

(a) SOA Layout (Static Structure Split): 6 memory transactions required

means coalesced (vector) access:

Requires only 1 transaction if simultaneously accessed by threads from the same warp, i.e.:
threads $\{ t_i, t_{i+1}, t_{i+2}, t_{i+3} \mid i \bmod 4 = 0 \}$

(b) Clustered Layout with Structure Split: 6 memory transactions required

For illustration purposes, we assume:

- Warp size: 4 threads (instead of 32 threads)
- Vector length: 32 bytes (instead of 128 bytes)
