Testing quantum master equations for complete positivity: A direct approach

Timur V. Tscherbul

Department of Physics, University of Nevada, Reno, Nevada, 89557, USA

(Dated: October 2, 2024)

While quantum master equations (QMEs) are the primary workhorse in quantum information science, quantum optics, spectroscopy, and quantum thermodynamics, verifying complete positivity of the associated N-level quantum dynamical maps remains an outstanding challenge for $N \geq 3$. We address this challenge by establishing a direct mapping between the Liouvillian and Kossakowski matrices of an arbitrary Markovian QME. The mapping relies on the Moore-Penrose pseudo-inverse of a rectangular matrix composed of the structure constants of $SU(N)$. As an application, we establish complete positivity of the quantum optical Bloch-Redfield QME for a three-level V-system driven by incoherent light. Our approach makes it possible to test QMEs for complete positivity without solving them, and to restore complete positivity by keeping only non-negative eigenvalues of the Kossakowski matrix.

Quantum master equations (QMEs) describe the time evolution of a quantum subsystem of interest coupled to a (typically) much larger environment $[1-3]$ $[1-3]$. As such, they play a vital role in many areas of physics and chemistry, where the accurate description of environmental effects on quantum dynamics is essential, such as quantum information science $[4-14]$ $[4-14]$, quantum optics $[2, 15]$ $[2, 15]$ $[2, 15]$, quantum thermodynamics $[16–23]$ $[16–23]$, spectroscopy $[24–28]$ $[24–28]$, and chromophoric energy transport [\[29–](#page-6-3)[33\]](#page-6-4). When used within their respective domains of validity, QMEs offer a robust and physically meaningful description of environmentinduced relaxation and decoherence in N-level quantum systems $[1-3]$ $[1-3]$.

A crucial property of any QME is complete positivity (CP) of the quantum dynamical map associated with it [\[1–](#page-5-0)[3\]](#page-5-1). The CP condition requires not only that the reduced dynamics of a subsystem of interest be positive, but also that it remains so when the subsystem is entangled with arbitrary ancillae $[1-3]$ $[1-3]$. This condition is a defining property of a quantum channel [\[3\]](#page-5-1) and its violation can lead to unphysical effects, such as entanglement generation by purely local interactions [\[34,](#page-6-5) [35\]](#page-6-6) and violations of the second law of thermodynamics [\[22,](#page-6-7) [36\]](#page-6-8). Given recent advances in quantum thermodynamics [\[21,](#page-5-7) [23\]](#page-6-0) and quantum information processing [\[37,](#page-6-9) [38\]](#page-6-10) with multilevel quantum systems (qudits), the question of whether the dynamical map generated by a given QME satisfies the CP condition acquires critical importance.

In principle, this question can be resolved by mapping the QME's Liouvillian matrix (expressed in terms of relaxation and decoherence rates) to the so-called Kossakowski matrix A, which parametrizes the canonical Gorini-Kossakowski-Lindblad-Sudarshan (GKLS) generator of the quantum dynamical semigroup associated with the QME $[1]$. The dynamical map is CP if **A** has only nonnegative eigenvalues [\[1\]](#page-5-0). The Kossakowski matrix determines the key properties of the quantum dynamical map, and plays an essential role in, e.g., quantifying the extent of non-Markovianity of quantum evolutions [\[12,](#page-5-8) [39\]](#page-6-11).

While the analytical mapping between the Liouvillian and Kossakowski matrices is well-established for the twolevel system [\[1\]](#page-5-0), this is not the case for multilevel quantum systems $(N > 3)$. Although heroic efforts [\[1,](#page-5-0) pp. 69] did yield analytic expressions for the relaxation and decoherence rates in terms of the elements of the Kossakowski matrix for $N = 3$, these expressions are highly complicated and it is unclear whether these expressions can be inverted. As a result, Kossakowski matrices are presently calculated via indirect methods, which are applicable only to specific subclasses of QMEs, such as the secular QME [\[1\]](#page-5-0) and certain nosecular QMEs of the Bloch-Redfield type, both Markovian and non-Markovian [\[5,](#page-5-9) [6,](#page-5-10) [40–](#page-6-12)[42\]](#page-6-13). These QMEs are typically expressed in operator form, with the Kossakowski matrices expressed via Fourier transforms of environmental correlation functions. However, a limitation of these approaches is their lack of generality, i.e., it is not always clear whether a given QME can be expressed in one of the prescribed operator forms. Thus, calculating the Kossakowski matrices associated with multilevel QMEs from their Liouvillians remains an outstanding challenge [\[1\]](#page-5-0), preventing robust CP testing of the underlying quantum dynamical maps.

