# Moments of characteristic polynomials and their derivatives for  $SO(2N)$  and  $USp(2N)$  and their application to one-level density in families of elliptic curve L-functions

I.A. Cooper, N.C. Snaith <sup>∗</sup>

#### Abstract

Using the ratios theorems, we calculate the leading order terms in  $N$  for the following averages of the characteristic polynomial and its derivative:  $\left\langle |\Lambda_A(1)|^r \frac{\Lambda'_A(e^{i\phi})}{\Lambda_A(e^{i\phi})}\right\rangle$  $SO(2N)$ and  $\left\langle \left| \Lambda_A(1) \right|^r \frac{\Lambda_A'(e^{i\phi})}{\Lambda_A(e^{i\phi})} \right\rangle$ . Our expression, derived for integer r, permits analytic con-<br> $USp(2N)$ tinuation in  $r$  and we conjecture that this agrees with the above averages for non-integer exponents. We use this result to obtain an expression for the one level density of the 'excised ensemble', a subensemble of  $SO(2N)$ , to next-to-leading order in N. We then present the analogous calculation for the one level density of quadratic twists of elliptic curve Lfunctions, taking into account a number theoretical bound on the central values of the L-functions. The method we use to calculate the above random matrix averages uses the contour integral form of the ratios theorems, which are a key tool in the growing literature on averages of characteristic polynomials and their derivatives, and as we evaluate the next-to-leading term for large matrix size  $N$ , this leads to some multi-dimensional contour integrals that are slightly asymmetric in the integration variables, which might be useful in other work.

### 1 Introduction

We define the characteristic polynomial  $\Lambda_A(s)$  of  $A \in U(N)$  as

$$
\Lambda_A(s) = \det(I - sA^*) = \prod_{j=1}^N (1 - s e^{-i\theta_j}),
$$
\n(1)

with the eigenvalues of A denoted by  $e^{i\theta_1}, \ldots, e^{i\theta_N}$ , and  $A^*$  being the conjugate transpose.

Mixed moments for  $U(N)$ , in the spirit of  $\left\langle |\Lambda_A(1)|^k |\Lambda'_A(1)|^r \right\rangle$  $A\in U(N)$ (actually in some cases

the results are for a variation of the characteristic polynomial that is multiplied by a factor so as to be real on the unit circle) have been studied extensively, starting with Hughes in 2001 [\[24\]](#page-33-0), by Dehaye [\[18,](#page-33-1) [19\]](#page-33-2), by Winn [\[37\]](#page-34-0) and Conrey, Rubinstein and Snaith in [\[16\]](#page-33-3), and more recently in two large collaborations [\[8\]](#page-32-0) and [\[11\]](#page-32-1). These results have led to an understanding of the rate of growth of the leading order term when the matrix size  $N$  is large, and several varied expressions for the leading order coefficient in terms of determinants, combinatorial sums, integrals or relating it to solutions of Painlevé equations. This has been extended to circular beta ensembles by Forrester [\[22\]](#page-33-4) and to higher derivatives in  $U(N)$  by Keating and Wei [\[29,](#page-33-5) [30\]](#page-33-6), Barhoumi-Andréani [\[9\]](#page-32-2) and Assiotis, Gunes, Keating and Wei [\[5\]](#page-30-0) and generalised to  $USp(2N)$ ,  $SO(2N)$  and  $O^-(2N)$  by Altuğ et al [\[1\]](#page-30-1) and Andrade and Best [\[3\]](#page-30-2). There is an ongoing effort to give explicit expressions for the leading order coefficient also when the exponents  $k$  and  $r$  are

<sup>∗</sup>Thanks to Jon Keating for his help at the start of this project.

non-integer. Early results in this direction generalised to  $k \in \mathbb{Z}$ ,  $2r \in \mathbb{Z}$  [\[37\]](#page-34-0) or  $k \in \mathbb{R}$ ,  $r \in \mathbb{Z}$  [\[19\]](#page-33-2), and in the past few years Assiotis, Keating and Warren [\[7\]](#page-30-3) have extended both the exponent on the characteristic polynomial and its derivative to real numbers and expressed the leading order coefficient as the expectation value of a certain random variable, with an extremely recent extension of this to averages of products of many derivatives of any order raised to any positive real powers in [\[5\]](#page-30-0). Similar work has been carried out for other ensembles by Assiotis, Gunes and Soor in [\[6\]](#page-30-4).

Here, we calculate similar quantities over  $SO(2N)$  and  $USp(2N)$ , with the distinction that for the purposes of our application to the one level density of zeros of L-functions, we do not always evaluate the characteristic polynomial at the point 1, as is the case in the aforementioned literature. To start with, in Section [2,](#page-3-0) we shall focus on the expected value

<span id="page-1-0"></span>
$$
\left\langle |\Lambda_A(1)|^r \frac{\Lambda'(e^{i\phi})}{\Lambda(e^{i\phi})} \right\rangle_{SO(2N)},
$$
\n(2)

(note that the equivalent quantity for  $SO(2N+1)$  would always be zero due to the functional equation of the characteristic polynomial). The same method may also be applied to  $USp(2N)$ , and we have included the result of the equivalent calculation in Section [3.](#page-16-0)

An analogous quantity, a joint average of the Riemann zeta function and it's logarithmic derivative, have been studied in the number theory literature for a slightly different purpose by Fazzari in [\[21\]](#page-33-7). Similar moments on the random matrix theory side have been considered by Simm and Wei [\[35\]](#page-34-1).

In random matrix theory, the one level density gives us information about how the density of eigenvalues varies around the unit circle - about the likelihood of finding an eigenvalue in a particular interval on the unit circle if we draw a matrix at random from our ensemble. If one could write  $\left\langle \left| \Lambda_A(1) \right|^r \frac{\Lambda'(e^{i\phi})}{\Lambda(e^{i\phi})} \right\rangle$  $\frac{\Lambda^\prime(\mathrm{e}^{\mathrm{i}\phi})}{\Lambda(\mathrm{e}^{\mathrm{i}\phi})}\bigg>$ s $SO(2N)$  as an analytic expression in r, then we could use this quantity to calculate the one level density for the excised ensemble  $\{A|A \in SO(2N), \Lambda_A(1) >$  $e^{\chi}$ , which was introduced in [\[20\]](#page-33-8) as a model for quadratic twist families of elliptic curve Lfunctions. In Section [5](#page-17-0) we make the assumption that our expression for [\(2\)](#page-1-0) holds for complex r with  $\text{Re}(r) > 0$ .

Although our motivation is number theoretical, we do not need to call on much number theoretical knowledge because the hard work has been done for us by Conrey, Farmer and Zirnbauer in [\[14\]](#page-33-9) who conjecture forms for averages of ratios of L-functions. These expressions have identical structure to their random matrix analogues. So in Sections [6](#page-21-0) and [7](#page-28-0) we use these ratios conjectures to investigate the one-level density of L-functions associated with a family of elliptic curves, but we do so by simply mimicking the steps used in the random matrix calculation. However, for completeness we give a little introduction to the relevant number theory in the next section.

#### 1.1 Elliptic curve  $L$ -functions

An elliptic curve E may be described by an equation of the form  $E: y^2 = x^3 + ax + b$ , and a quadratic twist of E by a fundamental discriminant d would be the curve  $E_d : dy^2 = x^3 + ax + b$ .

For such an elliptic curve, we can construct an L-function which has similar properties to the Riemann zeta function, for example an Euler product, a Dirichlet series, a Riemann Hypothesis. We write  $L_E(s)$  for the L-function associated to E and  $L_E(s, \chi_d)$  for the L-function associated to  $E_d$ . A theme in analytic number theory is that one can often deduce arithmetic information about number theoretical objects from properties of a related L-function. The Euler product of an  $L$ -function of an elliptic curve  $E$  is

$$
L_E(s) = \prod_{\text{bad primes}} \frac{1}{1 - \lambda(p)p^{-s}} \prod_{\text{good primes}} \frac{1}{1 - \lambda(p)p^{-s} + p^{-2s}},\tag{3}
$$

where  $\lambda(p) := (p+1-N_p)/\sqrt{p}$ , and  $N_p$  counts solutions to the elliptic curve over the finite field of order p. This obeys the functional equation

$$
L_E(s) = \omega(E) \left(\frac{2\pi}{\sqrt{M}}\right)^{2s-1} \frac{\Gamma(3/2 - s)}{\Gamma(1/2 + s)} L_E(1 - s).
$$
 (4)

Here, the conductor M is an integer associated to  $E$ , and the 'good primes' are those which do not divide the conductor([\[4\]](#page-30-5), [\[34\]](#page-34-2)). The Generalised Riemann Hypothesis suggests that zeros of such an L-function are constrained to lie on the critical line in the complex plane with real part 1/2.

#### 1.2 RMT and number theory

Characteristic polynomials of unitary matrices have many features in common with L-functions. According to the Katz-Sarnak philosophy, in some appropriate limit the zero statistics of a naturally-related family of L-functions tend to the equivalent statistics of eigenvalues from some subgroup of  $U(N)$  [\[26\]](#page-33-10) [\[27\]](#page-33-11). For unitary matrices, the analogue of the critical line is the unit circle, and the 'Riemann hypothesis' is known to be true (as the eigenvalues are all constrained to lie on the unit circle). All of the zeros of the derivative lie inside the unit circle, which is equivalent to the hypothesis in number theory that all of the relevant zeros of derivatives of L-functions lie to the right of the critical line. For all subgroups of the unitary group, we have a functional equation, for example

$$
\Lambda_A(s) = (-1)^N \det(A) s^N \Lambda_{A^*}(s^{-1})
$$
\n(5)

for unitary matrices. Here, the appropriate Katz-Sarnak limit is the limit of large matrix size N, where N plays the same role in the functional equation as the log of the conductor in the elliptic curve L-function case. The analogue of the critical value  $L_E(1/2)$ , where we are particularly interested in the value (or the order of vanishing) of the L-functions due to the Birch Swinnerton-Dyer conjecture, is the central value  $\Lambda_A(1)$ , which, as one would expect, is at the symmetry point of the functional equation.

The excised model was proposed in [\[20\]](#page-33-8) as a random matrix model for families of quadratic twists of elliptic curve L-functions which is applicable in the finite conductor regime. The one level density for the excised model was calculated in that paper using Gaudin's lemma. Here, we recalculate the one level density for the excised model using a method which requires the mixed moment

$$
\int_{SO(2N)} \frac{\Lambda(1)^r \Lambda'(e^{-\phi})}{\Lambda(e^{-\phi})} dA.
$$
\n(6)

This is of interest, even though this calculation is already possible using an easier method, since the present method has an analogue in number theory - namely, via the ratios conjecture of [\[14\]](#page-33-9), which involves averages (for example over a family) of ratios of L-functions. This allows us in principle to repeat the calculation in the number theory setting - e.g. calculating the one level density for zeros of elliptic curve L-functions in a family of quadratic twists - by simply following the same steps as in random matrix theory.

Our method is based on that used in [\[25\]](#page-33-12), where a conjecture for the one level density for quadratic twists of elliptic curve L-functions was derived. While this provided a very accurate conjecture for the one level density higher up the critical line, it failed to capture the behaviour of zeros close to the real axis. We expect that this is due to the approximations in the 'recipe' of [\[14\]](#page-33-9) leading to a loss of information about the constraints on the central value of the L-functions in our family([\[31\]](#page-34-3), [\[33\]](#page-34-4),[\[36\]](#page-34-5)), which force the central values either to take the value zero, or else obey

<span id="page-2-0"></span>
$$
L_E\left(\frac{1}{2}, \chi_d\right) > \kappa_E \left|d\right|^{-1/2}.\tag{7}
$$

For more discussion of how this bound should be interpreted in a random matrix model, see [\[20\]](#page-33-8) and [\[17\]](#page-33-13). Our goal here is to use the calculation for the excised model as a template to conjecture an expression for the one level density for the L-functions.

The means we have to do this, without calling too deeply on number theoretical knowledge, is the similarity of the following two formulae. Theorem 4.3 and Lemma 6.8 from [\[14\]](#page-33-9) tell us that

$$
\int_{SO(2N)} \frac{\Lambda(1)^{K-1} \Lambda(e^{-\alpha})}{\Lambda(e^{-\gamma})} dA \n= \frac{(-1)^{K(K-1)/2} 2^{K}}{(2\pi i)^{K} K!} e^{-N\alpha} \n\times \oint \cdots \oint \exp\left(N \sum_{l=1}^{K} w_{l}\right) \frac{H_{\alpha,\gamma}^{SO(2N)}(w_{1},...,w_{K}) \Delta(w_{1}^{2},...,w_{K}^{2})^{2} \prod_{i=1}^{K} w_{i} dw_{i}}{\prod_{n=1}^{K} (w_{n}-\alpha)(w_{n}+\alpha) w_{n}^{2K-2}},
$$
\n(8)

and Conjecture 5.3 with Lemma 6.8 in [\[14\]](#page-33-9) gives us

$$
\sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = 1}} \left[ \frac{L_E^{K-1}(1/2, \chi_d) L_E(1/2 + \alpha, \chi_d)}{L_E(1/2 + \gamma, \chi_d)} \right]
$$
\n
$$
= \frac{(-1)^{K(K-1)/2} 2^K}{K!(2\pi i)^K} \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = 1}} \left( \frac{M|d|^2}{4\pi^2} \right)^{(-\alpha/2)}
$$
\n
$$
\times \oint \cdots \oint \left( \frac{M|d|^2}{4\pi^2} \right)^{\frac{1}{2} \sum_{k=1}^K (w_k)} \left( \frac{H_{\alpha,\gamma}(w_1, \ldots, w_k) \Delta(w_1^2, \ldots, w_k^2)^2 \prod_{i=1}^K w_i dw_i}{\prod_{n=1}^K (w_n - \alpha)(w_n + \alpha) w_n^{2K-2}} \right)
$$
\n
$$
+ \mathcal{O}\left(X^{1/2 + \epsilon}\right). \tag{9}
$$

Here the contours enclose zero and  $\pm \alpha$ . The components such as  $z(x)$  and  $H_{\alpha,\gamma}$  will be discussed when we come to use these formulae in later sections (see [\(12\)](#page-4-0) and [\(83\)](#page-21-1) plus [\(84\)](#page-22-0)), but the point here is to notice that if N is equated to  $\frac{1}{2} \log(M |d|^2/(4\pi^2))$ , then the structure of these two formula, one for an average over matrices from  $SO(2N)$  with Haar measure, and one an average over a family of elliptic curve L-functions, is near identical.

## <span id="page-3-0"></span>2 A mixed moment for  $SO(2N)$

We would like to calculate the following ratio of characteristic polynomials averaged over  $SO(2N)$ :

<span id="page-3-1"></span>
$$
\int_{SO(2N)} \frac{\Lambda(1)^r \Lambda'(e^{-\phi})}{\Lambda(e^{-\phi})} dA.
$$
\n(10)

Note that as the eigenvalues of matrices  $A \in SO(2N)$  occur in conjugate pairs, the characteristic polynomial has the form

$$
\Lambda_A(s) = \prod_{j=1}^N (1 - s e^{-i\theta_j})(1 - s e^{i\theta_j}).
$$
\n(11)

We idealy want an expression for [\(10\)](#page-3-1) valid for any complex value of r with positive real part. In order to do so, we shall use the ratios theorem (which is only valid for integer  $r$ , but which eventually gives us an expression which can be analytically continued).

