \int_{\mathbb{R}} \left| \frac{d\left(\dot{\omega} - \frac{1}{2} \Delta^* \omega_t\right)}{d\mu_t^0} y \right|^2 \mu_t^0(dy) dt & \text{if } \mu_t^0 \in \mathcal{H}_{\omega_0}, \\ \infty & \text{otherwise.} \end{cases}
$$
(17)

**Theorem 3.** Let  $\mathcal{P}_{\beta}(\mathbb{R})$  *be the probability measure analog of*  $\mathcal{M}_{\beta}(\mathbb{R})$ *. If*  $\omega_0 \in \mathcal{P}_{\beta}(\mathbb{R})$  *such that*  $F \in \mathbb{B}_{\alpha,\beta_0}$ *, then, Fleming-Viot process,*  $\{\mu^{\varepsilon}\}_{\varepsilon>0}$ *, satisfies the MDP on*  $\mathcal{C}([0,1];\mathcal{P}_{\beta}(\mathbb{R}))$ *with speed*  $a(\varepsilon)$  *and rate function,* 

<span id="page-5-1"></span>
$$
I(\omega) = \begin{cases} \frac{1}{2} \int_0^1 \int_{\mathbb{R}} \left| \frac{d\left(\dot{\omega}_t - \frac{1}{2} \Delta^* \omega_t\right)}{d\mu_t^0} y \right|^2 \mu_t^0(dy) dt & \text{if } \mu_t^0 \in \tilde{\mathcal{H}}_{\omega_0}, \\ \infty & \text{otherwise.} \end{cases}
$$
(18)

As mentioned in the introduction, there are different types of LIL that appear in the literature. Below we provide a definition for each type.

**Definition 2** (Law of the Iterated Logarithm (LIL)). Let  $\{X_j\}_{j\geq 1}$  be an *i.i.d.* sequence *of random variables with*  $S_n := \sum_{j=1}^n X_j$ .

*i. Classical LIL:*  $\{X_j\}_{j\geq 1}$  *is said to satisfy the classical LIL, also referred to as the Khintchine's LIL, if*

<span id="page-6-0"></span>
$$
\limsup_{n \to \infty} \frac{S_n - n\mu}{\sigma \sqrt{2n \log \log n}} = 1 \ a.s. \tag{19}
$$

$$
\liminf_{n \to \infty} \frac{S_n - n\mu}{\sigma \sqrt{2n \log \log n}} = -1 \quad a.s.
$$
\n(20)

*for common mean*  $\mu$  *and variance*  $\sigma^2$ *. We note that this version is also given by* [\(19\)](#page-6-0) *and* [\(20\)](#page-6-0) with  $S_n - n\mu$  replaced by  $X_n$  with  $\mu = 0$  and  $\sigma^2 = 1$ . For examples of this form see *for instance [\[32,](#page-21-0) [43\]](#page-21-2).*

*ii. Strassen's Compact LIL: A class of functions* F *satisfies Strassen's compact LIL with respect to*  $\{X_j\}_{j\geq 1}$  *if there is a compact set* J *in*  $\ell_{\infty}(\mathcal{F})$  *such that*  $\{X_j\}_{j\geq 1}$  *is a.s. relatively compact and its limit set is* J*. See for example [\[2,](#page-19-1) [17,](#page-20-11) [44\]](#page-21-9).*

*iii. Chover-type LIL:*  $\{X_j\}_{j\geq 1}$  *satisfies Chover-type LIL if* 

$$
\limsup_{n \to \infty} \left( \frac{|S_n|}{n^{1/\alpha}} \right)^{\frac{1}{\log \log n}} = e^{1/\alpha} \ a.s.
$$
 (21)

*for*  $0 < \alpha < 2$ *. For examples of this form see [\[38,](#page-21-15)47].* 

*iv.* Chung-type LIL: Let  $S_n^* = max_{k \leq n} |S_k|$ . Chung-type LIL for  $\{X_j\}_{j \geq 1}$  holds if

$$
\liminf_{n \to \infty} \frac{S_n^* \sqrt{\log \log n}}{\sqrt{n}} = \frac{\pi}{\sqrt{8}} \ a.s. \tag{22}
$$

*For results of this type see for example, [\[11,](#page-20-2) [34\]](#page-21-1).*

We are now ready to give our results on LIL. For  $0 < \varepsilon < 1$ , let,

$$
Z_t^{\varepsilon}(y) := \frac{1}{\sqrt{2\varepsilon \log \log \frac{1}{\varepsilon}}} \left( u_t^{\varepsilon}(y) - u_t^0(y) \right),\tag{23}
$$

more precisely,

$$
Z_t^{\varepsilon}(y) = \frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}} \int_0^t \int_U G_s^{\varepsilon}(a, y, Z_s^{\varepsilon}(y)) W(dads) + \int_0^t \frac{1}{2} \Delta Z_s^{\varepsilon}(y) ds,
$$
 (24)

where,

$$
G_s^{\varepsilon}(a, y, Z_s^{\varepsilon}(y)) := G\left(a, y, \sqrt{2\varepsilon \log \log \frac{1}{\varepsilon}} Z_s^{\varepsilon}(y) + u_s^0(y)\right). \tag{25}
$$

Therefore, we have the process  $\{v_t^{\varepsilon}(y)\}_{{\varepsilon}>0}$  from moderate deviations used in Theorem [1](#page-4-3) with  $a(\varepsilon) = 1/\sqrt{2 \log \log(1/\varepsilon)}$ . One can check that this fulfills the requirements of  $a(\varepsilon)$ 

going to zero as  $\varepsilon$  tends to zero, at a rate slower than  $\sqrt{\varepsilon}$ . Also based on conditions [\(9\)](#page-3-2) and [\(10\)](#page-3-2),

$$
\int_{U} \left| G_{s}^{\varepsilon}\left(a, y, Z_{s,1}^{\varepsilon}(y)\right) - G_{s}^{\varepsilon}\left(a, y, Z_{s,2}^{\varepsilon}(y)\right) \right|^{2} \lambda(da) \leq K_{3} \sqrt{2\varepsilon \log \log \frac{1}{\varepsilon}} \left| Z_{s,1}^{\varepsilon}(y) - Z_{s,2}^{\varepsilon}(y) \right|,
$$
\n(26)

<span id="page-7-2"></span>
$$
\int_{U} |G_{s}^{\varepsilon}(a, y, Z_{s}^{\varepsilon}(y))|^{2} \lambda(da) \leq K_{4} \left(1 + \left(2\varepsilon \log \log \frac{1}{\varepsilon}\right) Z_{s}^{\varepsilon}(y)^{2} + e^{2\beta_{0}|y|}\right),\tag{27}
$$

where we have used the fact that  $F \in \mathbb{B}_{\alpha,\beta_0}$ , giving by condition [\(3\)](#page-2-0),

<span id="page-7-1"></span>
$$
|u_s^0(y)| \le K_2 e^{\beta_0 |y|}.
$$
 (28)

We point out that the proof of the existence and uniqueness of solutions to SPDE,  $\{u_{t}^{\varepsilon}(y)\}_{\varepsilon>0}$  given in [\[45\]](#page-21-11) only relies on condition [\(9\)](#page-3-2). Thus, we obtain the well-posedness of solutions to  $Z_t^{\varepsilon}(y)$  and can use its mild solution given as,

$$
Z_t^{\varepsilon}(y) := \frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}} \int_0^t \int_U P_{t-s} G_s^{\varepsilon}(a, y, Z_s^{\varepsilon}(y)) W(dads), \tag{29}
$$

where  $P_{t-s}$  is the Brownian semigroup defined as  $P_t f(y) = \int_{\mathbb{R}} p_t(x-y) f(x) dx$  with  $p_t(x-y) = \frac{1}{\sqrt{2}}$  $\frac{1}{2\pi t}e^{-\frac{|x-y|^2}{2t}}$ . We prove the following results using Theorems 1-3.