In 2007, Andersson, Cresser, and Hall showed that any time-local QME can be decomposed into Kraus operators, and thereby tested for CP by constructing the Choi matrix associated with its Kraus-type representation [\[43\]](#page-6-14). Specifically, a quantum dynamical map is CP if and only if the corresponding Choi matrix is positive [\[43,](#page-6-14) [44\]](#page-6-15). This method is applicable to a wide class of QMEs, including non-Markovian QMEs written in a time-local form (which can be obtained from the generalized Nakajima-Zwanzig-type QME via the time-convolutionless projection operator method [\[45–](#page-6-16)[48\]](#page-6-17)). However, the construction of the Choi matrix and the associated Kraus decomposition requires explicitly solving the QME [\[43\]](#page-6-14), which can be a computationally intensive task for multilevel QMEs. As such, applications of this approach have been limited to few-level systems [\[43\]](#page-6-14).

Here, we present a direct mapping between the Liouvillian and Kossakowski matrices of N-level Markovian QMEs. A key ingredient is the transformation tensor T expressed via the structure constants of $SU(N)$, whose Moore-Penrose preudoinverse transforms the Liouvillian

matrix of an N-level QME directly to its Kossakowski matrix. The latter can be diagonalized to provide the eigenvalues λ_i , and the associated quantum dynamical map proven to be CP if all $\lambda_i \geq 0$. Unlike the approach of Ref. [\[43\]](#page-6-14), our method does not require solving the QME. As such, it may be expected to be readily applicable to multilevel quantum systems, such as atoms and molecules interacting with environmental noise, for which the analytical or numerical solution of the QME can be impractical. As a nontrivial application of the approach, we establish the CP property of the quantum optical Bloch-Redfield QME [\[49\]](#page-6-18), which describes noiseinduced Fano coherences in multilevel quantum systems interacting with incoherent blackbody radiation [\[50–](#page-6-19)[57\]](#page-7-0). Finally, our method can be used to obtain regularized QMEs, whose quantum dynamical maps are guaranteed to be CP by discarding the negative eigenvalues of the Kossakowski matrix [\[12–](#page-5-8)[14\]](#page-5-3). Our approach makes it possible to apply the regularization procedure to any QME expressible in the GKLS form; all that it required is knowledge of its Liouvillian matrix.

Theory. We begin by specifying the general Markovian QME for the reduced density operator $\hat{\rho}$ of an N-level quantum system interacting with an environment $[1, 2]$ $[1, 2]$ $[1, 2]$

$$
d\hat{\rho}/dt = \hat{\mathbf{L}}\hat{\rho} = (\hat{\mathbf{L}}_H + \hat{\mathbf{L}}_D)\hat{\rho},\tag{1}
$$

where the time-independent Liouvillian \tilde{L} can be separated into the Hamiltonian $(\mathbf{L}_H = -i[\hat{H}_S, \hat{\rho}])$ and dissipative parts. The latter can be expressed in the GKLS form [\[1\]](#page-5-0)

$$
\hat{\mathbf{L}}_{D}\hat{\rho} = \frac{1}{2} \sum_{i,k} a_{ik} \left(2\hat{F}_{i}\hat{\rho}\hat{F}_{k} - \hat{\rho}\hat{F}_{k}\hat{F}_{i} - \hat{F}_{k}\hat{F}_{i}\hat{\rho} \right), \qquad (2)
$$

where a_{ik} are the elements of the Kossakowski matrix A , and the basis set $\{\hat{F}_i\}$ is composed of $M = N^2 - 1$ Hermitian traceless $N \times N$ matrices, which satisfy $\text{Tr}(\hat{F}_i \hat{F}_k^{\dagger}) =$ δ_{ik} [\[1\]](#page-5-0). For $N=3$, the basis matrices \hat{F}_i correspond to the generators of the SU(3) Lie group (the Gell-Mann matrices [\[58\]](#page-7-1)). Our goal is to obtain the matrix elements of **A** in terms of those of the Liouvillian $\hat{\mathbf{L}}_D$.