The ratios theorem [\[14\]](#page-33-9), in its contour integral statement, (see Theorem 4.3 and Lemma 6.8 from [\[14\]](#page-33-9)) tells us that

$$
\mathcal{R}_{SO(2N)}(\alpha, \gamma, K) := \int_{SO(2N)} \frac{\Lambda(1)^{K-1} \Lambda(e^{-\alpha})}{\Lambda(e^{-\gamma})} dA \n= \frac{e^{-N\alpha}(-1)^{K(K-1)/2} 2^{K}}{(2\pi i)^{K} K!} \n\times \oint \cdots \oint \frac{\prod_{1 \le j < k \le K} z(w_j + w_k) z(2\gamma) \exp\left(N \sum_{l=1}^{K} w_l\right) \Delta(w_1^2, \dots, w_K^2)^2 \prod_{i=1}^{K} w_i dw_i}{\prod_{n=1}^{K} z(w_n + \gamma)(w_n - \alpha)(w_n + \alpha) w_n^{2K-2}},
$$
\n(12)

where  $z(x) = (1 - e^{-x})^{-1} = (\frac{1}{x} + \frac{1}{2} + \mathcal{O}(x))$ , and the contours of integration enclose 0,  $\alpha$  and  $-\alpha$ . To avoid ambiguity, we shall take the contours to be nested, i.e. the w<sub>i</sub> contour shall completely enclose the  $w_j$  contour whenever  $j > i$ . The Vandermonde determinant is

$$
\Delta(x_1, \dots, x_K) = \begin{vmatrix} 1 & x_1 & \cdots & x_1^{K-2} & x_1^{K-1} \\ 1 & x_2 & \cdots & x_2^{K-2} & x_2^{K-1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & x_K & \cdots & x_K^{K-2} & x_K^{K-1} \end{vmatrix} = \prod_{1 \le j < m \le K} (x_m - x_j). \tag{13}
$$

Returning to [\(12\)](#page-4-0), we shall define

<span id="page-4-2"></span><span id="page-4-1"></span><span id="page-4-0"></span>
$$
C_{\alpha,\gamma,K}^{SO(2N)} = \frac{e^{-N\alpha}(-1)^{K(K-1)/2} 2^{K} z(2\gamma)}{(2\pi i)^{K} \Gamma(K+1)}.
$$
\n(14)

First, we simplify the products slightly to obtain

$$
\mathcal{R}_{SO(2N)}(\alpha,\gamma,K) = C_{\alpha,\gamma,K}^{SO(2N)} \oint \cdots \oint \prod_{1 \le j < k \le K} z \left( w_j + w_k \right) \Delta \left( w_1^2, \dots, w_K^2 \right)^2
$$
\n
$$
\times \prod_{n=1}^K \left( \frac{\exp \left( N w_n \right) \left( w_n \right)^{3-2K} \mathrm{d} w_n}{z \left( w_n + \gamma \right) \left( w_n - \alpha \right) \left( w_n + \alpha \right)} \right). \tag{15}
$$

Note that we do not get poles from the  $z(w_i+w_j)$  term due to cancellation with the Vandermonde  $\Delta(w_1^2,\ldots,w_K^2)$ . Each contour has poles at 0,  $\alpha$  and  $-\alpha$ . We contract each contour onto the poles so that it consists of a small circle around each pole, with narrow necks connecting the circles. The integral will cancel on each side of the neck as there are no branch points (note we are still assuming  $K$  is an integer at this point). This leaves a sum in each variable over three circular contours:

$$
\mathcal{R}_{SO(2N)}(\alpha,\gamma,K) = C_{\alpha,\gamma,K}^{SO(2N)} \sum_{\epsilon \in \{\pm \alpha,0\}^K} \oint_{\epsilon_K} \cdots \oint_{\epsilon_1} \prod_{1 \le j < k \le K} z(w_j + w_k) \Delta \left(w_1^2, \ldots, w_K^2\right)^2
$$
\n
$$
\times \prod_{n=1}^K \left( \frac{\exp\left(Nw_n\right)\left(w_n\right)^{3-2K}}{z\left(w_n + \gamma\right)\left(w_n - \alpha\right)\left(w_n + \alpha\right)} \mathrm{d}w_n \right),\tag{16}
$$

where an integral with a subscript  $\epsilon_j$  is the integral around a small circle centred on  $\epsilon_j$ , and  $\epsilon = (\epsilon_1, \epsilon_2, \dots, \epsilon_K)$  is a K-tuple.

#### <span id="page-5-2"></span>2.1 Evaluating the contributions to the sum

We are aiming to evaluate  $\mathcal{R}_{SO(2N)}(\alpha, \gamma, K)$  for large values of N. We will look at this asymptotically and also at the next-to-leading order term. To perform the sum over  $\epsilon$  in [\(16\)](#page-4-1) we need to consider separately terms where different numbers of variables are integrated round each of the three potential poles: 0,  $\alpha$  and  $-\alpha$ . We show in the next section that in the case of a term where two or more of the K variables are integrated around a pole away from  $0$ , that term contributes zero to the sum for any value of N. If all variables are on contours around zero, that term will be zero at leading order (see Section [2.1.2\)](#page-5-0). This leaves us with evaluating the contribution when all variables except for one are evaluated around the pole at zero, which will be considered in Section [2.1.3.](#page-7-0)

#### 2.1.1 Two or more variables integrated around  $\pm \alpha$

Without loss of generality, we can choose  $w_1$  and  $w_2$  to be integration variables which we shall be integrating around either  $\alpha$  or  $-\alpha$ . Consider the case where  $\epsilon_1 = \epsilon_2 = \alpha$ . The only singular parts of the integrand are the factors of  $(w_1 - \alpha)$  and  $(w_2 - \alpha)$  in the denominator. Considering performing, say, the w<sub>1</sub> integral first, after evaluation of the residue at  $w_1 = \alpha$ , this will leave us with factors of  $(w_2 - \alpha)$  from the Vandermonde in the numerator. These exactly cancel out the  $(w_2 - \alpha)$  in the denominator, so the integrand has no singularities and therefore no residues in  $w_1$  or  $w_2$ . The same thing happens for  $w_1 = w_2 = -\alpha$ .

There are only two possible non-zero values for the  $\epsilon_i$ s, namely  $\pm \alpha$ , so if we have more than two non-zero  $\epsilon_i$ s then at least two of them must be equal and the integral will vanish.

Let us next consider the case where two of the  $\epsilon_i$ s are non-zero and non-equal. For the purposes of doing the integrals in  $w_1$  and  $w_2$ , the other  $w_i$ s may be treated as constants. Let us consider only the parts of the integrand that either diverge or tend to zero as  $w_1$  and  $w_2$ approach  $\pm \alpha$ . We shall show that this vanishes when we do the contour integrals in  $w_1$  and  $w_2$ . This may be achieved by showing that

<span id="page-5-1"></span>
$$
\oint_{-\alpha} \oint_{\alpha} \frac{z(w_1 + w_2)(w_1 + w_2)^2 (w_1 - w_2)^2}{(w_1 - \alpha)(w_1 + \alpha)(w_2 - \alpha)(w_2 + \alpha)} dw_1 dw_2 \tag{17}
$$

vanishes. In order to do the integrals in  $(17)$ , we evaluate them sequentially. Let us do the  $w_1$ residue first, treating  $w_2$  as a constant independent of  $\alpha$ :

$$
=-2\pi i \oint_{-\alpha} \frac{z(\alpha+w_2)(\alpha+w_2)(\alpha-w_2)}{(2\alpha)} dw_2.
$$
\n(18)

This has no poles in  $w_2$ , since the  $(\alpha + w_2)^{-1}$  term from the series expansion of  $z(\alpha + w_2)$  is cancelled out. This completes our demonstration that terms in [\(16\)](#page-4-1) with two or more residues at evaluated at  $\pm \alpha$  will have zero contribution to the total sum.

#### <span id="page-5-0"></span>2.1.2 All the poles at zero

We have established that terms with fewer than  $K-1$  poles at zero do not contribute at all to the sum for any value of  $N$ . Let us now evaluate the contribution from the terms where all of the poles are integrated around zero, but this time we will scale the variables of integration by  $1/N$  and look at the leading order term. We will find that even the leading order term of this calculation is negligible compared to the size of other terms in the sum [\(16\)](#page-4-1) (see Section [2.1.3\)](#page-7-0), but we can show that the coefficient of the leading order term here is zero, and as the method is useful later, we will demonstrate it in full detail. We start with the terms in [\(16\)](#page-4-1) where all

poles are evaluated at zero:

<span id="page-6-0"></span>
$$
C_{\alpha,\gamma,K}^{SO(2N)} \oint_0 \cdots \oint_0 \prod_{1 \le j < k \le K} z \left( \frac{w_j}{N} + \frac{w_k}{N} \right) \exp \left( \sum_{l=1}^K w_l \right) \Delta \left( \left( \frac{w_1}{N} \right)^2, \dots, \left( \frac{w_K}{N} \right)^2 \right)^2
$$

$$
\times \prod_{n=1}^K \left( \frac{\left( \frac{w_n}{N} \right)^{3-2K} d \left( \frac{w_n}{N} \right)}{z \left( \frac{w_n}{N} + \gamma \right) \left( \frac{w_n}{N} - \alpha \right) \left( \frac{w_n}{N} + \alpha \right)} \right). \tag{19}
$$

We can shrink the contours down to arbitrarily small circles around zero so that the  $w_n$  variables are powers of N smaller than  $\alpha$  and  $\gamma$ . We can use  $z(x) = (x)^{-1} + \mathcal{O}(1)$  to simplify the z factor in the numerator, and then have cancelation with the Vandermonde factor.

We will just consider the leading order term, so we also now take the large  $N$  limit to find that [\(19\)](#page-6-0) equals

$$
\frac{C_{\alpha,\gamma,K}^{SO(2N)}}{z(\gamma)^K(-\alpha^2)^K} \oint_0 \cdots \oint_0 \prod_{1 \le j < k \le K} \left(\frac{w_j}{N} - \frac{w_k}{N}\right) \left(\left(\frac{w_j}{N}\right)^2 - \left(\frac{w_k}{N}\right)^2\right) \exp\left(\sum_{l=1}^K w_l\right)
$$
\n
$$
\times \prod_{n=1}^K \left(\frac{w_n}{N}\right)^{3-2K} \mathrm{d}\left(\frac{w_n}{N}\right) \left(1 + O(1/N)\right),\tag{20}
$$

where the next-to-leading order term, which is one power of  $N$  lower, comes only from the lower terms in the expansion of the  $z(x)$  functions.

Taking the N dependence out of the integral, we get

$$
\frac{C_{\alpha,\gamma,K}^{SO(2N)} N^{\frac{1}{2}K^2 - \frac{5}{2}K}}{z(\gamma)^K (-\alpha^2)^K} \times \oint_0 \dots \oint_{0} \prod_{1 \le j < k \le K} (w_j - w_k) \left( w_j^2 - w_k^2 \right) \exp \left( \sum_{l=1}^K w_l \right) \prod_{n=1}^K w_n^{3-2K} \mathrm{d}w_n \left( 1 + O(1/N) \right).
$$
\n(21)

Note that

<span id="page-6-1"></span>
$$
\Delta(x_1, x_2, \dots, x_n) = \prod_{1 \le j < k \le n} (x_j - x_k) = \sum_{\sigma \in S_n} \text{sgn}(\sigma) x_1^{\sigma_0} x_2^{\sigma_1} \dots x_n^{\sigma_{n-1}},\tag{22}
$$

where  $S_n$  is the permutation group of size n, where for convenience we have permutations of the numbers  $0, 1, 2, \ldots, n-1$ . Using [\(22\)](#page-6-1), we can rewrite the Vandermonde in terms of sums over the permutation group of size  $K$ :

<span id="page-6-2"></span>
$$
\frac{C_{\alpha,\gamma,K}^{SO(2N)} N^{\frac{1}{2}K^2 - \frac{5}{2}K}}{z(\gamma)^K (-\alpha^2)^K} \oint_0 \cdots \oint_0 \exp\left(\sum_{l=1}^{K-1} w_l\right) \left(\sum_{\sigma \in S_K} \text{sgn}(\sigma) w_1^{2\sigma_0} w_2^{2\sigma_1} \dots w_K^{2\sigma_{K-1}}\right) \tag{23}
$$
\n
$$
\times \left(\sum_{\rho \in S_K} \text{sgn}(\rho) w_1^{\rho_0} w_2^{\rho_1} \dots w_K^{\rho_{K-1}}\right) \prod_{n=1}^K w_n^{3-2K} \text{d}w_n \ (1 + O(1/N)).
$$

In each term of the sum over  $\rho \in S_K$  in [\(23\)](#page-6-2), let us relabel the variables of integration so that  $w_1$  appears with exponent 0,  $w_2$  with exponent 1 etc. This results in K! identical terms, and the sign change from the relabelling cancels with the sign in the sum over  $\sigma$ . So, at leading order we have

$$
K! \frac{C_{\alpha,\gamma,K}^{SO(2N)} N^{\frac{1}{2}K^2-\frac{5}{2}K}}{z(\gamma)^K(-\alpha^2)^K} \oint_0 \cdots \oint_0 \exp\left(\sum_{l=1}^K w_l\right)
$$
  
\n
$$
\times \left(\sum_{\sigma \in S_K} \text{sgn}(\sigma) w_1^{2\sigma_0} w_2^{2\sigma_1} \cdots w_K^{2\sigma_{K-1}}\right) w_1^{3-2K} w_2^{4-2K} \cdots w_K^{2-K} dw_1 \cdots dw_K
$$
  
\n
$$
= K! \frac{C_{\alpha,\gamma,K}^{SO(2N)} N^{\frac{1}{2}K^2-\frac{5}{2}K}}{z(\gamma)^K(-\alpha^2)^K} \oint_0 \cdots \oint_0 \exp\left(\sum_{l=1}^K w_l\right)
$$
  
\n
$$
\times \begin{vmatrix}\n1 & w_1^2 & w_1^4 & \cdots & w_1^{2K-2} \\
1 & w_2^2 & w_2^4 & \cdots & w_2^{2K-2} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & w_K^2 & w_K^4 & \cdots & w_K^{2K-2}\n\end{vmatrix} w_1^{3-2K} w_2^{4-2K} \cdots w_K^{2-K} dw_1 \cdots dw_K
$$
  
\n
$$
= K! \frac{C_{\alpha,\gamma,K}^{SO(2N)} N^{\frac{1}{2}K^2-\frac{5}{2}K}}{z(\gamma)^K(-\alpha^2)^K}
$$
  
\n
$$
\times \begin{vmatrix}\n\oint e^{w_1} w_1^{3-2K} dw_1 & \oint e^{w_1} w_1^{5-2K} dw_1 & \cdots & \oint e^{w_1} w_1^{-1} dw_1 & \oint e^{w_1} w_1^1 dw_1 \\
\oint e^{w_2} w_2^{4-2K} dw_2 & \oint e^{w_2} w_2^{6-2K} dw_2 & \cdots & \oint e^{w_2} w_2^0 dw_2 & \oint e^{w_1} w_1^2 dw_1 \\
\vdots & \vdots & \vdots & \vdots & \vdots \\
\oint e^{w_K} w_K^{2-K} dw_K & \oint e^{w_K} w_K^{4-K} dw_K & \cdots & \oint e^{w_K} w_K^{K
$$

We can do the integrals inside the determinant using

<span id="page-7-1"></span>
$$
\frac{1}{\Gamma(z)} = \frac{1}{2\pi i} \int_C (-t)^{-z} e^{-t} (-dt)
$$
\n(25)

where the contour of integration comes in from  $+\infty$ , encircles the origin in the anticlockwise direction and then returns to  $+\infty$ . The exponent on t will always be an integer in our case, so the integral on the two strands to  $+\infty$  will cancel, leaving just an anticlockwise circle around the origin. So, [\(24\)](#page-7-1) becomes

$$
K! \frac{C_{\alpha,\gamma,K}^{SO(2N)} N^{\frac{1}{2}K^2 - \frac{5}{2}K}}{z(\gamma)^K (-\alpha^2)^K} \begin{array}{|l|}\n\frac{1}{\Gamma(2K-3)} & \frac{1}{\Gamma(2K-5)} & \cdots & \frac{1}{\Gamma(3)} & \frac{1}{\Gamma(1)} & \frac{1}{\Gamma(-1)} \\
\frac{1}{\Gamma(2K-4)} & \frac{1}{\Gamma(2K-6)} & \cdots & \frac{1}{\Gamma(2)} & \frac{1}{\Gamma(0)} & \frac{1}{\Gamma(-2)} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
\frac{1}{\Gamma(K-2)} & \frac{1}{\Gamma(K-4)} & \cdots & \frac{1}{\Gamma(4-K)} & \frac{1}{\Gamma(2-K)} & \frac{1}{\Gamma(-K)}\n\end{array}
$$
\n(26)

and this is the leading order contribution from the term in [\(16\)](#page-4-1) where all residues are evaluated at zero. Since  $1/\Gamma(n) = 0$  when n is a negative integer, the final column consists entirely of zeros, which means the determinant is zero.