**Theorem 4.** *Process*  $\{Z_t^{\varepsilon}(y)\}_{0 \leq \varepsilon \leq 1}$  *is relatively compact in*  $\mathcal{C}([0,1];\mathbb{B}_{\beta})$  *and its set of limit points is exactly*  $L_1 := \{g \in \mathcal{C}([0,1];\mathbb{B}_{\beta}) : I(g) \leq 1\}$  *where*  $I(g)$  *is defined by* [\(14\)](#page-4-4)*.* 

Similarly using the MDP result for SBM and FVP, let

<span id="page-7-0"></span>
$$
\tilde{Z}_t^{\varepsilon} := \frac{1}{\sqrt{2\varepsilon \log \log \frac{1}{\varepsilon}}} \left( \mu_t^{\varepsilon}(dy) - \mu_t^0(dy) \right). \tag{30}
$$

**Theorem 5.** *Process*  $\{\tilde{Z}_t^{\varepsilon}\}_{0\leq \varepsilon \leq 1}$  *formed by SBM process,*  $\{\mu_t^{\varepsilon}\}_{\varepsilon > 0}$  *in* [\(30\)](#page-7-0) *is relatively com-* $\text{pact in } \mathcal{C}([0,1];\mathcal{M}_{\beta}(\mathbb{R})) \text{ with set of limit points being } L_2 := \{ \omega \in \mathcal{C}([0,1];\mathcal{M}_{\beta}(\mathbb{R})) : I(\omega) \leq 1 \},$ *where*  $I(\omega)$  *is given by* [\(17\)](#page-5-0)*.* 

**Theorem 6.** *Process*  $\{\tilde{Z}_t^{\varepsilon}\}_{0\leq \varepsilon \leq 1}$  *formed by FVP process,*  $\{\mu_t^{\varepsilon}\}_{\varepsilon > 0}$  *in* [\(30\)](#page-7-0) *is relatively compact in*  $\mathcal{C}([0,1];\mathcal{P}_{\beta}(\mathbb{R}))$  *with set of limit points being*  $L_3 := {\omega \in \mathcal{C}([0,1];\mathcal{P}_{\beta}(\mathbb{R})) : I(\omega) \leq 1},$ *where*  $I(\omega)$  *is given by* [\(18\)](#page-5-1)*.* 

Following the setup in [\[11,](#page-20-2)[42,](#page-21-17)[43\]](#page-21-2) we prove the classical LIL in our stochastic PDEs setting. We note that most results on classical LIL such as  $[14, 32]$  $[14, 32]$  have been achieved for a sum of independent identically distributed random variables, where the Borel-Cantelli lemma is the main ingredient of the proof. We prove the classical LIL for the class of SPDEs and the population models by showing that for each respective family,  $\{X^{\varepsilon}\}_{0\leq \varepsilon\leq 1}$  of solutions,

<span id="page-8-3"></span>
$$
\limsup_{\varepsilon \to 0} \frac{\|X^{\varepsilon} - X^0\|_{X}}{\sqrt{2\varepsilon \log \log \frac{1}{\varepsilon}}} = 1 \quad \text{a.s.},
$$
\n(31)

$$
\liminf_{\varepsilon \to 0} \frac{\|X^{\varepsilon} - X^0\|_{X}}{\sqrt{2\varepsilon \log \log \frac{1}{\varepsilon}}} = -1 \quad \text{a.s.},\tag{32}
$$

where  $\chi$  is  $\mathbb{B}_{\beta}$  for the class of SPDEs and it is  $\mathcal{M}_{\beta}(\mathbb{R})$  and  $\mathcal{P}_{\beta}(\mathbb{R})$  for SBM and FVP, respectively.

## 3. LIL for Class of SPDEs

We begin by proving Theorem 1, for which we derive the following Freidlin-Wentzell inequality based on our setting,

<span id="page-8-0"></span>
$$
P\left(\|Z_t^{\varepsilon} - S_t(h, y)\|_{\beta} > \rho, \left\|\frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}}W - h_s\right\|_{\infty} < \eta\right) \le \exp\left(-2R\log\log\frac{1}{\varepsilon}\right). \quad (33)
$$

Note that by Schilder's theorem, the LDP holds for Brownian sheet, W with rate function denoted here by  $\tilde{I}(\cdot)$ .

**Lemma 1.** For every  $a > 0$ ,  $S_t(\cdot, y) : \{\tilde{I} \le a\} \to C([0, 1]; \mathbb{B}_{\beta})$  is continuous with respect *to the uniform topology.*

*Proof.* Let  $a > 0$  and  $h_s, k_s \in L^2([0,1] \times U, ds\lambda(da))$  with  $|h_s| \vee |k_s| \le a$ . By Hölder's inequality and [\(10\)](#page-3-2), we have,

<span id="page-8-1"></span>
$$
||S_t(h_s, x) - S_t(k_s, x)||_{\beta}^2
$$
\n
$$
= \sup_{x \in \mathbb{R}} e^{-2\beta |x|} \left| \int_0^t \int_U P_{t-s} G(a, x, u_s^0(x)) (h_s(a) - k_s(a)) \lambda(da) ds \right|^2
$$
\n
$$
\leq \sup_{x \in \mathbb{R}} e^{-2\beta |x|} \left| \int_0^t \left( \int_U (P_{t-s} G(a, x, u_s^0(x)))^2 \lambda(da) \right)^{1/2} \left( \int_U |h_s(a) - k_s(a)|^2 \lambda(da) \right)^{1/2} ds \right|^2
$$
\n
$$
\leq t \sup_{x \in \mathbb{R}} e^{-2\beta |x|} \int_0^t \int_{\mathbb{R}} p_{t-s}^2(x - y) e^{2\beta |y|} dy \int_{\mathbb{R}} (1 + |u_s^0(y)|^2) e^{-2\beta |y|} dy \int_U |h_s(a) - k_s(a)|^2 \lambda(da) ds.
$$
\n
$$
= \sup_{x \in \mathbb{R}} e^{-2\beta |x|} \int_0^t \int_{\mathbb{R}} p_{t-s}^2(x - y) e^{2\beta |y|} dy \int_{\mathbb{R}} (1 + |u_s^0(y)|^2) e^{-2\beta |y|} dy \int_U |h_s(a) - k_s(a)|^2 \lambda(da) ds.
$$
\n(34)

Observe that,

<span id="page-8-2"></span>
$$
\int_{0}^{t} \int_{\mathbb{R}} p_{t-s}^{2}(x-y)e^{2\beta|y|} dyds = \int_{0}^{t} \int_{\mathbb{R}} \frac{1}{2\sqrt{\pi(t-s)}} p_{\frac{t-s}{2}}(x-y)e^{2\beta|y|} dyds
$$
  

$$
\leq \tilde{K}e^{2\beta|x|} \int_{0}^{t} \frac{1}{\sqrt{t-s}} ds = \tilde{K}\sqrt{t}e^{2\beta|x|}.
$$
 (35)

Thus, using [\(28\)](#page-7-1) with the convention that  $\beta_0 < \beta$ , we obtain,

$$
||S_t(h_s, x) - S_t(k_s, x)||_{\beta}^2 \le t^{3/2} \tilde{K} K_2 \int_U \sup_{0 \le s \le t} |h_s(a) - k_s(a)|^2 \lambda(da),
$$

where, by noting the domain  $L^2([0,1] \times U, ds\lambda(da))$  of  $h_s$  and  $k_s$ , we may apply the dominated convergence theorem to obtain the result.

 $\Box$ 

.