To this end, it is convenient to reformulate the QME in terms of the real coherence vector \bf{v} (identical to the Bloch vector for $N = 2$, whose components v_i are defined by the SU(N) decomposition of ρ [\[1,](#page-5-0) [59,](#page-7-2) [60\]](#page-7-3)

$$
\hat{\rho}(t) = \frac{1}{N}\hat{F}_0 + \sum_{i=1}^{M} v_i(t)\hat{F}_i
$$
\n(3)

The components of the coherence vector, $v_i(t)$ = $\text{Tr}(\hat{\rho}(t)\hat{F}_i)$ satisfy an inhomogeneous QME, which is equivalent to the original QME [\[1,](#page-5-0) [59,](#page-7-2) [60\]](#page-7-3)

$$
\dot{\mathbf{v}}(t) = [\mathbf{Q} + \mathbf{R}] \mathbf{v}(t) + \mathbf{k}, \tag{4}
$$

where \bf{k} is the driving vector and the matrix operators Q and R describe the Hamiltonian and dissipative evolution analogously to L_H and L_D in the density-matrix formulation [\(14\)](#page-2-0).

Using the identity $\hat{F}_m \hat{F}_n = \frac{1}{N} \hat{F}_0 \delta_{mn} + \frac{i}{2} \sum_{l=1}^{M} z_{mnl}^* \hat{F}_l$, where $z_{mnl} = f_{mnl} + id_{mnl}$, and

$$
f_{ijk} = -i\text{Tr}([F_i, F_j], F_k),
$$

\n
$$
d_{ijk} = \text{Tr}(\{F_i, F_j\}, F_k)
$$
\n(5)

are the symmetric and antisymmetric structure constants of SU(N) $[1, 59]$ $[1, 59]$ $[1, 59]$, we can express the elements of **R** and **k** in terms of those of $A \, [1, 59, 60]$ $A \, [1, 59, 60]$

$$
r_{sm} = \sum_{i,k=1}^{M} \mathcal{T}_{sm,ik} a_{ik} \quad (s, m = 1, ..., M), \qquad (6)
$$

$$
k_s = \frac{i}{N} \sum_{i,k=1}^{M} a_{ik} f_{kls} \quad (s = 1, ..., M), \tag{7}
$$

where

$$
\mathcal{T}_{sm,ik} = -\frac{1}{4} \sum_{l=1}^{M} [(f_{mnl} + id_{mnl}) f_{kls} + (f_{klm} - id_{klm}) f_{ils})],
$$
\n(8)

is an $M^2 \times M^2$ transformation tensor \mathcal{T} , which depends only on the symmetric and antisymmetric structure constants of $SU(N)$. To the author's knowledge, this tensor has not been explored beyond the two-level system. Its elements are subject to a set of constraints, which follow from the sum rules satisfied by the structure constants of $SU(N)$ as a compact semi-simple Lie group [\[58\]](#page-7-1). For example, one has, for $p = 1, \ldots, M$

$$
\sum_{i,k=1}^{M} \mathcal{T}_{sm,ik} f_{ikp} = iN d_{msp}/2.
$$
 (9)

We are interested in expressing the elements of the Kossakowski matrix a_{ik} in terms of the relaxation and decoherence rates $(r_{sm}$ and $k_s)$, which are available from either microscopic system-bath models or from experiment $[1]$. To this end, we note that Eqs. $(6)-(7)$ $(6)-(7)$ $(6)-(7)$ can be viewed as system of linear equations for the coefficients a_{ik} with the right-hand side given by the r_{sm} and k_s . Because of the constraints such as Eq. (9) , the complex square tensor $\mathcal T$ is not of full rank, and hence cannot be inverted, making the solution of linear equations $(6)-(7)$ $(6)-(7)$ $(6)-(7)$ a nontrivial task.

