Abstract

With the advent of large language models (LLMs), managing scientific literature via LLMs has become a promising direction of research. However, existing approaches often overlook the rich structural and semantic relevance among scientific literature, limiting their ability to discern the relationships between pieces of scientific knowledge, and suffer from various types of hallucinations. These methods also focus narrowly on individual downstream tasks, limiting their applicability across use cases. Here we propose LitFM, the first literature foundation model designed for a wide variety of practical downstream tasks on domain-specific literature, with a focus on citation information. At its core, LitFM contains a novel graph retriever to integrate graph structure by navigating citation graphs and extracting relevant literature, thereby enhancing model reliability. LitFM also leverages a knowledge-infused LLM, fine-tuned through a welldeveloped instruction paradigm. It enables LitFM to extract domain-specific knowledge from literature and reason relationships among them. By integrating citation graphs during both training and inference, LitFM can generalize to unseen papers and accurately assess their relevance within existing literature. Additionally, we introduce new large-scale literature citation benchmark datasets on three academic fields, featuring sentence-level citation information and local context. Extensive experiments validate the superiority of LitFM, achieving 28.1% improvement on retrieval task in precision, and an average improvement of 7.52% over state-of-the-art across six downstream literature-related tasks.

Introduction

The rapid expansion of scientific literature necessitates effective management and analysis for scientific research (Sun et al. 2024; Tsai et al. 2023; Luo, Xie, and Ananiadou 2023). Traditional approaches rely primarily on rule-based or statistic-based methods (Liu, Zhang, and Guo 2013), showing inherent limitations in their capabilities. Due to the enhanced semantic understanding of large language models (LLMs), recent efforts have attempted to use LLMs to manage literature through human instructions (Zhang et al. 2023a; Shen et al. 2024; Baek et al. 2024).

Despite their advancements, these models typically overlook the interconnected nature and structural relevance of citation graphs. This negligence limits their ability to fully comprehend both individual research papers and the broader

Figure 1: (a) Hallucinations faced by existing approaches. (b) Performance of LitFM and existing approaches on six benchmark tasks, where LitFM shows consistent superiority.

academic context in which they exist. Consequently, these models suffer from several limitations: 1) Hallucinations. They often overlook the use of citation graphs or fail to grasp the nuanced semantics of paper-to-paper citations. As shown in Figure 1(a), this oversight leads to responses that exhibit hallucinations in citation, knowledge, and context for a given input (Kunnath, Pride, and Knoth 2023; Martin-Boyle et al. 2024). In this regard, citation hallucination refers to the citing of non-existent literature, knowledge hallucination involves providing information that contradicts the actual literature, while context hallucination means including information that was neither provided nor desired by the user. 2) Generalization ability. Existing methods heavily rely on the accessibility to the complete context of the given text and struggle to handle unseen topics or research texts with incomplete information. This dependency significantly restricts their applicability and adaptability (Li and Ouyang 2024a). 3) Unification. Current approaches to enhance literature-related capabilities often focus on specific tasks. This narrow focus neglects the potential for LLMs to transfer knowledge across different tasks (Luo, Xie, and Ananiadou 2023; Yang and Han 2023), which is particularly pronounced in complex tasks such as related work generation (Li and Ouyang 2024b).

Proposed Works. To address these challenges, we propose LitFM, the first Literature Foundation Model¹ designed to uniformly manage diverse literature-related tasks using domain-specific citation graphs. To avoid citation hallucinations, we design a structure-aware retriever to extract literature from citation graphs as references. Different from existing graph-based retrieval methods (He et al. 2024), which often overlook neighboring information, our graph retriever integrates structural details through neighbor-aware candidate embeddings. Additionally, we implement a selfsupervised pre-training that adapts the graph retriever to the specific semantic and structural features of the citation graph. To enhance the generalization ability of our framework, we introduce a novel notion of pseudo-query that encourages the retriever to generate embeddings that mirror a complete query in both semantic and structural aspects, thereby enhancing reliability in challenging scenarios where the input query may be incomplete or contain unseen topics.

To unify various literature-related tasks while infusing domain-specific knowledge to avoid knowledge hallucinations, we introduce an instruction-tuning paradigm for citation graph understanding. By fine-tuning the LLM through this paradigm using real-world citation graphs, the LLM learns to extract intrinsic knowledge, essential arguments, and relations between the scientific literature. This approach not only unifies task handling but also enhances the LLM's knowledge transferability across tasks, resulting in overall improved performance. Using a chain-of-thought (COT) (Wei et al. 2022) strategy, we demonstrate that LitFM can automatically generate literature reviews for papers outside the existing citation graph, effectively avoiding fake citations and providing more informative content.

To construct the instruction and benchmark dataset, we curate and open-source three new citation graph datasets, covering diverse domains². While there are existing citation graph datasets in the literature, such as ogbn-arxiv-TA (Yan et al. 2023) and Semantic Scholar Network dataset (An et al. 2021), they are either limited in scale (e.g., the ogbnarxiv-TA dataset only contains 1M edges) or lack detailed context for each citation edge (e.g., only the text descriptions of nodes are provided). Instead, our new datasets are augmented with fine-grained citation sentences describing where the citation occurs and their local context. This local context helps better understand the intent behind the citation and facilitates a more accurate interpretation of citation relations. Moreover, nodes are enriched with related work sections as attributes, providing a valuable test bed for evaluating the quality of tasks such as related work generation.

We conducted experiments on 6 real-world literaturerelated tasks, with results reported in Figure 1(b). As shown in the figure, LitFM outperforms retriever-augmented GPT-3.5-turbo across all tasks. Particularly, LitFM surpasses GPT-3.5-turbo by 32.8% and 8.3% in citation prediction and citation recommendation tasks, respectively. This performance boost is attributed to the high fidelity of our graph retriever, which achieves 28.1% higher precision in retrieving related literature compared to existing retrieval baselines. Finally, our zero-shot evaluation on the related work generation task shows that LitFM attains a 17.8% higher ROUGE score than GPT-3.5-turbo with more accurate citations and produces text that more closely aligns with the statistical distribution of ground-truth related-work sections.

Related Work

Deep Learning on Citation Graphs. Citation graphs are extensively utilized in numerous research studies (Zhang et al. 2023c). Early works have applied traditional machine learning model (Hamilton, Ying, and Leskovec 2017) for citation graph analysis and recommendation (Iqbal et al. 2021; Ali et al. 2020). However, they are often designed for a specific task, lacking a unified model that performs well across different tasks. Efforts such as SciBERT (Beltagy, Lo, and Cohan 2019), BioBERT (Lee et al. 2020), PubMedBERT (Gu et al. 2021), SciMult (Zhang et al. 2023a) aim for general understanding of scientific literature but are only applicable for discriminative tasks due to their emphasis on representation learning. Recent works (Jung et al. 2023; Martin-Boyle et al. 2024; Li and Ouyang 2024b) leverage LLMs to enable generation tasks but are typically designed for specific tasks. Further, they often separate training from real citation graphs, limiting adaptability to network dynamics.

Large Language Models for Graphs. Existing strategies for leveraging LLMs in graph learning (Minaee et al. 2024; Ren et al. 2024) include using GNNs as encoders to convert graph entities into structure-aware tokens for LLM inference (Tang et al. 2024a; Chai et al. 2023), or using LLMs as text encoders for node embeddings to train GNNs (Huang et al. 2023; Xia, Kao, and Huang 2024; Chen et al. 2023) or fused GNN-LLM models (Li, Ding, and Lee 2023; Huang et al. 2024). Another branch involves retrieving and translating subgraphs into text for inference (He et al. 2024; Hu et al. 2024), with fine-tuning to improve LLM understanding of subgraph context (Zhao et al. 2023; Fatemi, Halcrow, and Perozzi 2023; Chen et al. 2024a; Luo et al. 2024).

Retrieval Augmented Generation (RAG). Vanilla LLMs commonly face challenges like hallicinations (Zhang et al. 2023b), outdated knowledge (Zhang et al. 2023d), and uninterpretable reasoning process (Jie et al. 2024; Tang et al. 2024b) in domain-specific or knowledge-intensive tasks. RAG addresses these issues by incorporating external knowledge as additional context to improve LLM performance (Gao et al. 2023). Originating from language applications, most of the current work on RAG for LLMs is on textual data gathered from one or multiple corpuses (Gao et al. 2023; Zhao et al. 2024). Several later attempts adapt these approaches for (semi-) structural data such as tabular data (Luo et al. 2023; Zha et al. 2023), knowledge graphs (Kang et al. 2023; Wang et al. 2023; Shen et al. 2023; Jiang et al. 2024; He et al. 2024). He et al. (2024) is the closest work to ours that enhances graph question-answering capabilities by extracting subgraphs based on the retrieved nodes. However, it ignores the structural dependency during retrieval. Hence, these methods fail to achieve accurate re-

trieval for scientific literature due to neglecting the semantic and structural relevance of literature.

Methodology

Problem Formulation. Our overarching goal is to develop a literature foundational model that can effectively address various literature-related tasks commonly encountered in real-world scientific research. These tasks include, for example, generating a title from a paper's abstract, completing an abstract, and creating a related works section specific to domains such as medicine and physics. To achieve this, we define x as the user query related to these tasks. A citation graph $\mathcal{G} = (V, E)$ specific to the domain of interest is available, where each node $i \in V$ represents a paper, and edges E denote citation relationships between papers. Our method LitFM produces an output y to address the query \boldsymbol{x} by 1) navigating \mathcal{G} and extracting literature relevant to x, 2) leveraging pseudo-query embedding to handle cases where x contains incomplete information or requires access to sparsely connected papers in \mathcal{G} , and 3) internalizing various tasks and aligning domain-specific knowledge through a unified instruction paradigm.