As shown in [\[35\]](#page-21-14), by an application of Girsanov's transformation theorem, to obtain in-equality [\(33\)](#page-8-0), it is sufficient to prove for all  $h_s \in L^2([0,1] \times U, ds\lambda(da))$ ,  $R, \rho > 0$ , there exist  $\eta > 0, \varepsilon_0 \in (0, 1)$ , such that for all  $\varepsilon \in (0, \varepsilon_0)$ ,

<span id="page-9-1"></span>
$$
P\left(\|Y_t^{\varepsilon} - S_t(h, y)\|_{\beta} > \rho, \left\|\frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}}W\right\|_{\infty} < \eta\right) \le \exp\left(-2R\log\log\frac{1}{\varepsilon}\right),\qquad(36)
$$

with,

<span id="page-9-0"></span>
$$
Y_t^{\varepsilon}(y) = \frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}} \int_0^t \int_U G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) W(dads) + \int_0^t \frac{1}{2} \Delta Y_s^{\varepsilon}(y) ds + \int_0^t \int_U G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) h_s(a) \lambda(da) ds,
$$
\n(37)

where the well-posedness of  $Y_t^{\varepsilon}(y)$  may be verified following similar reasoning as in the proof of the well-posedness of  $u_t^{\varepsilon}(y)$  in [\[45\]](#page-21-11). For our estimates, we use the following lemma, the proof of which is very similar to that of Lemma 1 in [\[28\]](#page-20-7) and it is thus omitted.

**Lemma 2.** Suppose  $Y_t^{\varepsilon}(y)$  is the unique solution to SPDE [\(37\)](#page-9-0), then for every  $p \geq 1, \varepsilon > 0$  $and T > 0$ , there exists a positive constant  $M_1$  such that,

<span id="page-9-2"></span>
$$
\sup_{\varepsilon>0} \mathbb{E}\left(\sup_{0\leq t\leq T} \int_{\mathbb{R}} Y_t^{\varepsilon}(x)^2 e^{-2\beta|x|} dx\right)^p \leq M_1. \tag{38}
$$

In order to obtain [\(36\)](#page-9-1), we apply a time discretization of  $Y_t^{\varepsilon}$ . For  $n \in \mathbb{N}$ ,  $i = 0, 1, ..., n$ , let  $\Delta_i^n = [t_i^n, t_{i+1}^n]$ , where  $t_i^n = iT/n$ , then by the following two estimates we can achieve inequality [\(36\)](#page-9-1).

$$
P\left(\|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\|_{\beta} > \mu\right) \le \exp\left(-2R\log\log\frac{1}{\varepsilon}\right),\tag{39}
$$

$$
P\left(\|Y_t^{\varepsilon} - S_t(h, y)\|_{\beta} > \rho, \left\|\frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}}W\right\|_{\infty} < \eta, \|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\|_{\beta} \le \mu\right) \le \exp\left(-2R\log\log\frac{1}{\varepsilon}\right)
$$
\n(40)

**Lemma 3.** For all  $R > 0, \mu > 0$  there exists  $n_0 \in \mathbb{N}$  such that for all  $n \geq n_0$ , and  $\varepsilon \in (0,1),$ 

<span id="page-10-0"></span>
$$
P\left(\|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\|_{\beta} > \mu\right) \le \exp\left(-2R\log\log\frac{1}{\varepsilon}\right). \tag{41}
$$

*Proof.* For  $n \in \mathbb{N}$ , let  $t \in \Delta_i^n$  and denote for  $0 < t_1 < t_2$ ,

<span id="page-10-1"></span>
$$
\Delta p(t_2, t_1) := p_{t_2 - s}(x - y) - p_{t_1 - s}(x - y). \tag{42}
$$

Then we have,

$$
\sup_{0 \leq t \leq 1} \sup_{y \in \mathbb{R}} e^{-\beta |y|} |Y_t^{\varepsilon}(y) - Y_{t_i^{\varepsilon}}^{\varepsilon}(y)|
$$
\n
$$
\leq \sup_{0 \leq t \leq 1} \left| \sup_{y \in \mathbb{R}} \frac{e^{-\beta |y|}}{\sqrt{2 \log \log \frac{1}{\varepsilon}}} \int_{t_i^n}^t \int_U P_{t-s} G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) W(dads) \right|
$$
\n
$$
+ \sup_{0 \leq t \leq 1} \left| \sup_{y \in \mathbb{R}} \frac{e^{-\beta |y|}}{\sqrt{2 \log \log \frac{1}{\varepsilon}}} \int_0^{t_i^n} \int_U \int_{\mathbb{R}} \Delta p(t, t_i^n) G_s^{\varepsilon}(a, x, Y_s^{\varepsilon}(x)) dx W(dads) \right|
$$
\n
$$
+ \sup_{0 \leq t \leq 1} \sup_{y \in \mathbb{R}} e^{-\beta |y|} \left| \int_{t_i^n}^t \int_U P_{t-s} G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) h_s(a) \lambda(da) ds \right|
$$
\n
$$
+ \sup_{0 \leq t \leq 1} \sup_{y \in \mathbb{R}} e^{-\beta |y|} \left| \int_0^{t_i^n} \int_U P_{t-s} G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) h_s(a) \lambda(da) ds \right|
$$
\n
$$
= I_1 + I_2 + I_3 + I_4,
$$

leading to,

$$
P\left(\sup_{0\leq t\leq 1}||Y_t^{\varepsilon}-Y_{t_i^n}^{\varepsilon}||_{\beta}>\mu\right)\leq \sum_{i=1}^n\sum_{j=1}^4 P\left(\sup_{t\in\Delta_i^n}I_j(t)>\frac{\mu}{4}\right).
$$

Similar to estimates in [\(34\)](#page-8-1) and noting the domain  $L^2([0,1] \times U, ds\lambda(da))$  of  $h_s(a)$ , we have by Lemma 2,

$$
P\left(\sup_{t\in\Delta_i^n} I_3(t) > \frac{\mu}{4}\right) \leq \frac{16}{\mu^2} \mathbb{E} \sup_{t\in\Delta_i^n} |I_3(t)|^2 \leq M_1 \tilde{K}_1 \frac{16}{\mu^2} \sup_{t\in\Delta_i^n} |t - t_i^n|^2,
$$
  
and 
$$
P\left(\sup_{t\in\Delta_i^n} I_4(t) > \frac{\mu}{4}\right) \leq \frac{16}{\mu^2} \mathbb{E} \sup_{t\in\Delta_i^n} |I_4(t)|^2 \leq M_1 \tilde{K}_2 \frac{16}{\mu^2} \sup_{t\in\Delta_i^n} |t - t_i^n|^2.
$$

Then for any fixed  $R > 0, \varepsilon \in (0, 1)$ , there exists  $n_0$  such that for all  $n \ge n_0$ ,

$$
P\left(\sup_{t\in\Delta_i^n} I_3(t) > \frac{\mu}{4}\right) + P\left(\sup_{t\in\Delta_i^n} I_4(t) > \frac{\mu}{4}\right) \le \tilde{K}_3 \frac{16}{\mu^2} \sup_{t\in\Delta_i^n} |t - t_i^n|^2 \le \exp\left(-2R\log\log\frac{1}{\varepsilon}\right).
$$

 $\overline{\phantom{a}}$  $\overline{\phantom{a}}$  $\overline{\phantom{a}}$  $\overline{\phantom{a}}$  $\overline{\phantom{a}}$  $\mid$  Continuing, we obtain,

$$
P\left(\sup_{0\leq t\leq 1}\|Y_{t}^{\varepsilon}-Y_{t_{i}^{n}}^{\varepsilon}\|_{\beta}>\mu\right)
$$
  
\n
$$
\leq \sum_{i=1}^{n}\left(P\left(\sup_{t\in\Delta_{i}^{n}}I_{1}>\frac{\mu}{4}\right)+P\left(\sup_{t\in\Delta_{i}^{n}}I_{2}>\frac{\mu}{4}\right)\right)
$$
  
\n
$$
\leq \sum_{i=1}^{n}\left[P\left(\sup_{t\in\Delta_{i}^{n}}\left|\sup_{y\in\mathbb{R}}\frac{e^{-\beta|y|}}{\sqrt{2\log\log\frac{1}{\varepsilon}}}\int_{t_{i}^{n}}^{t}\int_{U}P_{t-s}G_{s}^{\varepsilon}(a,y,Y_{s}^{\varepsilon}(y))W(dads)\right|>\frac{\mu}{4}\right)
$$
  