#### <span id="page-7-0"></span>2.1.3 Setting up the case of one pole away from zero

We shall consider the case where exactly one of the integrals is integrated around  $\pm \alpha$ , and the rest are integrated around zero. Let us first integrate  $w_1, \ldots, w_{K-1}$  around zero and  $w_K$  around  $\alpha$ , and call this term  $\mathcal{T}_1^{SO(2N)}$  $1^{250(2N)}$ . There will be K other terms exactly equivalent to this term (i.e. identical up to relabelling of the integration variables) contributing to our final result, and K terms equivalent to to integrating  $w_1, \ldots, w_{K-1}$  around zero and  $w_K$  around  $-\alpha$ . If we call the latter  $\mathcal{T}_2^{SO(2N)}$ <sup>2</sup><sup>2</sup>/<sub>2</sub><sup>*N*</sup>, then the total contribution to  $\mathcal{R}_{SO(2N)}(K,\alpha,\gamma)$  from the terms with one pole

away from zero will be  $KT_1^{SO(2N)} + KT_2^{SO(2N)}$  $T_2^{SO(2N)}$ . Let us find  $\mathcal{T}_1^{SO(2N)}$  $\int_1^{\infty}$  first, where we shall start by separating the  $w_K$  variable from the products:

<span id="page-8-0"></span>
$$
\mathcal{T}_{1}^{SO(2N)} = C_{\alpha,\gamma,K}^{SO(2N)} \oint_{\alpha} \oint_{0} \cdots \oint_{0} \prod_{1 \leq j < k \leq K} z \left( w_{j} + w_{k} \right) \Delta \left( w_{1}^{2}, \ldots, w_{K}^{2} \right)^{2}
$$
\n
$$
\times \prod_{n=1}^{K} \left( \frac{\exp(Nw_{n}) w_{n}^{3-2K}}{z \left( w_{n} + \gamma \right) \left( w_{n} - \alpha \right) \left( w_{n} + \alpha \right)} \right) \, \mathrm{d}w_{1} \cdots \mathrm{d}w_{K}
$$
\n
$$
= C_{\alpha,\gamma,K}^{SO(2N)} \oint_{0} \cdots \oint_{0} \prod_{1 \leq j < k \leq K-1} z \left( w_{j} + w_{k} \right) \Delta \left( w_{1}^{2}, \ldots, w_{K-1}^{2} \right)^{2}
$$
\n
$$
\times \prod_{n=1}^{K-1} \frac{\exp(Nw_{n}) w_{n}^{3-2K}}{z \left( w_{n} + \gamma \right) \left( w_{n} - \alpha \right) \left( w_{n} + \alpha \right)}
$$
\n
$$
\times \left( \oint_{\alpha} \left[ \prod_{j=1}^{K-1} z \left( w_{j} + w_{K} \right) \left( w_{K}^{2} - w_{j}^{2} \right)^{2} \right] \frac{\exp(Nw_{K}) w_{K}^{3-2K}}{z \left( w_{K} + \gamma \right) \left( w_{K} - \alpha \right) \left( w_{K} + \alpha \right)} \mathrm{d}w_{K} \right) \mathrm{d}w_{1} \cdots \mathrm{d}w_{K-1}.
$$
\n(27)

To continue, we integrate out  $w_K$  (noting that the contour encircles only the pole at  $\alpha$ , making this a simple residue calcuation) and scale the remaining variables by  $1/N$  (observing that the powers of  $N$  from the Vandermonde cancel out with the factors from  $\prod_{n=1}^{K-1} (w_n/N)^{3-2K} d(w_n/N))$ :

$$
\mathcal{T}_1^{SO(2N)} = C_{\alpha,\gamma,K}^{SO(2N)}(2\pi i) \frac{e^{N\alpha} \alpha^{3-2K}}{z(\alpha+\gamma)(2\alpha)}
$$
\n
$$
\times \oint_0 \cdots \oint_{0} \prod_{1 \le j < k \le K-1} z\left(\frac{w_j}{N} + \frac{w_k}{N}\right) \Delta \left(w_1^2, \dots, w_{K-1}^2\right)^2
$$
\n
$$
\times \prod_{n=1}^{K-1} \left[ z\left(\frac{w_n}{N} + \alpha\right) \left(\alpha^2 - \left(\frac{w_n}{N}\right)^2\right)^2 \frac{\exp(w_n) w_n^{3-2K} dw_n}{z\left(\frac{w_n}{N} + \gamma\right) \left(\frac{w_n}{N} - \alpha\right) \left(\frac{w_n}{N} + \alpha\right)} \right].
$$
\n(28)

We see that the  $(\frac{w_n}{N} \pm \alpha)$  factors from the denominator cancel one of the similar factors in the numerator.

From here, we shall keep track of both the leading order and the next-to-leading order term in N. Let us expand all the factors which have a  $1/N$  term. To do so, we shall use

$$
z\left(\frac{x}{N}\right) = N\left(\frac{1}{x} + \frac{1}{2N} + \frac{x}{12N^2}\right) + \mathcal{O}\left(N^{-2}\right) \tag{29}
$$

$$
z\left(\alpha + \frac{x}{N}\right) = z\left(\alpha\right)\left(1 + z(-\alpha)\frac{x}{N}\right) + \mathcal{O}\left(N^{-2}\right) \tag{30}
$$

$$
\frac{1}{z\left(\gamma + \frac{x}{N}\right)} = \frac{1}{z(\gamma)}\left(1 - z(-\gamma)\frac{x}{N}\right) + \mathcal{O}\left(N^{-2}\right) \tag{31}
$$

<span id="page-8-1"></span>
$$
\left(\frac{w_n}{N}\right)^2 - \alpha^2 = -\alpha^2 + \mathcal{O}(N^{-2}).\tag{32}
$$

Using these, [\(27\)](#page-8-0) becomes

$$
\mathcal{T}_{1}^{SO(2N)} = N^{(K-1)(K-2)/2} C_{\alpha,\gamma,K}^{SO(2N)}(\pi i) \frac{e^{N\alpha} \alpha^{2-2K}}{z(\alpha + \gamma)}
$$
\n
$$
\times \oint_{0} \cdots \oint_{0} \prod_{1 \leq j < k \leq K-1} \left[ \frac{1}{w_{j} + w_{k}} + \frac{1}{2N} + \mathcal{O}(N^{-2}) \right] \Delta(w_{1}^{2}, \dots, w_{K-1}^{2})^{2}
$$
\n
$$
\times \exp \left( \sum_{l=1}^{K-1} w_{l} \right) \prod_{n=1}^{K-1} \left[ \left( z(\alpha) + \frac{w_{n}}{N} z(\alpha) z(-\alpha) \right) (-\alpha^{2}) \frac{1}{z(\gamma)}
$$
\n
$$
\times \left( 1 - \frac{w_{n}}{N} z(-\gamma) \right) w_{n}^{3-2K} dw_{n} \left( 1 + \mathcal{O}(N^{-2}) \right) \right]
$$
\n
$$
= (-1)^{K-1} N^{(K-1)(K-2)/2} C_{\alpha,\gamma,K}^{SO(2N)}(\pi i) \frac{e^{N\alpha}}{z(\alpha + \gamma)}
$$
\n
$$
\times \oint_{0} \cdots \oint_{0} \prod_{1 \leq j < k \leq K-1} \left[ \frac{1}{w_{j} + w_{k}} + \frac{1}{2N} \right] \exp \left( \sum_{l=1}^{K-1} w_{l} \right) \Delta(w_{1}^{2}, \dots, w_{K-1}^{2})^{2}
$$
\n
$$
\times \prod_{n=1}^{K-1} \left[ \left( z(\alpha) + \frac{w_{n}}{N} z(\alpha) z(-\alpha) \right) \frac{1}{z(\gamma)} \left( 1 - \frac{w_{n}}{N} z(-\gamma) \right) w_{n}^{3-2K} dw_{n} \right] \left( 1 + \mathcal{O}(N^{-2}) \right). \tag{33}
$$

We now rewrite this so that all the terms take a similar form:

<span id="page-9-0"></span>
$$
\mathcal{T}_{1}^{SO(2N)} = (-1)^{K-1} N^{(K-1)(K-2)/2} C_{\alpha,\gamma,K}^{SO(2N)}(\pi i) e^{N\alpha} \frac{z(\alpha)^{K-1}}{z(\alpha + \gamma)z(\gamma)^{K-1}} (1 + \mathcal{O}(N^{-2}))
$$
\n
$$
\times \left[ \oint \cdots \oint \prod_{1 \leq j < k \leq K-1} \left( \frac{1}{w_{j} + w_{k}} \right) \exp \left( \sum_{l=1}^{K-1} w_{l} \right) \Delta \left( w_{1}^{2}, \dots, w_{K-1}^{2} \right)^{2} \prod_{n=1}^{K-1} w_{n}^{3-2K} \mathrm{d}w_{n} + \frac{z(-\alpha)}{N} \oint \cdots \oint \left( \sum_{m=1}^{K-1} w_{m} \right) \prod_{1 \leq j < k \leq K-1} \left( \frac{1}{w_{j} + w_{k}} \right) \exp \left( \sum_{l=1}^{K-1} w_{l} \right) \times \Delta(w_{1}^{2}, \dots, w_{K-1}^{2})^{2} \prod_{n=1}^{K-1} w_{n}^{3-2K} \mathrm{d}w_{n}
$$
\n
$$
- \frac{z(-\gamma)}{N} \oint \cdots \oint \left( \sum_{m=1}^{K-1} w_{m} \right) \prod_{1 \leq j < k \leq K-1} \left( \frac{1}{w_{j} + w_{k}} \right) \exp \left( \sum_{l=1}^{K-1} w_{l} \right) \times \Delta(w_{1}^{2}, \dots, w_{K-1}^{2})^{2} \prod_{n=1}^{K-1} w_{n}^{3-2K} \mathrm{d}w_{n}
$$
\n
$$
+ \frac{1}{2N} \oint \cdots \oint \left( \sum_{1 \leq m < n \leq K-1} (w_{m} + w_{n}) \right) \prod_{1 \leq j < k \leq K-1} \left( \frac{1}{w_{j} + w_{k}} \right) \exp \left( \sum_{l=1}^{K-1} w_{l} \right) \times \Delta(w_{1}^{2}, \dots, w_{K-1}^{2})^{2} \prod_{n=1}^{K-1} w_{n}^{3-2K} \mathrm{d}w_{n} \right].
$$

Let

<span id="page-10-0"></span>
$$
\mathcal{M}^{SO(2N)} = \oint \cdots \oint \prod_{1 \le j < l \le K-1} \left( \frac{1}{w_j + w_l} \right) \exp \left( \sum_{l=1}^{K-1} w_l \right) \times \Delta(w_1^2, \dots, w_{K-1}^2)^2 \prod_{n=1}^{K-1} w_n^{3-2K} \, \mathrm{d}w_n, \tag{35}
$$
\n
$$
\mathcal{J}^{SO(2N)} = \oint \cdots \oint \left( \sum_{m=1}^{K-1} w_m \right) \prod_{1 \le j < l \le K-1} \left( \frac{1}{w_j + w_l} \right) \exp \left( \sum_{l=1}^{K-1} w_l \right) \times \Delta(w_1^2, \dots, w_{K-1}^2)^2 \prod_{n=1}^{K-1} w_n^{3-2K} \, \mathrm{d}w_n. \tag{36}
$$

## <span id="page-10-2"></span>2.1.4 Evaluating  $M^{SO(2N)}$

In this section we will evaluate  $\mathcal{M}^{SO(2N)}$  directly because we build on the method in the following section, although we will see in Section [2.1.6](#page-14-0) that this integral in fact shows up in the moment of the characteristic polynomial itself and so has already indirectly been evaluated in previous literature.

Cancelling the  $\frac{1}{w_j+w_l}$  factors from [\(35\)](#page-10-0) with Vandermonde factors we have

<span id="page-10-1"></span>
$$
\mathcal{M}^{SO(2N)} = \oint \cdots \oint \prod_{1 \le j < l \le K-1} (w_l^2 - w_j^2)(w_l - w_j) \exp\left(\sum_{l=1}^{K-1} w_l\right) \prod_{n=1}^{K-1} w_n^{3-2K} \mathrm{d}w_n
$$
\n
$$
= (K-1)! \oint \cdots \oint \begin{vmatrix} 1 & w_1^2 & w_1^4 & \cdots & w_1^{2K-4} \\ 1 & w_2^2 & w_2^4 & \cdots & w_2^{2K-4} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & w_{K-1}^2 & w_{K-1}^4 & \cdots & w_{K-1}^{2K-4} \end{vmatrix}
$$
\n
$$
\times w_1^{3-2K} w_2^{4-2K} \cdots w_{K-1}^{1-K} \exp\left(\sum_{l=1}^{K-1} w_l\right) \mathrm{d}w_1 \ldots \mathrm{d}w_{K-1}, \tag{37}
$$

where for the second line we have used the identical method to Section [2.1.2](#page-5-0) (see the similarities with [\(24\)](#page-7-1) - the difference being that we have just  $K - 1$  variables).

Continuing to follow the method from Section [2.1.2](#page-5-0) we write  $\mathcal{M}^{SO(2N)}$  as a determinant of gamma functions. Then, in the second line below, we write the gamma functions as factorials, and then reverse the order of the columns (acquiring an overall sign from the  $(K-1)(K-2)/2$ column exchanges). We then multiply the new jth column by  $(2j - 2)!$ :

<span id="page-10-3"></span>
$$
\mathcal{M}^{SO(2N)} = (2\pi i)^{K-1}(K-1)!\det_{(K-1)\times(K-1)} \begin{pmatrix}\n\frac{1}{\Gamma(2K-3)} & \frac{1}{\Gamma(2K-5)} & \frac{1}{\Gamma(2K-7)} & \cdots & \frac{1}{\Gamma(1)} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\frac{1}{\Gamma(K-1)} & \frac{1}{\Gamma(K-3)} & \frac{1}{\Gamma(K-5)} & \cdots & \frac{1}{\Gamma(3-K)}\n\end{pmatrix}
$$
\n
$$
= (-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} (K-1)!\prod_{j=1}^{K-1} \frac{1}{(2j-2)!}
$$
\n
$$
\times \det_{(K-1)\times(K-1)} \begin{pmatrix}\n\frac{0!}{0!} & \cdots & \frac{(2K-8)!}{(2K-8)!} & \frac{(2K-6)!}{(2K-6)!} & \frac{(2K-4)!}{(2K-6)!} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{0!}{(2K-8)!} & \frac{(2K-6)!}{(2K-7)!} & \frac{(2K-4)!}{(2K-5)!} \\
\vdots & \ddots & \vdots & \vdots \\
\frac{0!}{(2-K)!} & \cdots & \frac{(2K-8)!}{(K-6)!} & \frac{(2K-6)!}{(K-6)!} & \frac{(2K-4)!}{(K-2)!}\n\end{pmatrix}
$$
\n(38)

We now use a trick from [\[2\]](#page-30-6) to turn this matrix into a Vandermonde determinant. We note that the first row above is all 1's. The element in the jth position in row two is  $2j - 2$ . Thus we can reduce the j<sup>th</sup> element in the second row to just j by adding twice the first row to the second row (this does not change the determinant) and then pulling a factor of 2 out of the second row. Note that this procedure works equally well for the first entry in row two, which is zero.

<span id="page-11-1"></span>
$$
\mathcal{M}^{SO(2N)} = 2 \times (-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} (K-1)! \prod_{j=1}^{K-1} \frac{1}{(2j-2)!}
$$
(39)

× det (K−1)×(K−1) 1 2 · · · (K − 3) (K − 2) (K − 1) 0! (−2)! 2! 0! · · · (2K−8)! (2K−10)! (2K−6)! (2K−8)! (2K−4)! (2K−6)! . . . . . . . . . . . . . . . . . . 0! (2−K)! 2! (4−K)! · · · (2K−8)! (K−6)! (2K−6)! (K−4)! (2K−4)! (K−2)! .

We note that in the rest of the matrix the j<sup>th</sup> entry in the mth row is a polynomial in j of order  $m-1$  with leading coefficient  $2^{m-1}$ : for example, the jth entry in the third row is  $(2j-2)(2j-3)$ . Working one row at a time, all but the leading order term of the polynomial can be removed by adding multiples of rows higher up the matrix, and the power of 2 is pulled out of the determinant. This leaves us with

$$
\mathcal{M}^{SO(2N)} = (-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} 2^{(K-1)(K-2)/2} (K-1)! \prod_{j=1}^{K-1} \frac{1}{(2j-2)!} \tag{40}
$$

$$
\times \det_{(K-1)\times(K-1)} \begin{pmatrix} 1 & 1 & \cdots & 1 & 1 & 1 \\ 1 & 2 & \cdots & (K-3) & (K-2) & (K-1) \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 1 & 2^{K-2} & \cdots & (K-3)^{K-2} & (K-2)^{K-2} & (K-1)^{K-2} \end{pmatrix}
$$
  
=  $(-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} 2^{(K-1)(K-2)/2} (K-1)! \prod_{j=1}^{K-1} \frac{(j-1)!}{(2j-2)!}$   
=  $(-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} (K-1)! \prod_{j=1}^{K-2} \frac{1}{(2j-1)!!},$  (41)

where we have used that the Vandermonde  $V(1, 2, 3, \ldots, n) = \prod_{j=1}^{n} (j-1)!$ .