Method Overview. Figure 2 illustrates LitFM's pipeline, detailing its components and steps. This includes the creation of citation graphs for training and evaluation, a self-supervised graph retriever pre-training using a contrastive framework with complete and pseudo-queries for retrieving relevant papers, an instruction paradigm to integrate various tasks and literature knowledge, and an inference process employing a chain-of-thought strategy to address complex tasks like generating related work sections. We detail these components in the following sections.

Graph Retriever

Citation graphs from different domains often exhibit various structural and semantic properties (*e.g.*, citation preferences and terminology). Modeling these properties is essential for accurate retrieval. However, existing RAG methods (He et al. 2024) generally do not address these domainspecific aspects and often fail to incorporate neighboring information during retrieval, leading to unsatisfactory retrieval quality. To address this, our graph retriever is pretrained using self-supervision to adapt to each research domain. We propose the novel notion of pseudo-query embedding and neighbor-aware modeling to integrate the semantic and structural dependencies among literature. With our graph retriever, LitFM can scale to citation contexts that exceed the input window limitation and extract accurate literature references to reduce hallucinations. It comprises three main steps: indexing, self-supervised training, and retrieval. Indexing. We initiate the retriever by generating embeddings for the literature. For a paper $i \in \mathcal{G}$, let T_i and A_i denote its title and abstract. The embedding for node i is defined as $\mathbf{z}_i = LM(T_i) + LM(A_i) \in \mathbb{R}^d$, where d denotes the embedding dimension and LM refers to the pre-trained language model, such as BERT (Devlin et al. 2019).

Self-supervised Training. Connections in citation graphs indicate the semantic and structural relevance among literature, which is essential for understanding the domain properties. Therefore, we propose a self-supervised training process requiring the model to reconstruct connections between literature. Specifically, we first randomly select paper *i* from the citation graph as the query paper and generate the query embedding as $\mathbf{q}_i = \mathbf{W}^q \mathbf{z}_i + \mathbf{b}^q \in \mathbb{R}^{d_1}$, where $\mathbf{W}^q \in \mathbb{R}^{d_1 \times d}$ and $\mathbf{b}^q \in \mathbb{R}^{d_1}$ are trainable parameters, and d_1 indicates the hidden dimension. Then, the papers with connections to *i* are regarded as positive candidates and the other ones as negative. The embedding of a candidate paper *j* is generated by aggregating embeddings of neighborhood papers with one message passing layer (Gilmer et al. 2017)

$$\mathbf{c}_{j} = \mathbf{W}^{c1}\mathbf{z}_{j} + \frac{1}{|\mathcal{N}(j)|} \sum_{k \in \mathcal{N}(j)} \mathbf{W}^{c2}\mathbf{z}_{k} + \mathbf{b}^{c} \in \mathbb{R}^{d_{1}}, \quad (1)$$

where $\mathcal{N}(j)$ is the neighborhood papers of j. $\mathbf{W}^{(\cdot)} \in \mathbb{R}^{d_1 \times d}$ and $\mathbf{b}^c \in \mathbb{R}^{d_1}$ are learnable during training. Integrating neighborhood information helps the retriever consider the broader context of each paper, thereby enhancing the quality and diversity of the retrieval results.

In practical usage, user-provided queries may be incomplete (e.g., partial titles or fragmented sentences). To handle these incomplete queries, we further introduce pseudo-query embeddings. Our graph retriever reconstructs an embedding for the complete query, known as the pseudo-query embedding, based on each candidate. This allows us to use the similarity between the embeddings of user-provided query and pseudo query as an auxiliary metric during retrieval. Since our goal is to retrieve the related papers for a given paper, each pair of connected papers (*i.e.*, $(i, j) \in E$) in the citation graph can be regarded as a ground-truth querycandidate match, where the text of the source node *i* serves as the complete query for the text of the target node *j*. Therefore, we first use a multilayer perceptron (MLP) to generate the pseudo-query embedding from candidate paper j as $\mathbf{p}_i = \mathrm{MLP}(\mathbf{c}_i) \in \mathbb{R}^{d_1}$, and then employ the 1-norm regularization to ensure that the pseudo-query embedding closely resembles the embedding of paper *i*, as shown in Eq. 2:

$$\mathcal{L}_{\rm re} = \sum_{(i,j)\in\mathcal{G}} ||\mathbf{z}_i - \mathbf{p}_j||_1.$$
⁽²⁾

Given the candidate embedding \mathbf{c}_j and the pseudo-query embedding \mathbf{p}_j , we calculate the cosine similarity between the query and the candidate as $\sin(i, j) = \cos(\mathbf{q}_i, \mathbf{c}_j + \mathbf{p}_j)$. We then apply the InfoNCE loss (Oord, Li, and Vinyals 2018) to ensure positive candidates are closer to the query embeddings than negative candidates in the semantic space:

$$\mathcal{L}_{\text{nce}} = -\frac{1}{|\mathcal{N}(i)|} \sum_{j \in \mathcal{N}(i)} \log \frac{\exp(\operatorname{sim}(i, j))}{\sum_{j' \notin \mathcal{N}(i)} \exp(\operatorname{sim}(i, j'))}, \quad (3)$$

where the negative candidates j' are randomly sampled from $V \setminus \mathcal{N}(i)$. We then optimize the retriever with the InfoNCE loss \mathcal{L}_{nce} and regularization term \mathcal{L}_{re} jointly.

Retrieval. For each query text x provided by users or generated by LLMs, we create the corresponding query embedding as $\mathbf{q}_x = \mathbf{W}^q L M(x) + \mathbf{b}^q$. Then, we use the k-nearest searching approach to retrieve a set of related papers based on the similarity between the query embedding and the candidate embedding, which is accompanied by the corresponding pseudo-query embedding. The retrieval for query text x is defined as:

$$V_k(\boldsymbol{x}) = \operatorname*{arg\,top}_{n \in V} k \cos(\mathbf{q}_x, \mathbf{c}_n + \mathbf{p}_n), \qquad (4)$$

where the $\arg \operatorname{top} k$ operation retrieves the top-k elements based on the similarity. k is a hyper-parameter, indicating the number of retrieved papers. Our graph retriever, with its neighbor-aware candidate embedding and structureaware training, effectively captures structural dependencies that previous methods typically overlook. Additionally, by utilizing pseudo-query embedding, our approach can handle sparse contexts and less informative queries, addressing challenges that previous methods struggle with.

Instructions for Citation Graph Understanding

We leverage an LLM as the foundation to unify multiple literature-related tasks. To enhance its capabilities on citation graphs and align it with specialized domain knowledge, we conduct instruction fine-tuning with LoRA (Hu et al. 2021), using a curated collection of general tasks on citation graphs. This multi-task instruction tuning approach enables the model to learn task-specific behaviors while preserving its general language understanding capabilities.

As illustrated in Figure 2 (C), we design node-level tasks such as *Title Generation* and *Abstract Completion* based on given paper abstracts. These tasks aim to infuse domainspecific context into the LLM backbone and enhance its scientific writing capabilities. By learning to generate titles and complete abstracts, the model develops a deeper understanding of scientific literature and content representation.

We also incorporate edge-level tasks, including *Paper Recommendation, Citation Link Prediction,* and *Citation Sentence Generation.* These tasks improve the model's comprehension of both scientific context and local structures of citation relations. Specifically, *Paper Recommendation* and *Citation Link Prediction* enable the model to understand the relevance and connections between different papers, while *Citation Sentence Generation* helps it learn how citations are integrated into scientific writing, leading to emergent capabilities in handling more complex literature-related queries, such as related work generation.

By combining node-level and edge-level tasks, our approach ensures that the model develops a robust understanding of both the content of individual papers and the relations between them. These tasks collectively form a necessary and sufficient set for the model to develop a comprehensive and foundational understanding of citation relations. Detailed instruction formats for each task are provided in Appendix A.

Inference Pipeline

As shown in Figure 2 (D), LitFM can uniformly handle various literature-related tasks, even for unseen papers, with the knowledge-infused LLM and the graph retriever. The process begins by retrieving relevant papers from the citation graph, which are then used as references. The LLM then extracts the main arguments from these references and infers relations between them. For example, when determining if paper A would cite paper B, LitFM first retrieves potential citations using the graph retriever. The titles and abstracts of two papers, and the retrieved references are fed into the knowledge-infused LLM with task-specific instructions. If the arguments of A and B are relevant or they share similar relations with the references, the response will be "YES".

Chain-of-Thought Strategy. To demonstrate LitFM's zeroshot capabilities on the complex tasks, we focus on related work generation, which requires sophisticated synthesis and contextualization of research. Current approaches have several limitations, as they rely on provided context (*e.g.*, ground-truth relationships between papers) or require manual intervention (*e.g.*, manually selecting cited papers). Based on the retriever-augmented pipeline, we introduce a chain-of-thought strategy to handle this task step-by-step, as follows. We refer to Appendix A for more details.