\n
$$
+P\left(\sup_{t\in\Delta_{i}^{n}}\left|\sup_{y\in\mathbb{R}}\frac{e^{-\beta|y|}}{\sqrt{2\log\log\frac{1}{\varepsilon}}}\int_{0}^{t_{i}^{n}}\int_{U}\int_{\mathbb{R}}\Delta p(t,t_{i}^{n})G_{s}^{\varepsilon}(a,x,Y_{s}^{\varepsilon}(x))dxW(dads)\right|>\frac{\mu}{4}\right)
$$
  
\n
$$
=\sum_{i=1}^{n}P\left(\sup_{t\in\Delta_{i}^{n}}J_{1}^{i}(t)>\frac{\mu\sqrt{2\log\log\frac{1}{\varepsilon}}}{4}\right)+\sum_{i=1}^{n}P\left(\sup_{t\in\Delta_{i}^{n}}J_{2}^{i}(t)>\frac{\mu\sqrt{2\log\log\frac{1}{\varepsilon}}}{4}\right).
$$

Similar to [\(34\)](#page-8-1) and [\(35\)](#page-8-2) and by Burkholder-Davis-Gundy inequality, [\(27\)](#page-7-2) and Lemma 2,

$$
\mathbb{E} \sup_{t \in \Delta_i^n} |J_1^i|^2 = \mathbb{E} \sup_{t \in \Delta_i^n} \sup_{y \in \mathbb{R}} e^{-2\beta |y|} \left| \int_{t_i^n}^t \int_U P_{t-s} G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) W(dads) \right|^2
$$
\n
$$
\leq \mathbb{E} \sup_{t \in \Delta_i^n} \sup_y e^{-2\beta |y|} \int_{t_i^n}^t \int_U \left( \int_{\mathbb{R}} p_{t-s}(x-y) G_s^{\varepsilon}(a, x, Y_s^{\varepsilon}(x)) dx \right)^2 \lambda(da) ds
$$
\n
$$
\leq \mathbb{E} \sup_{t \in \Delta_i^n} \sup_y e^{-2\beta |y|} \int_{t_i^n}^t \int_U \int_{\mathbb{R}} p_{t-s}(x-y)^2 e^{2\beta |x|} dx \int_{\mathbb{R}} G_s^{\varepsilon}(a, x, Y_s^{\varepsilon}(x))^2 e^{-2\beta |x|} dx \lambda(da) ds
$$
\n
$$
\leq K_4 \tilde{K}_4 \mathbb{E} \sup_{t \in \Delta_i^n} |t - t_i^n|^{1/2} \int_{\mathbb{R}} \left( 1 + (2\varepsilon \log \log \frac{1}{\varepsilon}) \sup_{t_i^n \leq s \leq t} Y_s^{\varepsilon}(x)^2 + e^{2\beta_0 |x|} \right) e^{-2\beta |x|} dx
$$
\n
$$
\leq \tilde{K}_5 M_1 |t - t_i^n|^{1/2}.
$$

Following the same steps as above we find,

$$
\mathbb{E} \sup_{t \in \Delta_i^n} |J_2(t)|^2 \le \tilde{K}_6 M_1 |t_i^n|^{1/2}.
$$

Notice that to obtain [\(41\)](#page-10-0), it is sufficient to prove,

<span id="page-11-0"></span>
$$
\sum_{i=1}^{n} \mathbb{E} \exp\left(\sup_{t \in \Delta_i^n} |J_1^i(t)|^2\right) + \sum_{i=1}^{n} \mathbb{E} \exp\left(\sup_{t \in \Delta_i^n} |J_2^i(t)|^2\right) \leq \tilde{C},\tag{43}
$$

for some positive constant,  $\tilde{C}$ . Inspired by the proof of Theorem 3.2 in [\[10\]](#page-20-21), we write the left hand side of [\(43\)](#page-11-0) as,

$$
\sum_{i=1}^n \mathbb{E} \lim_{k \to \infty} \sum_{p=0}^k \frac{1}{p!} \sup_{t \in \Delta_i^n} |J_1^i(t)|^{2p} + \sum_{i=1}^n \mathbb{E} \lim_{k \to \infty} \sum_{p=0}^k \frac{1}{p!} \sup_{t \in \Delta_i^n} |J_2^i(t)|^{2p}.
$$

Then observing that [\(38\)](#page-9-2) holds for all  $p \geq 1$ , we may apply the Monotone convergence theorem to arrive at [\(43\)](#page-11-0) and since the above estimates hold for any  $\mu > 0$ , we obtain [\(41\)](#page-10-0).

 $\Box$ 

**Lemma 4.** For all  $R > 0, \rho > 0, n \in \mathbb{N}$ , there exist  $\mu_0, \eta_0 > 0$  such that for all  $\mu \leq \mu_0, \eta \leq \mu_0$  $\eta_0$ *, and*  $\varepsilon \in (0,1)$ *,* 

<span id="page-12-0"></span>
$$
P\left(\left\|Y_t^{\varepsilon} - S_t(h, y)\right\|_{\beta} > \rho, \left\|\frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}}W\right\|_{\infty} < \eta, \left\|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\right\|_{\beta} \le \mu\right) \le \exp\left(-2R\log\log\frac{1}{\varepsilon}\right). \tag{44}
$$

*Proof.* For the simplicity of notation, we let,

$$
\Delta G_s^\varepsilon(v(x),w(x)):=G_s^\varepsilon(a,x,v(x))-G_s^\varepsilon(a,x,w(x)).
$$

By the uniqueness of solutions of  $S_t(h, y)$ , we use its mild form and obtain,

$$
||Y_t^{\varepsilon} - S_t(h, y)||_{\beta} \le \sup_{y \in \mathbb{R}} \frac{e^{-\beta |y|}}{\sqrt{2 \log \log \frac{1}{\varepsilon}}} \int_0^t \int_U P_{t-s} G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) W(dads)
$$
  
+ 
$$
\sup_{y \in \mathbb{R}} e^{-\beta |y|} \int_0^t \int_U P_{t-s} \Delta G_s^{\varepsilon}(Y_s^{\varepsilon}(y), 0) h_s(a) \lambda(da) ds
$$
  
= 
$$
\frac{B_1^{\varepsilon}(t)}{\sqrt{2 \log \log \frac{1}{\varepsilon}}} + B_2^{\varepsilon}(t).
$$

Thus, we may write,

$$
P\left(\|Y_t^{\varepsilon} - S_t(h, y)\|_{\beta} > \rho, \left\|\frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}} W\right\|_{\infty} < \eta, \|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\|_{\beta} \le \mu\right)
$$
  

$$
\le P\left(B_1^{\varepsilon}(t) > \frac{\rho\sqrt{2\log\log\frac{1}{\varepsilon}}}{2}, \left\|\frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}} W\right\|_{\infty} < \eta\right)
$$
  

$$
+ P\left(B_2^{\varepsilon}(t) > \frac{\rho}{2}, \|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\|_{\beta} \le \mu\right)
$$
  

$$
= I_1 + I_2.
$$

By the same reasoning as in the proof of Lemma 3, there exists a constant  $C > 0$  such that  $\mathbb{E}(\exp(B_1^{\varepsilon}(t)^2)) \leq C$ , which yields,

