

Diagram illustrating the proposed U-Net architecture for low-resolution super-resolution. The network processes an input LR image through a series of convolutional layers (green arrows) and max pooling (red arrows) to extract features. The architecture includes skip connections (purple arrows) that concatenate the input features with the output of the decoder path. The final output is the Denoised Output LR image, which is added to the input LR image via a residual connection (indicated by a plus sign in a circle).

Legend:

- Green arrow: Conv 3x3, Leaky ReLU
- Orange arrow: Up conv 2x2
- Red arrow: Max pool 2x2
- Purple arrow: Skip / concatenation

Diagram illustrating the proposed network architecture. The input is a **Denoised Input LR** image. This input is processed by a **Conv** layer, followed by a sequence of **Attention Group** blocks. Skip connections (indicated by colored arcs) connect the input of each Attention Group to the output of the subsequent group. The final output of the Attention Groups is added to the original **Denoised Input LR** via a **Skip connection** (indicated by a black line and a circle with a plus sign). The result is then processed by a **Pixel Shuffle** layer and a final **Conv** layer to produce the **Output HR** image.