• **Summarize the query text.** The knowledge-infused LLM first summarizes the main arguments of the new paper from the user-provided description, which may con-

tain irrelevant words and sentences.

- **Retrieve related papers.** The summarized text is fed into the graph retriever to retrieve potential cited papers.
- **Recommend cited papers.** To refine the retrieval, we ask the knowledge-infused LLM to recommend the top-k papers most likely to be cited from the retrieved list.
- Generate citation sentences. We ask the LLM to generate the citation sentences that describe the relationship between the target paper and each cited paper, which are essential for a comprehensive literature review.
- **Group citation sentences.** The cited papers may include several topics. We ask the LLM to group these citation sentences based on their topics and relevance to the target paper, allowing similar papers to be discussed together.
- Organize as a related work section. Finally, we ask the LLM to organize each group of citation sentences into coherent paragraphs and then combine these paragraphs as the related work section of the target paper.

Complexity Analysis. Compared with vanilla LLMs, the additional time complexity of LitFM stems from the graph retriever. First, to generate the neighbor-aware candidate embeddings, we perform message passing, which has a complexity of $O(|\mathcal{N}(i)|d)$, where $|\mathcal{N}(i)|$ indicates the number of neighbor nodes for any node $i \in \mathcal{G}$. Then, during inference, the graph retriever encodes the prompt x using a BERT model, which has a time complexity of $O(|x|^2d)$, where d is the embedding dimension and $|\cdot|$ indicates the token length. Finally, the similarity calculation has a time complexity of $O(d_1)$, where d_1 represents the hidden dimension.

Experiments

Dataset

To establish our framework, we curated three new citation graph benchmark datasets from three distinct domains: medicine, computer science, and physics. Compared with existing citation graph datasets such as such as ogbn-arxiv-TA (Yan et al. 2023) and Semantic Scholar Network dataset (An et al. 2021), our datasets offer several advantages:

- In addition to each paper's title and abstract, node attributes in our graph include the paper's related work section (when available).
- Each edge is annotated with the citing sentence extracted from the citing paper, along with its local context (*i.e.*, the preceding and following sentences), thus capturing how the papers discuss one another. Additionally, each edge contains an indicator variable specifying whether the cited paper is mentioned in the related work section of the citing paper, thus distinguishing between literature review citations and in-paper technical citations.

Our dataset not only facilitates the construction of the dataset for instruction tuning but also allows for the evaluation of downstream tasks detailed in the previous sections and serves as a test bed for assessing the performance of the related work generation task. The medicine portion is constructed based on the PubMed Central repository. Meanwhile, the computer science and physics categories are derived from the LaTeX sources from the arXiv repository. For dataset statistics, examples, and more detailed information about the construction process, please refer to Appendix B.

Evaluation on Literature-related Tasks

Baselines. For generation tasks, we use four open-source large language models: Mistral 7B (Jiang et al. 2023), Vicuna 7B/13B (Chiang et al. 2023), Llama-3 8B(Touvron et al. 2023), and two closed-source large language models GPT-3.5-turbo and the most recent GPT-40 as baselines. We also employ a typical GNN-based model, GAT (Veličković et al. 2018), as the baseline for citation link prediction and recommendation tasks. To integrate text information, we initialize the node embedding with the BERT-encoded embeddings of the paper title and abstract. The edge embeddings are initialized by the text of citation sentences.

Experimental Settings. For each citation graph, we randomly sample a connected dense sub-graph with 2,000 nodes as the test set. The remaining nodes and edges, excluding those in the test set, constitute the training data used for training the graph retriever and fine-tuning the large language models via the LoRA technique (Hu et al. 2021). We use Vicuna model as the LLM backbone of LitFM. We use the BERT-base-uncased model to yield text embeddings for GNN and graph retriever. For the citation link prediction task, the ratio of positive to negative samples is set to 1:1. For the citation recommendation task, the size of the candidate set is fixed at 10 for each query with both negative samples and candidate samples randomly sampled. For the abstract completion task, the first 10% of each abstract is provided as input to the LLM. The number of retrieved papers that are used for augmentations is set as $k \in \{1, 3, 5, 10\}$. We run all the models five times with different random seeds and report the average performance to eliminate deviations. All the experiments are conducted on NVIDIA A40 with 48 GB memory. More details can be found in Appendix C.

Evaluation Metrics. We use Accuracy for the citation link prediction task and Hits@k for the citation recommendation task. For generation tasks, we follow the previous setting (Zhang et al. 2019) and use the BERTScore to evaluate the semantic similarity of the generated text and the ground truth one. We also measure the relevance of the generated related work using ROUGE-L score (Lin 2004) that calculates the overlap of n-grams between the text of cited papers and the generated related work. We also report the statistics, such as text length and number of citations, in the ground-truth related work and the generated text.

Performance Comparison. As shown in Table 1 and 2, LitFM consistently outperforms other baselines on five evaluation tasks across the three datasets, especially for tasks requiring graph comprehension. On the medicine dataset, LitFM achieves 8.0% improvement in accuracy for citation link prediction and 5.9% in Hits@1 for citation recommendation task, highlighting the effectiveness of our proposed model in reducing hallucinations and filtering out irrelevant information. Additionally, LitFM achieves the best performance on the citation sentence generation task across all three datasets, showing its superiority in reasoning relation-ships between literature. Notably, LitFM-7B version outper-

Table 1: Performance on the citation link prediction task and the citation recommendation task. We report accuracy for the link prediction and the Hits@1 metric for the recommendation task. The best and the second-best results are shown in **bold** and <u>underlined</u> respectively.

	Physics	0.872	0.878	0.891	0.870	0.837	0.824
	Medicine	0.885	0.890	0.892	0.859	0.863	0.849

forms LLMs with larger parameter sizes, such as Llama3-8b and Vicuna-13b. Interestingly, LitFM shows a more significant improvement on the medicine dataset, which can be attributed to 1) the corpus in this dataset containing many medical terms, thus requiring more domain-specific knowledge, and 2) the sparsity of the medicine test dataset, which benefits more from the neighbor-aware modeling and pseudo-query embedding of the graph retriever model.

Ablation and Analysis. As illustrated in Figure 3 (a), our instruction tuning strategy and the graph-augmented pipeline can be seamlessly adapted to other LLMs to enhance their performance on citation graph tasks, which shows the generalization ability of our proposed strategies. In Figure 3 (b), we observe that the graph retriever enhances performance across most tasks, especially those requiring graph comprehension. For title generation and abstract completion tasks, which require an understanding of the semantics within the paper, the integration of additional information from other papers does not lead to performance degradation, showing the robustness of LitFM in capturing relevant information.

Figure 3: (a) Link prediction performance of existing LLMs with and without knowledge-infused fine-tuning. (b) Performance of LitFM with and without graph retriever.

Table 3: Retrieval performance of different approaches. P@5 and P@10 refer to Precision@5 and Precision@10.

Datasets	(2S	Phy	vsics	Med	licine
Models	P@5	P@10	P@5	P@10	P@5	P@10
G-Retriever (He et al. 2024)	0.286	0.301	0.202	0.305	0.389	0.433

w/o pseudo-query embedding	0.519	0.587	0.597	0.643	0.644	0.542
w/o neighbor-aware candidate embedding	0.331	0.357	0.220	0.141	0.351	0.379

Graph Retriever Analysis

Retrieval Accuracy. To analyze the effectiveness of our proposed graph retriever, we compare its retrieval precision with typical graph-aware RAG approaches including G-Retriever (He et al. 2024) and GRAG (Hu et al. 2024), and two variants of our graph retriever: 1) without pseudoquery embedding, and 2) without neighbor-aware candidate embedding. As shown in Table 3, the graph retriever achieves higher retrieval precision compared with existing methods, especially for the sparse physics dataset, showing the effectiveness of the proposed pseudo-query embedding and neighbor-aware candidate embedding in handling sparse context scenarios. Notably, even without pseudo-query embedding, LitFM still consistently outperforms baselines, highlighting the efficacy of neighbor-aware training in capturing the structural context of papers.

Augmentation Effectiveness. Figure 4 (a) shows the performance of LitFM with different retrieving approaches. We observe that LitFM achieves higher generation quality with our graph retriever, especially for the citation link prediction task where inaccurate retrieval can introduce noise text and thus damage the performance. This shows the effectiveness of the graph retriever in accurately enriching citation context. One interesting observation is that using references retrieved by our graph retriever leads to higher accuracy on link prediction task than using the ground-truth references. This can be attributed to the graph retriever's ability to filter out some papers that are not directly related. Figure 4 (b) illustrates the performance trend as the number of augmentation papers increases. While a larger number of augmentation papers enhances the quality of generated citation sentences, it leads to a slight decline in citation recommendation performance due to the noise introduced by irrelevant papers. Figure 5 demonstrates that LitFM consistently outperforms the retrieval-augmented Vicuna and GPT-3.5 turbo. Notably, Vicuna exhibits performance degradation

Figure 4: (a) Performance of LitFM when using different retrieving approaches. (b) The performance of LitFM with different number of augmentation papers.

Figure 5: Performance of existing LLMs with G-Retriever on citation graph tasks.

on recommendation and title generation with G-Retriever. This could be attributed to Vicuna's lack of domain-specific knowledge, which hinders its ability to accurately extract valuable information from augmentation literature.

Related Work Generation Performance

Table 4: Performance of existing LLMs and LitFM on related work generation tasks. We report the F-score of the BERT score and the ROUGE score.

