Abstract

Recently, text-to-image (T2I) editing has been greatly pushed forward by applying diffusion models. Despite the visual promise of the generated images, inconsistencies with the expected textual prompt remain prevalent. This paper aims to systematically improve the text-guided image editing techniques based on diffusion models, by addressing their limitations. Notably, the common idea in diffusion-based editing firstly reconstructs the source image via inversion techniques e.g., DDIM Inversion. Then following a fusion process that carefully integrates the source intermediate (hidden) states (obtained by inversion) with the ones of the target image. Unfortunately, such a standard pipeline fails in many cases due to the interference of texture retention and the new characters creation in some regions. To mitigate this, we incorporate human annotation as an external knowledge to confine editing within a “Mask-informed” region. Then we carefully Fuse the edited image with the source image and a constructed intermediate image within the model’s Self-Attention module. Extensive empirical results demonstrate the proposed “MaSaFusion” significantly improves the existing T2I editing techniques.

1 Introduction

The field of Text-to-Image (T2I) generation has witnessed significant advancements through the development of large-scale diffusion probabilistic generative models, e.g., Stable Diffusion [22]. These powerful models create high-quality images that align with the provided text prompts [19]. Additionally, these T2I models are further applied as backbones for image editing tasks. During editing, compared with the source image, the ideal target image alters specific features to be consistent with the target text prompt, while maintaining the other features invariant [15]. In contrast to the training-based editing methods [40; 41; 2], the training-free T2I editing methods are more tractable [14; 9; 15; 3; 30] due to their convenience in practice. However, these methods often fall short of practical needs, with many instances of failures that lead to unsatisfactory visual results [15].

The goal of this paper is to enhance the current editing techniques to make them meet practical requirements. Our analysis begins with an examination of the failures in existing methods. We find that the failures are usually caused by the interference between preserving existing characteristics and generating new ones (as in Figure 2). To make this clear, we notice that the common idea in diffusion-based editing consists of two steps i.e., “Inversion then Fusion” [9; 15]. That says we first apply inversion techniques on the source image (e.g., DDIM Inversion [26], Null-Text-Inversion [15]) to get its intermediate hidden states (from image to noise). Then, fusing these intermediate hidden states with the ones of the target image during its denoising (generation) process to make it similar to the source image. However, during the fusion process, the generation of variant features may occur (especially for the editing with variant shapes of objects) in mismatched positions relative to the source image, leading to confusion between preservation and generation. This confusion can result in a dominance of one mode in these positions, and through the neural network’s attention mechanism [31], potentially propagates the dominance throughout the entire image.

To counter this interference, we propose using external human annotations to define the boundaries of the edited area, thereby limiting both the editing itself and the possible spread of interference. Additionally, to make the fusion process easier, we create an intermediate image that has a consistent shape (while potentially different textures) with the target image. Concretely, we incorporate further external factors (e.g., the sketch of a desired target image) to produce such an intermediate image with a strong conditional generative model i.e., T2I Adapter [16; 3]. Notably, the correlation between pixels (self-attention map [31]) of such intermediate image is potentially consistent with the ideal target image, as they have the same shape, while such correlation may vary from the source to target images. Inspired by this, we propose to fuse the final target image with the intermediate ones in the self-attention module of model [31; 23] for pixels in given edited regions, to generate desired varied characteristics. Oppositely, the source image is applied to fuse with the target ones for pixels out of the given edited region so that keep unedited pixels invariant. By doing so, we separate the preservation and generation during editing, thus alleviating the interference between them. We term the proposed method as “Masked region informed Self-Attention Fusion” abbreviated as *MaSaFusion*.

Empirical results of real-world image editing demonstrate the effectiveness of our proposed MaSaFusion. Concretely, we evaluate our approach on MagicBrush [39], which is a benchmark dataset in T2I editing with expertise in constructed ground-truth source-target image pairs. The quantitative results on the alignments of generated images with target images and text prompts show that the proposed MaSaFusion has superior performance, compared with the existing methods.

2 Related Work

Text-to-Image Generation. As the backbone technique of T2I editing, the goal of T2I generation is generating images that are aligned with provided textual prompts through a multi-modal vision-language model. The earlier works rely on the auto-regressive conditional prediction [35; 21] or generative adversarial networks [7; 37; 38; 36; 13], yet often resulted in images of suboptimal quality or misaligned with the textual prompts. Fortunately, the recent advancements in diffusion models have significantly advanced the field [10; 27; 34; 32]. By combing the multi-modal vision-language model e.g., CLIP [19], a succession of studies have attained state-of-the-art results in T2I generation. Notably, GLIDE [17], VQ-Diffusion [8], DALL.E 2 [20], Imagen [24], and Stable-Diffusion [22] are the most successful among them up till now. In our research, we leverage the Stable Diffusion as the backbone model, due to its superior performance and practicality in editing applications.

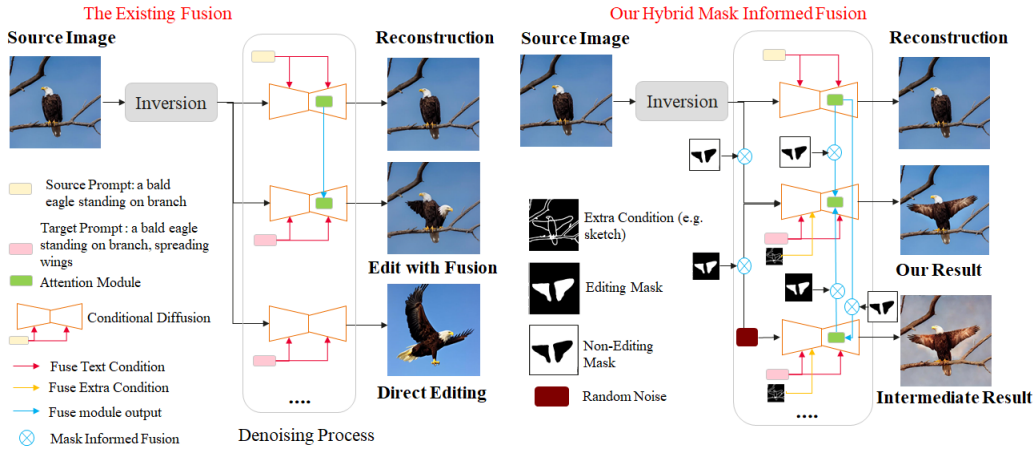

Figure 2: The comparison of the existing (left) and our (right) fusion processes (e.g. [9]) of generating desired target image. The standard pipeline is inverting the source image, and then fusing it with the target one. For the existing method on the left, the target image can be quite different from the source one. Thus, the fusion process between them is different in practice. We propose to first generate an *intermediate image* with the desired shape under external conditions (e.g. T2I Adapter [16]), then obtain the target image by fusing it with the source and intermediate images, depending on the pixels’ relative position to a prior given editing region.