Note that Eq. [\(6\)](#page-1-0) can be written as a superoperator $\hat{\mathcal{T}}$ (or a process matrix [\[3\]](#page-5-1)), which acts on the Kossakowski matrix to produce the rate matrix, $\hat{T}A = R$. It is convenient to define vectorized (Liouville) representations [\[61\]](#page-7-4) of the Kossakowski and rate matrices $\boldsymbol{a} = \text{vec}(\mathbf{A})$ and $r_0 = \text{vec}(\mathbf{R})$, where the components a_α and $r_{0\alpha}$ are uniquely related to the elements of A and R , respectively, and $\alpha = \{ik\} = 1, \ldots, M^2$ is a composite index. We can now rewrite Eq. [\(6\)](#page-1-0) in vectorized notation as $Ta = r_0$, where the superoperator $\hat{\mathcal{T}}$ is represented by a square $M^2 \times M^2$ tensor $\mathcal T$ with elements $\mathcal T_{\alpha\beta}$ (note that the elements of ordinary $M \times M$ matrices, such as $\mathbf{A} = \{a_{ik}\},\$ are indexed by Latin letters).

FIG. 1. (a) Schematic structure of the matrix equation [\(11\)](#page-2-1). The complex rectangular matrix of $SU(N)$ structure constants T is composed of the complex $M^2 \times M^2$ transformation tensor $\mathcal T$ given by Eq. [\(8\)](#page-1-3) augmented by the $M \times M^2$ matrix [see Eq. (10)]. The right-hand side consists of the vectorized rate matrix $r_0 = \text{vec}(\mathbf{R})$ augmented at the bottom by the driving vector **k**. (b) Singular values of the tensor \mathcal{T} for $N = 3$. Note the presence of 8 zero singular values in the bottom right corner. The solid line is a guide to the eye.

Because the tensor $\mathcal T$ is not of full rank (see above), the linear system $\mathcal{T}a = r_0$ has infinitely many solutions. To obtain a unique solution, we need to specify M additional constraints, which come in the form of Eq. [\(7\)](#page-1-1). To incorporate these constraints, we define a rectangular tensor T with elements (the essential difference between the indices s and $\beta = \{ik\}$ is noted above)

$$
T_{\alpha\beta} = T_{\alpha\beta} \quad (\alpha, \beta = 1, \dots, M^2),
$$

$$
T_{M^2+s,\beta} = \frac{i}{3} f_{sik} \ (s = 1, \dots, M). \tag{10}
$$

As illustrated in Fig. $1(a)$, this definition amounts to augmenting the square tensor $\mathcal T$ with additional rows populated by the structure constants $(i/3) f_{sik}$ [see Eq. [\(10\)](#page-2-2)]. The system of linear equations $(6)-(7)$ $(6)-(7)$ $(6)-(7)$ can then be recast in tensor form

$$
Ta = r,\tag{11}
$$

where r is an augmented vectorized rate matrix with $r_{\alpha} = r_{0\alpha} = r_{ik}$ for $\alpha = 1, ..., M^2$ and $r_{M^2+s} = k_s$ [see Eqs. $(6)-(7)$ $(6)-(7)$ $(6)-(7)$].

The $(M^2+M)\times M^2$ complex rectangular tensor T has rank M^2 , and thus the vectorized Kossakowski matrix

 $a = \text{vec}(\mathbf{A})$ can be obtained as

$$
a = T^+ r,\tag{12}
$$

where

$$
\boldsymbol{T}^+ = (\boldsymbol{T}^\dagger \boldsymbol{T})^{-1} \boldsymbol{T}^\dagger \tag{13}
$$

is the Moore-Penrose pseudo-inverse of T [\[62–](#page-7-5)[64\]](#page-7-6) (the superscript $+$ should not be confused with that for Hermitian conjugation, \dagger). Equation [\(12\)](#page-2-3) gives the Kossakowski matrix $\mathbf{a} = \text{vec}(\mathbf{A})$ in terms of the relaxation and decoherence rates of a general-form QME encapsulated in r. It is the central result of this work.