<span id="page-13-0"></span>
$$
I_1 = P\left(\exp(B_1^{\varepsilon}(t)^2) > \exp\left(\frac{\rho^2(2\log\log\frac{1}{\varepsilon})}{4}\right), \left\|\frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}}W\right\|_{\infty} < \eta\right)
$$
  

$$
\leq C \exp\left(\frac{-\rho^2(2\log\log\frac{1}{\varepsilon})}{4}\right) \leq \exp(-2R\log\log\frac{1}{\varepsilon}), \tag{45}
$$

since the first inequality in [\(45\)](#page-13-0) is true for any  $\rho > 0$ . As for  $I_2$ , noting that  $t \in \Delta_i^n$ , we have,

$$
B_2^{\varepsilon}(t) = \sup_{y \in \mathbb{R}} e^{-\beta |y|} \int_0^{t_i^n} \int_U P_{t_i^n - s} G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) h_s(a) \lambda(da) ds + \sup_y e^{-\beta |y|} \int_{t_i^n}^t \int_U P_{t-s} G_s^{\varepsilon}(a, y, Y_s^{\varepsilon}(y)) h_s(a) \lambda(da) ds - \sup_y e^{-\beta |y|} \int_0^{t_i^n} P_{t_i^n - s} G_s^{\varepsilon}(a, y, 0) h_s(a) \lambda(da) ds - \sup_y e^{-\beta |y|} \int_{t_i^n}^t P_{t-s} G_s^{\varepsilon}(a, y, 0) h_s(a) \lambda(da) ds,
$$

which leads to,

$$
\sup_{t \in \Delta_i^n} B_2^{\varepsilon}(t) = \sup_{t \in \Delta_i^n} \sup_y e^{-\beta |y|} \int_0^{t_i^n} \int_U P_{t_i^n - s} \Delta G_s^{\varepsilon}(Y_s^{\varepsilon}(y), Y_{s_i^n}^{\varepsilon}(y)) h_s(a) \lambda(da) ds \n+ \sup_{t \in \Delta_i^n} \sup_y e^{-\beta |y|} \int_0^{t_i^n} \int_U P_{t_i^n - s} \Delta G_s^{\varepsilon}(Y_{s_i^n}^{\varepsilon}(y), 0) h_s(a) \lambda(da) ds \n+ \sup_{t \in \Delta_i^n} \sup_y e^{-\beta |y|} \int_{t_i^n}^t \int_U P_{t-s} \Delta G_s^{\varepsilon}(Y_s^{\varepsilon}(y), 0) h_s(a) \lambda(da) ds \n= \sup_{t \in \Delta_i^n} I_{21} + \sup_{t \in \Delta_i^n} I_{22} + \sup_{t \in \Delta_i^n} I_{23}.
$$

Using [\(9\)](#page-3-2) and condition  $||Y_s^{\varepsilon}(y) - Y_{s_i^{\varepsilon}}^{\varepsilon}(y)||_{\beta} < \mu$ , we have  $\mathbb{E} \exp(|I_{21}|^2) \leq \mu^2 \tilde{k}_1 |t_i^n|^{1/2}$  and we may bound  $\mathbb{E} \exp(|I_{22}|^2)$  and  $\mathbb{E} \exp(|I_{23}|^2)$  by  $\tilde{k}_2|t_i^n|^{1/2}$  and  $\tilde{k}_3|t-t_i^n|^{1/2}$ , respectively. Then for any fixed  $R > 0$  and  $\varepsilon \in (0, 1)$  using the fact that  $t_i^n := (Ti)/n$ , we may choose an  $n_0 \in \mathbb{N}$  such that for any  $n \geq n_0$  the following inequality holds.

$$
I_2 \le P\left(\sup_{t\in\Delta_i^n} I_{21} > \frac{\rho}{6}, \left\|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\right\|_{\beta} \le \mu\right) + P\left(\sup_{t\in\Delta_i^n} I_{22} > \frac{\rho}{6}, \left\|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\right\|_{\beta} \le \mu\right) + P\left(\sup_{t\in\Delta_i^n} I_{23} > \frac{\rho}{6}, \left\|Y_t^{\varepsilon} - Y_{t_i^n}^{\varepsilon}\right\|_{\beta} \le \mu\right) \le \exp(-2R \log \log \frac{1}{\varepsilon}).
$$

Hence, we obtain [\(44\)](#page-12-0).

Notice that the above estimates hold with any  $a(\varepsilon)$  instead of  $1/\sqrt{2 \log \log(1/\varepsilon)}$  satisfying [\(12\)](#page-4-5) and thus we achieve the MDP for the class of SPDEs by Azencott method, where using the rate function from Schilder's theorem and letting  $\Phi(h) = S_t(h, y)$ , we obtain [\(14\)](#page-4-4). For the Strassen's compact LIL to prove the relative compactness of  $Z_t^{\varepsilon}(y)$ , we show its tightness property by following the well established theorem stated below.

**Theorem 7** (Theorem 12.3 in [\[4\]](#page-19-3)). *The sequence*  $\{X^{\varepsilon}\}_{\varepsilon>0}$  *is tight in*  $\mathcal{C}([0,1];\mathbb{R})$ *, if* (*i*) *the sequence*  $\{X^{\varepsilon}(0)\}_{{\varepsilon}>0}$  *is tight,* 

(*ii*) *there exist constants*  $\gamma \geq 0$  *and*  $\alpha > 1$  *and a nondecreasing, continuous function* F *on* [0, 1] *such that*

<span id="page-14-1"></span>
$$
P(|X^{\varepsilon}(t_2) - X^{\varepsilon}(t_1)| \ge \lambda) \le \frac{1}{\lambda^{\gamma}} |F(t_2) - F(t_1)|^{\alpha}, \qquad (46)
$$

*holds for all*  $t_1, t_2$  *and n and all positive*  $\lambda$ *.* 

We need the following analogous result to Lemma 2 for the process  $\{Z_t^{\varepsilon}(y)\}_{0 \leq \varepsilon \leq 1}$ , where its proof is omitted due to its similarity with the proof of Lemma 1 in [\[28\]](#page-20-7).

<span id="page-14-0"></span>**Lemma 5.** Let  $Z_t^{\varepsilon}(y)$  be the unique solution to SPDE [\(8\)](#page-3-1), then for any  $p \geq 1, 0 < \varepsilon < 1$ and  $T > 0$ , there exists a positive constant  $M_2$  such that,

$$
\sup_{\varepsilon>0} \mathbb{E}\left(\sup_{0\leq t\leq T} \int_{\mathbb{R}} Z_t^{\varepsilon}(x)^2 e^{-2\beta|x|} dx\right)^p \leq M_2. \tag{47}
$$

**Theorem 8.** *Family,*  $\{Z_t^{\varepsilon}\}_{0 \leq \varepsilon \leq 1}$  *takes values in*  $\mathcal{C}([0,1];\mathbb{B}_{\beta})$  *and is tight.* 

*Proof.* It was shown in Lemma 3 of [\[28\]](#page-20-7) that  $v_t^{\varepsilon}(y)$  defined by [\(11\)](#page-4-0) takes values in  $\mathcal{C}([0,1];\mathbb{B}_{\beta})$ and its solution is unique allowing us to use the mild solution,

$$
Z_t^{\varepsilon}(y) := \frac{1}{\sqrt{2\log\log\frac{1}{\varepsilon}}} \int_0^t \int_U P_{t-s} G_s^{\varepsilon}(a, y, Z_s^{\varepsilon}(y)) W(dads), \tag{48}
$$

where  $P_{t-s}$  is the Brownian semigroup. Let  $0 < \varepsilon < 1$  and  $t_1, t_2 \in [0, 1]$  be arbitrary with  $t_1 < t_2$ . For  $n > 8$ , we proceed as follows,

$$
\mathbb{E} \left\| Z_{t_2}^{\varepsilon}(x) - Z_{t_1}^{\varepsilon}(x) \right\|_{\beta}^{n}
$$
\n
$$
= \mathbb{E} \sup_{x \in \mathbb{R}} e^{-n\beta |x|} \left| \frac{1}{\sqrt{2 \log \log \frac{1}{\varepsilon}}} \int_0^{t_2} \int_U \int_{\mathbb{R}} \frac{1}{\sqrt{2\pi (t_2 - s)}} e^{-\frac{|x - y|^2}{2(t_2 - s)}} G_s^{\varepsilon}(a, y, Z_s^{\varepsilon}(y)) dy W(dads) - \frac{1}{\sqrt{2 \log \log \frac{1}{\varepsilon}}} \int_0^{t_1} \int_U \int_{\mathbb{R}} \frac{1}{\sqrt{2\pi (t_1 - s)}} e^{-\frac{|x - y|^2}{2(t_1 - s)}} G_s^{\varepsilon}(a, y, Z_s^{\varepsilon}(y)) dy W(dads) \right|^{n}.
$$