Text-to-Image Editing. As we have claimed, with the advancements in foundational techniques (T2I generation), T2I editing has made substantial progress. The methodologies can be categorized into training-based or training-free methods, depending on whether an extra fine-tuning stage is required before the editing process. Considering the extra fine-tuning stage potentially hinders the application of training-based methods (e.g., InstructP2P [2], Paint by Example [33], SINE [42], ControlNet [40] or HIVE [41]), our research prioritizes training-free approaches, which offer greater flexibility in terms of inference speed and computational resource demands. To date, the existing training-free techniques mainly include SDE-Diffedit [5; 18], Prompt-to-Prompt (P2P) [9], Plug-and-Play (PnP) [30], and Masactrl [3], where the first three methods are suitable to editing with invariant objects’ shapes, and the last method is devised for objects’ shapes variant editing. As clarified in Section 1, the common idea among these methods follows the pipeline “Inversion then Fusion”. However, as in Figure 2, these methods fail in many cases owing to inappropriate fusion processes.

Editing with External Knowledge. As in this paper, much-existing literature introduces the external information e.g., the sketch map of the target image in T2I Adapter [16] and ControlNet [40], the mask-informed editing region in Blended Diffusion [1] and GLIDE [17]. According to their observations, the external information significantly improves the quality of edited images. Thus, during our MaSaFusion, we properly combine the induced external information in the T2I Adapter and mask-informed editing region and improve the existing external knowledge-induced methods.

3 Preliminaries

Latent Diffusion Model. This study examines the standard methodology of text-to-image synthesis with diffusion models [10; 25], which crafts the desired image from Gaussian noise through a gradual denoising process. To do so, the model is learned to predict the noise that has been added to the data. Our focus is on the Stable (latent) Diffusion model [22], wherein the diffusion process occurs within the latent space of an image, encoded by a Vector Quantized (VQ) model [6]). In practice, given the generated latent, the synthesized real-world image is then reconstructed by an image decoder as in [6].

The process of diffusion model is: given data \mathbf{x}_0 and condition \mathcal{C} (textual prompt embedding from CLIP encoder [19] in this paper) from target distribution, we construct noisy data \mathbf{x}_t as

$$\mathbf{x}_t = \sqrt{\bar{\alpha}_t} \mathbf{x}_0 + \sqrt{1 - \bar{\alpha}_t} \boldsymbol{\epsilon}_t, \quad (1)$$

with $0 \leq t \leq T$, where $\boldsymbol{\epsilon}_t \sim \mathcal{N}(0, \mathbf{I})$ and is independent with \mathbf{x}_0 , $\bar{\alpha}_t$ monotonically decreases with t , and $\bar{\alpha}_t \rightarrow 0$ (resp. $\bar{\alpha}_t \rightarrow 1$) for $t \rightarrow 1$ (resp. $t \rightarrow T$). By minimizing

$$\min_{\theta} \mathbb{E} [\|\boldsymbol{\epsilon}_{\theta}(t, \mathbf{x}_t, \mathcal{C}, \theta) - \boldsymbol{\epsilon}_t\|^2], \quad (2)$$

Figure 3: The typical failure cases of existing methods. The failures are mainly twofold, reconstructing source image (PnP, P2P) or generating .

the model learns to predict the injected noise in \mathbf{x}_t . It is worthy to note that the noise prediction $\epsilon_{\theta}(t, \mathbf{x}_t, \mathcal{C}, \emptyset)$ is constructed by classifier-free guidance model [11], such that

$$\epsilon_{\theta}(t, \mathbf{x}_t, \mathcal{C}, \emptyset) = w\tilde{\epsilon}_{\theta}(t, \mathbf{x}_t, \mathcal{C}) + (1 - w)\tilde{\epsilon}_{\theta}(t, \mathbf{x}_t, \emptyset), \quad (3)$$

where \emptyset is CLIP embedding of null text “”, w is guidance scale, and $\tilde{\epsilon}_{\theta}$ is a model e.g., UNet [23].

Since $\mathbf{x}_T \approx \mathcal{N}(0, \mathbf{I})$, we substitute it with standard Gaussian, then implement the following deterministic DDIM sampling process to gradually remove the noise starting from a Gaussian \mathbf{x}_T .

$$\mathbf{x}_{t-1} = \sqrt{\frac{\bar{\alpha}_{t-1}}{\bar{\alpha}_t}} \mathbf{x}_t + \left(\sqrt{\frac{1 - \bar{\alpha}_{t-1}}{\bar{\alpha}_{t-1}}} - \sqrt{\frac{1 - \bar{\alpha}_t}{\bar{\alpha}_t}} \right) \epsilon_{\theta}(t, \mathbf{x}_t, \mathcal{C}, \emptyset). \quad (4)$$

Technically, the forward process of DDIM is a discretion of an ordinary differential equation (ODE) [26]. Then, owing to the reversibility of it, the following DDIM inversion [26; 15] process on \mathbf{x}_0 gives the corresponding initial noise \mathbf{x}_T such that \mathbf{x}_0 is reconstructed by DDIM (4).

$$\mathbf{x}_t = \sqrt{\frac{\bar{\alpha}_t}{\bar{\alpha}_{t-1}}} \mathbf{x}_{t-1} + \left(\sqrt{\frac{1 - \bar{\alpha}_t}{\bar{\alpha}_t}} - \sqrt{\frac{1 - \bar{\alpha}_{t-1}}{\bar{\alpha}_{t-1}}} \right) \epsilon_{\theta}(t, \mathbf{x}_{t-1}, \mathcal{C}, \emptyset). \quad (5)$$

Interestingly, it has been found in [15] that running the DDIM inversion (5) with source textual prompt involved in it can not reconstruct the ideal \mathbf{x}_0 . To tackle this, [15] proposes the technique called “null-text inversion”, more details of this can be checked in Appendix A.

In this paper, the intermediate states of source and target images are respectively represented as \mathbf{x}_t^S and \mathbf{x}_t^T . The source and target prompt conditions are \mathcal{C}^S and \mathcal{C}^T , respectively.

Blocks in Conditional UNet. The standard network structure of conditional diffusion model is UNet [23; 27; 10], which consists of an encoder and another decoder structure with self-attention [31] and cross-attention blocks in them, capturing the “pixel-pixel” and “pixel-condition” correlations, respectively. The attention layer in UNet takes value of (Q, K, V) with output $\text{Attention}(Q, K, V) = \text{softmax}(QK^T/\sqrt{d})V$, and d is the dimension of pixel-wise embedding. Here

$$Q = W_Q \phi(\mathbf{x}_t); K = W_K \phi(\mathbf{x}_t); V = W_V \phi(\mathbf{x}_t), \quad (6)$$

for self-attention Attention_{SA} , $\phi(\mathbf{x}_t) \in \mathbb{R}^{N \times d}$ is the flattened intermediate hidden states of \mathbf{x}_t , and

$$Q = W_Q \phi(\mathbf{x}_t); K = W_K \mathcal{C}; V = W_V \mathcal{C} \quad (7)$$

for cross-attention Attention_{CA} .