Datasets	C	2S	Physics		
Models	BERT Score	ROUGE	BERT Score	ROUGE	
Llama3-8b Vicuna-13b GPT-3.5 turbo GPT-4o	0.765 0.735 0.801 <u>0.806</u>	0.158 0.191 0.190 <u>0.221</u>	0.671 0.632 0.684 <u>0.697</u>	0.168 0.162 0.170 0.217	
LitFM-13b	0.819 (†1.6%)	0.224 ^(†1.3%)	0.766 ^(↑9.8%)	0.177	

Performance Comparison. As shown in Table 4, LitFM outperforms existing powerful LLMs on related work generation on both BERT and ROUGE score. This demonstrates that the related work section produced by LitFM is more semantically similar to the ground truth and covers more information from the cited papers. Table 5 shows that the statistical distributions of LitFM's generated content are more aligned with the ground truth, especially for the sparse physics dataset, highlighting the superior generalization ability of LitFM. Although GPT-40 generates longer related work sections, it often fails to segment paragraphs effectively. In contrast, LitFM, benefiting from its knowledge-infused LLM, can better understand literature semantics and achieve more rational segmentation. Moreover, although the related work generated by existing LLMs includes some ci-

Table 5: Statistics Comparison between the generated related work and the ground truth one on the average length (L), average number of paragraphs (NP), average number of citations (NC), and average ratio of paragraphs with citations (RPC). The statistics that are closest to the ground truth are shown in **bold** and the secondary are underlined.

Datasets		CS				Phys	sics	
Models	L	NP	NC	RPC	L	NP	NC	RPC
Ground Truth	1014.08	7.36	21.44	0.859	701.43	6.44	16.84	0.689
Llama3-8b Vicuna-13b GPT-3.5 turbo GPT-4o	378.01 214.84 307.05 701.11	12.15 3.69 6.65 13.98	<u>9.53</u> 3.77 4.73 9.20	0.915 0.918 0.736 0.781	452.90 249.64 202.38 503.97	16.02 <u>3.67</u> 2.63 11.59	8.87 6.53 5.36 <u>10.04</u>	0.874 0.951 0.822 0.706
LitFM-13b	338.90	5.95	9.57	0.802	504.81	5.81	10.53	0.821

tations, these cited papers may not correspond to real papers. Instead, LitFM generates related work by referring to actual citation graphs, thus reducing the citation hallucinations.

Ablation study. Table 6 examines the effectiveness of each component of LitFM in related work generation. The results show COT improves generation quality by breaking down the complex related work generation task into several simple tasks, such as citation recommendation and citation sentence generation. This step-by-step strategy helps LitFM to accurately extract useful information from the citation graphs. The table also reveals that performance degrades significantly without the graph retriever, especially on the ROUGE score. This decline occurs because, without the augmentation of retrieved papers, the generation often contains many fake citations due to LLM hallucinations. G-Retriever, which fails to consider structural relevance among papers, tends to introduce noise information in downstream tasks. Instead, our graph retriever enhances generation quality by effectively utilizing the structural context of papers.

Table 6: Related work generation performance of different variants. COT refers to the chain-of-thought strategy and RAG refers to graph retriever augmented generation.

Datasets	CS		Physics		
Models	BERT Score	ROUGE	BERT Score	ROUGE	
w/o COT w/o Graph retriever with G-Retriever	0.803 0.792 0.798	0.204 0.127 0.176	0.621 0.616 0.631	0.104 0.096 0.164	
LitFM-13b	0.819	0.224	0.766	0.177	

Case Study. In Appendix D, we conduct case study of LitFM and powerful LLMs (*e.g.*, GPT-3.5 turbo) on the citation sentence generation, title generation, abstract completion, and related work generation tasks.

Conclusion

In this paper, we develop the first literature foundation model LitFM that uniformly handle various citation graph-related tasks. It consists of a graph retriever and a knowledgeinfused LLM to avoid hallucinations and generalize to handle new papers outside the citation graph. Extensive experimental results demonstrate both the versatility of LitFM and its superior performance across six benchmark tasks.

Appendix A: Instruction Paradigm

As shown in Figure 6, we provide the detailed instruction prompt for each fine-tuning task. The instruction prompt can be seamlessly instantiated through the domain literature and used to inject domain-specific knowledge into the LLM. As illustrated in Figure 7, we provide detailed chain-of-thought instructions for related work generation.

Appendix B: Dataset Details

Extraction Procedure

Arxiv Papers To create the citation graphs for the CS and physics category, we start with a cleaning procedure that involves the following: 1) removing comments, 2) flattening LaTeX sources, 3) substituting user-defined macros with standard LaTeX commands, 4) eliminating LaTeX native commands, and 5) standardizing citation commands. Next, we identified and parsed the bibliography file (.bib) to create a dictionary mapping citation IDs to arXiv paper IDs. In cases where a .bib file was unavailable, we processed the .bbl file instead. If neither was present, we extracted inline citations using the LaTeX 'thebibliography' environment.

After extracting both the content and the citation library, we proceeded to locate citations within each paper. For each citation, we extracted the citing sentence and the local context (defined as the preceding and following sentences). Additionally, we extracted the "Related Work" sections from each paper. A related work section is identified by titles such as "Related Work," "Literature Review," "Related Research," "Existing Research," and 20 other possible variations we defined to find a match. If no match is found, we use the "Introduction" section as an alternative. Finally, for each citation, we provide an indicator variable that specifies whether the citation belongs to the related work section.

PubMed papers For PubMed Central papers, we begin our cleaning process by filtering out XML files that do not have PMIDs. Next, we unify the citation style, converting superscript numbers and author names to citations within brackets [\cdot]. Using regular expressions, we then extract citations and map them to the PMIDs of the papers in the graph. Similar to our approach with arXiv papers, we extract the citing sentence and local context for each citation. We also extract the related work section using the same procedure, mapping section titles to predefined possible matches, with the introduction taken as the default last resort. Finally, for each citation, we provide an indicator variable specifying whether the citation belongs to the related work section.

Examples

The statistics of our datasets are provided in Table 7. We further provide below an example of a node and an edge in each citation graph category. The [...] symbol is inserted below to reduce the size of the related work.

Vitrimers

Abstract: Bisphenol A epoxy resin cured with a mixture of dimerized and trimerized fatty acids is the first epoxy vitrimer and has been extensively studied. However, the cure behavior and thermal and mechanical properties of this epoxy vitrimer depend on the epoxy/acid stoichiometry. To address these issues, epoxy vitrimers with three epoxy/acid stoichiometries (9:11, 1:1 and 11:9) were prepared and recycled four times. Differential scanning calorimetry (DSC) was used to study the cure behavior of the original epoxy vitrimers. The dynamic mechanical properties and mechanical performance of the original and recycled epoxy vitrimers were investigated by using dynamic mechanical analysis (DMA) and a universal testing machine. Furthermore, the reaction mechanism of epoxy vitrimer with different epoxy/acid stoichiometry was interpreted. With an increase in the epoxy/acid ratio, the reaction rate, swelling ratio, glass transition temperature and mechanical properties of the original epoxy vitrimers decreased, whereas the gel content increased. The recycling decreased the swelling ratio and elongation at break of the original epoxy vitrimers. Moreover, the elongation at break of the recycled epoxy vitrimers decreased with the epoxy/acid ratio at the same recycling time. However, the gel content, tensile strength and toughness of the original epoxy vitrimers increased after the recycling. The mechanical properties of epoxy vitrimers can be tuned with the variation in the epoxy/acid stoichiometry.

Related Work: 1. Introduction Epoxy resin, one of the most important and popular classes of thermosetting polymers, is firmly rooted in many areas, both in our daily lives and in industry [1,2,3,4,5]. Due to its outstanding mechanical strength, dimensional and thermal stability, as well as creep, chemical and electrical insulation resistance, epoxy resin has been widely used in construction, adhesives, electronic and electrical devices, coatings, composites and so on [1,6,7,8,9,10]. However, due to their insoluble and infusible nature, the irreversible covalent networks restrict epoxy resin from being recycled and reprocessed [...] To investigate the effect of recycling on the solvent stability, thermal and mechanical properties of the original epoxy vitrimers, solvent immersion, dynamic mechanical analysis (DMA) and uniaxial tests were performed.

Edge ID: ('36234872', '28757995')

Sentence: To solve these problems, a thrust to develop a novel class of thermosetting polymers with recyclable, healable and reprocessable features has been carried out during the last two decades [11,12].

Preceding Sentence: Thus, most of the epoxy wastes are

Title: Semi-Mamba-UNet: Pixel-Level Contrastive Cross-Supervised Visual Mamba-based UNet for Semi-Supervised Medical Image Segmentation

Abstract: Medical image segmentation is essential in diagnostics, treatment planning, and healthcare, with deep learning offering promising advancements. Notably, Convolutional Neural Network (CNN) excel in capturing local image features, whereas Vision Transformer (ViT) adeptly model long-range dependencies through multi-head self-attention mechanisms. Despite their strengths, both CNN and ViT face challenges in efficiently processing long-range dependencies within medical images, often requiring substantial computational resources. This issue, combined with the high cost and limited availability of expert annotations, poses significant obstacles to achieving precise segmentation. To address these challenges, this

paper introduces the Semi-Mamba-UNet, which integrates a visual mamba-based UNet architecture with a conventional UNet into a semi-supervised learning (SSL) framework. This innovative SSL approach leverages dual networks to jointly generate pseudo labels and cross supervise each other, drawing inspiration from consistency regularization techniques. Furthermore, we introduce a self-supervised pixel-level contrastive learning strategy, employing a projector pair to further enhance feature learning capabilities. Our comprehensive evaluation on a publicly available MRI cardiac segmentation dataset, comparing against various SSL frameworks with different UNet-based segmentation networks, highlights the superior performance of Semi-Mamba-UNet. The source code has been made publicly accessible.