Application to the quantum optical partial secular Bloch-Redfield QME. To flesh out the formalism developed above, we apply it to the quantum optical partial secular Bloch-Redfield (PSBR) QME [\[49\]](#page-6-18), which describes multilevel atoms and molecules interacting with incoherent radiation fields, such as blackbody radiation. This process plays a central role in photoexcitation of atoms, molecules, and photosynthetic light-harvesting complexes by solar light [\[50–](#page-6-19)[57,](#page-7-0) [65\]](#page-7-7). Significantly, these dynamics can generate the so-called noise-induced Fano coherences between nearly degenerate ground and/or excited states of a multilevel quantum system, even when the initial state of the system is a coherence-free thermal mixture [\[50–](#page-6-19)[57,](#page-7-0) [66\]](#page-7-8). The Fano coherences can strongly affect thermalization dynamics of a multilevel quantum system interacting with a bath, leading to anomalously slow approach to thermal equilibrium $[51, 54, 56]$ $[51, 54, 56]$ $[51, 54, 56]$ $[51, 54, 56]$ $[51, 54, 56]$, which occurs over multiple, often vastly different, timescales [\[51–](#page-6-20)[56,](#page-7-9) [67–](#page-7-10)[69\]](#page-7-11). The resulting coherent steady states can break detailed balance [\[50,](#page-6-19) [53,](#page-6-22) [55,](#page-7-12) [70\]](#page-7-13) thereby enhancing the efficiency of photovoltaic devices [\[70\]](#page-7-13). In addition, closely related pre-thermal states can have promising applications in quantum thermometry [\[71\]](#page-7-14).

However, even though CP of several PSBR equations has recently been established using alternative methods (see, e.g., $[40, 41]$ $[40, 41]$ $[40, 41]$), to our knowledge, it is an open question whether or not the dynamical map that corresponds to the quantum optical PSBR equations is CP. Here, we settle this question by using our key result [Eq. (12)] to explicitly calculate the Kossakowski matrix from the relaxation and decoherence rates. We show that the eigenvalues of the Kossakowski matrix are non-negative, establishing the CP property of the dynamical map.

The quantum optical PSBR equation for the threelevel V-system driven by a thermal bath is [\[49,](#page-6-18) [52,](#page-6-24) [66,](#page-7-8) [72\]](#page-7-15)

$$
\dot{\rho}_{ii} = -(r_i + \gamma_i)\rho_{ii} + r_i \rho_{33} - p(\sqrt{r_1 r_2} + \sqrt{\gamma_1 \gamma_2})\rho_{12}^R,
$$

\n
$$
\dot{\rho}_{12} = -i\rho_{12}\Delta - \frac{1}{2}(r_1 + r_2 + \gamma_1 + \gamma_2)\rho_{12} \qquad (14)
$$

\n
$$
+ \frac{p}{2}\sqrt{r_1 r_2}(2\rho_{33} - \rho_{11} - \rho_{22}) - \frac{p}{2}\sqrt{\gamma_1 \gamma_2}(\rho_{11} + \rho_{22}),
$$

\n
$$
\dot{\rho}_{13} = -\frac{1}{2}(2r_1 + r_2 + \gamma_1)\rho_{13} - \frac{p}{2}(\sqrt{r_1 r_2} + \sqrt{\gamma_1 \gamma_2})\rho_{23},
$$

\n
$$
\dot{\rho}_{23} = -\frac{1}{2}(r_1 + 2r_2 + \gamma_2)\rho_{23} - \frac{p}{2}(\sqrt{r_1 r_2} + \sqrt{\gamma_1 \gamma_2})\rho_{13},
$$

FIG. 2. (a) Schematic of the three-level V-system driven by incoherent radiation. (b) Nonzero eigenvalues of the Kossakowski matrix calculated using Eq. [\(12\)](#page-2-3) for the partial secular BR equation as a function of the ratio of spontaneous decay rates γ_1/γ_2 for collinear transition dipoles $(p = 1)$. The eigenvalues are plotted in the weak ($\bar{n} = 0.01$, solid lines), intermediate ($\bar{n} = 1$, circles), and strong ($\bar{n} = 100$, dashed lines) pumping regimes, where $\bar{n} = r_i/\gamma_i$ is the effective photon occupation number [\[50–](#page-6-19)[52\]](#page-6-24).

where $i = 1, 2$ denote the excited states of the V-system [see Fig. 2(a)], 3 stands for the ground state, r_i and γ_i are incoherent absorption and spontaneous emission rates, $\Delta = \omega_{12}$ is the excited-state energy splitting, $p = \mu_{31} \cdot \mu_{32}/(|\mu_{31}||\mu_{32}|)$ quantifies the alignment of transition dipole moments μ_{3i} , and ρ_{12}^R and ρ_{12}^I denote the real and imaginary parts of ρ_{12} [\[50](#page-6-19)[–52\]](#page-6-24). Equation [\(14\)](#page-2-0) is derived in the standard Born-Markov approximation, which is well-justified for multilevel quantum systems interacting with incoherent radiation fields [\[2,](#page-5-4) [49\]](#page-6-18). We retain the nonsecular population-to-coherence coupling terms proportional to p in Eq. [\(14\)](#page-2-0), which are responsible for the generation of Fano coherences [\[50,](#page-6-19) [51\]](#page-6-20).