Inversion then Fusion. This is a common idea in diffusion based editing originated from [9]. Generally, the ideal output of target image keeps unedited characteristics invariant as in source image. To conduct this, one should inject the information from source image into the target one. Thus, a natural initial state of denoising process to generate target image is the ones obtained via inverting source image. However, as in [9] or Appendix B of this paper, the information from intermediate states \mathbf{x}_t^S should be injected into the denoising process of \mathbf{x}_t^T to guarantee the similarity between source and target images. For example, in [9], the cross-attention module $\text{Attention}_{CA}(Q^T, K^T, V^T)$ of generating \mathbf{x}_t^T for each t is substituted by $\text{Attention}_{CA}(Q^S, K^S, V^T)$, during denoising process. Here (Q^S, K^S, V^S) and (Q^T, K^T, V^T) are respectively the hidden states of generating \mathbf{x}_t^S and \mathbf{x}_t^T .

4 Method

In this section, we provide our method to tackle the image editing problem. We start our analysis with the failure cases in the existing methods. Following our analysis, we speculate that fusing an image close to the target one may improve the editing quality. To get such a close intermediate image, we incorporate extra human annotation required in T2I-Adapter [16] (e.g., sketch of target image). Next, we leverage this intermediate image during the fusion process and restrict the editing in a prior known annotated region to further improve the generation of the target image.

4.1 Interference During Fusion

We start with the failures of existing methods following “inversion then fusion” in Figure 3, which requires altering a “running horse” into a “standing horse”. As can be seen, the failures are two-fold. 1): Reconstructing the source image, no desired features are generated e.g., PnP, P2P; 2): Generating image consistent with target prompt, but undesired features are generated e.g., SDE-Diffedit.

As claimed in Section 3, the idea of existing methods is based on making a fusion of the source image and a generated slightly related image, by manipulating the intermediate hidden states of the source and target images. However, this fusion process is particularly challenging, especially for the tasks with objects’ shapes being variant (e.g., in Figure 3). Because, for such tasks, the requirement of generating images to have differing shapes, leading to significant interference in certain regions, during the fusion with the source image. This interference stems from the competing demands of the target prompt, which encourages the generation of new content, and the source image, which necessitates preservation. Striking a balance in these regions is complex and has led to failure cases as noted. To check this formally, we note that in both cross-attention and self-attention modules of UNet, the output (N -pixel values) is

$$\text{Softmax}\left(\frac{QK^\top}{\sqrt{d}}\right)V = \left(\sum_j P_{1j}V_j, \dots, \sum_j P_{Nj}V_j\right), \quad (8)$$

where $\{P_{ij}\}$ in $\text{Softmax}(QK^\top/\sqrt{d})$ is the attention map, and they are decided by the correlation between tokens in text prompt or pixels in image, respectively for cross-attention and self-attention modules. It is worth noting that the fusion process usually substitutes the attention map (cross-attention module in P2P [9], self-attention module in MasaCtrl [3]) in the target image with the ones in the source image. However, if the objects’ shapes are varied in the target images, both pixel-token level (cross-attention) and pixel-pixel (self-attention) correlations will vary from source to target images. This explains the failures of existing methods.

Remark 1. *For the editing with invariant objects’ shapes, the existing methods e.g., P2P have relative better performances. However, when generating target prompt by textual encoder, its embedding of invariant tokens will vary, compared with the ones in source prompt. The variation of these unrelated tokens deteriorates the performance of existing methods. Thus we propose another simple method (does not require external information) tailored to such task, details are in Appendix B.*

Based on our preceding analysis, we speculate that the attention map injected into the target image should be consistent with an underlying correct image for those regions to be edited. This speculation is further explored in Appendix C. Nevertheless, such attention maps are unknown in practice. Consequently, we establish our first goal of editing: *Obtaining an underlying correct attention map.* This aims to reduce interference during the fusion process.

4.2 Constructing Intermediate Image with Human Annotation

Notably, the image that has a shape consistent with the underlying target image and correct textures (not necessarily consistent with the source image), is likely to have the same attention-map with the target image. Because the corresponding attention map creates a correct image with the desired shape. Thus, we propose to construct such an intermediate image to borrow its attention map in the fusion process of generating a target image. To this end, we leverage the T2I-adapter [16] which can generate the image with a shape consistent with the external signal³ (e.g., a sketch of target image)⁴. Concretely, we leverage T2I-Adapter to generate an intermediate image with a shape consistent with the given external condition, under a target text prompt. To further guarantee the correct textures of such an intermediate image, we fuse it with the source image.

Additionally, the practical applications often involve prior knowledge of the regions that require editing, though these regions do not need to be defined with high precision. Consequently, we restrict the editing (as intermediate image fuses with the source ones) within these known, mask-informed regions, denoted as A . To do this, during the DDIM step (4) to generate the target image, we

³These signals are integrated into a pretrained stable diffusion model via injecting their encoded features into the hidden states of the model.

⁴Please note that T2I-Adapter enables shape control instead of textures. So that it can not be directly applied to editing.

Figure 4: The generated *intermediate image* with different initial noise x_T^{t2i} where x_T^S is obtained by inversion, x is a Gaussian noise, and $\mathbf{1}_A$ is the indicator function on set A . The external condition (target image sketch) and shape of A are also presented.

Algorithm 1 MaSaFusion.

Input: source prompt \mathcal{S} , source image x_0^S , target prompt \mathcal{T} , diffusion model ϵ_θ , annotation mask region A , T2I-Adapter condition \mathcal{C}^{t2i} .

- 1: **Inversion Step**
 - 2: Inversion (NTI Algorithm 2 or DI Algorithm 3) to generate x_T^S and intermediate hidden states $\{Q^S, K^S, V^S\}$ for each t ;
 - 3: **T2I-Adapter Intermediate Step**
 - 4: Initialize $x_T^{t2i} = x$ with x as a Gaussian noise;
 - 5: DDIM (4) to generate x_t^{t2i} with ϵ_θ in (9), invoking annotation region A , T2I-Adapter condition \mathcal{C}^{t2i} , cached the hidden states $\{Q^{t2i}, K^{t2i}, V^{t2i}\}$ for each t ;
 - 6: **Generating Target Image by Fusion**, i.e., *fuse cached intermediate hidden states* $\{Q^S, K^S, V^S\}$ and $\{Q^{t2i}, K^{t2i}, V^{t2i}\}$
 - 7: Initialize $x_T^\mathcal{T} = \mathbf{1}_{A^c}x_T^S + \mathbf{1}_Ax$;
 - 8: DDIM (4) to generate $x_t^\mathcal{T}$ with ϵ_θ in (10), by invoking annotation region A , T2I-Adapter condition \mathcal{C}^{t2i} ;
 - 9: **return** Target image $x_0^\mathcal{T}$.
-

substitute the backbone model with pre-trained stable diffusion model in T2I-Adapter [16], and inject the external signal \mathcal{C}^{t2i} as a conditional factor. The generated T2I-Adapter-based intermediate states are denoted as x_t^{t2i} , and their attention maps are cached to be used in the fusion process of the target image.