Related Work: Medical image segmentation is essential in enabling precise diagnostics and effective treatment strategies, and deep learning-based networks, particularly those based on the CNN-based UNet architecture, have been extensively investigated [...] The source code of Semi-Mamba-UNet and all baseline methods are made public available.\end{enumerate}

Edge ID: ('2402.07245', '1804.03999')

Sentence: For example, U-Net++ \cite{zhou2018unet++} introduces a nested UNet structure with deep supervision mechanisms, while Attention UNet \cite{oktay2018attention} incorporates attention gates to bolster the decoders' feature learning capabilities.

Title: Geometry induced domain-walls of dipole lattices on curved structures

Abstract: We investigate the ground state properties of rectangular dipole lattices on curved surfaces. The curved geometry can 'distort' the lattice and lead to dipole equilibrium configurations that strongly depend on the local geometry of the surface. We find that the system's ground state can exhibit domain-walls separating domains with different dipole configurations. Furthermore, we show how, regardless of the surface geometry, the domain-walls locate along the lattice sites for which the (Euclidean) distances to nearest and next-nearest neighbors are equal. We analyze the response of the domain-walls to an external electric field and observe displacements and splittings thereof below and above a critical electric field, respectively. We further show that the domain-wall acts as a boundary that traps low-energy excitations within a domain.

Related Work: Topology based concepts are widely used for the description of physical systems. A prominent example is that of domains and domain-walls (DW) arising from spontaneous symmetry breaking [....]. Finally, our results are summarized in Sec. \ref{Sec:Summary}.

Edge ID: ('2302.13728', '1510.04481')

Sentence: These studies range from experimental investigations (eg of the dipole equilibrium configurations in stacks of BTA (trialkylbenzene-1,3,5-tricarboxamide) molecules \cite{cornelissen2019,urbanaviciute2019})

to model systems, such as Hubbard models with long-range hopping terms \cite{ xiong1992,wang1991,stockhofe2015a,stockhofe2016, guo2020}.

Preceding Sentence: The first steps in this direction were already done in studies of dipoles confined to cylindrical or helical geometries.

Following Sentence: Already in such (comparatively) simple curved geometries, the GS properties show a strong dependence on the geometrical parameters: for example, for dipoles with fixed positions along a helical path, it was demonstrated that the GS configurations are described by a complex self-similar bifurcation diagram \cite{siemens2022}.

Visualizations

In this subsection, we provide visualizations of each academic graph. These visualizations highlight the graph density, the concentration of citations in specific fields, and the overall connectivity of the graphs. The visualization is performed using Yifan Hu's (Chen et al. 2024b) algorithm by taking a random connected subgraph of 30k nodes, with nodes in darker colors representing those with high indegree (i.e., citation counts), as seen in Fig. 8. As seen in the visualizations, the CS graph is the densest, mainly due to the surge of papers, most of which are available on arXiv. For physics, the graph is less dense because it focuses on a subcategory of general physics, and inter-domain physics papers are not captured. As for the medicine graph, the sparsity is due to the small number of nodes compared to the full graph. However, there is still a medium level of connectivity between the papers, with a concentration of citations among a small number of papers.

Appendix C: Implementation Details

Fine-tune LLM. We construct LitFM-7b and LitFM-13b by fine-tuning vicuna-7b and vicuna-13b on domain-specific literature through our proposed institution paradigm. During fine-tuning, the LLMs are loaded in 8-bits and the rank of LoRa is set as 8. Only the Q, K, V, and O matrices within a large language model will be updated during fine-tuning. We set the batch size to 2 with the maximum number of update steps to 40000, and the gradient accumulation step to 8. The learning rate is set as 0.0002 and we use AdamW (Loshchilov and Hutter 2017) for optimization. The scaling hyperparameter *lora_alpha* is set to 32, and the dropout rate during fine-tuning is set to 0.05. To construct the training instruction set for each citation graph dataset, we randomly sample 20,000 nodes from the citation graph and use the title and abstract part of each paper to construct the title generation instructions and the abstract completion instructions. We extract the induced subgraph of these nodes to construct other instructions. Specifically, each edge in the induced subgraph will be used to construct a positive citation link prediction instruction. Then, we replace the target node of the edge with a random node to construct a negative citation link prediction instruction. The ratio of positive to negative samples is set to 1:1. Each citation sentence generation instruction is constructed based on the citation sentence of each edge as well as the titles and abstracts of the connected nodes. For citation recommendation instructions, we randomly sample 10 negative nodes for each edge to construct the candidate set. These instructions will be gathered and shuffled during fine-tuning.

Graph retriever. We train the graph retriever model with Adam (Kingma and Ba 2014) optimizer. The number of training epochs is set as 500 and we use the early stopping strategy with a patience of 5. To integrate the text information, we use the pre-trained language model (i.e., BERTbase-uncased³) to get the representations of text attributes, and then these representations are used to initialize the embeddings of nodes and edges in models. The dimensions of the pre-trained representations are 768 and the maximum text length is set as 512. The BERT model is frozen during training. We set the number of negative samples and the maximum number of neighbor nodes as 10. We use random sampling to generate negative samples. We randomly split the edges in citation graphs into train/validation/test sets by 7:1.5:1.5 and select the best model based on the Precision@5 metric on the validation set.

Baselines. During inference, the baseline LLMs (e.g., vicuna 7b/13b and GPT) share the same instruction form as our LitFM. For all of them, we set the temperature as 0.7 and the nucleus sampling size (i.e., top_p) is set as 0.95, these two hyperparameters are used to control the randomness of LLMs' output. The repetition penalty is set as 1.15 to discourage the repetitive and redundant output. The maximum number of tokens that the LLM generates is set as 1024. We ran all the models five times with different random seeds and reported the average performance to eliminate deviations.

Appendix D: Case Study

Title and abstract generation. As shown in Figure 9, the red-colored text indicates the content that exists in the ground-truth title, and the green-colored text indicates the content that has not been included in the ground-truth title and abstract, which demonstrates the hallucinations of LLM. We can see that the title generated by LitFM is more similar to the ground-truth title without fake information, showcasing the effectiveness of our knowledgeinfused LLM in avoiding Knowledge hallucinations. Moreover, LitFM gets more brief titles than vicuna-13b and GPT-3.5 turbo, which may be because of the better summary ability of LitFM. Especially, in the second example, we can see that vicuna-13b suffers from the logical error. It wrongly describes the relationship between "Sensing and Communication" and "Multi-Domain Cooperation". Instead, LitFM can accurately infer relationships between different concepts.

In Figure 10, we can see that the generated abstract of LitFM can include the most concepts and keywords existing in the ground-truth abstract section. Because only limited information (i.e., the paper's title) is provided for the LLM to generate the abstract, all of these models inevitably contain hallucinations. However, compared with vicuna-13b and GPT-3.5 turbo, LitFM can more accurately predict the potential techniques and knowledge because of the Knowledge-infused LLM.

Citation sentence generation. In Figure 11, we provide the generation examples of different LLMs on the citation sentence generation task. There are two main observations: 1) Thanks to the Knowledge-infused LLM, LitFM can extract the main arguments of the paper and thus more accurately describe the previous work in the citation sentence. For example, LitFM accurately extracts the keyword "high resolution" from the cited paper. Instead, the generated sentences of vicuna-13b and GPT-3.5 turbo contain fake information such as "we extend these ideas to demonstrate ...". 2) Thanks to the graph retriever, LitFM can refer to the citation sentences of other papers and thus more accurately describe the relationship between papers. For example, in the second generation example, LitFM can accurately describe their relationships as "Following" rather than "In contrast to" and "Building on" generated by vicuna-13b and GPT-3.5 turbo. Related work generation. As illustrated in Figure 12, LitFM has several advantages in generating literature reviews compared with existing powerful LLM such as GPT-3.5 turbo. Firstly, It contains more domain-specific words such as "OLink proteomics", "scRNA-Seq", and "zeroforcing beamforming", showing that LitFM contains more domain-specific knowledge. Moreover, LitFM can generate related work sections with explicit citations, and all cited papers are extracted from the citation graph. However, the generation of GPT 3.5-turbo contains fake citations. Finally, LitFM shows more reasonable paragraph segmentation compared with GPT 3.5-turbo. This is because our COT strategy has explicitly asked the LitFM to group different papers based on their topic and thus achieves a better summary of these cited papers.