#### <span id="page-11-2"></span>2.1.5 Evaluating  $\mathcal{J}^{SO(2N)}$

As in [\(37\)](#page-10-1), we have

<span id="page-11-0"></span>
$$
\mathcal{J}^{SO(2N)} = (K-1)!\oint \cdots \oint \begin{vmatrix} 1 & w_1^2 & w_1^4 & \cdots & w_1^{2K-4} \\ 1 & w_2^2 & w_2^4 & \cdots & w_2^{2K-4} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & w_{K-1}^2 & w_{K-1}^4 & \cdots & w_{K-1}^{2K-4} \end{vmatrix} \begin{pmatrix} K-1 \\ \sum_{m=1}^{K} w_m \end{pmatrix}
$$

$$
\times w_1^{3-2K} w_2^{4-2K} \dots w_{K-1}^{1-K} \exp\left(\sum_{l=1}^{K-1} w_l\right) dw_1 \dots dw_{K-1}.
$$
 (42)

Using the usual method from Section [2.1.2](#page-5-0) (noting that the integrand of [\(42\)](#page-11-0) is symmetric as long as we retain the sum over m intact) to pull all the factors containing  $w_i$  into the jth row of the determinant, and also bringing the integration inside the determinant and evaluating the matrix elements as gamma functions, we see that each term in the sum over  $m$  gives zero except for the  $m = K - 1$  term. This is because all terms except the  $K - 1$ th raise the power on  $w_m$ ,  $m = 1, \ldots, K - 2$  by one, making the power equal to that on  $w_{j+1}$ . This results in two identical rows of gamma functions, and so the determinant is zero. For  $m = K - 1$ , however, we get the following non-zero determinant, which has a jump of 2 in the argument of the gamma function between the second-to-last and last row instead of the usual change by 1:

$$
\mathcal{J}^{SO(2N)} = (2\pi i)^{K-1}(K-1)!\det_{(K-1)\times(K-1)} \begin{pmatrix}\n\frac{1}{\Gamma(2K-3)} & \frac{1}{\Gamma(2K-5)} & \frac{1}{\Gamma(2K-7)} & \cdots & \frac{1}{\Gamma(1)} \\
\frac{1}{\Gamma(2K-4)} & \frac{1}{\Gamma(2K-6)} & \frac{1}{\Gamma(2K-8)} & \cdots & \frac{1}{\Gamma(0)} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\frac{1}{\Gamma(K)} & \frac{1}{\Gamma(K-2)} & \frac{1}{\Gamma(K-4)} & \cdots & \frac{1}{\Gamma(4-K)} \\
\frac{1}{\Gamma(K-2)} & \frac{1}{\Gamma(K-4)} & \frac{1}{\Gamma(K-6)} & \cdots & \frac{1}{\Gamma(2-K)}\n\end{pmatrix}
$$
\n
$$
= (-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} (K-1)!\prod_{j=1}^{K-1} \frac{1}{(2j-2)!}
$$
\n
$$
\begin{pmatrix}\n\frac{0!}{0!} & \frac{2!}{2!} & \cdots & \frac{(2K-8)!}{(2K-8)!} & \frac{(2K-6)!}{(2K-6)!} & \frac{(2K-4)!}{(2K-4)!} \\
\frac{0!}{(-1)!} & \frac{2!}{1!} & \cdots & \frac{(2K-8)!}{(2K-9)!} & \frac{(2K-6)!}{(2K-7)!} & \frac{(2K-4)!}{(2K-5)!}\n\end{pmatrix}
$$
\n(43)

$$
\times \det_{(K-1)\times(K-1)} \begin{bmatrix} \frac{0!}{(-1)!} & \frac{2!}{1!} & \cdots & \frac{(2K-8)!}{(2K-9)!} & \frac{(2K-0)!}{(2K-7)!} & \frac{(2K-4)!}{(2K-5)!} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ \frac{0!}{(3-K)!} & \frac{2!}{(5-K)!} & \cdots & \frac{(2K-8)!}{(K-5)!} & \frac{(2K-6)!}{(K-3)!} & \frac{(2K-4)!}{(K-1)!} \\ \frac{0!}{(1-K)!} & \frac{2!}{(3-K)!} & \cdots & \frac{(2K-8)!}{(K-7)!} & \frac{(2K-6)!}{(K-5)!} & \frac{(2K-4)!}{(K-3)!} \end{bmatrix}.
$$

As in the previous section, we note that for the first  $K-2$  rows the matrix element in the j<sup>th</sup> column and mth row is a polynomial in j of order  $m-1$ . For example, the jth element in the 2nd row is just  $2j-2$  and the *j*th element in the  $(K-2)$ th row is  $(2j-2)(2j-3)\cdots(2j-(K-2))$ . Working sequentially from the top, each polynomial can be reduced to just its highest order term,  $(2j)^{m-1}$  by adding multiples of previous rows. The final row, the only one that differs from [\(39\)](#page-11-1), contains polynomials of order  $K - 1$ :  $(2j - 2)(2j - 3) \dots (2j - K) = (2j)^{K-1} (2j)^{K-2}(2+3+\cdots+K)+\mathcal{O}(j^{K-3})$ . So, splitting the determinant into two determinants, each one containing just one of the two surviving terms from the bottom row, we have

<span id="page-12-0"></span>
$$
\mathcal{J}^{SO(2N)} = (-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} 2^{(K-1)(K-2)/2} (K-1)! \prod_{j=1}^{K-1} \frac{1}{(2j-2)!}
$$
(44)  
\n
$$
\times \begin{bmatrix}\n1 & 1 & \cdots & 1 & 1 & 1 \\
2 & \det \\
\frac{1}{K-1} \times (K-1) & \frac{1}{K-3} & \frac{2^{K-3}}{2^{K-3}} & \cdots & \frac{1}{K-3} \\
1^{K-1} & 2^{K-1} & \cdots & \frac{1}{K-3} & \frac{1}{K-1} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
1^{K-1} & 2^{K-1} & \cdots & \frac{1}{K-3} & \frac{1}{K-2} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
1^{K-2} & 2^{K-3} & \cdots & \frac{1}{K-3} & \frac{1}{K-3} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
1^{K-3} & 2^{K-3} & \cdots & \frac{1}{K-3} & \frac{1}{K-3} \\
1^{K-2} & 2^{K-2} & \cdots & \frac{1}{K-3} & \frac{1}{K-2} \\
\end{bmatrix} \begin{bmatrix}\n1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
$$

The second determinant above is the Vandermonde  $\Delta(1,2,3,\ldots K-1) = \prod_{j=1}^{K-1} (j-1)!$ , while the first determinant is what is called in [\[23\]](#page-33-14) a "Vandemondian" (the notation for this matrix in that paper is  $V_{K-1,1}$ ). Theorem I of [\[23\]](#page-33-14) tells us that

$$
\begin{vmatrix}\n1 & 1 & 1 & \cdots & 1 \\
x_1 & x_2 & x_3 & \cdots & x_n \\
x_1^2 & x_2^2 & x_3^2 & \cdots & x_n^2 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
x_1^{n-2} & x_2^{n-2} & x_3^{n-2} & \cdots & x_n^{n-2} \\
x_1^n & x_2^n & x_3^n & \cdots & x_n^n\n\end{vmatrix} = (x_1 + x_2 + \cdots + x_n) \begin{vmatrix}\n1 & 1 & 1 & \cdots & 1 \\
x_1 & x_2 & x_3 & \cdots & x_n \\
x_1^2 & x_2^2 & x_3^2 & \cdots & x_n^2 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
x_1^{n-2} & x_2^{n-2} & x_3^{n-2} & \cdots & x_n^{n-2} \\
x_1^{n-1} & x_2^{n-1} & x_3^{n-1} & \cdots & x_n^{n-1}\n\end{vmatrix}
$$
\n(45)

This gives us a relation between the two determinants in [\(44\)](#page-12-0) and so we have

<span id="page-13-0"></span>
$$
\mathcal{J}^{SO(2N)} = (-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} 2^{(K-1)(K-2)/2} (K-1)! \prod_{j=1}^{K-1} \frac{1}{(2j-2)!}
$$

$$
\times \frac{(K-1)(K-2)}{2} \Delta(1,2,3,\dots,K-1)
$$

$$
= \frac{(K-1)(K-2)}{2} \mathcal{M}^{SO(2N)}.
$$
(46)

Note we have inadvertently proven the interesting determinant relation:

$$
\frac{(K-1)(K-2)}{2} \det_{(K-1)\times(K-1)} \begin{pmatrix}\n\frac{1}{\Gamma(2K-3)} & \frac{1}{\Gamma(2K-5)} & \frac{1}{\Gamma(2K-7)} & \cdots & \frac{1}{\Gamma(1)} \\
\frac{1}{\Gamma(2K-4)} & \frac{1}{\Gamma(2K-6)} & \frac{1}{\Gamma(2K-8)} & \cdots & \frac{1}{\Gamma(0)} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\frac{1}{\Gamma(K)} & \frac{1}{\Gamma(K-2)} & \frac{1}{\Gamma(K-4)} & \cdots & \frac{1}{\Gamma(4-K)} \\
\frac{1}{\Gamma(K-1)} & \frac{1}{\Gamma(K-3)} & \frac{1}{\Gamma(K-5)} & \cdots & \frac{1}{\Gamma(3-K)}\n\end{pmatrix}
$$
\n
$$
= \det_{(K-1)\times(K-1)} \begin{pmatrix}\n\frac{1}{\Gamma(2K-3)} & \frac{1}{\Gamma(2K-5)} & \frac{1}{\Gamma(2K-6)} & \frac{1}{\Gamma(2K-7)} & \cdots & \frac{1}{\Gamma(1)} \\
\frac{1}{\Gamma(2K-4)} & \frac{1}{\Gamma(2K-6)} & \frac{1}{\Gamma(2K-8)} & \cdots & \frac{1}{\Gamma(0)} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\frac{1}{\Gamma(K)} & \frac{1}{\Gamma(K-2)} & \frac{1}{\Gamma(K-4)} & \cdots & \frac{1}{\Gamma(4-K)}\n\end{pmatrix}.
$$
\n(47)

By identical methods it can be shown that the third integral in [\(34\)](#page-9-0) is

$$
\oint \cdots \oint \left( \sum_{1 \le m < n \le K-1} (w_m + w_n) \right) \prod_{1 \le j < l \le K-1} \left( \frac{1}{w_j + w_l} \right) \exp \left( \sum_{k=1}^{K-1} w_k \right) \times \Delta(w_1^2, \dots, w_{K-1}^2)^2 \prod_{n=1}^{K-1} w_n^{3-2K} \, \mathrm{d}w_n
$$
\n
$$
= (K-2) \mathcal{J}^{SO(2N)}.\tag{48}
$$

#### <span id="page-14-0"></span>2.1.6 Pulling together the case of one pole away from zero

We now feed the results of Sections [2.1.4](#page-10-2) and [2.1.5](#page-11-2) into [\(34\)](#page-9-0), giving

$$
\mathcal{T}_{1}^{SO(2N)} = (-1)^{K-1} C_{\alpha,\gamma,K}^{SO(2N)} N^{(K-1)(K-2)/2}(\pi i) e^{N\alpha} \frac{z(\alpha)^{K-1}}{z(\alpha+\gamma)z(\gamma)^{K-1}} \left(1 + \mathcal{O}\left(N^{-2}\right)\right)
$$

$$
\times \left[\mathcal{M}^{SO(2N)} + \frac{\mathcal{J}^{SO(2N)}}{N} \left(z(-\alpha) - z(-\gamma) + \frac{K-2}{2}\right)\right]
$$

$$
= (-1)^{K-1} C_{\alpha,\gamma,K}^{SO(2N)} N^{(K-1)(K-2)/2}(\pi i) e^{N\alpha} \frac{z(\alpha)^{K-1}}{z(\alpha+\gamma)z(\gamma)^{K-1}} \left(1 + \mathcal{O}\left(N^{-2}\right)\right)
$$

$$
\times \mathcal{M}^{SO(2N)} \left(1 + \frac{(K-1)(K-2)}{2N} \left(z(-\alpha) - z(-\gamma) + \frac{K-2}{2}\right)\right), \tag{49}
$$

where in the second equality we have used [\(46\)](#page-13-0).

The corresponding contribution from a pole at  $-\alpha$  is simply

$$
\mathcal{T}_{2}^{SO(2N)} = (-1)^{K-1} C_{\alpha,\gamma,K}^{SO(2N)} N^{(K-1)(K-2)/2}(\pi i) e^{-N\alpha} \frac{z(-\alpha)^{K-1}}{z(-\alpha+\gamma)z(\gamma)^{K-1}} \left(1 + \mathcal{O}\left(N^{-2}\right)\right) \times \mathcal{M}^{SO(2N)} \left(1 + \frac{(K-1)(K-2)}{2N}\left(z(\alpha) - z(-\gamma) + \frac{K-2}{2}\right)\right). \tag{50}
$$

The total contribution from all the terms with one pole evaluated away from zero is

$$
K\mathcal{T}_{1}^{SO(2N)} + K\mathcal{T}_{2}^{SO(2N)} =
$$
  
\n
$$
\frac{K(-1)^{K-1}C_{\alpha,\gamma,K}^{SO(2N)}N^{(K-1)(K-2)/2}(\pi i)\mathcal{M}^{SO(2N)}}{z(\gamma)^{K-1}} \left(1 + \mathcal{O}(N^{-2})\right)
$$
  
\n
$$
\times \left[e^{N\alpha} \frac{z(\alpha)^{K-1}}{z(\alpha+\gamma)} \left(1 + \frac{(K-1)(K-2)}{2N} \left(z(-\alpha) - z(-\gamma) + \frac{K-2}{2}\right)\right) + e^{-N\alpha} \frac{z(-\alpha)^{K-1}}{z(-\alpha+\gamma)} \left(1 + \frac{(K-1)(K-2)}{2N} \left(z(\alpha) - z(-\gamma) + \frac{K-2}{2}\right)\right)\right].
$$
\n(51)

We note that another approach would be to relate the quantities  $\mathcal{M}^{SO(2N)}$  and  $\mathcal{J}^{SO(2N)}$  to the leading order terms of the well-studied moment of characteristic polynomials obtained by setting  $\alpha = \gamma$ . The moment for finite matrix size N can also be written as a multiple contour integral [\[13\]](#page-32-3)

$$
\int_{A \in SO(2N)} \Lambda(1)^{K-1} dA = (-1)^{(K-1)(K-2)/2} 2^{K-1} (2\pi i)^{-K+1} ((K-1)!)^{-1}
$$
\n
$$
\times \oint \cdots \oint \frac{\prod_{1 \le j < k \le K-1} z(w_j + w_k) \exp\left(N \sum_{l=1}^{K-1} w_l\right) \Delta(w_1^2, w_2^2, \dots, w_{K-1}^2)^2 \prod_{i=1}^{K-1} w_i dw_i}{\prod_{n=1}^{K-1} w_n^{2K-2}}, \quad (52)
$$

where the contours of integration encircle zero.

Upon scaling the w variables by  $1/N$  in the manner of Section [2.1.2](#page-5-0) we find the relation with the integrals  $\mathcal{M}^{SO(2N)}$  and  $\mathcal{J}^{SO(2N)}$  from [\(35\)](#page-10-0).

<span id="page-14-1"></span>
$$
\int_{A \in SO(2N)} \Lambda(1)^{K-1} dA = (-1)^{(K-1)(K-2)/2} 2^{K-1} (2\pi i)^{-K+1} ((K-1)!)^{-1}
$$
\n(53)

$$
\times N^{(K-1)(K-2)/2}\left(\mathcal{M}^{SO(2N)} + \frac{K-2}{2N}\mathcal{J}^{SO(2N)} + \mathcal{O}\left(\frac{1}{N^2}\right)\right).
$$

The moment was calculated in [\[28\]](#page-33-15) using the Selberg integral and the leading order was expressed as (also obtained independently by [\[12\]](#page-32-4))

$$
\int_{A \in SO(2N)} \Lambda(1)^{K-1} dA = N^{(K-1)(K-2)/2} 2^{(K-1)^2/2} \frac{G(K)\sqrt{\Gamma(2K-1)}}{\sqrt{G(2K-1)\Gamma(K)}} \left(1 + \mathcal{O}\left(\frac{1}{N}\right)\right)
$$
\n
$$
= N^{(K-1)(K-2)/2} 2^{K-1} \prod_{j=1}^{K-2} \frac{1}{(2j-1)!!} \left(1 + \mathcal{O}\left(\frac{1}{N}\right)\right),\tag{54}
$$

where G is the Barnes G-function introduced in  $[10]$ . (The G-function is uniquely defined by the functional equation

<span id="page-15-0"></span>
$$
G(s+1) = \Gamma(s)G(s)
$$
\n<sup>(55)</sup>

and the conditions that  $G(0) = 0$ ,  $\frac{d^3}{ds^3}$  $\frac{d^3}{ds^3}G(s) \geq 0.$  So we see that we have a representation of  $\mathcal{M}^{SO(2N)}$  in terms of Barnes G-functions:

$$
\mathcal{M}^{SO(2N)} = (-1)^{(K-1)(K-2)/2} (2\pi i)^{K-1} 2^{(K-1)(K-3)/2} \frac{G(K)\sqrt{\Gamma(2K-1)\Gamma(K)}}{\sqrt{G(2K-1)}}.
$$
(56)

#### 2.2 Completing the mixed moment for  $SO(2N)$

Returning to  $(16)$ , we have found that in the sum over the  $\epsilon$ 's the leading and next-to-leading order terms when N is large result from one variable being integrated around a pole at  $\alpha$  or  $-\alpha$  with all the other variables integrated around the pole at zero. The leading order term is of order  $N^{(K-1)(K-2)/2}$  and when all poles are evaluated around zero the result is at most order  $N^{\frac{1}{2}}$  $\frac{1}{2}K^2 - \frac{5}{2}$  $\frac{3}{2}K-1$  so this is at least two orders lower than the leading order as long as  $K \geq 0$ .