To get x_t^{t2i} while fusing it with x_t^S , for its i -th pixel $x_t^{t2i}(i)$, we revise the noise prediction as

$$\epsilon_\theta(i) = \begin{cases} \bar{\epsilon}_\theta(t, x_t^{t2i}, \mathcal{C}^S, \mathcal{C}^{t2i}, \emptyset), & i \notin A; \\ \epsilon_\theta(t, x_t^{t2i}, \mathcal{C}^\mathcal{T}, \mathcal{C}^{t2i}, \emptyset), & i \in A. \end{cases} \quad (9)$$

We get $\bar{\epsilon}_\theta(t, x_t^{t2i}, \mathcal{C}^S, \mathcal{C}^{t2i}, \emptyset)$ by substituting all the $\text{Attention}_{SA}(Q^\mathcal{T}, K^\mathcal{T}, V^\mathcal{T})$ as $\text{Attention}_{SA}(Q^S, K^S, V^S)$, for corresponded layers of model, with \mathcal{C}^{t2i} injected. By doing so, the pixels in A^c are guaranteed to be similar with the source image, so that preserving correct features. On the other hand, the $\epsilon_\theta(t, x_t^{t2i}, \mathcal{C}^\mathcal{T}, \emptyset)$ in A is used to generate desired variant features in the prior given editing region A .

Remark 2. Notably, the existing mask-based editing methods (e.g. GLIDE [17] or Blended Diffusion [1]) reconstruct the unedited features out of editing regions A^c by directly copying from the source image. Unlike theirs, we borrow the self-attentions from the intermediate hidden states of the source image to reconstruct unedited features. Compared with theirs, our method produces smoother and more natural features at the edge of editing regions. See Section 5 for more details.

Remark 3. Our method necessitates specific external conditions and defined editing regions. The former (which is similarly used in MasaCtrl [3]) can be obtained as follows. We may first extract such conditions from the source image as in [28; 16]. Then a simple handcrafted revision (e.g., revising several lines in sketch) on these conditions aligned with the target prompt yields the desired external conditions. As for the editing regions, they can be delineated by localizing the revised features within the external conditions. More details on these human annotations are in Section 5.2.

In our experiments, we observed that the initial noise vector x_T^{t2i} significantly impacts the generated images. To see this, we generate the target image with revised noise prediction (9) under different initialized x_T^{t2i} in Figure 4. As can be seen, expected for the data generated under $x_T^{t2i} = x$, though the other two initialized x_T^{t2i} generate images consistent with the desired shape, their textures are

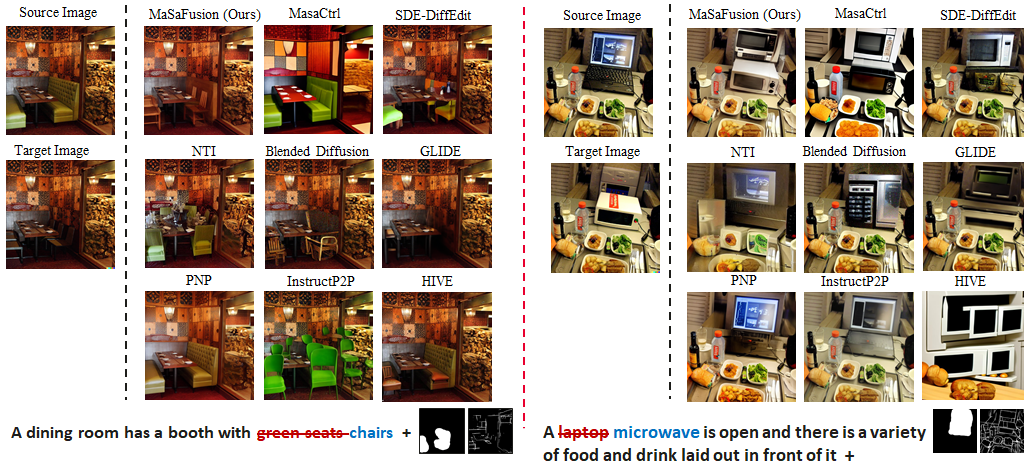

Figure 5: The edited images of existing methods and our MaSaFusion (NTI based). Here we present the results of single-turn editing, more results of multi-turn editing are in Appendix D.

incorrect.⁵ Therefore, we suggest to generate the intermediate image under $x_T^{t2i} = x$. Besides that, we note that the two failure cases are originated from the incorrect self-attention map in A , as the pixels in A are showed as inappropriate weighted sum of the other pixels. For example, the pixels under $x_T^{t2i} = \mathbf{1}_{A^c}x_T^S + \mathbf{1}_A x$ incorrectly pay attentions to branch and sky, instead of the eagle itself. This again illustrates the necessity of correct attention map.

4.3 Mask Region Informed Self-Attention Fusion

With the correct attention-map from intermediate image, we propose to borrow it into the fusion process of generating target image as clarified before. To do this, we revise the noise prediction as of generating final target image as

$$\epsilon_{\theta}(i) = \begin{cases} \bar{\epsilon}_{\theta}(t, \mathbf{x}_t^T, \mathcal{C}^S, \mathcal{C}^{t2i}, \emptyset), & i \notin A; \\ \hat{\epsilon}_{\theta}(t, \mathbf{x}_t^T, \mathbf{x}_t^{t2i}, \mathcal{C}^T, \mathcal{C}^{t2i}, \emptyset), & i \in A, \end{cases} \quad (10)$$

where $\hat{\epsilon}_{\theta}(t, \mathbf{x}_t^T, \mathbf{x}_t^{t2i}, \mathcal{C}^T, \mathcal{C}^{t2i}, \emptyset)$ is obtained via substituting the self attention module $\text{Attention}_{SA}(Q^T, K^T, V^T)$ as $\text{Attention}_{SA}(Q^{t2i}, K^{t2i}, V^T)$ (Algorithm 1) for corresponded layers of model. By doing so, the self-attention map of \mathbf{x}_t^T is exactly the ones of \mathbf{x}_t^{t2i} . The $\bar{\epsilon}_{\theta}$ is same as in (9), which preserves the features from source image in unediting region A^c .

We summarize our method as Mask region informed Self-attention Fusion (MaSaFusion) in Algorithm 1 and Figure 2. Please note that, we initialize \mathbf{x}_T^T with $\mathbf{1}_{A^c}x_T^S + \mathbf{1}_A x$, so that \mathbf{x}_t^T can generate new features in editing region A . The complete process of our method is summarized as firstly generating the intermediate image, then wisely fusing it and the source image with the desired target image.

