

Figure 1: OptU PerfP (*ideal*).

Figure 2: Illustration of the relationships between random variables X, Y, M under different scenarios: PerfU (upper left points in Fig. ?? below), intermediate points on the Pareto frontier, and PerfP (lower right points in Fig. ??; typically the optimal solution will have $H(X|M) > I(X; Y)$).

This is the system model of the (linear) Kalman filter. At each time step the vertex vector \mathbf{x}_k is propagated to the new vertex estimation \mathbf{x}_{k+1} by multiplication with the constant vertex transition matrix \mathbf{A} . The vertex vector \mathbf{x}_{k+1} is additionally influenced by the control input vector \mathbf{u}_{k+1} multiplied by the input matrix \mathbf{B} , and the system noise vector \mathbf{w}_{k+1} . The system vertex cannot be measured directly. The measurement vector \mathbf{z}_k consists of the information contained within the vertex vector \mathbf{x}_k multiplied by the measurement matrix \mathbf{H} , and the additional measurement noise \mathbf{v}_k .