The leading order and next-to-leading order terms were evaluated in the previous section. Also recall that

$$
C_{\alpha,\gamma,K}^{SO(2N)} = \frac{e^{-N\alpha}(-1)^{K(K-1)/2} 2^{K} z(2\gamma)}{(2\pi i)^{K} \Gamma(K+1)}.
$$
\n(57)

Plugging these into [\(16\)](#page-4-1) and replacing  $K - 1$  with r, we have

$$
\int_{SO(2N)} \frac{\Lambda(1)^r \Lambda(e^{-\alpha})}{\Lambda(e^{-\gamma})} dA
$$
\n
$$
= 2^{r^2/2} N^{r(r-1)/2} \left(1 + \mathcal{O}\left(N^{-2}\right)\right)
$$
\n
$$
\times \left[\frac{z(2\gamma)z(\alpha)^r}{z(\alpha + \gamma)z(\gamma)^r} \left(1 + \frac{r(r-1)}{2N}\left(z(-\alpha) - z(-\gamma) + \frac{r-1}{2}\right)\right)\right]
$$
\n
$$
+ \frac{e^{-2N\alpha}z(2\gamma)z(-\alpha)^r}{z(-\alpha + \gamma)z(\gamma)^r} \left(1 + \frac{r(r-1)}{2N}\left(z(\alpha) - z(-\gamma) + \frac{r-1}{2}\right)\right)\right]
$$
\n
$$
\times \frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}}.
$$
\n(58)

To get the logarithmic derivative, we first differentiate with respect to  $\alpha$ , noting that  $z'(x) =$ 

 $z(x)z(-x)$ , and that  $d/dx$   $[z(x)^{-1}] = e^{-x}$ . Then, we set  $\alpha = \gamma = \phi$ : :

<span id="page-16-1"></span>
$$
\int_{SO(2N)} -e^{-\phi} \frac{\Lambda(1)^r \Lambda'(e^{-\phi})}{\Lambda(e^{-\phi})} dA
$$
\n
$$
= 2^{r^2/2} N^{r(r-1)/2} \left(1 + \mathcal{O}\left(N^{-2}\right)\right) \times \frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}}
$$
\n
$$
\times \left[ (rz(-\phi) - z(-2\phi)) \left(1 + \frac{r(r-1)^2}{2N}\right) - z(\phi)z(-\phi) \frac{r(r-1)}{2N} -e^{-2N\phi} \left( z(2\phi) \frac{z(-\phi)^r}{z(\phi)^r} \left(1 + \frac{r(r-1)}{2N} \left(z(\phi) - z(-\phi) + \frac{r-1}{2}\right)\right) \right) \right],
$$
\n(59)

where we have used  $z(2\phi)e^{-2\phi} = -z(-2\phi)$ .

## <span id="page-16-0"></span>3 A mixed moment for  $USp(2N)$

Note that the method in Section [2](#page-3-0) may also be used to find the equivalent quantity over the symplectic group. To do so, one starts from the contour integral statement of the ratios theorem (from Theorem 4.2 and Lemma 6.8 in [\[14\]](#page-33-9)):

$$
\mathcal{R}_{USp(2N)}(\alpha, \gamma, K) := \int_{USp(2N)} \frac{\Lambda(1)^{K-1} \Lambda(e^{-\alpha})}{\Lambda(e^{-\gamma})} dA = \frac{e^{-N\alpha}(-1)^{K(K-1)/2} 2^{K}}{(2\pi i)^{K} K!} \times \oint \frac{\prod_{1 \le j \le k \le K} z(w_j + w_k) \exp\left(N \sum_{l=1}^{K} w_l\right) \Delta(w_1^2, \dots, w_K^2)^2 \prod_{i=1}^{K} w_i dw_i}{\prod_{n=1}^{K} z(w_n + \gamma)(w_n - \alpha)(w_n + \alpha) w_n^{2K-2}},
$$
\n(60)

where  $z(x) = (1 - e^{-x})^{-1} = (\frac{1}{x} + \frac{1}{2} + \mathcal{O}(x))$ , and the contours of integration enclose 0,  $\alpha$  and  $-\alpha$ . Following the steps in Section [2](#page-3-0) exactly, one finds

$$
\int_{USp(2N)} -e^{-\phi} \frac{\Lambda(1)^r \Lambda'(e^{-\phi})}{\Lambda(e^{-\phi})} dA
$$
\n
$$
= 2^{r(r-2)/2} N^{r(r+1)/2} \left(1 + \mathcal{O}(N^{-2})\right) \times \frac{G(r+1)\sqrt{\Gamma(r+1)}}{\sqrt{G(2r+1)\Gamma(2r+1)}}
$$
\n
$$
\times \left[ (2z(2\phi)z(-2\phi) + rz(-\phi) - z(-2\phi)) \left(1 + \frac{r(r-1)(r+1)}{2N}\right) - z(2\phi)z(\phi)z(-\phi) \frac{r(r+1)}{2N} + e^{-2N\phi}z(2\phi)z(-2\phi) \frac{z(-\phi)^r}{z(\phi)^r} \left(1 + \frac{r(r+1)}{2N} \left(z(\phi) - z(-\phi) + \frac{r+1}{2}\right)\right) \right].
$$
\n(61)

#### 4 Analytic continuation in  $r$

Until this point,  $r$  has been constrained to be an integer greater than zero. However, have now written our moment as an expression which permits analytic continuation in r. We might hope that we can now relax the constraint that  $r$  must be an integer and analytically continue  $r$  in the half plane  $\mathbb{R}[\mathbf{r}] > 0$ . As can be seen in Table [1,](#page-17-1) this may well be the case (note that we would not expect perfect agreement for finite  $N$  since [\(59\)](#page-16-1) only captures the first two terms in the large  $N$  expansion). Given that there is some evidence that the analytic continuation matches the ensemble average, we will proceed with the one-level density application.

<span id="page-17-1"></span>Table 1: Numerically generated values of  $\int_{SO(200)} -e^{-\phi} \frac{\Lambda(1)^r \Lambda'(e^{-\phi})}{\Lambda(e^{-\phi})}$  $\frac{\Lambda(e^{-\phi})}{\Lambda(e^{-\phi})} dA$ , compared with the pre-diction of [\(59\)](#page-16-1). We have chosen  $\phi = 2.0 + 3.5$  for this test. The numerical values were calculated using  $10^6$  matrices generated uniformly with respect to Haar measure on  $SO(200)$ .

r	Predicted value	Numerical value
1.0	0.255807-0.0993974i	0.26529-0.103092i
2.0	97.3408-35.0436i	98.0627-36.3916i
0.5	$-0.031109 - 0.0273784i$	$-0.04091 - 0.02978$ i
$1.0 + 1.0i$	$-0.002565 + 0.007075i$	$-0.003478 + 0.009805$ i
$0.5 + 1.0i$	0.049486-0.021654i	0.052749-0.023028i

## <span id="page-17-0"></span>5 An application of mixed moments - calculating the one level density of eigenvalues for the excised model

The excised ensemble  $T_{\chi}(2N)$  is the ensemble of matrices in  $SO(2N)$ , introduced in [\[20\]](#page-33-8), whose characteristic polynomial  $\Lambda(s)$  evaluated at 1 is greater than a cut-off value  $e^{\chi}$ .

We will denote the joint probability distribution function for the eigenvalues over  $SO(2N)$ by  $P(\theta_1, \ldots, \theta_N)$ , so that Haar measure for  $SO(2N)$  can be written as:

$$
dA = P(\theta_1, ..., \theta_N) \prod_{l=1}^N d\theta_l
$$
  
=  $S_N \prod_{1 \le j < k \le N} (\cos \theta_k - \cos \theta_j)^2 \prod_{l=1}^N d\theta_l.$ 

Here,  $S_N := \frac{2^{(N-1)^2}}{\pi^N N!}$  $\frac{N-1}{\pi^N N!}$  is a normalisation constant and the  $\theta_l$ s are the eigenangles.

The functional equation for the characteristic polynomial of an even orthogonal matrix is

<span id="page-17-2"></span>
$$
\Lambda(s) = s^{2N} \Lambda(s^{-1}).\tag{62}
$$

Differentiating this gives the following identity:

$$
s\frac{\Lambda'(s)}{\Lambda(s)} = 2N - s^{-1}\frac{\Lambda'(s^{-1})}{\Lambda(s^{-1})}.
$$
\n(63)

Changing variables gives

$$
e^{i\phi} \frac{\Lambda'(e^{i\phi})}{\Lambda(e^{i\phi})} = 2N - e^{-i\phi} \frac{\Lambda'(e^{-i\phi})}{\Lambda(e^{-i\phi})}.
$$
\n(64)

Using residue calculus, we can write the Heaviside function  $H(f(x) - \chi)$  as:

<span id="page-17-3"></span>
$$
H(f(x) - \chi) = \frac{1}{2\pi i} \int_{d-i\infty}^{d+i\infty} \frac{\exp(r f(x) - r\chi)}{r} dr \tag{65}
$$

for  $d > 0$ .

Let

$$
\mathcal{V}(N,r) := N^{r(r-1)/2} 2^{r^2/2} \frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}}\tag{66}
$$

and

$$
\mathcal{U}(N,r,\phi) := \left[ (rz(-\phi) - z(-2\phi)) \left( 1 + \frac{r(r-1)^2}{2N} \right) - z(\phi)z(-\phi) \frac{r(r-1)}{2N} - e^{-2N\phi}z(2\phi) \frac{z(-\phi)^r}{z(\phi)^r} \left( 1 + \frac{r(r-1)}{2N} \left( z(\phi) - z(-\phi) + \frac{r-1}{2} \right) \right) \right].
$$
 (67)

For the rth moment, we know from [\(53\)](#page-14-1) that

<span id="page-18-1"></span>
$$
\int_{SO(2N)} \Lambda(1)^r dA
$$
\n
$$
= N^{r(r-1)/2} 2^{r^2/2} \frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}} \left(1 + \frac{r(r-1)^2}{2N} + \mathcal{O}(N^{-2})\right)
$$
\n
$$
= \mathcal{V}(N,r) \left(1 + \frac{r(r-1)^2}{2N} + \mathcal{O}(N^{-2})\right). \tag{68}
$$

Using [\(59\)](#page-16-1), we also have

<span id="page-18-0"></span>
$$
\int_{SO(2N)} -e^{-\phi} \frac{\Lambda(1)^r \Lambda'(e^{-\phi})}{\Lambda(e^{-\phi})} dA
$$
  
=  $\mathcal{U}(N, r, \phi) \mathcal{V}(N, r) (1 + +\mathcal{O}(N^{-2})).$  (69)

We wish to find the one level density  $R_f^{T_X}$  $f_f^{I_{\chi}}$ . Formally, for a suitable test function  $f(\phi)$ ,

$$
R_f^{T_X} = \int_{T_X} \sum_{j=1}^N f(\theta_j) \, dA_{T_X} \tag{70}
$$

where  $dA_{T_{\chi}}$  is the measure for the excised ensemble (which we shall write out explicitly later). Using the argument principle, we may rewrite this in terms of the logarithmic derivative of the characteristic polynomial:

$$
R_f^{T_X} = \int_{T_X} \frac{1}{2\pi i} \oint_C i e^{i\phi} \frac{\Lambda'(e^{i\phi})}{\Lambda(e^{i\phi})} f(\phi) d\phi dA_{T_X}.
$$
 (71)

Here, C is a contour surrounding the segment of the real axis between  $-\pi$  and  $\pi$ , and we have exploited the fact that all the eigenvalues of an orthogonal matrix lie on the unit circle in the complex plane. To continue, we first switch the order of integration:

$$
R_f^{T_\chi} = \frac{1}{2\pi} \oint_C \int_{T_\chi} \frac{\mathrm{e}^{\mathrm{i}\phi} \Lambda'(\mathrm{e}^{\mathrm{i}\phi})}{\Lambda(\mathrm{e}^{\mathrm{i}\phi})} f(\phi) \mathrm{dA}_{T_\chi} \, \mathrm{d}\phi. \tag{72}
$$

Then, we note that the measure  $dA_{T_\chi}$  on  $T_\chi$  is equal to  $dA$  (Haar measure on  $SO(2N))$  multiplied by a Heaviside function:

$$
R_f^{T_\chi} = \frac{1}{2\pi} \oint_C \int_{SO(2N)} H(\log \Lambda(1) - \chi) \frac{e^{i\phi} \Lambda'(e^{i\phi})}{\Lambda(e^{i\phi})} f(\phi) dA d\phi.
$$
 (73)

Let us explicitly choose the contour  $C$  to be a rectangle of height  $2\epsilon$ :

$$
R_f^{T_X} = \frac{1}{2\pi} \left[ \int_{\pi}^{-\pi} \int_{SO(2N)} H(\log \Lambda(1) - \chi) \frac{e^{i(\phi + i\epsilon)} \Lambda'(e^{i(\phi + i\epsilon)})}{\Lambda(e^{i(\phi + i\epsilon)})} f(\phi + i\epsilon) dA d\phi \right. + \int_{-\pi}^{\pi} \int_{SO(2N)} H(\log \Lambda(1) - \chi) \frac{e^{i(\phi - i\epsilon)} \Lambda'(e^{i(\phi - i\epsilon)})}{\Lambda(e^{i(\phi - i\epsilon)})} f(\phi - i\epsilon) dA d\phi + \int_{\epsilon}^{-\epsilon} \int_{SO(2N)} H(\log \Lambda(1) - \chi) \frac{e^{i(-\pi + i\phi)} \Lambda'(e^{i(-\pi + i\phi)})}{\Lambda(e^{i(-\pi + i\phi)})} f(-\pi + i\phi) dA d\phi + \int_{-\epsilon}^{\epsilon} \int_{SO(2N)} H(\log \Lambda(1) - \chi) \frac{e^{i(\pi + i\phi)} \Lambda'(e^{i(\pi + i\phi)})}{\Lambda(e^{i(\pi + i\phi)})} f(\pi + i\phi) dA d\phi \right].
$$
 (74)

If we restrict ourselves to test functions that are  $2\pi$ -periodic, even, and analytic in a strip about the real axis, then the last two terms will cancel. Let us now rewrite the first two integrals so that they have all their poles on the same side of the contour (as this will allow us to move the contour onto the real line). To do so, we change variables on the first integral from  $\phi \to -\phi$ , then use the functional equation [\(64\)](#page-17-2) (which takes  $\phi - i\epsilon \to -\phi + i\epsilon$ ) on the second to find that:

$$
R_f^{T_X} = \lim_{\epsilon \to 0^+} \frac{1}{2\pi} \int_{-\pi}^{\pi} \int_{SO(2N)} H(\log \Lambda(1) - \chi) \left( -e^{-i(\phi - i\epsilon)} \frac{\Lambda'(e^{-i(\phi - i\epsilon)})}{\Lambda(e^{-i(\phi - i\epsilon)})} \right) f(\phi - i\epsilon) dA d\phi
$$
  
+ 
$$
\frac{1}{2\pi} \int_{-\pi}^{\pi} \int_{SO(2N)} H(\log \Lambda(1) - \chi) \left( 2N - e^{-i(\phi - i\epsilon)} \frac{\Lambda'(e^{-i(\phi - i\epsilon)})}{\Lambda(e^{-i(\phi - i\epsilon)})} \right) f(\phi - i\epsilon) dA d\phi
$$
(75)