5 Experiments

In this section, we empirically verify the effect of the proposed MaSaFusion in the task of T2I editing.

5.1 Comparison with Existing Methods

Dataset. Magicbrush [39] is an expertise-constructed dataset consisting of many couples of source and human-evaluated edited target images. The editing includes many practical requirements e.g., object addition/replacement/removal, action changes, color/texture/pattern modifications. We evaluate our method and baseline methods in 1053 (including single and multi-turn editing) test data from Magicbrush by comparing the edited images with ground-truth target images provided by Magicbrush.

Notably, the used external conditions (sketch map of target images in T2I Adapter and masked region) are extracted from target images as in [28]. These external conditions are also used in the baseline methods with external information so that the comparisons with them are fair.

⁵In fact, when taking different x , initializing \mathbf{x}_T^T with $\mathbf{1}_{A^c}x_T^S + \mathbf{1}_A x$ occasionally generates desired intermediate image.

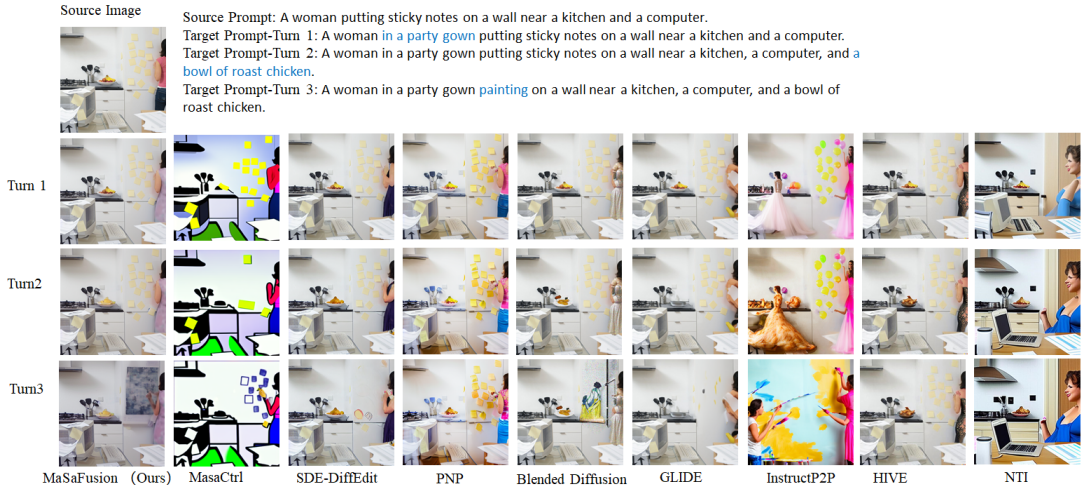

Figure 6: Multi-turn editing over different editing methods. The compared target images in Magicbrush are same for single-turn and multi-turn editing. The difference is that for multi-turn editing, the source image is set as the output of former editing.

Table 1: The alignments with the target image/prompt of images generated under various T2I editing methods on MagicBrush dataset. We respectively compare the single-turn and multi-turn editing results of all methods with the same 1053 test data in MagicBrush. Please note that the multi-turn editing takes the previously edited images as source images, and the number of turns varies. The results with minimal average rank are marked in bold.

	MaSaFusion (NTI-based)	0.0976	0.0307	0.9007	0.8457	0.2789	2.0

Evaluation Metric. We adopt the ones in [39], where the alignments of obtained images to the ground-truth target images and the target text prompt are measured. Concretely, the L_1 , L_2 distance between the generated and target images, DINO [4], Image-Image CLIP (CLIP-I) scores between the target and generated images, and Image-Text CLIP Scores (CLIP-T) between the generated images and target prompts [19].

Setup. We use Stable Diffusion [20] model v1.4 integrated with T2I Adapter [16] as backbone model. During inference stage (inversion (5) or generation (4)), we use 50 steps DDIM [26]. For the inversion technique, our method can be combined with any proper ones. In this paper, we combine our MaSaFusion with null-text inversion (NTI) [15] and direct inversion (DI) [12]. It is worth noting that DI is computational efficient than NTI, i.e., 43s v.s. 184s for single image editing. However, the results in Table 1 shows that MaSaFusion under NTI has slightly better result compared with combining it with DI. Therefore, a trade-off between efficiency and quality is existed when selecting inversion techniques (more details are in Appendix A).

Figure 7: Variation of given editing region A in our MaSaFusion. Obviously, the region should be somehow accurate, otherwise the editing is not satisfactory.

We compare our methods with training-based/free editing methods. For the first, we consider the standard methods HIVE [41] and InstructP2P [2]. For fair comparison, we do not fine-tune them on MagicBrush as in [39]. For training free methods, we mainly consider SDE-Diffedit [5; 18], P2P [9], PnP [30], Masactrl [3], GLIDE [17], and Blended Diffusion [18]. Here, the Masactrl, GLIDE, and Blended Diffusion use the external information as well, i.e., target sketch map for Masactrl, and editing region for the last two. These used conditions are exactly the ones used in our MaSaFusion.

Main Results. We present some of the edited images in Figures 5&6. Moreover, we refer readers to more of them in Appendix D. As can be seen, our method significantly improves the existing ones in terms of feature preserving and consistency to target prompt.

Besides, the quantitative comparisons with the baseline methods are in Table 1. For each method, we report its averaged rank (from 1-10) under each metric, and we have the following observations.

1. Owing to the diversity of consistency metrics, the representative metric should be the “averaged rank” of each method. By comparing them, we conclude that the proposed MaSaFusion indeed has the best performance over the other baseline methods.
2. The features in the edges of the editing region provided by the mask-informed methods GLIDE and Blended Diffusion are unsmooth and unnatural, which results in the large L_1 and L_2 distances. This originates from the directly copied out-of-mask features from the source image as clarified in Section 4.2.
3. Compared with single-turn editing, implementing the existing methods of multi-turns generally preserves features at a poor level. We speculate this is because the unedited features from source images may gradually interrupted during the multi-turn editing, as its source images are outputs of former editing instead of the original ones.

5.2 Ablation Study

In this subsection, we perform ablation studies on the additional T2I-Adapter’s external conditions and the annotated editing regions.

Varying T2I-Adapter External Conditions. In Figure 5, the external condition used in the T2I Adapter is a sketch map of the desired target image. In practice, the condition can be substituted by the ones that are suitable to the T2I Adapter e.g., pose or canny map as visualized in Figure 1.