To obtain the rate matrix \bf{R} and the driving vector **k** for the three-level V-system, we first define the eightcomponent coherence vector $\mathbf{v} = \sqrt{2}(\rho_{12}^R, -\rho_{12}^I, \frac{1}{2}(\rho_{11} - \rho_{12}^I))$ $(\rho_{22}), \rho_{13}^R, -\rho_{13}^I, \rho_{23}^R, -\rho_{23}^I, \frac{1}{\sqrt{12}}(\rho_{11} + \rho_{22} - 2\rho_{33}))^T$ in terms of the density matrix elements using the $SU(3)$ decomposition (3) , and then recast the QME (14) in the form of Eq. [\(4\)](#page-1-5), as described in the Supplemental Material [\[73\]](#page-7-16). The resulting 8×8 **R** matrix, whose elements are expressed in terms of r_i , γ_i , and p [\[73\]](#page-7-16), is vectorized to form the 64-component vector r_0 . The latter is subsequently augmented with the 8-component k vector to obtain the 72-component vector r on the right-hand side of Eq. [\(11\)](#page-2-1) (see above and Fig. 1).

The elements of the transformation tensor T are calculated using Eq. [\(10\)](#page-2-2) using the structure constants for the ${F_i}$ basis of SU(3) [\[1\]](#page-5-0). Next, the Moore-Penrose pseudoinverse of T is calculated using Eq. [\(13\)](#page-2-4). To verify the correctness of this procedure, we calculated the singular value decomposition of the 64×64 complex tensor $\mathcal T$ shown by the blue square in Fig. $1(a)$

$$
\mathcal{T} = \mathbf{U} \Sigma \mathbf{V}^{\dagger},\tag{15}
$$

where Σ contains the singular values of $\mathcal T$ and U and V are unitary matrices. Figure 1(b) shows that 8 of the 64 singular values of τ are zero. This is consistent with the expectation that the rank of \mathcal{T} is $M^2 - M$, with M additional constraints needed to define T (note that $M = N^2 - 1 = 8$ for the three-level system). We also verified that Eq. [\(11\)](#page-2-1) is consistent with Eq. (164) of Ref. [\[1,](#page-5-0) p. 69] (see also Ref. [\[74\]](#page-7-17)). To our knowledge, the authors of Refs. [\[1,](#page-5-0) [74\]](#page-7-17) expressed the Liouvillian matrix elements in terms of the a_{ik} for $N = 3$, and did not perform the crucial inversion step accomplished in this work [see Eq. [\(12\)](#page-2-3)], which gives the desired Kossakowski matrix in terms of relaxation and decoherence rates.

Figure 2(b) shows nonzero eigenvalues of the 8×8 Kossakowski matrix for the quantum optical PSBR equation [\(14\)](#page-2-0) calculated using this procedure. We observe that while most of the eigenvalues are zero, there are two positive eigenvalues, which increase monotonically as a function of the ratio of spontaneous emission rates γ_1/γ_2 . Importantly, the eigenvalues remain positive over wide intervals of parameters γ_1/γ_2 and \bar{n} , which indicates that the dynamical map generated by the quantum optical PSBR equations is CP across all dynamical regimes studied. In the weak pumping regime, where the incoherent pumping is much slower than spontaneous decay $(\bar{n} \ll 1)$ [\[51,](#page-6-20) [52\]](#page-6-24), one of the eigenvalues is much larger than the other. The gap between the eigenvalues closes with increasing the pumping rate. At $\bar{n} = 1$ the eigenvalues are within a factor of two of each other, and become very similar at $\bar{n} = 100$ [the dashed lines in Fig. 2(b)].