 $\Box$ 

For better presentation, let  $K_0 := \frac{1}{\sqrt{2 \log \log n}}$  $\frac{1}{2 \log \log \frac{1}{\varepsilon} \sqrt{2\pi}}$  and  $\tilde{G}_{s}^{\varepsilon}(a, y) := G_{s}^{\varepsilon}(a, y, Z_{s}^{\varepsilon}(y))$ . We will call the first integral above  $I(t_2, t_2)(x)$ , where the first  $t_2$  appears in the upper limit of the integral and the second is the time parameter in the Gaussian density. Similarly, the second integral is denoted as  $I(t_1, t_1)(x)$ . Using this notation we have,

$$
\mathbb{E} \|Z_{t_2}^{\varepsilon}(x) - Z_{t_1}^{\varepsilon}(x)\|_{\beta}^n = \mathbb{E} \|I(t_2, t_2)(x) - I(t_1, t_1)(x)\|_{\beta}^n
$$
\n
$$
\leq 2^{n-1} K_0^n \left[ \mathbb{E} \|I(t_2, t_2)(x) - I(t_1, t_2)(x)\|_{\beta}^n + \mathbb{E} \|I(t_1, t_2)(x) - I(t_1, t_1)(x)\|_{\beta}^n \right]
$$
\n
$$
\leq 2^{n-1} (J_1 + J_2).
$$

As for  $J_1$ , applying the Burkholder-Davis-Gundy inequality yields,

$$
J_1 \leq K_0^n \mathbb{E} \sup_{x \in \mathbb{R}} e^{-n\beta|x|} \left| \int_{t_1}^{t_2} \int_U \left( \int_{\mathbb{R}} \frac{1}{\sqrt{t_2 - s}} e^{-\frac{|x-y|^2}{2(t_2 - s)}} \tilde{G}_s^{\varepsilon}(a, y) dy \right)^2 \lambda(da) ds \right|^{\frac{n}{2}},
$$

where by Hölder's inequality and condition  $(27)$ ,

$$
\int_{U} \left( \int_{\mathbb{R}} \frac{1}{\sqrt{t_2 - s}} e^{-\frac{|x - y|^2}{2(t_2 - s)}} \tilde{G}_s^{\varepsilon}(a, y) dy \right)^2 \lambda(da) \tag{49}
$$
\n
$$
\leq \int_{U} \int_{\mathbb{R}} \frac{1}{t_2 - s} e^{-\frac{|x - y|^2}{t_2 - s}} e^{2\beta |y|} dy \int_{\mathbb{R}} \tilde{G}_s^{\varepsilon}(a, y)^2 e^{-2\beta |y|} dy \lambda(da)
$$
\n
$$
\leq K_4 \int_{\mathbb{R}} \frac{1}{t_2 - s} e^{-\frac{|x - y|^2}{t_2 - s}} e^{2\beta |y|} dy \int_{\mathbb{R}} \left( 1 + \left( 2\varepsilon \log \log \frac{1}{\varepsilon} \right) Z_s^{\varepsilon}(y)^2 + e^{2\beta_0 |y|} \right) e^{-2\beta |y|} dy,
$$

and by our assumption,  $\beta_0 < \beta$  and  $\beta > 0$ . Moreover, similar to [\(35\)](#page-8-2),

$$
\int_{t_1}^{t_2} \int_{\mathbb{R}} \frac{1}{t_2 - s} e^{-\frac{|x - y|^2}{t_2 - s}} e^{2\beta |y|} dy ds \le k_1 \int_{t_1}^{t_2} \int_{\mathbb{R}} p_{t_2 - s}^2 (x - y) e^{2\beta |y|} dy ds \le k_2 e^{2\beta |x|} \sqrt{t_2 - t_1},
$$

therefore, using Lemma [5,](#page-14-0)

<span id="page-15-0"></span>
$$
J_1 \leq K_0^n K_4 k_3 \mathbb{E} \left| \sqrt{t_2 - t_1} \int_{\mathbb{R}} \left( 2\varepsilon \log \log \frac{1}{\varepsilon} \right) \sup_{t_1 \leq s \leq t_2} Z_s^{\varepsilon}(y)^2 e^{-2\beta |y|} dy \right|^{\frac{n}{2}} \leq k_4 M_2 |t_2 - t_1|^{\frac{n}{4}}, \tag{50}
$$

where  $k_4M_2$  is independent of  $\varepsilon$ . Using notation [\(42\)](#page-10-1), we continue by estimating  $J_2$ ,

$$
J_2 = K_0 \mathbb{E} \left\| \int_0^{t_1} \int_U \int_{\mathbb{R}} \Delta p(t_2, t_1) G_s^{\varepsilon}(a, y) dy W(dads) \right\|_{\beta}^n
$$
  
\n
$$
\leq K_0^n \mathbb{E} \sup_{x \in \mathbb{R}} e^{-n\beta|x|} \left| \int_0^{t_1} \int_U \int_{\mathbb{R}} (\Delta p(t_2, t_1))^2 e^{2\beta|y|} dy \int_{\mathbb{R}} \tilde{G}_s^{\varepsilon}(a, y)^2 e^{-2\beta|y|} dy \lambda(da) ds \right\|^{\frac{n}{2}}
$$
  
\n
$$
\leq k_5 \sup_{x \in \mathbb{R}} e^{-n\beta|x|} \left| \int_0^{t_1} \int_{\mathbb{R}} (\Delta p(t_2, t_1))^2 e^{2\beta|y|} dy ds \right\|^{\frac{n}{2}},
$$

where steps similar to those taken for estimating  $J_1$  were applied. It can be seen that for  $0<\alpha\leq 1/2,$ 

<span id="page-16-0"></span>
$$
(\Delta p(t_2, t_1))^2 = |p_{t_2-s}(x-y) - p_{t_1-s}(x-y)|^{\alpha} |p_{t_2-s}(x-y) - p_{t_1-s}(x-y)|^{2-\alpha} \qquad (51)
$$
  
 
$$
\leq 2^{1-\alpha} |p_{t_2-s}(x-y) - p_{t_1-s}(x-y)|^{\alpha} (p_{t_2-s}(x-y)^{2-\alpha} + p_{t_1-s}(x-y)^{2-\alpha}).
$$

Also  $\Delta p(t_2, t_1)$  may be written as,

$$
\frac{1}{\sqrt{2\pi}} \frac{1}{\sqrt{t_2 - s}} \left| e^{-\frac{|x - y|^2}{2(t_2 - s)}} - e^{-\frac{|x - y|^2}{2(t_1 - s)}} \right| + \frac{1}{\sqrt{2\pi}} e^{-\frac{|x - y|^2}{2(t_1 - s)}} \left| \frac{1}{\sqrt{t_2 - s}} - \frac{1}{\sqrt{t_1 - s}} \right| =: I_1 + I_2. (52)
$$