(making use of the fact that we have chosen  $f$  to be even). The time has come to rewrite the Heaviside function in integral form using equation [\(65\)](#page-17-3):

$$
R_f^{T_X} = \lim_{\epsilon \to 0^+} \frac{1}{2\pi} \int_{-\pi}^{\pi} \int_{SO(2N)} \frac{1}{2\pi i} \int_{d-i\infty}^{d+i\infty} \frac{\exp(r \log \Lambda(1) - r\chi)}{r} f(\phi - i\epsilon)
$$
  
\n
$$
\times \left(2N - e^{-i(\phi - i\epsilon)} \frac{\Lambda'(e^{-i(\phi - i\epsilon)})}{\Lambda(e^{-i(\phi - i\epsilon)})} - e^{-i(\phi - i\epsilon)} \frac{\Lambda'(e^{-i(\phi - i\epsilon)})}{\Lambda(e^{-i(\phi - i\epsilon)})} \right) dr dA d\phi
$$
  
\n
$$
= \lim_{\epsilon \to 0^+} \frac{1}{4\pi^2 i} \int_{-\pi}^{\pi} \int_{SO(2N)} \int_{d-i\infty}^{d+i\infty} \frac{e^{-\chi r} \Lambda(1)^r}{r} f(\phi - i\epsilon)
$$
  
\n
$$
\times \left(2N - 2e^{-i(\phi - i\epsilon)} \frac{\Lambda'(e^{-i(\phi - i\epsilon)})}{\Lambda(e^{-i(\phi - i\epsilon)})} \right) dr dA d\phi
$$
  
\n
$$
= \lim_{\epsilon \to 0^+} \frac{1}{4\pi^2 i} \int_{-\pi}^{\pi} \int_{d-i\infty}^{d+i\infty} \frac{e^{-\chi r}}{r} f(\phi - i\epsilon)
$$
  
\n
$$
\times \left(2N \int_{SO(2N)} \Lambda(1)^r dA - 2 \int_{SO(2N)} e^{-i(\phi - i\epsilon)} \frac{\Lambda(1)^r \Lambda'(e^{-i(\phi - i\epsilon)})}{\Lambda(e^{-i(\phi - i\epsilon)})} dA \right) dr d\phi.
$$
 (76)

We can do the integrals over  $SO(2N)$  to next-to-leading-order in N using [\(69\)](#page-18-0) and [\(68\)](#page-18-1), assuming they hold for complex r:

$$
R_f^{T_X} = \frac{1}{4\pi^2 i} \lim_{\epsilon \to 0} \int_{-\pi}^{\pi} \int_{d-i\infty}^{d+i\infty} \frac{e^{-\chi r}}{r} f(\phi - i\epsilon) \mathcal{V}(N, r)
$$
  
 
$$
\times \left(2N\left(1 + \frac{r(r-1)^2}{2N} + \mathcal{O}(N^{-2})\right) + 2\mathcal{U}(N, r, i(\phi - i\epsilon))\left(1 + \mathcal{O}(N^{-2})\right)\right) dr d\phi.
$$
 (77)

Here we are assuming that any r-dependence in the error term will not cause the error term to become unmanageably large when we integrate it. This seems a reasonable assumption since this method ultimately gives us good agreement with numerical results (see Figure [1\)](#page-21-2). Note that  $\frac{e^{-\chi r}}{r}V(N,r)\mathcal{U}(N,r,i\phi)$  has no poles in  $\phi$  on the real line (the poles from the z functions at 0 cancel out), so we can take the  $\epsilon \to 0$  limit:

$$
R_f^{T_X} = \frac{1}{4\pi^2 i} \int_{-\pi}^{\pi} \int_{d-i\infty}^{d+i\infty} \frac{e^{-\chi r}}{r} \mathcal{V}(N, r)
$$
  
 
$$
\times \left(2N\left(1 + \frac{r(r-1)^2}{2N}\right) + 2\mathcal{U}(N, r, i\phi)\right) \left(1 + \mathcal{O}\left(N^{-2}\right)\right) \, dr f(\phi) d\phi. \tag{78}
$$

We can write this as a series of residues in  $r$ :

<span id="page-19-0"></span>
$$
R_f^{T_X} = \frac{2\pi i}{4\pi^2 i} \int_{-\pi}^{\pi} \sum_{\text{residues } r} R_r(\phi) f(\phi) d\phi.
$$
 (79)

We shall show that  $R_0(\phi)$  is the one level density for  $SO(2N)$ . This  $R_0(\phi)$  term comes from the real part of the leading order term in N from the residue at  $r = 0$ :

$$
\frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ \text{Residue} \left| \frac{e^{-\chi r}}{r} \mathcal{V}(N, r) \right| \right] \times \left( 2N \left( 1 + \frac{r(r-1)^2}{2N} \right) + 2\mathcal{U}(N, r, i\phi) \right) \Big|_{r=0} \right] f(\phi) d\phi
$$
\n
$$
= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ (2N + 2\mathcal{U}(N, 0, i\phi)) \right] f(\phi) d\phi
$$
\n
$$
= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ 2N - 2z(-2i\phi) - 2e^{-2Ni\phi} z(2i\phi) \right] f(\phi) d\phi
$$
\n
$$
= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ 2N - \frac{2}{1 - e^{2i\phi}} - 2 \frac{e^{-2Ni\phi}}{1 - e^{-2i\phi}} \right] f(\phi) d\phi
$$
\n
$$
= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ 2N - \frac{2(\cos(\phi) - i\sin(\phi))}{-2i\sin(\phi)} + \frac{2(\cos((2N - 1)\phi) + i\sin((2N - 1)\phi))}{2i\sin(\phi)} \right] f(\phi) d\phi
$$
\n
$$
= \frac{1}{2\pi} \int_{-\pi}^{\pi} (2N - 1 + \sin((2N - 1)\phi)) \sin(\phi) f(\phi) d\phi.
$$
\n(80)

Note that this is equal to the one level density from the full  $SO(2N)$  ensemble.

To see why the other residues take the form they do in [\(79\)](#page-19-0), note that the higher residues To see why the other residues take the form they do in (19), note that the ingner residues<br>will come from the poles of  $\frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}}$ . We know that  $G(r+1)$  and  $\Gamma(r+1)^{-1}$  are entire functions, so the poles will arise from  $\Gamma(2r+1)^{1/2}G(2r+1)^{-1/2}$ . For the following, note that a Puiseaux series in r is just a Laurent series in  $r^{1/m}$ , where m is some positive integer.

Firstly, note that away from the negative integers and half-integers,  $G(2r+1)^{-1/2}$  cannot diverge, since  $G(2r+1)$  will be non-zero, and  $\Gamma(2r+1)$  is meromorphic with poles only at the diverge, since  $G(2r + 1)$  will be non-zero, and  $T(2r + 1)$  is meromorphic with poles only at the negative half integers. This rules out the possibility of poles in  $\frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}}$  everywhere in the complex plane except at points in the set  $\{-n/2\|n \in \mathbb{N}\}\.$  Let us consider what happens at these points.

The G-function  $G(2r + 1)$  has zeros at  $r \in \{-n/2\|n \in \mathbb{N}\}\)$ , each one of multiplicity n. If we expand  $G(2r + 1)^{-1}$  as a Laurent series about  $-n/2$ , then, we get terms proportional to  $(r+n/2)^{-n}, (r+n/2)^{-n+1}, (r+n/2)^{-n+2}, \ldots$  etc. So, when we expand  $G(2r+1)^{-1/2}$  around  $-n/2$ , we get a Puiseaux series with terms proportional to  $(r+n/2)^{-n/2}$ ,  $(r+n/2)^{-n/2+1}$ ,  $(r+n/2)^{-n/2}$  $n/2$ <sup>-n/2+2</sup>... etc. Note that we do not get powers of  $(r+n/2)^{-n/2+1/2}$ ,  $(r+n/2)^{-n/2+3/2}$ etc., since this series must square to the Laurent series for  $G(2r+1)^{-1}$ .

We also know that  $\Gamma(2r+1)$  has poles at  $\{-n/2\|n \in \mathbb{N}\}\$ . In the Laurent expansion of  $\Gamma(2r+1)$ 1) around such a point  $-n/2$ , there are terms proportional to  $(r+n/2)^{-1}$ ,  $(r+n/2)^0$ ,  $(r+n/2)^1$ etc. This means that in the Puiseaux expansion of  $\Gamma(2r+1)^{1/2}$  around the pole at  $-n/2$ , we have terms proportional to  $(r + n/2)^{-1/2}$ ,  $(r + n/2)^{1/2}$ ,  $(r + n/2)^{3/2}$  etc. Again, we do not get integer powers in this series, since it must square to the Laurent series for  $\Gamma(2r+1)$ .

Consider  $\Gamma(2r+1)^{1/2}G(2r+1)^{-1/2}$  at a negative integer  $\{-m\|m\in\mathbb{N}\}\.$  The series expansion of this product at  $-m$  will have terms proportional to  $(r+m)^{-m-1/2}$ ,  $(r+m)^{-m+1/2}$ , ... etc. from multiplying the Puiseaux series together. This series will not have a  $(r+m)^{-1}$  term, so will not contribute a residue to [\(79\)](#page-19-0).

However, at the negative half-integers  $\{-\frac{2n+1}{2} \mid n \in \mathbb{N}\}$ , when we consider the product  $\Gamma(2r+1)^{1/2}G(2r+1)^{-1/2}$ , the product of the two Puiseaux series will be a Laurent series with terms proportional to  $(r + \frac{2n+1}{2})$  $\frac{n+1}{2})^{-n-1}, (r+\frac{2n+1}{2})$  $\frac{n+1}{2})^{-n}$ ,  $(r + \frac{2n+1}{2})$  $\frac{n+1}{2}$  $\binom{n+1}{2}$  etc. This will have a term proportional to  $(r + n/2)^{-1}$ , so we will get a residue contributing to [\(79\)](#page-19-0). This completes

our demonstration that the sum of residues in [\(79\)](#page-19-0) can be written as  $\sum_{n=1}^{\infty}$  $k=0$  $b_k \exp ((k + 1/2) \chi).$ 

So,

$$
R_f^{T_\chi} = R_0 + \frac{1}{2\pi} \mathbb{Re} \left[ \int_{-\pi}^{\pi} \left( \sum_{k=0}^{\infty} b_k \exp\left( (k+1/2) \chi \right) \right) f(\phi) d\phi \right],\tag{81}
$$

which is consistent with Theorem 1.3 from [\[20\]](#page-33-8).

<span id="page-21-2"></span>Figure [1](#page-21-2) shows that for suitably chosen N and  $\chi$ , just using the first four residues gives an excellent approximation to the one level density.

**Figure 1:** One level density for the excised  $SO(24)$  ensemble with  $\chi = \log(0.0001)$ , generated numerically using  $10^7$  matrices, with the first four terms (up to  $k = 3$ ) from [\(79\)](#page-19-0) plotted in green. Both plots are normalised to have unit area under the curve.

## <span id="page-21-0"></span>6 A mixed moment of elliptic curve  $L$ -functions

The equivalent quantity to the random matrix moment we calculated in the last section is

$$
\mathcal{R}_{E,X}(\phi,r) := \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M)=1}} \left[ \frac{L'_E(1/2 + i\phi, \chi_d)}{L_E(1/2 + i\phi, \chi_d)} L_E(1/2, \chi_d)^r \right]. \tag{82}
$$

We will obtain an expression for this by differentiating once the ratios conjecture below, choosing K to be  $r+1$ .

In [\[14\]](#page-33-9), Conrey, Farmer and Zirnbauer derived the following ratios conjecture. It is not stated explicitly in that paper, but is mentioned after their equation (6.31) as following from their Conjecture 5.3 and their Lemma 6.8 in analogy with (6.31). There are possibly some typos in that paper, so another resource is [\[32\]](#page-34-6) where the conjecture is stated at Conjecture 5.1 using a slightly different set notation.

<span id="page-21-1"></span>
$$
\sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M)=1}} \left[ \frac{\prod_{k=1}^K L_E(1/2 + \alpha_k, \chi_d)}{L_E(1/2 + \gamma, \chi_d)} \right] = \mathcal{Q}_{E,X}(\alpha, \gamma) + \mathcal{O}\left(X^{1/2 + \epsilon}\right),\tag{83}
$$

where

$$
\mathcal{Q}_{E,X}(\alpha,\gamma) = \frac{(-1)^{K(K-1)/2} 2^K}{K!(2\pi i)^K} \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = 1}} \left(\frac{M|d|^2}{4\pi^2}\right)^{-\frac{1}{2}\sum_{k=1}^K \alpha_k}
$$
\n
$$
\times \oint \left(\frac{M|d|^2}{4\pi^2}\right)^{\frac{1}{2}\sum_{k=1}^K (w_k)} \left(\frac{H_{\alpha,\gamma}(w_1,\ldots,w_K)\Delta(w_1^2,\ldots,w_K^2)^2 \prod_{k=1}^K w_k}{\prod_{j=1}^K \prod_{k=1}^K (w_j - \alpha_k)(w_j + \alpha_k)}\right) \mathrm{d}w_1 \ldots \mathrm{d}w_K, \quad (84)
$$

with

$$
H_{\alpha,\gamma}(w_1,\ldots,w_K)
$$
  
=  $Y_E(w_1,\ldots,w_K;\gamma)A_E(w_1,\ldots,w_K;\gamma)\prod_{k=1}^K g\left(\frac{\alpha_k-w_k}{2}\right),$  (85)

$$
Y_E(\alpha; \gamma) := \frac{\prod_{j < k \le K} \zeta(1 + \alpha_j + \alpha_k) \zeta(1 + 2\gamma)}{\prod_{k=1}^K \zeta(1 + \alpha_k + \gamma)}.
$$
\n(86)

and

<span id="page-22-0"></span>
$$
g(s) := \frac{\Gamma(1-s)}{\Gamma(1+s)}.\tag{87}
$$

Here,  $\alpha = (\alpha_1, \dots, \alpha_K)$  and  $\gamma$  is a scalar and the contours of integration enclose all the  $\alpha$ 's but avoid the singularities of  $g(s)$ .

The arithmetic factor  $A_E(\alpha, \gamma)$  is a product over primes which is convergent where we need to use it. It was first derived in [\[14\]](#page-33-9) and is examined in some detail. It is stated in general at equation (5.37) in that paper (they call it  $A_{E(D)}(\alpha, \gamma)$ ) and examined further in Section 6.3, however there are possible typos to beware of. We use the version in Mason and Snaith [\[32\]](#page-34-6) in Conjecture 5.1 and translate here their set notation for an example for the specific family of quadratic twists of the L-function associated with the elliptic curve  $E_{11}$ .

$$
A_{E}(\alpha, \gamma) := \frac{\prod_{1 \leq j < k \leq K} (1 - 11^{-1 - \alpha_{j} - \alpha_{k}})(1 - 11^{-1 - 2\gamma})}{\prod_{k=1}^{K} (1 - 11^{-1 - \alpha_{k} - \gamma})}
$$
\n
$$
\times \left( \frac{(1 - \lambda(11)11^{-1/2 - \gamma})}{\prod_{k=1}^{K} (1 - \lambda(11)11^{-1/2 - \alpha_{k}})} \right)
$$
\n
$$
\times \prod_{p \neq 11} \left[ \frac{\prod_{1 \leq j < k \leq K} (1 - p^{-1 - \alpha_{j} - \alpha_{k}})(1 - p^{-1 - 2\gamma})}{\prod_{k=1}^{K} (1 - p^{-1 - \alpha_{k} - \gamma})} \right]
$$
\n
$$
\times \frac{1}{1 + \frac{1}{p}} \left( \frac{1}{2} \frac{(1 - \lambda(p)p^{-1/2 - \gamma} + p^{-1 - 2\gamma})}{\prod_{k=1}^{K} (1 - \lambda(p)p^{-1/2 - \alpha_{k}} + p^{-1 - 2\alpha_{k}})} + \frac{1}{2} \frac{(1 + \lambda(p)p^{-1/2 - \alpha_{k}} + p^{-1 - 2\alpha_{k}})}{\prod_{k=1}^{K} (1 + \lambda(p)p^{-1/2 - \alpha_{k}} + p^{-1 - 2\alpha_{k}})} + \frac{1}{p} \right).
$$
\n(89)

If we start using  $(\alpha_1, \ldots, \alpha_k) = (\alpha, 0, \ldots, 0)$ :

$$
Q_{E,X}(\alpha,\gamma) = \sum_{\substack{0 < d \leq X \\ \omega_E \chi_d(-M) = 1}} \exp\left(-\mathcal{N}_d\alpha\right) \frac{(-1)^{K(K-1)/2} 2^K}{K!(2\pi i)^K}
$$

$$
\times \oint \exp\left(\mathcal{N}_d \sum_{k=1}^K w_k\right) \left(\frac{H_{\alpha,\gamma}(w_1,\ldots,w_K)\Delta(w_1^2,\ldots,w_K^2)^2 \prod_{n=1}^K w_n^{3-2K}}{\prod_{n=1}^K (w_n - \alpha)(w_n + \alpha)}\right) dw_1 \ldots dw_K.
$$