Abstract	Ground-truth	Vicuna-13b	GPT-3.5 turbo	LitFM-13b
We theoretically study the dynamics and spatio-temporal pattern formation of dissipative lattices of nonlinear optical microresonators and analyze the formation of dissipative structures, in particular dissipative Kerr solitons. We consider both equally coupled one-dimensional chains, as well as the topological Su-Schrieffer-Heeger model. We show the complexity of the four-wave mixing pathways arising in these systems with the increasing dimensionality due to the combined spatial and synthetic frequency dimension of each resonator, and show that it can be modeled using a two- dimensional variant of the Lagato1-lefter equation. We demonstrate the existence of two findamentally different dynamical regimes in one-dimensional chains - elliptic and hyperbolic - inherent to the system. In the elliptic regime, we generate hexagonal patterns and a two-dimensional dissipative Ker model, we generate hexagonal patterns and a two-dimensional dissipative Ker and that the presence of two- dimension leads to the observation of regularized wave collapse. Furthermore, we study similarities and differences between a one-dimensional collapsical lattice. We di- spatio-temporal mode1-locking and discuss its similarity to edge-state solitons in the two-dimensional tadda to topological lattice. We find that the presence of the second dimension leads to the observation of regularized wave collapse. Furthermore, we study similarities and differences between a one-dimensional topological lattice. But he suita soliton formation can both be impaired in trivial but, importantly, also topologically protected bands due to nonlinear bulk dege scattering. With the continuous increase of the spectrum and antennas, endogenous sensing is now possible in the fifth generation and future wireless communication systems. However, enseming is a highly complex task for a heterogeneous communication network with massive connections. Seeking multi-domain cooperation is necessary. In this article, we present an integrated sensing and communication (ISAC) system that performs active, passive, and interactive sensing in different studges about how multi-user and multi-frequency band cooperate to further enhance the ISAC system's performance. Finally, we elaborate on the advantages of multi-domain cooperation from the physical layer to the network layer for the ISAC system.	Integrated Sensing and Communication with Multi- Domain Cooperation	Integrated Sensing and Communication System for Multi- Domain Cooperation in Future Wireless Networks	Enhancing Integrated Sensing and Communication (ISAC) Systems: Multi- Domain Cooperation and Performance Optimization in Future Wireless Networks	Integrated Sensing and Communication System: Multi-Domain Cooperation
We analytically show how a superposition of beamlets produces terahertz radiation with greater spatial homogeneity and efficiency compared to tilted-pulse-fronts generated by diffraction gratings. The advantages are particularly notable for large pump bandwiths and beam sizes, alluding to better performance in the presence of cascading effects and higher energy pumping. A theory of terahertz generation using a superposition of beamlets is developed. It is shown how such an arrangement produces a distorion free tilted-pulse-front. Closed form expressions for terahertz spectra and transients in three spatial dimensions are derived. Conditions for obtaining performance parity and boands for optimal parameters are furnished. Adversarial Attacks on Deep Learning Based Power Allocation in a Massive MIMO Network	Deep learning (DL) is becoming popular as a new tool for many applications in wireless communication systems. However, for many classification tasks (e.g., modulation classification) it has been shown that DL-based wireless systems are susceptible to adversarial examples; adversarial examples are well-crafted malicious inputs to the neural network (NN) with the objective to cause erroneous outputs. In this paper, we extend this to regression problems and show that adversarial attacks can break DL-based power allocation in the downlink of a massive multiple- input-malitiple-output (mAMIMG) network. Specifically, we extend the fast gradient sign method (FGSM), momentum iterative FGSM, and projected gradient descent adversarial attacks in the context of power allocation in a maMIMO system. We benchmark the performance of thesa tacks and show that with a small perturbation in the input of the NN, the white-box attacks can outcetd in this work are based on an open dataset and NN models, which are publicly available.	Deep learning (DL) has emerged as a powerful tool for optimizing power allocation in wireless communication systems, particularly in the context of complex and dynamic environments. However, the vulnerability of DL models to adversarial attacks poses significant challenges to their reliability and security. This paper investigates the impact of adversarial attacks on DL-based power allocation strategies in wireless communication networks. We explore how carefully crafted perturbations can degrade the performance of DL models, leading to suboptimal or even detrimental power allocation decisions. Our study analyzes various types of adversarial attacks, and evaluates their effects on both the accuracy and robustness of DL models in different scenarios. We also discuss potential defense mechanisms to mitigate these attacks and improve the need for incorporating security considerations into the design of DL algorithms for wireless networks, ensuring that they can operate reliably even in the presence of adversarial threats.	Deep learning (DL) has emerged as a powerful tool for optimizing power allocation in massive multiple-input multiple-output (MIMO) networks, significantly improving network efficiency and performance. However, the deployment of DL models in real-world can lead to suboptimal or even catastrophic power allocation decisions. In this paper, we investigate the susceptibility of DL-based power allocation algorithms in massive MIMO networks to adversarial attacks. We explore various attack strategies and demonstrate their effectiveness in disrupting the performance of these algorithms. Our analysis includes both white-box and black-box attack scenarios, highlighting the potential risks posed by adversarially crafted inputs. To mitigate these risks, we propose a set of defense mechanisms designed to enhance the robustness of DL- based power allocation models. Through extensive simulations, we demonstrate that these defenses can significantly reduce the impact of adversarial attacks. Our findings underscore the importance of considering adversarial threats in the design and deployment of DL-based solutions in wireless communication systems.	Deep learning (DL) is becoming popular as a new tool for many applications in wireless communication systems. Howewer, it is known hat DL models are highly sensitive to adversarial attacks In this paper, we investigate the impact of adversarial attacks on DL-based power allocation in a massive multiple-input-multiple-output (MIMO) network. Firstly, we introduce two types of adversarial attacks, and then we formulate them as optimization problems. Secondly, we develop efficient algorithms to solve the formulate problems. Thirdly, we conduct simulations to evaluate the effectiveness of our proposed attacks. Our results indicate that both white-box and black- box attacks, an effectively degrade the performance of DL-based power allocation in a massive MIMO network.
U n i v ersal Sparse Superposition Codes with Spatial Coupling and GAMP Decoding	Sparse superposition codes, or sparse regression codes, constitute a new class of codes which was first introduced for communication over the additive white Gaussian noise (AWGN) channel. It has been shown that such codes are capacity- achieving over the AWGN channel under optimal maximum- likelihood decoding as well as under various efficient iterative decoding schemes equipped with power allocation or spatially coupled constructions. Here, we generalize the analysis of these codes to a much broader setting that includes all memoryless channels. We show, for a large class of memoryless channels, that spatial coupling allows an efficient decoder, based on the generalized approximate message-passing (GAMP) algorithm, to reach the potential (or Bayes optimal) threshold of the underlying (or uncoupled) code ensemble. Moreover, we argue that spatially computed sparse superposition codes universally achieve capacity under GAMP decoding by showing, through analytical computations, that the error floor vanishes and the potential threshold tends to capacity as one of the code parameter gees to infinity. Furthermore, we provide a closed form formula for the algorithmic threshold of the underlying code ensemble in terms of a Fisher information. Relate evolution analysis and uses the potential method developed in the theory of low-density parity- check (LDPC) codes and compressed sensing.	Sparse superposition codes have gained significant attention in recent years due to their a bility to achieve near-optimal performance while maintaining low complexity. These codes are characterized by having a small number of nonzero coefficients, making them well-suited for applications where memory efficiency and computational resources are limited. In this paper, we propose a novel approach to construct universal sparse superposition codes that can be used in various communication scenarios. Our method relies on spatial coupling techniques and generalized approximate message passing (GAMP) decoding to achieve high error correction capabilities. We demonstrate the effectiveness of our proposed codes through simulations and compare them against evisuing state-of-the-art methods. The results show that our codes outperform other approaches in terms of both performance and complexity, making them an attractive option for practical applications.	Sparse superposition codes (SSC) have emerged as a powerful technique in the realm of communication systems, offering near- optimal performance in various channels. This paper explores the integration of universal sparse superposition codes with spatial coupling and the Generalized Approximate Message Passing (GAMP) algorithm for decoding. Spatial coupling, a technique known to enhance the robustness and efficiency of codes, is combined with SSC to achieve better performance over a wide range of channel conditions. The GAMP decoding algorithm is utilized to decode the spatially coupled SSC, leveraging its computational efficiency and ability to handle large-scale systems. Through both theoretical analysis and simulation, we demonstrate that the proposed system achieves reliable communication at rates approaching the channel capacity, while maintaining computational feasibility. The results suggest that the integration of spatial coupling with SSC, decode via GAMP, offers a promising approach for future communication systems, particularly in scenarios demanding high reliability and efficiency.	Sparse superposition codes, or sparse regression codes, constitute a new class of codes which was first introduced for communication over the additive white Gaussian noise channel. These codes are now known to be universal, i.e., they achieve capacity over any memoryless channel under generalized approximate message-passing (GAMP) decoding. However, the GAMP decoder has never been explicitly designed for sparse superposition codes, in this work, we propose a novel GAMP decoder for sparse superposition codes, and we analyze its behavior on several channels. Our numerical simulations indicate that the GAMP decoder for chieves near-capacity performance on the AWGN channel, while it reach the Bayes optimal on the binary erasure channel. We also demonstrate that the GAMP decoder exhibits a vanishing error floor when the number of nonzero coefficients increases. Finally, we discuss the impact of the choice of the encoding matrix on the performance of the GAMP decoder.
Hybrid Combining Based on Constant Phase Shiflers and Active/Inactive Switches	In this paper, we propose a new hybrid analog and digital combining architecture for millimeter wave (mmWave) multi- user multiple-input multiple-output (MU-MIMO) systems. The proposed structure employs antenna subset selection per radio frequency (RF) chain based on active/inactive switches and uses constant phase shifters (CPS) to control the phases of signals in the RF circuit. In this scheme, for each RF chain, a subset of receive antennas that contribute more to the desired signal power than the interference power is chosen for signal combining in the analog domain, whereas other receive antennas are excluded from signal combining, hereby enhancing sum-rates. Simultaneously, the proposed structure reduces power consumption in the RF circuit by exclusively activating switches that correspond to the antennas selected for each RF chain. We also develop three low- complexity algorithms for per-RF chain antenna subset selection. Finally, through numerical simulation, we show that the proposed structure provides higher spectral efficiency and higher energy efficiency han conventional hybrid analog and digital combining schemes for mmWave MU-MIMO systems.	In this paper, we propose a new hybrid analog and digital combining architecture for milimeter wave (mmWave) multi- antena systems. The proposed architecture employs constant phase shifters and active/inacities witches to achieve efficient power combination while maintaining low complexity. Simulation results demonstrate that our proposed method outperforms existing techniques in terms of both performance and complexity. This work paves the way for practical implementation of high-gain mWave MIMO systems with reduced hardware requirements.	In this paper, we propose a novel hybrid combining architecture that integrates constant phase shifters with active and inactive switches for millimeter wave (mmWave) multi-user multiple input single output (MISO) systems. This architecture aims to enhance the performance of mmWave communication by leveraging the benefits of both analog and digital combining techniques. The proposed system optimizes beamforming and signal reception through a strategic combination of phase shifting and switching, which improves overall system efficiency and signal quality. Simulation results demonstrate the effectiveness of the hybrid approach in achieving significant gains in signal-to-noise ratio (SNR) and overall system capacity, making it a promising solution for advanced mmWave communication networks.	In this paper, we propose a new hybrid analog and digital combining architecture for millimeter wave (mrWave) multi-user multiple inpat single output (MISO) systems. The proposed architecture consists of two parts: an active part that uses constant phase shifters to combine the signals from different users at the transmitter side; and an inactive part that uses switches to selectively turn off some of the antennas at the receiver side. We first derive the optimal power allocation strategy based on the maximum ratio transmission (MRT) principle. Then, we analyze the performance of the proposed architecture by deriving closed form expressions for the achievable rate and outage probability. Simulation results show that our proposed architecture can achieve significant gains over conventional architectures with only one type of combining scheme. Moreover, it achieves similar or beter performance than the state-of-the-art hybrid analog and digital combining schemes while requiring fewer hardware components.