Varying Editing Region. In MaSaFusion, the mask-informed region is predetermined, while it ideally should encompass the areas to be edited without overlapping with features that should remain unaltered. To check the sensitivity of MaSaFusion to the predetermined region, we vary the shape of the prior mask in Figure 7. As can be seen, an extremely large region can not retain the textures on the target image. We speculate such inappropriate region results in an undesired intermediate image in line 6 of Algorithm 1, which is borrowed to decide the target image’s self-attention map. Thus, we suggest to invoke an appropriate editing region in MaSaFusion.

6 Conclusion

In this paper, we improve the existing training-free diffusion-based text-to-image editing. Based on the failure cases of existing methods, we propose to generate intermediate hidden states with proper attention-map compared with the desired target image. During generating such intermediate image, we induce some external knowledge (i.e., the external conditions used in T2I Adapter). Then, these attention-maps are wisely borrowed in the following fusion process of generating target image, where the editing of target image is restricted in a prior given region.

We empirically verify our proposed method MaSaFusion on a benchmark T2I editing dataset. Compared to the existing methods, our MaSaFusion significantly improves the existing methods in T2I editing, both visually and quantitatively.

A Discussion to Inversion Techniques

In this section, we present a brief introduction to the technique of null-text inversion [15], which is a backbone inversion technique of our method. It has been found in [15], the standard DDIM inversion (5) with source prompt injected into $\epsilon_\theta(t, \mathbf{x}_t^S, \mathcal{C}^S, \emptyset)$ can not reconstruct the source image. Thus they propose to learn a series of $\{\emptyset_t\}_{t=1}^T$ by iteratively minimizing

$$\min_{\emptyset_t} \left\| \mathbf{x}_{t-1}^S - \text{DDIM}(\epsilon_\theta, \hat{\mathbf{x}}_t^S, \mathcal{C}, \emptyset_t) \right\|^2, \quad (11)$$

where \mathbf{x}_t^S is obtained by DDIM inversion (5), starting from source image \mathbf{x}_0^S , and $\hat{\mathbf{x}}_t^S$ is obtained by DDIM (4) from $\hat{\mathbf{x}}_{t+1}^S$ with $\hat{\mathbf{x}}_T^S = \mathbf{x}_T^S$ and $\emptyset = \emptyset_t$ in (3). Then, plugging these $\{\emptyset_t\}$ into (4) from \mathbf{x}_T^S reconstructs the source image. The complete NTI is summarized in Algorithm 2 [15].

The null-text inversion incorporates the information from the source prompt into the learned initial state \mathbf{x}_0^T and $\{\emptyset_t\}$ so that it is friendly to preserve features when generating target image. In this paper, the hyperparameters of null-text inversion are adopted from [15] with $N = 10, T = 50, \eta = 2e - 4$. We refer readers for more details of this method in [15].

In NTI Algorithm 2, obtaining the null-conditions $\{\emptyset_t\}$ requires an extra inner loop of optimization. The inner is used to make $\hat{\mathbf{x}}_t^S$ approximates \mathbf{x}_t^S so that fits the text prompt condition with $w = 7.5$ in generating target image. However, the extra inner loop increases the computational complexity, which somehow restricts the editing technique in practice. Recently, another inversion technique Direct Inversion [12] was proposed to accelerate NTI. It improves the NTI by canceling the inner loop in lines 6-8 of Algorithm 2 to accelerate the editing process. The idea in [12] is simple, instead of optimizing $\{\emptyset_t\}$ to lead $\hat{\mathbf{x}}_t^S$ approximates \mathbf{x}_t^S , they directly make $\hat{\mathbf{x}}_t^S = \mathbf{x}_t^S$ and feed them into the DDIM process for $w = 7.5$ to obtain intermediate hidden states $\{(Q^S, K^S, V^S)\}$. Notably, combining MaSaFusion with DI slightly drops its performance, compared with conducting it under NTI, as in Table 1. However, DI decreases the whole editing process from 184.2s to 43.9s (evaluated

Figure 8: The results of existing methods under shape invariant editing task.

 - 2: Inversion Algorithm 2 or 3 on (\mathcal{S}, x_0^S) to get $\{\theta_t\}$ (NTI) and x_T^S ;
 - 3: Create new target prompt embedding \tilde{c}^T as in (12);
 - 4: **Generating Target Image**
 - 5: Initialize $x_T^T = x_T^S$;
 - 6: **for** $t = T, \dots, 1$ **do**
 - 7: $x_{t-1}^T = \text{DDIM}(\epsilon_\theta, x_t^T, \tilde{c}^T, \theta)$ (process of (5));
 - 8: **end for**
 - 9: **return** Target image x_0^T .
-

on a workstation with one NVIDIA V100). Thus, we prefer to use DI as our backbone inversion technique in practice.

B Shape Invariant Editing

In this section, we explore Text-to-Image (T2I) editing tasks where the shapes of the features being edited remain largely unchanged. The typical scenarios include background or color transformations. As we have clarified in Section 4.1, the existing methods (e.g., P2P) have better performance under these tasks than the other shape variant editing tasks. However, they can be further improved without the external knowledge as in MaSaFusion.

B.1 Control Unrelated Textual Embedding

In the existing methods, though the edited target image roughly preserves the characteristics of the source image, the overall performance is far from satisfactory, e.g., the characteristic of humanity face varies in Figure 8. In the rest of this subsection, we aim to improve the null-text-inversion, and fix the issues as in Figure 8.

Prompt: a woman with brown(pink) hair

Figure 10: The visualization cross attention map of image with given source prompt.

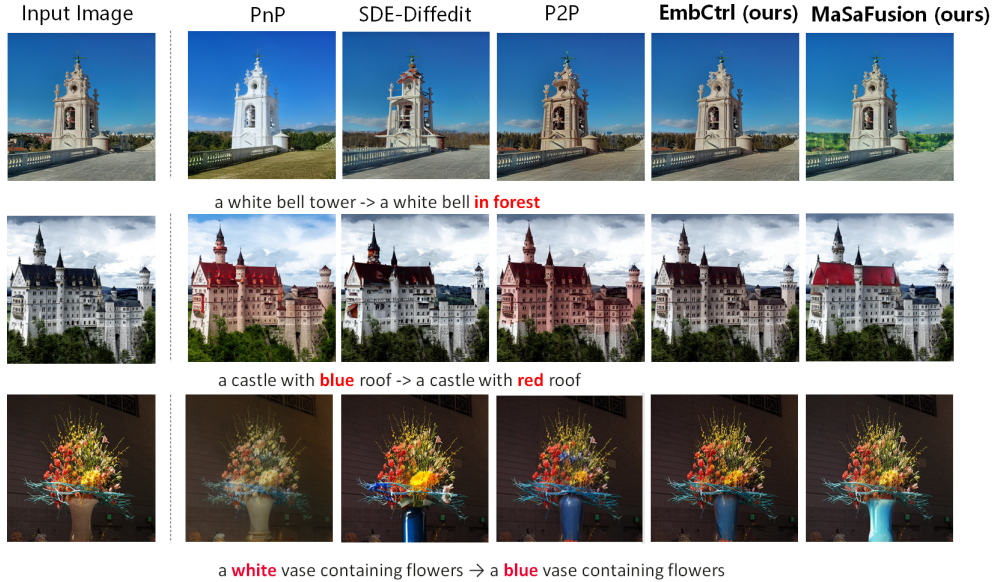

Figure 11: The comparison over editing methods on shape invariant editing task. The compared baseline methods are mainly tailored to such editing task.