This has exactly the same polar structure as [\(15\)](#page-4-2) - it behaves like the equivalent integral for SO(2N). In the above we have defined  $\mathcal{N}_d = \log \left( \frac{\sqrt{Md}}{2\pi} \right)$  $\left(\frac{\overline{Md}}{2\pi}\right)$  to make the comparison easier. The  $\mathcal N$  associated with the largest d in the sum,  $\mathcal N_X$ , can be thought to be equivalent to the matrix size  $N$  in the random matrix version. Note that in the random matrix case we found both the leading order term and the next to leading order term in  $N$ , while here, for simplicity, we shall just work with the leading order term in  $\mathcal{N}_X$ . Acting in analogy to the random matrix case at [\(15\)](#page-4-2) we know that we can shrink the contours of integration onto the poles, with narrow necks connecting them. As we showed in Section [2.1,](#page-5-2) the integral will cancel on either side of the necks, leaving a sum over three circular contours for each  $w$  variable. The only terms which contribute to this sum will have the residue from one  $w_i$  evaluated at  $\pm \alpha$ , and the rest evaluated at 0. Using this fact, and in analogy with [\(27\)](#page-8-0), we get

<span id="page-24-0"></span>
$$
\mathcal{Q}_{E,X}(\alpha,\gamma) = \sum_{\substack{0 < d \le X \\ \omega_{EXd}(-M)=1}} \exp\left(-\mathcal{N}_d\alpha\right) \frac{(-1)^{K(K-1)/2} 2^K}{K!(2\pi i)^K} (K\mathcal{T}_+^E + K\mathcal{T}_-^E),\tag{90}
$$

where

$$
\mathcal{T}_{\pm}^{E} = \zeta(1+2\gamma) \oint_{0} \cdots \oint_{0} \exp\left(\mathcal{N}_{d} \sum_{k=1}^{K-1} w_{k}\right)
$$
\n
$$
\times \left( \frac{\prod_{1 \leq j < k \leq K-1} \zeta(1+w_{j}+w_{k}) \Delta(w_{1}^{2}, \ldots, w_{K-1}^{2})^{2} \prod_{n=1}^{K-1} w_{n}^{3-2K}}{\prod_{k=1}^{K-1} \zeta(1+w_{k}+\gamma) \prod_{n=1}^{K-1} (w_{n}-\alpha)(w_{n}+\alpha)} \right) \prod_{k=1}^{K-1} g\left(-\frac{w_{k}}{2}\right)
$$
\n
$$
\times \oint_{\pm\alpha} A_{E}(w_{1}, \ldots, w_{K}; \gamma) g\left(\frac{\alpha-w_{K}}{2}\right) \prod_{j=1}^{K-1} \left[ \zeta(1+w_{j}+w_{K})(w_{K}^{2}-w_{j}^{2})^{2} \right]
$$
\n
$$
\times \frac{\exp(\mathcal{N}_{d}w_{K}) w_{K}^{3-2K}}{\zeta(1+w_{K}+\gamma)(w_{K}-\alpha)(w_{K}+\alpha)} dw_{K} dw_{1} \cdots dw_{K-1}.
$$
\n(91)

Evaluating the  $w_{\boldsymbol{K}}$  integral:

$$
\mathcal{T}_{\pm}^{E} = \zeta(1+2\gamma)(2\pi i) \frac{\exp(\pm \mathcal{N}_{d}\alpha)(\pm \alpha)^{3-2K} g\left(-(\pm 1-1)\frac{\alpha}{2}\right)}{\zeta(1\pm \alpha + \gamma)(\pm 2\alpha)} \oint_{0} \cdots \oint_{0} \exp\left(\mathcal{N}_{d} \sum_{k=1}^{K-1} w_{k}\right)
$$

$$
\times \left(\frac{\prod_{1 \leq j < k \leq K-1} \zeta(1+w_{j}+w_{k}) \Delta(w_{1}^{2}, \ldots, w_{K-1}^{2})^{2} \prod_{n=1}^{K-1} w_{n}^{3-2K}}{\prod_{k=1}^{K-1} \zeta(1+w_{k}+\gamma) \prod_{n=1}^{K-1} (w_{n}-\alpha)(w_{n}+\alpha)}\right)
$$

$$
\times A_{E}(w_{1}, \ldots, w_{K-1}, \pm \alpha; \gamma) \prod_{k=1}^{K-1} g\left(-\frac{w_{k}}{2}\right) \prod_{j=1}^{K-1} \left[\zeta(1+w_{j} \pm \alpha)(\alpha^{2}-w_{j}^{2})^{2}\right]
$$

$$
\times dw_{1} \cdots dw_{K-1}.
$$

$$
(92)
$$

We are interested in the large conductor limit, so let us scale the w-variables by  $\mathcal{N}_X = \log\left(\frac{\sqrt{M}X}{2\pi}\right)$ , and as in (28)  $\left(\frac{\overline{M}X}{2\pi}\right)$ , and as in [\(28\)](#page-8-1)

$$
\mathcal{T}_{\pm}^{E} = \zeta(1+2\gamma)(2\pi i) \frac{\exp(\pm \mathcal{N}_{d}\alpha)(\pm \alpha)^{3-2K} g\left(-(\pm 1-1)\frac{\alpha}{2}\right)}{\zeta(1\pm \alpha + \gamma)(\pm 2\alpha)} \oint_{0} \cdots \oint_{0} \exp\left(\frac{\mathcal{N}_{d}}{\mathcal{N}_{X}} \sum_{k=1}^{K-1} w_{k}\right)
$$

$$
\times \left(\frac{\prod_{1 \leq j < k \leq K-1} \zeta(1 + \frac{w_{j}}{\mathcal{N}_{X}} + \frac{w_{k}}{\mathcal{N}_{X}}) \Delta(w_{1}^{2}, \dots, w_{K-1}^{2})^{2} \prod_{n=1}^{K-1} w_{n}^{3-2K}}{\prod_{k=1}^{K-1} \zeta(1 + \frac{w_{k}}{\mathcal{N}_{X}} + \gamma)}\right)
$$

$$
\times A_{E}(\frac{w_{1}}{\mathcal{N}_{X}}, \dots, \frac{w_{K-1}}{\mathcal{N}_{X}}, \pm \alpha; \gamma) \prod_{k=1}^{K-1} g\left(-\frac{w_{k}}{2\mathcal{N}_{X}}\right) \prod_{j=1}^{K-1} \left[\zeta(1 + \frac{w_{j}}{\mathcal{N}_{X}} \pm \alpha)((\frac{w_{j}}{\mathcal{N}_{X}})^{2} - \alpha^{2})\right]
$$

$$
\times dw_{1} \cdots dw_{K-1}.
$$
\n(93)

Keeping just the leading order term, we have:

$$
\zeta \left( 1 + \frac{x}{\mathcal{N}_X} \right) = \frac{\mathcal{N}_X}{x} + \mathcal{O} \left( 1 \right) \tag{94}
$$

$$
\zeta \left( 1 + \alpha + \frac{x}{\mathcal{N}_X} \right) = \zeta \left( 1 + \alpha \right) + \mathcal{O} \left( \mathcal{N}_X^{-1} \right) \tag{95}
$$

$$
\frac{1}{\zeta\left(1+\gamma+\frac{x}{N}\right)} = \frac{1}{\zeta(1+\gamma)} + \mathcal{O}\left(\mathcal{N}_X^{-1}\right) \tag{96}
$$

$$
\left(\frac{w_n}{\mathcal{N}_X}\right)^2 - \alpha^2 = -\alpha^2 + \mathcal{O}(\mathcal{N}_X^{-2})\tag{97}
$$

$$
A_E(\frac{w_1}{\mathcal{N}_X}, \dots, \frac{w_{K-1}}{\mathcal{N}_X}, \pm \alpha; \gamma) = A_E(0, \dots, 0, \pm \alpha; \gamma) + \mathcal{O}\left(\mathcal{N}_X^{-1}\right)
$$
(98)

$$
g\left(-\frac{w_k}{2\mathcal{N}_X}\right) = 1 + \mathcal{O}\left(\mathcal{N}_X^{-1}\right). \tag{99}
$$

Using these,

$$
\mathcal{T}_{\pm}^{E} = (-1)^{K-1} \mathcal{N}_{X}^{(K-1)(K-2)/2} \zeta(1+2\gamma) (\pi i) \frac{\exp(\pm \mathcal{N}_{d}\alpha)g\left(-(\pm 1-1)\frac{\alpha}{2}\right)}{\zeta(1\pm\alpha+\gamma)}
$$

$$
\times \oint_{0} \cdots \oint_{0} \exp\left(\frac{\mathcal{N}_{d}}{\mathcal{N}_{X}} \sum_{k=1}^{K-1} w_{k}\right) \prod_{1 \leq j < k \leq K-1} \left(\frac{1}{w_{j}+w_{k}}\right) \Delta(w_{1}^{2}, \ldots, w_{K-1}^{2})^{2}
$$

$$
\times \frac{\zeta(1\pm\alpha)^{K-1}}{\zeta(1+\gamma)^{K-1}} A_{E}(0,\ldots,0,\pm\alpha;\gamma) \prod_{n=1}^{K-1} w_{n}^{3-2K} dw_{n} (1+\mathcal{O}(\mathcal{N}_{X}^{-1})). \tag{100}
$$

The integral here is very nearly  $\mathcal{M}^{SO(2N)}$  with the exception of the exponential. In analogy with Section [2.1.4](#page-10-2) we write

$$
\mathcal{T}_{\pm}^{E} = (-1)^{K-1} \mathcal{N}_{X}^{(K-1)(K-2)/2} \zeta(1+2\gamma) (\pi i) \frac{\exp(\pm \mathcal{N}_{d}\alpha)g\left(-(\pm 1-1)\frac{\alpha}{2}\right)}{\zeta(1\pm \alpha + \gamma)}
$$

$$
\frac{\zeta(1\pm \alpha)^{K-1}}{\zeta(1+\gamma)^{K-1}} A_{E}(0,\ldots,0,\pm \alpha; \gamma) \mathcal{M}^{d} (1+\mathcal{O}(\mathcal{N}_{X}^{-1})), \tag{101}
$$

with

$$
\mathcal{M}^d = \oint_0 \cdots \oint_0 \prod_{1 \le j < l \le K-1} (w_l^2 - w_j^2)(w_l - w_j) \exp\left(\frac{\mathcal{N}_d}{\mathcal{N}_X} \sum_{k=1}^{K-1} w_k\right) \prod_{n=1}^{K-1} w_n^{3-2K} dw_n. \tag{102}
$$

Compare this with [\(37\)](#page-10-1). In exactly the same way as at [\(37\)](#page-10-1) we write

$$
\mathcal{M}^{d} = \left| \left\{ \begin{array}{ccc} f^{w_{1}^{3-2K} \exp\left(\frac{\mathcal{N}_{d}}{\mathcal{N}_{X}} w_{1}\right) dw_{1} & f^{w_{1}^{5-2K} \exp\left(\frac{\mathcal{N}_{d}}{\mathcal{N}_{X}} w_{1}\right) dw_{1} & \cdots & f^{w_{1}^{-1} \exp\left(\frac{\mathcal{N}_{d}}{\mathcal{N}_{X}} w_{1}\right) dw_{1} \\ \vdots & \vdots & \ddots & \vdots \\ f^{w_{K-1}^{1-K} \exp\left(\frac{\mathcal{N}_{d}}{\mathcal{N}_{X}} w_{K-1}\right) dw_{K-1} & f^{w_{K-1}^{3-K} \exp\left(\frac{\mathcal{N}_{d}}{\mathcal{N}_{X}} w_{K-1}\right) dw_{K-1} & \cdots & f^{w_{K-1}^{K-3} \exp\left(\frac{\mathcal{N}_{d}}{\mathcal{N}_{X}} w_{K-1}\right) dw_{K-1} \\ \left(\frac{\mathcal{N}_{X}}{\mathcal{N}_{d}}\right)^{4-2K} f^{w_{1}^{3-2K} \exp(w_{1}) dw_{1} & \cdots & f^{w_{1}^{-1} \exp(w_{1}) dw_{1}} \\ \vdots & \vdots & \ddots & \vdots \\ \left(\frac{\mathcal{N}_{X}}{\mathcal{N}_{d}}\right)^{2-K} f^{w_{K-1}^{1-K} \exp(w_{K-1}) dw_{K-1} & \cdots & \left(\frac{\mathcal{N}_{X}}{\mathcal{N}_{d}}\right)^{K-2} f^{w_{K-3}^{K-3} \exp(w_{K-1}) dw_{K-1}} \\ \left(\frac{\mathcal{N}_{X}}{\mathcal{N}_{d}}\right)^{2-K} f^{w_{K-1}^{1-K} \exp(w_{K-1}) dw_{K-1} & \cdots & \left(\frac{\mathcal{N}_{X}}{\mathcal{N}_{d}}\right)^{K-2} f^{w_{K-3}^{K-3} \exp(w_{K-1}) dw_{K-1}} \\ \left(\frac{\Gamma(2K-3)}{\Gamma(2K-3)} & \frac{1}{\Gamma(2K-6)} & \frac{1}{\Gamma(2K-7)} & \cdots & \frac{1}{\Gamma(1)} \\ \frac{1}{\Gamma(2K-4)} & \frac{1}{\Gamma(2K-5)} & \frac{1}{\Gamma(2K-5)} & \cdots & \frac
$$

by comparison with [\(38\)](#page-10-3).

Returning to [\(90\)](#page-24-0)

$$
Q_{E,X}(\alpha, \gamma) = \sum_{\substack{0 < d \leq X \\ \omega_{E} \chi_d(-M) = 1}} \exp\left(-\mathcal{N}_d\alpha\right) \frac{(-1)^{K(K-1)/2} 2^K}{K!(2\pi i)^K} (K\mathcal{T}_+^E + K\mathcal{T}_-^E) \tag{105}
$$
\n
$$
= \sum_{\substack{0 < d \leq X \\ \omega_{E} \chi_d(-M) = 1}} \exp\left(-\mathcal{N}_d\alpha\right) \frac{(-1)^{K(K-1)/2} 2^K}{(K-1)!(2\pi i)^K}
$$
\n
$$
\times \left(\frac{\mathcal{N}_d}{\mathcal{N}_X}\right)^{(K-1)(K-2)/2} \mathcal{M}^{SO(2N)}(-1)^{K-1} \mathcal{N}_X^{(K-1)(K-2)/2}(\pi i)
$$
\n
$$
\times \left(\frac{\exp(\mathcal{N}_d\alpha)\zeta(1+2\gamma)}{\zeta(1+\gamma)^{K-1}\zeta(1+\alpha+\gamma)}\zeta(1+\alpha)^{K-1} A_E(0,\ldots,0,\alpha;\gamma)\right) + \frac{\exp(-\mathcal{N}_d\alpha)\zeta(1+2\gamma)g(\alpha)}{\zeta(1+\gamma)^{K-1}\zeta(1-\alpha+\gamma)}\zeta(1-\alpha)^{K-1} A_E(0,\ldots,0,-\alpha;\gamma)\right) (1+\mathcal{O}(\mathcal{N}_X^{-1})).
$$
\n(105)

Using [\(56\)](#page-15-0) for  $\mathcal{M}^{SO(2N)}$ ,

$$
\mathcal{Q}_{E,X}(\alpha, \gamma) = \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = 1}} 2^{(K-1)^2/2} \mathcal{N}_d^{(K-1)(K-2)/2} \frac{G(K)\sqrt{\Gamma(2K-1)}}{\sqrt{G(2K-1)\Gamma(K)}} \\
\times \left( \frac{\zeta(1+2\gamma)}{\zeta(1+\gamma)^{K-1}\zeta(1+\alpha+\gamma)} \zeta(1+\alpha)^{K-1} A_E(0, \dots, 0, \alpha; \gamma) + \frac{\exp(-2\mathcal{N}_d \alpha) \zeta(1+2\gamma) \Gamma(1-\alpha)}{\zeta(1+\gamma)^{K-1} \zeta(1-\alpha+\gamma) \Gamma(1+\alpha)} \zeta(1-\alpha)^{K-1} A_E(0, \dots, 0, -\alpha; \gamma) \right) (1 + \mathcal{O}(\mathcal{N}_X^{-1})).
$$