Observation of higher order exceptional points in pseudo- Hermitian radio- frequency circuits	Exceptional points (EP) in non-Hermitian system have been widely investigated due to her- enhanced sensitivity in comparison to standard systems. In his letter, we report the observation of higher-order pseudo-Hermitian degeneracies in an electronic platform comprised of three inductively coupled gain-loss-loss LC resonators. Theoretical analysis demonstrates that the proposed system can realize third-order EP with asymmetric coupling between adjacent inductors and an arbitrary scaling factor between two loss resonators. When capacitive perturbation is introduced on the middle resonator, the perturbed eigenfrequencies follow a cub-errol dependence on the perturbation parameter, in this case, the sensitivity is significantly greater than conventional wireless readout methods. Our work enriches the explorations of higher-order EP on electronic platforms and provides a new degree of design frequencing for the non-Hermitian-EP- enhanced wireless sensing system.	Generalized Parity- Time Symmetry Condition for Enhanced Sensor Telemetry	Wireless sensors based on micro-machined numble resonators are important in a variety of applications, ranging from medical diagnosis to industrial and environmental monitoring. The sensitivity of these devices is, however, roften limited by their low quality (Q) factor. Here, we introduce the concept of isospectual party time reciprocal scaling (PTX) symmetry and show that it can be used to build a new tamily of radiofrequency wireless microsensors. Authority and the sensitive sensitive sensors. We show theoretically, and the limitations of conventional passive sensors. We show theoretically using microelectromechanical based wireless pressure sensors, that PTX-symmetric electronic systems share the same eigenfrequencies as their parity ime (PT)- symmetric counterparts, but crucially have different criteriu profiles and eigenmodes. This simplifies the electronic circuit design and enables further enhancements to the extrinsic Q factor of the sensors.	Recently, it has been proposed that a PT-symmetry-based wireless sensing system can improve the resolution of the readout spectrum	R ecently, Paper A observed higher-order exceptional points in pseudo-Hermitian radio- frequency circuits, which showed e nhanced sensitivity in wireless sensing systems	Inspired by the concept of isospectal parity-time reciprocal scaling (PTX) symmetry, as discussed in (Paper B], we extend these ideas to demonstrate higher- order exceptional points in pseudo-Hermitian circuits	Recently, several studies have shown that the PT-symmetric systems possess unique properties such as un i di rec ti on al transmission, high resolution, and robustness against fabrication errors.
A. Data - Driven Statistic-Tochastic Surrogate Modeling Strategy for Complex N on J in ear N on- stationary Dynamics	We propose a statistical-stochastic surrogate modeling approach to predict the response of the menn and variance statistics under various initial conditions and external forcing perturbations. The proposed modeling framework extends the purely statistical modeling granorach that is practically limited to the homogeneous statistical regime for high-dimensional state variables. The new closure system allows one to overcome several practical issues that emerge in the non-homogeneous statistical regimes. First, the proposed ensemble modeling that couples the mean statistics and stochastic fluctuations naturally produces positive- definite covariance matrix estimation, which is a challenging issue that hampers the purely statistical modeling approaches. Second, the proposed closure model, which enbeds a non- Markovian neural-network model for the unresolved fluctus such that the variance of the dynamics is consistent, overcomes the inherent instability of the stochastic fluctuation dynamics. Effectively, the proposed framework extends the classical stochastic parametric modeling paradigm for the unresolved dynamics to a semi-parametric parameterizatial information meric, we provide an efficient and effective training procedure by fitting a loss function that measures the differences between response statistical Supporting munerical examples are provided with the Lorenz-96 model, a system of ODEs that admits the characteristic of chardis dynamics with both homogeneous and inhomogeneous satistical regimes. In the latter case, ve will see the effectiveneous of the statistical prediction event hough the resolved Fourier models corresponding to the leading mean energy and variance spectra do not coincide.	Machine Learning- Based Statistical Closure Models for Turbulent Dynamical Systems	We propose a Machine Learning (ML) non- Markovian closure modeling framework for accurate predictions of statistical responses of turbulent dynamical systems subjected to external foreings. One of the difficulties in this statistical closure problem is the lack of maining data, which is a configuration that is not desirable in supervised learning with the 40-dimensional Lorenz-96 model, the shortage of data (in temporal) is due to the stationarity of the statistics beyond the ecorer laits its intermets. We adopted a unified closure framework on various therained statistics we adopted a unified closure framework on various thort-time transien statistics. We adopted a unified closure framework we avail to adopted closure framework employ a Long-Short-Term-Memory architecture to ensideration secunds for the intrinsic instability yet producing stable long-time predictions. We found that its unified agnostic ML approach performs well under various truncation sequations unerically predi- tic long-time statistical. We found that is unified agnostic ML approach performs well under the long-time statistical responses subjected to various time-dependent external forces that are not (and maximum forcing amplitudes that are relatively larger than those) in the training dataset.	Following the work in vene (qi2022machine), we will consider the class of residual network with vanilla LSTM architecture.	In contrast to previous works [1, 2], our proposed statistical-stochastic surrogate modeling strategy effectively addresses the challenges associated with non- homogeneous statistical regimes, as demonstrated through supporting numerical examples with the Lorenz-96 model [3]	Building on the previous work, who proposed a machine learning-based closure modeling frame work for turbulent dynamical systems, our study extends the statistical-stochastic address non-homogeneous statistical regimes and improve covariance matrix estimation.	Following the same strategy as in vicie qi2024machine], we adopt a vanilla LSTM architecture to a proximate the unresolved dynamics
PtyLab: a cross- platform, open-source to o the source of the source to o the source of the source conventional and Fourier ptychography	Conventional (CP) and Fourier (FP) ptychography have emerged as versatile quantitative phase imaging techniques. While the main application cases for each technique are different, namely lens-less short wavelength imaging for CP and lens-based visible light imaging for FP, both methods share a common algorithmic ground. CP and FP have in part independently evolved to include experimentally robust forward models and inversion techniques. This separation has resulted in a plethora of algorithmic extensions, some of which have not crossed the boundary from one modality to the other. Here, we present an open source, cross-platform software, called PtyLab, enabling both CP and FP data analysis in a unified framework. With this framework, we aim to facilitate and acclerate cross-polliation between the two techniques. Moreover, the availability in Matlab, PtyMon, and Julia will set a low barrier to enter each field.	Using Automatic Differentiation as a General Framework for Ptychographic Reconstruction	Coherent diffraction imaging methods enable imaging beyond lens-imposed resolution limits. In these methods, the object can be recovered by minimizing an error metric that quantifies the difference between diffraction patterns as observed, and those calculated from a present guess of the object. Efficient minimization methods require analytical calculation of the derivatives of the error metric, which is not always straightforward. This limits our ability to explore variations of basic imaging approaches. In this paper, we propose to substitute analytical derivative expressions with the automatic differentiation method, where by we can achieve o bject reconstruction by specifying only the proposed method through straightforward object reconstruction for a variety of	Another line of research has investigated the capabilities opened up by modern automatic differentiation (AD) and machine learning (ML) toolboxes \cite{Kandel2019}.	Recent development in the field of ptychography is the introduction of PtyLab.	PtyLab builds on the automatic differentiation methods for ptychographic reconstruction introduced by [1].	Another example of a more recent development is the use of a utomatic differentiation and machine learning as a general framework for pty chog raphic reconstruction-cite [Ka ndcl2019]
Model discovery in the sparse sampling regime	To improve the physical understanding and the predictions of complex dynamic systems, such as predictions of complex dynamic systems, such as paramount interest to identify interpretable models from coarsely and off-grid sampled observations. In this work, we investigate how deep learning can improve model discovery of partial differential equations when the spacing between sensors is large and the samples are not placed on a grid. We show how leveraging physics informed neural network interpolation and automatic differentiation. allow to better fit the data and its spatiotemporal derivatives, compared to more classic spline interpolation and numerical differentiation dueld discover yallows to recover the underlying equations, even when sensors are placed further part than the data's characteristic and experimental data sets where combinations of physical processes such as (non)-linear advection, reaction, and diffusion are correctly identified.	SeiPy10-Fundamental Algorithms for Scientific Computing in Python	SuP) is an open source scientific computing lineary for the Python programming language. SciPy 10 was refeased in late 2017, about 16 years after the original version 0.1 refease. SciPy has become a de facto standard for leveraging scientific algorithms in the Python programming packages, over 100,000 dependent repositories, and millions of downloads per year. This includes usage of SciPy in almost half of all machine learning projects on GitHub, and usage by high profile projects including LIGO gravitational wave analysis indercation of the first-ever image of a black hole (M87). The library includes functionality agebra, image processing, some matrix handling, computational geometry, and statistics. In this work, we provide an overview of the capabilities and development practices of the SciPy library and highlight some recent technical	We would also like to thank the authors and contributors of Scipy (cite(scipy)) for making our work possible through their open-source software.	We cannot generate a citation sentence because there is no relationship or connection between the two papers	To address the challenges of interpolation and numerical differentiation in the sparse sampling regime, we utilize the SciPy library's advanced interpolation capabilities.	We have implemented the method long y described above in Python using the scipy libraryicite (scipy)

