

- $\hat{h} = \arg \min_h R(h)$  be the function that minimizes the expected risk.
- $h^* = \arg \min_{h \in \mathbb{H}} R(h)$  be the function in hypothesis space  $\mathbb{H}$  that minimizes the expected risk.
- $h^n = \arg \min_{h \in \mathbf{H}_n} R(h)$  be the function in hypothesis space  $\mathbf{H}_n$  that minimizes the expected risk.
- $h_I^n = \arg \min_{h \in \mathbf{H}_n} R_I(h)$  be the function in hypothesis space  $\mathbf{H}_n$  that minimizes the empirical risk.

The *total error* in AutoML can be decomposed as:

$$\mathcal{E}_{\text{total}} = \mathbb{E}[R(h_I^n) - R(\hat{h})] = \underbrace{\mathbb{E}[R(h^*) - R(\hat{h})]}_{\mathcal{E}_{\text{app}}(\mathbb{H})} + \underbrace{\mathbb{E}[R(h^n) - R(h^*)]}_{\mathcal{E}_{\text{opt}}(\mathbf{H}^n, \epsilon^n)} + \underbrace{\mathbb{E}[R(h_I^n) - R(h^n)]}_{\mathcal{E}_{\text{est}}(\mathbf{H}^n, I)}.$$

- The *approximation error*  $\mathcal{E}_{\text{app}}(\mathbf{H})$  measures how close the optimal function  $h^* \in \mathbb{H}$  can approximate the optimal learner  $\hat{h}$ .
- The *optimization error*  $\mathcal{E}_{\text{opt}}(\mathbf{H}^n, \epsilon^n)$  measures distance between optimal function  $h^n$  in  $\mathbf{H}^n$  to optimal function  $h^*$  in  $\mathbb{H}$ .
- The *estimation error*  $\mathcal{E}_{\text{est}}(\mathbf{H}^n, I)$  measures the effect of minimizing empirical risk  $R'(h)$  instead of expected risk  $R(h)$ .