We set  $K = r + 1$ , write  $A_E(0, \ldots, 0, \alpha; \gamma)$  as  $\tilde{A}_E(\alpha, \gamma)$  for simplicity, and differentiate this

with respect to  $\alpha$ :

$$
\frac{d}{d\alpha} \mathcal{Q}_{E,X}(\alpha,\gamma) = 2^{r^2/2} \sum_{\substack{0 < d \leq X \\ \omega_{EXd}(-M)=1}} \mathcal{N}_d^{r(r-1)/2} \frac{\zeta(1+2\gamma)}{\zeta(1+\gamma)^r} \left( \frac{d}{d\alpha} \tilde{A}_E(\alpha,\gamma) \frac{\zeta(1+\alpha)^r}{\zeta(1+\alpha+\gamma)} \right. \\
\left. + \tilde{A}_E(\alpha,\gamma) \frac{r\zeta(1+\alpha)^{r-1}\zeta'(1+\alpha)}{\zeta(1+\alpha+\gamma)} \right. \\
\left. - \tilde{A}_E(\alpha,\gamma) \frac{\zeta(1+\alpha)^r\zeta'(1+\alpha+\gamma)}{\zeta(1+\alpha+\gamma)^2} \right. \\
\left. + \frac{d}{d\alpha} \tilde{A}_E(-\alpha,\gamma) e^{-2\mathcal{N}_d\alpha} \frac{\Gamma(1-\alpha)}{\Gamma(1+\alpha)} \frac{\zeta(1-\alpha)^r}{\zeta(1-\alpha+\gamma)} \right. \\
\left. - \tilde{A}_E(-\alpha,\gamma) e^{-2\mathcal{N}_d\alpha} \frac{\Gamma(1-\alpha)}{\Gamma(1+\alpha)} \left( \Psi(1-\alpha) + \Psi(1+\alpha) \right) \frac{\zeta(1-\alpha)^r}{\zeta(1-\alpha+\gamma)} \right. \\
\left. - \tilde{A}_E(-\alpha,\gamma) \frac{\Gamma(1-\alpha)}{\Gamma(1+\alpha)} e^{-2\mathcal{N}_d\alpha} \frac{r\zeta(1-\alpha)^{r-1}\zeta'(1-\alpha)}{\zeta(1-\alpha+\gamma)} \right. \\
\left. - 2\mathcal{N}_d\tilde{A}_E(-\alpha,\gamma) \frac{\Gamma(1-\alpha)}{\Gamma(1+\alpha)} e^{-2\mathcal{N}_d\alpha} \frac{\zeta(1-\alpha)^r}{\zeta(1-\alpha+\gamma)} \right. \\
\left. + \tilde{A}_E(-\alpha,\gamma) \frac{\Gamma(1-\alpha)}{\Gamma(1+\alpha)} e^{-2\mathcal{N}_d\alpha} \frac{\zeta(1-\alpha)^r\zeta'(1-\alpha+\gamma)}{\zeta(1-\alpha+\gamma)^2} \right) \\
\times \frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}} \left( 1 + \mathcal{O} \left( \mathcal{N}_X^{-1} \right) \right). \tag{106}
$$

Here  $\Psi(x) = \Gamma'(x)/\Gamma(x)$ . Fortunately, when we set  $\alpha = \gamma = i\phi$  (note  $\phi$  is not necessarily real), several of these terms disappear. We note that  $\lim_{\alpha \to \gamma} \zeta'(1 - \alpha + \gamma)/\zeta(1 - \alpha + \gamma)^2 = 1$ . Also  $\lim\nolimits_{\alpha\to\gamma}1/\zeta(1-\alpha+\gamma)=0.$ 

$$
\sum_{\substack{0 < d \leq X \\ \omega_{E} \chi_d(-M)=1}} \left[ \frac{L'_E(1/2 + i\phi, \chi_d)}{L_E(1/2 + i\phi, \chi_d)} L_E(1/2, \chi_d)^r \right] \tag{107}
$$
\n
$$
= \sum_{\substack{0 < d \leq X \\ \omega_{E} \chi_d(-M)=1}} 2^{r^2/2} \mathcal{N}_d^{r(r-1)/2} \frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}} \left( \tilde{A}_E^1(i\phi) + \tilde{A}_E(i\phi, i\phi) \frac{r\zeta'(1+i\phi)}{\zeta(1+i\phi)} \right. \\
\left. - \tilde{A}_E(i\phi, i\phi) \frac{\zeta'(1+2i\phi)}{\zeta(1+2i\phi)} + \frac{\zeta(1+2i\phi)\zeta(1-i\phi)^r}{\zeta(1+i\phi)^r} \tilde{A}_E(-i\phi, i\phi) \frac{\Gamma(1-i\phi)}{\Gamma(1+i\phi)} e^{-2i\mathcal{N}_d\phi} \right) \left( 1 + \mathcal{O} \left( \mathcal{N}_X^{-1} \right) \right).
$$

Here,  $\tilde{A}_{E}^{1}(\phi) = d/d\alpha \tilde{A}_{E}(\alpha, \gamma)|_{\alpha = \gamma = \phi}$ . Now let

$$
\mathcal{V}(\mathcal{N}_d, r) := 2^{r^2/2} \mathcal{N}_d^{r(r-1)/2} \frac{G(r+1)\sqrt{\Gamma(2r+1)}}{\sqrt{G(2r+1)\Gamma(r+1)}}\tag{108}
$$

and

$$
\mathcal{U}_E(\mathcal{N}_d, r, \phi) := \tilde{A}_E^1(i\phi) + \tilde{A}_E(i\phi, i\phi) \frac{r\zeta'(1 + i\phi)}{\zeta(1 + i\phi)} - \tilde{A}_E(i\phi, i\phi) \frac{\zeta'(1 + 2i\phi)}{\zeta(1 + 2i\phi)} + \frac{\zeta(1 + 2i\phi)\zeta(1 - i\phi)^r}{\zeta(1 + i\phi)^r} \tilde{A}_E(-i\phi, i\phi) \frac{\Gamma(1 - i\phi)}{\Gamma(1 + i\phi)} e^{-2i\mathcal{N}_d\phi}
$$
(109)

$$
\sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M)=1}} \left[ \frac{L'_E(1/2 + i\phi, \chi_d)}{L_E(1/2 + i\phi, \chi_d)} L_E(1/2, \chi_d)^r \right]
$$
\n
$$
= \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M)=1}} \mathcal{V}(\mathcal{N}_d, r) \mathcal{U}_E(\mathcal{N}_d, r, \phi) \left(1 + \mathcal{O}\left(\mathcal{N}_X^{-1}\right)\right). \tag{110}
$$

#### <span id="page-28-0"></span>7 One level density for quadratic twists of elliptic curve L-functions

In Section [5,](#page-17-0) we used both the leading order term and the next to leading order terms (in  $N$ ) for the mixed moment in order to calculate the one level density over  $SO(2N)$ . However, to make the calculation easier, we shall only use the leading order term in  $\mathcal{N}_X$  this time. Let  $\gamma_d$ denote a zero of  $L_E(s, \chi_d)$  on the half line. For a test function f, let us consider the one level density

<span id="page-28-1"></span>
$$
\sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = +1}} \sum_{\gamma_d} f(\gamma_d),\tag{111}
$$

where  $f$  is a suitable test function (e.g. an even Schwartz function). Using the argument principle, we find

$$
\sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = +1}} \sum_{\gamma_d} f(\gamma_d) = \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = +1}} \frac{1}{2\pi i} \left( \int_{(c)} - \int_{(1-c)} \right) \frac{L'_E(s, \chi_d)}{L_E(s, \chi_d)} f(-i(s-1/2)) \, ds, \tag{112}
$$

where (c) denotes a vertical line from  $c - i\infty$  to  $c + i\infty$ , and  $3/4 > c > 1/2 + 1/\log X$ . One can continue from here by replacing the ratio of L-functions with the result of the ratios conjecture for  $\sum$  $0 < d \leq X$  $\omega$ <sub>E</sub> $\chi_d$ ( $-\overline{M}$ )=+1  $L_E^{'}(s,\chi_d)$  $\frac{L_E(s, \chi_d)}{L_E(s, \chi_d)}$ . This was done in [\[25\]](#page-33-12), and results in an excellent prediction for the

one level density away from the critical point  $s = 1/2$ , but which does not capture the extra zero repulsion at the origin, as can be seen in Figure [2.](#page-31-0) Based on the work done in [\[20\]](#page-33-8) and in [\[17\]](#page-33-13), we believe that this extra repulsion is linked to the discretisation of the central values  $L_E(1/2, \chi_d)$  due to the central value formula [\(7\)](#page-2-0). That is, the central value is either zero or it is greater than  $\kappa_E/|d|^{1/2}$ . Therefore, we might expect that if we explicitly enforce this bound using a Heaviside step function, we would get a prediction for the one level density which does contain information about the central value which might have been lost in the approximations of the ratios conjecture recipe. Therefore we define our one level density in the following way:

$$
S_1(f) = \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-\overline{M}) = +1}} \frac{1}{2\pi i} \left( \int_{(c)} - \int_{(1-c)} \right) \frac{L'_E(s, \chi_d)}{L_E(s, \chi_d)} H\left(\log(L_E(1/2, \chi_d) - \xi)\right) f(-i(s-1/2)) \, \mathrm{d}s \tag{113}
$$

where  $\xi = \log(\kappa_E/|d|^{1/2})$ . The value of  $\kappa_E$  has been computed for many families by Michael Rubinstein and can be found in Table 3 of [\[15\]](#page-33-16). Using the integral representation of the Heaviside function [\(65\)](#page-17-3), we get

$$
S_1(f) = \tag{114}
$$

$$
\sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = +1}} \frac{-1}{4\pi^2} \left( \int_{(c)} - \int_{(1-c)} \right) \frac{L_E'(s, \chi_d)}{L_E(s, \chi_d)} \int_{(b)} L_E(1/2, \chi_d)^r \frac{e^{-\xi r}}{r} dr f(-i(s-1/2)) dr ds
$$

so

where  $b > 0$ . We can move the logarithmic derivative of L inside the r integral:

$$
S_1(f) = \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = +1}} \frac{-1}{4\pi^2} \left( \int_{(c)} - \int_{(1-c)} \right) \left[ \int_{(b)} \frac{L'_E(s, \chi_d)}{L_E(s, \chi_d)} L_E(1/2, \chi_d)^r \frac{e^{-\xi r}}{r} dr \right] \times f(-i(s-1/2)) \, ds. \tag{115}
$$

Let us first consider the integral over  $s$  on the  $c$  line. If we replace the ratios of  $L$ -functions by the result in [\(110\)](#page-28-1), the integrand no longer has poles in s for  $\text{Im}[s] > 0$  on the  $1/2$  line, so we can then move the path of integration onto  $\mathbb{R}e[s] = 1/2$  to get

$$
\sum_{\substack{0 < d \le X \\ \omega E \chi_d(-M) = +1}} \frac{1}{4\pi^2 i} \int_{-\infty}^{\infty} \left[ \int_{(b)} \mathcal{V}(\mathcal{N}_d, r) \mathcal{U}_E(\mathcal{N}_d, r, i\phi) \left( 1 + \mathcal{O} \left( \mathcal{N}_X^{-1} \right) \right) \frac{e^{-\xi r}}{r} dr f(\phi) dr \right] d\phi. \tag{116}
$$

Here again we are assuming  $r$  can be a complex variable, rather than just an integer, and from here on we will neglect error terms. Our purpose is to show that this method gives qualitatively the correct behaviour of the one level density near the origin.

For the  $(1 - c)$  integral, we change variables  $s \to 1 - s$  so that we can write it as an integral over  $(c)$ :

$$
\sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M) = +1}} \frac{1}{4\pi^2} \int_{(c)} \left[ \int_{(b)} \frac{L'_E(1-s, \chi_d)}{L_E(1-s, \chi_d)} L_E(1/2, \chi_d)^r \frac{e^{-\xi r}}{r} dr \right] f(i(s-1/2)) ds. \tag{117}
$$

The functional equation for these L-functions looks like

$$
L_E(1/2 + i\phi, \chi_d) = \mathcal{X}(1/2 + i\phi, \chi_d) L_E(1/2 - i\phi, \chi_d), \tag{118}
$$

where

$$
\mathcal{X}(1/2 + i\phi, \chi_d) := \exp(-2\mathcal{N}_d i\phi) \frac{\Gamma(1 - i\phi)}{\Gamma(1 + i\phi)}.
$$
\n(119)

We take the derivative of the functional equation

$$
\frac{L'_{E}}{L_{E}}(1/2 - i\phi, \chi_{d}) = \frac{\mathcal{X}'}{\mathcal{X}}(1/2 + i\phi, \chi_{d}) - \frac{L'_{E}}{L_{E}}(1/2 + i\phi, \chi_{d}).
$$
\n(120)

We then replace the ratio of L-functions with the result in  $(110)$ , to find that for the integral over  $(1 - c)$ , we get:

<span id="page-29-0"></span>
$$
\approx \sum_{\substack{0 < d \le X \\ \omega_{E\chi_d(-M)=+1}}} \frac{1}{4\pi^2 i} \int_{-\infty}^{\infty} \left[ \int_{(b)} \left( \frac{\chi'}{\chi} (1/2 + i\phi, \chi_d) - \mathcal{U}_E(\mathcal{N}_d, r, i\phi) \right) \times \mathcal{V}(\mathcal{N}_d, r) \frac{e^{-\xi r}}{r} f(\phi) dr \right] d\phi. \tag{121}
$$

We know from Section [5](#page-17-0) that  $\mathcal{V}(\mathcal{N}_d, r)$  has poles at the negative half-integers, and the  $r = 0$ term is the one level density already derived in [\[25\]](#page-33-12), so we can write this as a series of residues:

$$
S_1(f) \approx \sum_{j=0,-1/2,-3/2,\dots} \sum_{\substack{0 < d \le X \\ \omega_E \chi_d(-M)=+1}} \frac{1}{2\pi} \int_{-\infty}^{\infty} \text{Res}\left[ \left( -\frac{\mathcal{X}'}{\mathcal{X}}(1/2 + i\phi, \chi_d) + 2\mathcal{U}_E(\mathcal{N}_d, r, i\phi) \right) \times \mathcal{V}_E(\mathcal{N}_d, r) \frac{e^{-\xi r}}{r} f(\phi) \right]_{r=j} d\phi.
$$
\n
$$
\times \mathcal{V}_E(\mathcal{N}_d, r) \frac{e^{-\xi r}}{r} f(\phi) \Big|_{r=j} d\phi.
$$
\n(122)

#### 7.1 The  $r = 0$  term

This corresponds to the one level density derived at Theorem 2.3 in [\[25\]](#page-33-12) (with slightly different notation for the arithmetic parts):

$$
\frac{1}{2\pi} \int_{-\infty}^{\infty} f(\phi) \sum_{\substack{0 < d \le X \\ \omega E \chi d(-M) = +1}} -\frac{X'}{X} (1/2 + i\phi, \chi_d) + 2\mathcal{U}_E(\mathcal{N}_d, 0, i\phi) d\phi
$$

$$
\omega_{E \chi d}(-M) = +1
$$

$$
= \frac{1}{2\pi} \int_{-\infty}^{\infty} f(\phi) \sum_{\substack{0 < d \le X \\ \omega_{E \chi d}(-M) = +1}} \left( 2 \log \left( \frac{\sqrt{M}d}{2\pi} \right) + \Psi(1 + i\phi) + \Psi(1 - i\phi) \right)
$$

$$
+2 \left[ -\tilde{A}_E(i\phi, i\phi) \frac{\zeta'}{\zeta} (1 + 2i\phi) + \tilde{A}_E^1(i\phi) + \left( \frac{\sqrt{M}d}{2\pi} \right)^{-2i\phi} \frac{\Gamma(1 - i\phi)}{\Gamma(1 + i\phi)} \zeta (1 + 2i\phi) \tilde{A}_E(-i\phi, i\phi) \right] \right) d\phi.
$$
(123)

<span id="page-30-7"></span>This is plotted in Figure [2.](#page-31-0)

#### 7.2 The contribution from higher residues

The higher residues will not take such a neat form, but may be calculated using a computational algebra package, and the resulting one level density prediction using the first three residues is shown in Figure [3.](#page-32-6) Near the origin, this is a marked improvement on the prediction using only the first residue, i.e. the prediction from [\[25\]](#page-33-12) in Figure [2.](#page-31-0) Away from the origin, it is less good, but since we are only using the first three residues and we are only working to leading order term in  $\mathcal{N}_X$ , it is reasonable to suppose that if we calculated more residues and/or higher order terms in  $\mathcal{N}_X$ , then we would get even better agreement. This supports the hypothesis that information about the discretisation of the central values is lost in the error term of the ratios conjecture for finite conductor.