current strategy to treat immunogenergy as to intestinal cancerre perspectives for a new era	Since penhrolizama), as anti-programmed data). (PD- 1) anthody, aboved a dramite response to immunopenic cancers with microsatellitic instability-high (MSI-H) and/or deficient ismanch repari (MMR) in the plito clinical trial KEYNOTE-10.6, subsequent studies have confirmed durable texposses of anti-PO-1 inhibitors for MSI-H/dMMR shold tumors. As immunotherapy is for MSI-H/dMMR shold instability of the stat decade. An MSI/MMR status haben estabilished as the predictive biomarker for immune checkpoint blockades, playing an indipensable rol locally advanced of platients with MSI-H/dMMR tumors. Immunotherapy is also now investigated for locally advanced of platients with MSI-H/dMMR tumors. Immunotherapy is also now investigated for locally advanced of platients with MSI-H/dMMR tumors. Immunotherapy is also now investigated for locally advanced of platients with MSI-H/dMMR tumors. Immunotherapy is also now investigated for locally advanced of shift H/dMMR of a triang out hyperic text structure of microscience remains a future task, whereas attempts to overcome resistance and medrying mechanisms of resistance remains a future task, whereas attempts to overcome resistance and medrying mechanisms of resistance irritans with paper a trians of the ristance of methyperic propervices to further in their rationale, and discuss prepreseives for the further therapeutic development of treatment in this field.	 The advent of immunotherapy, particularly with the use of immune checkpoint inhibitors like pembrolizams, his revuluations de treatment of immunogenic acners, sequilably these with microstallile instability-high (MSI-H) and deficient mismatch repair (dMMR) status. The pivotal KEYNOTE-016 rul (Let al., 2013) domonstrated the emarchabe effettacy of pembrolizamsh in MSI-HdMMR cancers, setting the stage for subsequent studies that have consistently confirmed darable responses to immune checkpoint blances, locked studies that have consistently confirmed darable responses to immune checkpoint blances (Cohen et al., 2017). For thermore, the exploration into routine clinical practice, where it guides therapeutic decision in treating MSI-HdMMR trans et al., 2017). The significance of this biomarker has been underscored by its incorporation into outine clinical practice, where it guides therapeutic decision in treating MSI-HdMMR turns (Cohen et al., 2017). Theremore, the exploration of immunotherapy, e challenge that has been attributed to the presence of intrinsic or acquired resistance and the devolpment of base been attributed to the presence of intrinsic or acquired resistance mechanism. Receiven the MSI-HdMMR turns (2020). The ongoin genetic devolutions (Dira et al., 2017). Let al., 2020). The ongoin genetic devolution of the set excesses, not all patients with MSI-HdMMR gastrointestinal cancers has operated to a structure, for the set excesses, not all patients with MSI-HdMMR gastrointestinal cancers respond to immunotherapy, e challenge that has been attributed to the presence of intrinsic or acquired resistance and the devolpment of the cascense on underscored or minutotherapy is a structure to efficiency of munotherapy is called exploring combination therapies and novel agents to enhance the efficacy of immunotherapy is a challenge that has been attributed to accent excesse the solution of the accenters. Ander, T., Shiu, K. K., Kim, T. W., Jensen, B. V., Jonen, L. H., Punt, C., & Ta	Recent studies have focused on improving our understanding of the role of immune checkpoints in cancer and developing strategies to overcome them [1]. The use of biomarkers such as unor mutational burden (TMB) has shown promise in dentifying patients who may respond well to immunotherapy [1, 12]. Other research has examined the relationship between microstatellite instability (MSI) and immune checkpoint inhibitors, finding that these darge [2, 13]. Additionally, combining immune elsekpoint blockade with traditional cytotoxic agents has shown promising results in clinical trials for various cancer types, particularly in MSI-high solid tumors [3, 14]. Several studies have explored the potential of biomarkers such as programmed deadtional biomarkers for predicting response to immunotherapy, including mutations in bat2 microglobulin and homologous recombination deficiency [7, 8]. Combinatorial approaches involving multiple immune checkpoint industifying a lash been studied. [7, 8].	1. Massive Access in Secure NOM ander Imperfect CSI: Security Quaranteed S um - R at ee Maximization with F ir st - O r d e r Algorithm	Non-orthogonal multiple access (NOAA) is a promising solution for sever transmission under massive access. However, in addition to the uncertain channel state information (CSI) of the acvestoppers due to help imperfect at the base station due to the limited feedback. Under both channel uncertainties, the optimal provide the base station of the solution of the difficulty of handling the probabilistic constraints. This article filts thin gap to proposing nover transformation of the probabilistic constraints and variable decoupling so that the security guaranteed sum-rate maximization problem can be solved by alternatively executing branch- and-bound method and difference of convex match solution of the conventional motion that the security access scenario, a first-order algorithm with very low complexity in future proposed. Simulation results about the result the conventional method but save at least two orders of magnitude in computation time. Moreover, the result transmission scheme significandly improves the security guaranteed sum-rate compared to the obscing CSI uncertainty.	Massive access scenarios in wireless communication systems have poored significant challenges, particularly in to context of secure transmissions. Non-orthogonal multiple access (NOMA) has emerged as a key enabler for efficient spectrum utilization and enhanced connectivity in such scenarios (Ding et al. 2017). NOMA allows multiple users to share the same frequency resources by superposing their signals, hereby improving spectral efficiency. However, ensuing security in NOMA systems, especially under imperfect channel state information (CSI), remains a critical challenge. Existing research has addressed various aspects of NOMA in secure communication. For instance, Wang et al. (2018) analyzed secure transmission strategies in NOMA under perfect CSI, demonstrating the potential of NOMA to enhance secure cycle acquires (Dargared to orthogonal multiple access (OMA) schemes. However, these works often assume perfect CSI, demonstrating the potential of NOMA to enhance secure cycle acquires (Dargared to orthogonal multiple access (OMA) schemes. However, these works often assume perfect CSI, demonstrating the potential of NOMA to enhance secure cycle access (DAI). The proposed is notwal schemes that the secure access containce the secure rest in NOMA systems. Nonetheless, these approach related to restaining errors or feedback dulys (Zhang et al., 2019).	Non-orthogonal multiple access (NOMA) has here recognized as a promising solution for secure transmission under massive access [1][2]. However, the use of NOMA in practice faces challenges useh as the uncertainty of channel state information (CSI), which affects the performance of the system [3][4]. In particular, the CSI of the legitimetuses rans be imperfect due to the limited feedback at the base station [5], while the CSI of the exvederopper optimal power allocation and transmission rule design for a secure NOMA scheme remain unclear due to the difficulty of handling the probabilities constraints [7]. To address this challenge, sevent research efforts have focused on developing algorithms to solve the security-guaranteed sum-rate maximization problem in NOMA systems with imperfect CSI to suppress interference annouglistics [11]. Another strategy is in puly successive interference anneellation (SIC) within each charter to improve the system performance [12]. These techniques an to enhance the security and efficiency of NOMA-based communication systems.	1. Securing Downlink Massive MIMO-NOMA Networks with Artificial Noise 2.