Using this form in [\(51\)](#page-16-0) we obtain,

$$
(\Delta p(t_2,t_1))^2 \leq K |I_1 + I_2|^{\alpha} (p_{t_2-s}(x-y)^{2-\alpha} + p_{t_1-s}(x-y)^{2-\alpha}),
$$

hence,

$$
J_2 \leq k_5 \sup_{x \in \mathbb{R}} e^{-n\beta |x|} \left| \int_0^{t_1} \int_{\mathbb{R}} |I_1|^\alpha p_{t_2-s}(x-y)^{2-\alpha} e^{2\beta |y|} dy ds + \int_0^{t_1} \int_{\mathbb{R}} |I_2|^\alpha p_{t_2-s}(x-y)^{2-\alpha} e^{2\beta |y|} dy ds \right| + \int_0^{t_1} \int_{\mathbb{R}} |I_1|^\alpha p_{t_1-s}(x-y)^{2-\alpha} e^{2\beta |y|} dy ds + \int_0^{t_1} \int_{\mathbb{R}} |I_2|^\alpha p_{t_1-s}(x-y)^{2-\alpha} e^{2\beta |y|} dy ds \right|^\frac{n}{2} = k_5 \sup_{x \in \mathbb{R}} e^{-n\beta |x|} |J_{2,1} + J_{2,2} + J_{2,3} + J_{2,4}|^\frac{n}{2}.
$$

For  $I_1$ , we use the mean value theorem to obtain,

$$
I_1 \le k_6 \frac{|x-y|^2}{2\sqrt{2\pi(t_2-s)}} \left| \frac{1}{t_2-s} - \frac{1}{t_1-s} \right| = k_6 \frac{|x-y|^2}{2\sqrt{2\pi(t_2-s)}} \frac{|t_2-t_1|}{(t_2-s)(t_1-s)}.
$$
(53)

In particular,

$$
J_{2,1} \leq k_6 \int_0^{t_1} \int_{\mathbb{R}} \frac{|x-y|^{2\alpha}}{2^{\alpha} (2\pi (t_2 - s))^{\frac{\alpha}{2}} (t_2 - s)^{\alpha} (t_1 - s)^{\alpha}} p_{t_2-s}(x - y)^{2-\alpha} e^{2\beta |y|} dy ds
$$
  
\n
$$
\leq k_7 \int_0^{t_1} \int_{\mathbb{R}} \frac{|t_2 - t_1|^{\alpha}}{(t_2 - s)^{\frac{3\alpha}{2}} (t_1 - s)^{\alpha}} |x - y|^{2\alpha} p_{t_2-s}(x - y)^{2-\alpha} e^{2\beta |y|} dy ds
$$
  
\n
$$
\leq k_7 \int_0^{t} \int_{\mathbb{R}} \frac{|t_2 - t_1|^{\alpha}}{(t_2 - s)^{\frac{3\alpha}{2}} (t_1 - s)^{\alpha}} \frac{|x - y|^{2\alpha}}{(t_2 - s)^{1-\frac{\alpha}{2}}} \sqrt{\frac{t_2 - s}{2 - \alpha}} p_{\frac{t_2-s}{2-\alpha}}(x - y) e^{2\beta |y|} dy ds
$$
  
\n
$$
\leq k_7 \int_0^{t_1} \int_{\mathbb{R}} \frac{|t_2 - t_1|^{\alpha}}{(t_2 - s)^{\frac{1}{2} + \alpha} (t_1 - s)^{\alpha}} |x - y|^{2\alpha} p_{\frac{t_2-s}{2-\alpha}}(x - y) e^{2\beta |y|} dy ds
$$
  
\n
$$
\leq k_8 e^{2\beta |x|} \int_0^{t_1} \frac{|t_2 - t_1|^{\alpha}}{(t_2 - s)^{\frac{1}{2} + \alpha} (t_1 - s)^{\alpha}} ds.
$$

Thus, noting the assumption  $t_1 < t_2$ , we arrive at,

$$
J_{2,1} \le k_8 e^{2\beta |x|} |t_2 - t_1|^\alpha \int_0^{t_1} (t_1 - s)^{-\left(\frac{1}{2} + 2\alpha\right)} ds \le k_9 e^{2\beta |x|} |t_2 - t_1|^\alpha,
$$

if  $2\alpha < 1/2$ . Similarly for  $J_{2,3}$ ,

$$
J_{2,3} \le k_{10} e^{2\beta |x|} |t_2 - t_1|^\alpha \,,
$$

if  $2\alpha < 1/2$ . To determine bounds for  $J_{2,2}$  and  $J_{2,4}$ , we have for  $i, j = 1, 2$  with  $i \neq j$ ,

$$
\int_{\mathbb{R}} \left| \frac{1}{\sqrt{t_1 - s}} - \frac{1}{\sqrt{t_2 - s}} \right|^{\alpha} p_{t_i - s} (x - y)^{2 - \alpha} e^{2\beta |y|} dy
$$
\n
$$
\leq k_{11} \int_{\mathbb{R}} \left| \frac{t_2 - t_1}{(t_1 - s) \sqrt{t_2 - s} + (t_2 - s) \sqrt{t_1 - s}} \right|^{\alpha} \frac{1}{(\sqrt{t_i - s})^{1 - \alpha}} p_{\frac{t_i - s}{2 - \alpha}} (x - y) e^{2\beta |y|} dy
$$
\n
$$
\leq k_{11} \frac{|t_2 - t_1|^{\alpha}}{(t_j - s)^{\alpha}} \frac{e^{2\beta |x|}}{(t_i - s)^{\frac{1}{2}}},
$$

and

$$
k_{11} \int_0^{t_1} \frac{|t_2 - t_1|^{\alpha}}{(t_j - s)^{\alpha}} \frac{e^{2\beta|x|}}{(t_i - s)^{\frac{1}{2}}} ds \le k_{11} e^{2\beta|x|} |t_2 - t_1|^{\alpha} \int_0^{t_1} (t_1 - s)^{-(\alpha + \frac{1}{2})} ds \le k_{11} e^{2\beta|x|} |t_2 - t_1|^{\alpha},
$$

for  $\alpha < 1/2$ . From values for  $\alpha$  found above for each term of  $J_2$ , we require  $0 < \alpha < 1/4$ and obtain,

$$
J_2 \leq k_{12} \left| t_2 - t_1 \right|^{\frac{\alpha n}{2}},
$$

where  $k_{12}$  is independent of  $\varepsilon$ . Furthermore, noting the bound for  $J_1$  in [\(50\)](#page-15-0) we confirm our assumption of  $n > 8$  required to satisfy condition [\(46\)](#page-14-1).

We now verify that the limit set for  $\{Z_t^{\varepsilon}(y)\}_{0\leq \varepsilon\leq 1}$  is  $L_1$  given in Theorem 4. For better presentation, we let  $\varepsilon = 1/(c^j)$ , where  $c > 1$  and  $j \ge 1$ .

**Lemma 6.** For any  $g \in L_1$ ,  $\varepsilon > 0$ , and  $c > 1$ , there exists  $j_0 \in \mathbb{N}$  such that for every  $j > j_0, P\left(\|Z^{\frac{1}{c^j}} - g\|_{\beta} \leq \varepsilon \ i.o.\right) = 1.$ 

*Proof.* Let  $g \in L_1$  and  $h_s \in L^2([0,1] \times U, ds\lambda(da))$  such that  $g = S_t(h_s, y)$  and 1  $\frac{1}{2} \int_0^t \int_U |h_s(a)|^2 \lambda(da)ds \leq 1.$  Denote,

$$
F_j := \left\{ \|Z^{\frac{1}{c^j}} - g\|_{\beta} \le \varepsilon \right\} \text{ and } G_j := \left\{ \left\| \frac{1}{\sqrt{2 \log \log c^j}} W - h \right\|_{\infty} \le \eta \right\},\
$$

for some constant  $\eta > 0$ . We need to prove that  $P(\limsup_{j\to\infty} F_j) = 1$ . Based on the Strassen's compact LIL for Brownian sheets proved in Section 1.4 in [\[19\]](#page-20-0),  $P(\limsup_j G_j) =$ 1. Let  $R > 1$ , then by [\(33\)](#page-8-0) we have,

<span id="page-17-0"></span>
$$
P\left(F_j^c \cap G_j\right) \le \exp\left(-2R\log\log c^j\right) = \frac{K_R}{j^{2R}} \le \frac{K_R}{j^2},\tag{54}
$$

where we used the fact that for  $k \in \mathbb{R}$ ,

$$
\exp\left(-k\log\log c^j\right) = \frac{K_k}{j^k}.
$$

Now by the Borel-Cantelli lemma applied to [\(54\)](#page-17-0), we arrive at,

$$
P\left(\limsup_{j\to\infty} F_j^c \cap G_j\right) = 0.
$$

Thus, we obtain,

$$
1 = P\left(\limsup_{j \to \infty} G_j\right) \le P\left(\limsup_{j \to \infty} G_j \cap F_j\right) + P\left(\limsup_{j \to \infty} G_j \cap F_j^c\right) \le P\left(\limsup_{j \to \infty} F_j\right),
$$
obtaining the result.