Due to (7), the textual prompt affects the generated image latent by cross-attention structure. For the intermediate hidden states $\phi(\mathbf{x}_t) \in \mathbb{R}^{N \times d}$ (flattened), where N is the number of pixels and d is the dimension of pixel-wise embedding, the i -pixel of cross-attention’s output is $\sum_{j=1}^{d_c} P_{ij} V_j$, where $P = \text{Softmax}(QK^\top / \sqrt{d})$, $V = W_V \mathcal{C}$. Thus, the representation of each pixel after the cross-attention layer is indeed a weighted sum of V which is a linear transformation of textual embedding \mathcal{C} obtained by CLIP [19] model. Ideally, the pixels in a specific feature of the generated image are only decided by the semantically related textual prompt. Then, the features can be appropriately edited by substituting tokens in the source prompt.

Unfortunately, this can not happen in practice. In Figure 10, by following [29], we visualize the cross-attention map of softmax for each word in prompt \mathcal{C} “a woman with brown hair”. It is worthy to note that \mathcal{C} is padded by “< |endoftext| >” into a length of 77 as in [22]. As can be seen, the unedited feature,⁶ e.g., the human face is decided by the other unchanged tokens (“woman”, “with”, “< |endoftext| >”). This dependence causes the failure of null-text-inversion. Because when altering the source textual prompt “woman with brown hair” into the target textual prompt “woman with pink hair”, the embedding of tokens after “pink” are all changed due to the auto-regressive embedding mechanism of CLIP model [19]. Then, the entirely changed target textual prompt affects the overall features in the target image.

To obviate this, a straightforward way of improving null-text-inversion is keeping the token embedding in the target prompt for unchanged tokens. That says, given textual embedding $\mathcal{C}^S = \{\tau(S)_1, \dots, \tau(S)_{77}\}$ ($\tau(\cdot)$ is CLIP model) of source prompt S , we use the target prompt

⁶Interestingly, though the image is encoded latent, the token can semantically relate to the corresponding image. Similar results are also observed in [29].

embedding

$$\tilde{\mathcal{C}}^{\mathcal{T}} = \{\tau(\mathcal{S})_1, \dots, \tau(\mathcal{T})_i, \dots, \tau(\mathcal{S})_{77}\}, \quad (12)$$

instead of $\mathcal{C}^{\mathcal{T}} = \tau(\mathcal{T})$, where $\tau(\mathcal{T}) = \mathcal{C}^{\mathcal{T}}$ is the textual embedding of target prompt \mathcal{T} differs from source prompt \mathcal{S} in the i -th token (i can be larger than 1). The pipeline of our method ‘‘Embedding Control’’ (EmbCtrl) to tackle shape invariant editing task is in Algorithm 4 where $\text{DDIM}(\epsilon_{\theta}, \mathbf{x}_t^{\mathcal{T}}, \tilde{\mathcal{C}}^{\mathcal{T}}, \emptyset)$ is defined as in (11).

The edited images of our method are in Figure 11. As can be seen, compared with the existing methods, our method maximally preserves the features of source images that are undesired to be edited. Besides that, the proposed EmbCtrl does not require extra external conditions as in the proposed MaSaFusion.

However, the proposed EmbCtrl can not be generally applied as MaSaFusion (for both shape invariant/variant editing). For those editing with variant objects’ shapes, the EmbCtrl will fail similarly to the other simple fusion-based methods (e.g., P2P).

C MaSaFusion without Intermediate Images

As we have clarified in Section 4.1, generating an intermediate image with the correct attention map is critical to the final fusion process. In this section, we verify this clarification. Instead of involving an external signal (e.g., sketch) to capture intermediate hidden states by T2I adapter as in Algorithm 1, we develop another pipeline to conduct text-to-image editing in the sequel. It is worth noting that MaSaFusion leverages human annotations in two-fold, i.e., external signal and editing region. We try to use none of them at first, and we will observe that without any of them, the editing is unstable.

Firstly, our method is as follows: for the procedure of DDIM in line 7 of Algorithm 4, we modify the noise prediction $\epsilon_{\theta}(t, \mathbf{x}_t, \mathcal{C}^{\mathcal{T}}, \emptyset_t)$ as follow. For the self-attention modules in the network, under specific t , we substitute the original output $\text{Attention}_{SA}(Q^{\mathcal{T}}, K^{\mathcal{T}}, V^{\mathcal{T}})$ with $\text{Attention}_{SA}(Q^{\mathcal{T}}, K^{\mathcal{S}}, V^{\mathcal{S}})$ for the corresponded layers.⁷ Besides that, instead of \emptyset_t , we should use empty embedding \emptyset when generating target image. The substituted noise prediction is denoted as

$$\hat{\epsilon}_{\theta}^{\text{w/o t2i}}(t, \mathbf{x}_t, \mathcal{C}^{\mathcal{T}}, \mathcal{C}^{\mathcal{S}}, \emptyset) \quad (13)$$

in the sequel to clarify the notation. The rationale of substituting $(Q^{\mathcal{T}}, K^{\mathcal{T}}, V^{\mathcal{T}})$ with $(Q^{\mathcal{T}}, K^{\mathcal{S}}, V^{\mathcal{S}})$ in self-attention module is intuitive because 1): The self-attention decides output by the image itself instead of target prompt as in cross-attention module (which generates unrelated image); 2): We want the generated features to be the composition of source image but in the way of target prompt, so that from $(Q^{\mathcal{T}}, K^{\mathcal{T}}, V^{\mathcal{T}})$ to $(Q^{\mathcal{T}}, K^{\mathcal{S}}, V^{\mathcal{S}})$.

Let us check the results without any human annotations. We vary the number of denoising steps that inject information from the source prompt in Figure 12. In the first row of Figure 12, the strength of artificial fusion is increased from the left to right. As can be seen, without the fusion operation, the generated image is consistent with the target prompt, while the characteristics are slightly related to the source image. On the other hand, increasing the strength of fusion rends the generated image close to the source one until degeneration happens. These observations inform that wisely modify the self-attention block of noise prediction $\epsilon_{\theta}(t, \mathbf{x}_t, \mathcal{C}^{\mathcal{T}}, \emptyset)$ in DDIM (4) potentially works, e.g., conducting fusion on the first 20 steps of DDIM (4) in Figure 12. However, this setting is not necessarily generalized to the other images.