In summary, we have established a direct mapping from the Liouvillian to the Kossakowski matrix of an arbitrary N-level Markovian QME, thereby enabling straightforward CP testing of the associated quantum dynamical maps. Our approach is general in the sense that it does not require one to specify an operator form of the QME, and could be applied in a straightforward manner to many interesting QMEs, such as those, which occur in quantum thermodynamics [\[16–](#page-5-6)[23,](#page-6-0) [70\]](#page-7-13), photosynthetic energy transfer [\[29–](#page-6-3)[33\]](#page-6-4), and spectroscopy [\[24–](#page-6-1) [28\]](#page-6-2). All that is required in the Liouvillian matrix, which can be expressed in terms of relaxation and decoherence rates available either from experiments or via microscopic system-bath models $[1, 2]$ $[1, 2]$ $[1, 2]$. This will enable one to readily identify the regimes, in which the CP condition breaks down, and to apply the recently developed regularization methods [\[12](#page-5-8)[–14\]](#page-5-3) to restore CP evolution. An extension of this approach to non-Markovian QMEs [\[75–](#page-7-18)[77\]](#page-7-19) may also be fruitful.

The author is grateful to Suyesh Koyu, Amro Dodin, Paul Brumer, Mikhail Lemeshko, and Johannes Feist for stimulating discussions.

Supplemental Material

In this Supplemental Material (SM) we provide a derivation of the quantum optical partial secular Bloch-Redfield (PSBR) master equation for the coherence vector [\[1\]](#page-5-0) defined through the SU(3) decomposition of the density matrix

$$
\hat{\rho}(t) = \frac{1}{3}\hat{F}_0 + \sum_{i=1}^{M} v_i(t)\hat{F}_i
$$
\n(1)

where $M = N^2 - 1 = 8$, \hat{F}_0 is the unit 3×3 matrix, and $F_1 - F_8$ are 3×3 Hermitian traceless matrices, which we choose to be the Gell-Mann matrices [\[1\]](#page-5-0).

The components of the M-component coherence vector \bf{v} are defined as [\[1\]](#page-5-0)

$$
v_i(t) = \text{Tr}(\hat{\rho}(t)\hat{F}_i)
$$
\n(2)

as can be verified by substituting $\hat{\rho}(t)$ from Eq. [\(1\)](#page-1-6) and using the orthonormality property $\text{Tr}(\hat{F}_i \hat{F}_k^{\dagger}) = \delta_{ik}$. For example (omitting the time variable for brevity)

$$
v_1 = \text{Tr}(\hat{\rho}\hat{F}_1) = \text{Tr}\left[\begin{pmatrix} \rho_{11} & \rho_{22} & \rho_{33} \\ \rho_{21} & \rho_{22} & \rho_{23} \\ \rho_{31} & \rho_{32} & \rho_{33} \end{pmatrix} \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}\right] = \frac{1}{\sqrt{2}}(\rho_{12} + \rho_{21}) = \sqrt{2}\rho_{12}^R,
$$
(3)

where ρ_{12}^R denotes the real part of ρ_{12} . Proceeding in the same way, we obtain all 8 components of the coherence vector as √

$$
\mathbf{v} = \begin{pmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \\ v_6 \\ v_7 \\ v_8 \end{pmatrix} = \begin{pmatrix} \sqrt{2}\rho_{12}^R \\ -\sqrt{2}\rho_{12}^I \\ \frac{1}{\sqrt{2}}(\rho_{11} - \rho_{22}) \\ \sqrt{2}\rho_{13}^R \\ -\sqrt{2}\rho_{13}^I \\ \sqrt{2}\rho_{23}^R \\ -\sqrt{2}\rho_{23}^I \\ -\sqrt{2}\rho_{23}^I \end{pmatrix}
$$
(4)

To derive the equations of motion for the coherence vector, we begin with the PSBR equations for the density matrix of the V-system $(N = 3)$ driven by incoherent radiation [\[49](#page-6-18)[–52\]](#page-6-24) (see also the main text)