As for the Classical LIL, note that it is sufficient to prove [\(31\)](#page-8-3), where [\(32\)](#page-8-3) may be proved analogously. As above, we use the notation,  $\varepsilon := 1/(c^j)$ . Then for every  $\varepsilon > 0$ , [\(31\)](#page-8-3) is equivalent to

$$
P\left(\left\|\frac{u_c^{\frac{1}{\sigma^j}}(y) - u_t^0(y)}{\sqrt{\frac{2}{c^j}\log\log c^j}} - 1\right\|_{\beta} > \varepsilon \text{ i.o.}\right) = 0,
$$

which may further be written as,

<span id="page-18-0"></span>
$$
\lim_{j \to \infty} P\left(\sup_{k \ge j} \left\| \frac{u_c^{\frac{1}{k}}(y) - u_t^0(y)}{\sqrt{\frac{2}{c^k} \log \log c^k}} - 1 \right\|_{\beta} > \varepsilon \right) = 0. \tag{55}
$$

By Chebyshev inequality,

$$
\lim_{j \to \infty} P\left(\sup_{k \ge j} \sup_y e^{-\beta|y|} \frac{|u_t^{\frac{1}{c^k}}(y) - u_t^0(y)|}{\sqrt{\frac{2}{c^k} \log \log c^k}} > \varepsilon + \sup_{y \in \mathbb{R}} e^{-\beta|y|}\right)
$$
  

$$
\le (\varepsilon + \sup_y e^{-\beta|y|})^{-2} \lim_{j \to \infty} \mathbb{E} \sup_{k \ge j} \sup_y e^{-2\beta|y|} \frac{|u_t^{\frac{1}{c^k}}(y) - u_t^0(y)|^2}{\frac{2}{c^k} \log \log c^k}.
$$

Furthermore,

$$
\mathbb{E} \sup_{k \geq j} \sup_y e^{-2\beta|y|} \left| u_t^{\frac{1}{c^k}}(y) - u_t^0(y) \right|^2
$$
\n
$$
\leq \mathbb{E} \sup_{k \geq j} \sup_y e^{-2\beta|y|} \frac{1}{c^k} \left| \int_0^t \int_U \int_{\mathbb{R}} p_{t-s}(x-y) G(a, x, u_s^{\varepsilon}(x)) dx W(dads) \right|^2, \quad (56)
$$

which analogous to previous estimates in this section may be bounded above by  $(1/c<sup>k</sup>)\tilde{M}$ for a positive constant,  $\tilde{M}$ . Hence, we arrive at,

$$
\lim_{j \to \infty} P\left(\sup_{k \ge j} \sup_{y \in \mathbb{R}} e^{-\beta |y|} \frac{|u_t^{\frac{1}{c^k}(y)} - u_t^0(y)|}{\sqrt{\frac{2}{c^k} \log \log c^k}} > \varepsilon + \sup_y e^{-\beta |y|}\right)
$$
  

$$
\le (\varepsilon + \sup_y e^{-\beta |y|})^{-2} \lim_{j \to \infty} \sup_{k \ge j} \frac{\tilde{M}}{(2 \log \log c^k)},
$$

which implies [\(55\)](#page-18-0), noting that  $\varepsilon > 0$  was arbitrarily chosen.

### 4. LIL for SBM and FVP

In this section we apply the results from Section Three to derive the MDP and the two types of LIL for SBM and FVP. To achieve the MDP for these models, using relations [\(5\)](#page-3-3) and [\(6\)](#page-3-4), we have by [\(16\)](#page-5-2),  $v_t^{\varepsilon}(y) = \int_0^y \omega_t^{\varepsilon}(dx)$  for SBM and  $v_t^{\varepsilon}(y) = \int_{-\infty}^y \omega_t^{\varepsilon}(dx)$  for FVP. In Lemma 6 in  $[27]$  it was shown that for  $A$ , the set of nondecreasing functions, the map,  $\xi : \mathbb{B}_{\beta} \cap \mathcal{A} \to \mathcal{M}_{\beta}(\mathbb{R})$  defined as,

<span id="page-19-4"></span>
$$
\xi(u)(B) = \int 1_B(y) du(y),\tag{57}
$$

is continuous for all  $B \in \mathbb{B}(\mathbb{R})$ . Also the same reasoning may be applied to prove that the map  $\tilde{\xi}: \mathbb{B}_{\beta} \cap \mathcal{A} \to \mathcal{P}_{\beta}(\mathbb{R})$  defined by [\(57\)](#page-19-4) is continuous. Hence, SBM and FVP may be written as continuous functions of the solution of SPDE,  $v_t^{\varepsilon}(y)$ , and thus by the contraction principle, MDP follows for SBM and FVP. It is left to determine their exact form of rate function. In Section 4 of [\[28\]](#page-20-7), for  $h_s \in L^2([0,1] \times U, ds\lambda(da))$ , the following expression was derived for  $\frac{1}{2}$  inf  $\int_0^1 \int_U |h_s(a)|^2 \lambda(da)ds$  for both SBM and FVP by letting  $a = u_t^0(y)$ ,

$$
\frac{1}{2}\int_0^1 \int_U |h_s(a)|^2 \lambda(da)ds = \frac{1}{2}\int_0^1 \int_{\mathbb{R}} \left| \frac{d\left(\dot{\omega} - \frac{1}{2}\Delta^*\omega\right)}{d\mu_t^0} y \right| \mu_t^0(dy)dt,
$$

where  $\mu_t^0 \in \mathcal{H}_{\omega_0}$  in the case of SBM and  $\mu_t^0 \in \tilde{\mathcal{H}}_{\omega_0}$  for FVP and hence we obtain [\(17\)](#page-5-0) and [\(18\)](#page-5-1).

For the two types of LIL, as stated in Section Two, based on the SPDE characterization of the two population models, SBM and FVP are given by the class of SPDE [\(8\)](#page-3-1) with  $G(a, y, u_s^{\varepsilon}(y)) := 1_{0 < a < u_s^{\varepsilon}(y)} + 1_{u_s^{\varepsilon}(y) < a < 0}$  and  $G(a, y, u_s^{\varepsilon}(y)) := 1_{a \le u_s^{\varepsilon}(y)} - u_s^{\varepsilon}(y)$ , respectively, where in both cases,  $G(a, y, u_s^{\varepsilon}(y))$  satisfies conditions [\(9\)](#page-3-2) and [\(10\)](#page-3-2). Using these SPDE characterizations we may form the analog process  $Z_t^{\varepsilon}(y)$  and by estimates in Section Three obtain the Freidlin-Wentzell inequality [\(33\)](#page-8-0) and tightness of  $\{Z_t^{\varepsilon}(y)\}_{0\leq \varepsilon\leq 1}$  in  $\mathcal{C}([0,1];\mathcal{M}_{\beta})$ and  $\mathcal{C}([0,1];\mathcal{P}_{\beta})$ , respectively. Furthermore, we have the continuity of their controlled PDE version  $S_t(h, y)$  with respect to uniform topology when restricted on level sets  $\{\tilde{I} \leq a\}$ . Thus, we obtain the Strassen's compact LIL for SBM and FVP with limit sets being  $L_2$ and  $L_3$ , respectively. The classical LIL may also be achieved in respective spaces following the same steps as in Section Three with no additional conditions required.