C.1 Injecting Prior Knowledge Editing Region

In this subsection, we promote the method in above by involving editing region. To do so, we revise the noise-prediction as

$$\epsilon_{\theta}(i) = \begin{cases} \bar{\epsilon}_{\theta}(t, \mathbf{x}_t^{\mathcal{T}}, \mathcal{C}^{\mathcal{S}}, \emptyset), & i \notin A; \\ \hat{\epsilon}_{\theta}^{\text{w/o t2i}}(t, \mathbf{x}_t, \mathcal{C}^{\mathcal{T}}, \mathcal{C}^{\mathcal{S}}, \emptyset), & i \in A, \end{cases} \quad (14)$$

to restrict the potential interfere of generating new features and preserving source image in the prior editing region, where $\bar{\epsilon}_{\theta}(t, \mathbf{x}_t^{\mathcal{T}}, \mathcal{C}^{\mathcal{S}}, \emptyset_t)$ is defined in (9). By leveraging the annotation region, the

⁷According to our empirical observations, this works better than the other blocks, i.e., cross-attention and residual blocks.

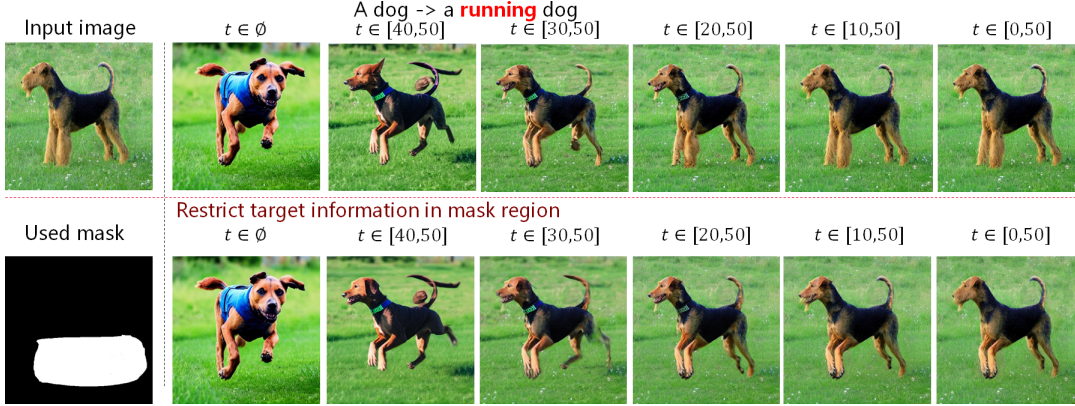

Figure 12: The edited images of injecting information from source prompt as in (13) over different time interval of DDIM (4). In the first (resp. second) row, the interval $t \in [a, b]$ means substituting ϵ_θ in DDIM (4) with noise prediction defined in (13) (resp. (9)) when $t \in [a, b]$. Please note that in the row of images, the target information are restricted in the mask region.

Algorithm 5 MaSaFusion without T2I Adapter.

Input: source prompt \mathcal{S} , source image x_0^S , target prompt \mathcal{T} , diffusion model ϵ_θ , annotation mask, null-text embedding $\emptyset = \tau(\text{" "})$.

- 1: **Inversion Step**
 - 2: Inversion Algorithm (2) or 3 on (\mathcal{S}, x_0^S) to get $\{\emptyset_t\}$ (NTI) and x_T^S ;
 - 3: DDIM (4) with $x_T^S, \{\emptyset_t\}$ and get intermediate hidden states $\{Q^S, K^S, V^S\}$ for each t ;
 - 4: **Generating Target Image**
 - 5: Initialize $x_T^T = x_T^S$;
 - 6: **Fuse cached intermediate hidden states** $\{Q^S, K^S, V^S\}$
 - 7: $x_{t-1}^T = \text{DDIM}(\epsilon_\theta, x_t^T, \mathcal{C}^T, \emptyset)$ (9);
 - 8: **Fuse cached intermediate hidden states** $\{Q^S, K^S, V^S\}$
DDIM (4) with ϵ_θ in (14), by invoking annotation region A ;
 - 9: **return** Target image x_0^T .
-

interference is greatly mitigated since the generated new features are restricted in a small region. Besides that, with this mask, injecting the information from the source prompt can be conducted over the whole DDIM process as in Figure 12, so obviating the collapse into the source image. The pipeline of this method is summarized in Figure 13 and Algorithm 5.

However, though the Algorithm 5 works well in some cases, we observe the method is unstable in practice. For example, in Figure 2, the generated eagle is unrealistic. Comparing the existing results, the generated dog for $t \in \emptyset$ and source image in Figure 12 accidentally has legs in the same prior editing region, so that the fusion between them is relatively simple. However, for the eagle in Figure 2, the edited characteristics in these two images are not in the same prior editing region. Thus, the mismatch results in an inappropriate fusion process.

To obviate this, we should guarantee the generated image to be fused has edited characteristics in the prior given editing region. One way to doing this is leveraging the T2I Adapter as in our MaSaFusion 1.

D More Results of MaSaFusion

In this section, we show more results and discussion of our MaSaFusion 1. Firstly, we present some intermediate results on our method, i.e., the generated image used to be fused in line 6 of Algorithm 1 and the target image directly obtained by T2I Adapter. The results are in Figure 14. As can be seen, though the intermediate images and images generated by the T2I Adapter are consistent with the target prompt, some features are not preserved as we hope. This explains our claims about them

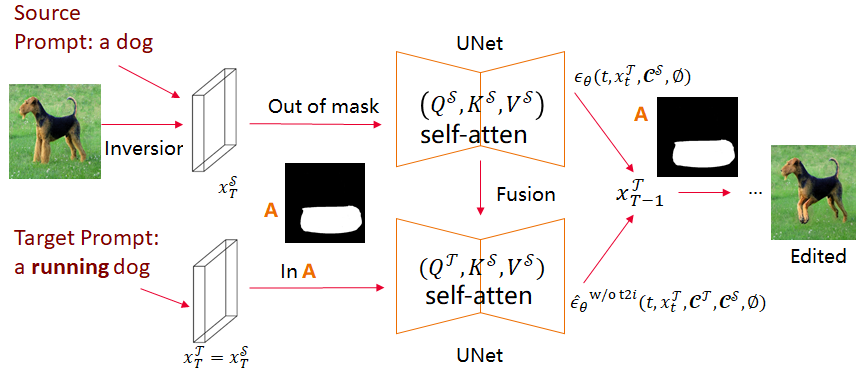

Figure 13: The visualization of our method without T2I adapter [16] for shape variant editing, i.e., MaSaFusion without T2I adapter Algorithm 5.

in Section 4.2. Besides that, one can notice that the generated target image has an inconsistent facial identity for images in the first row of Figure 14. This originates from the limitation of Stable Diffusion in some cases of generation e.g., human face or hand.

Moreover, we present more edited images of our and other baseline methods. The results are in Figure 15.