$$
\dot{\rho}_{ii} = -(r_i + \gamma_i)\rho_{ii} + r_i \rho_{33} - p(\sqrt{r_1 r_2} + \sqrt{\gamma_1 \gamma_2})\rho_{12}^R,
$$
\n
$$
\dot{\rho}_{12} = -i\rho_{12}\Delta - \frac{1}{2}(r_1 + r_2 + \gamma_1 + \gamma_2)\rho_{12}
$$
\n
$$
+ \frac{p}{2}\sqrt{r_1 r_2}(2\rho_{33} - \rho_{11} - \rho_{22}) - \frac{p}{2}\sqrt{\gamma_1 \gamma_2}(\rho_{11} + \rho_{22}),
$$
\n
$$
\dot{\rho}_{13} = -\frac{1}{2}(2r_1 + r_2 + \gamma_1)\rho_{13} - \frac{p}{2}(\sqrt{r_1 r_2} + \sqrt{\gamma_1 \gamma_2})\rho_{23},
$$
\n
$$
\dot{\rho}_{23} = -\frac{1}{2}(r_1 + 2r_2 + \gamma_2)\rho_{23} - \frac{p}{2}(\sqrt{r_1 r_2} + \sqrt{\gamma_1 \gamma_2})\rho_{13}.
$$
\n(5)

To obtain the equations of motion for the components of the coherence vector, we first separate the above equations into their real and imaginary parts, and then form their linear combinations to match the components in Eq. [\(4\)](#page-1-5). For example, the equation of motion for ρ_{13} becomes

$$
\dot{\rho}_{13}^R = -\frac{1}{2}(2r_1 + r_2 + \gamma_1)\rho_{13}^R - \frac{p}{2}(\sqrt{r_1r_2} + \sqrt{\gamma_1\gamma_2})\rho_{23}^R,
$$

\n
$$
\dot{\rho}_{13}^I = -\frac{1}{2}(2r_1 + r_2 + \gamma_1)\rho_{13}^I - \frac{p}{2}(\sqrt{r_1r_2} + \sqrt{\gamma_1\gamma_2})\rho_{23}^I,
$$
\n(6)

Multiplying these equations by \pm 2 and using Eq. [\(4\)](#page-1-5), we get

$$
\dot{v}_4 = \sqrt{2}\dot{\rho}_{13}^R = -\frac{1}{2}(2r_1 + r_2 + \gamma_1)\sqrt{2}\rho_{13}^R - \frac{p}{2}(\sqrt{r_1r_2} + \sqrt{\gamma_1\gamma_2})\sqrt{2}\rho_{23}^R = -\frac{1}{2}(2r_1 + r_2 + \gamma_1)v_4 - \frac{p}{2}(\sqrt{r_1r_2} + \sqrt{\gamma_1\gamma_2})v_6,
$$
\n
$$
\dot{v}_5 = -\sqrt{2}\dot{\rho}_{13}^I = -\frac{1}{2}(2r_1 + r_2 + \gamma_1)(-\sqrt{2})\rho_{13}^I - \frac{p}{2}(\sqrt{r_1r_2} + \sqrt{\gamma_1\gamma_2})\rho_{23}^I = -\frac{1}{2}(2r_1 + r_2 + \gamma_1)v_5 - \frac{p}{2}(\sqrt{r_1r_2} + \sqrt{\gamma_1\gamma_2})v_7,
$$
\n(7)

Proceeding in the same way for the other components of **v**, we obtain the dissipative part of the QME as [cf. Eq. (4) of the main text]

$$
\dot{\mathbf{v}}(t) = \mathbf{R}\mathbf{v}(t) + \mathbf{k},\tag{8}
$$

where the rate matrix \bf{R} is given by

where $\gamma_{12} = \sqrt{\gamma_1 \gamma_2}$, $r_{12} = \sqrt{r_1 r_2}$, $\bar{r} = \frac{1}{2}(r_1 + r_2)$, and $\bar{\gamma} = \frac{1}{2}(\gamma_1 + \gamma_2)$. Finally, the driving vector **k** is given by $\sqrt{\gamma_1 \gamma_2}$, $r_{12} = \sqrt{r_1 r_2}$, $\bar{r} = \frac{1}{2}(r_1 + r_2)$, and $\bar{\gamma} = \frac{1}{2}$

$$
\mathbf{k} = \begin{pmatrix} -\frac{p\sqrt{2}}{3}\gamma_{12} \\ 0 \\ -\frac{1}{3\sqrt{2}}(\gamma_1 - \gamma_2) \\ 0 \\ 0 \\ 0 \\ 0 \\ -\frac{1}{\sqrt{6}}(\gamma_1 + \gamma_2) \end{pmatrix} .
