Abstract

We present a new supergiant-rich stellar cluster hidden by extinction and christen it as Barbá 2, in honor of its discoverer Rodolfo Barbá. The cluster is at a distance of $7.39^{+0.65}_{-0.55}$ kpc and contains several supergiants, of which we provide spectral classifications for one blue, one yellow, and five red ones. The cluster extinction indicates an above-average grain-size ($R_{5495} \sim 3.7$), its age has a minimum value of 10 Ma, and its core radius is 0.84 ± 0.19 pc.

1 Motivation and summary

A decade ago, our colleague Rodolfo Barbá discovered two very interesting Galactic clusters. One of them is a large highly-extincted globular cluster, the Sequoia cluster which may be the remnant of a dwarf galaxy absorbed by the Milky Way (Barbá et al. 2019). The results for the other one, a young and massive cluster rich in supergiant stars, were never published, as Rodolfo unexpectedly passed away in December 2021. Having worked with Rodolfo on this project, we collected our previous analysis and combined it with new data, mostly from *Gaia*, and we present it here for the first time. In honor of Rodolfo, we christen the two clusters he discovered as Barbá 1 (Sequoia cluster) and Barbá 2 (new one). As Rodolfo was an active participant in the Villafranca project to identify and characterize Galactic OB stellar groups (Maíz Apellániz et al. 2020, 2022), we add Barbá 2 to that project and we assign it the catalog name Villafranca B-006 (Maíz Apellániz et al. 2025).

2 Discovery

Rodolfo discovered Barbá 2 scanning the plane of the MW using multi-wavelength surveys and looking for stellar clustering, possibly associated with warm dust. The region with $l = 287-292°$ (Fig. 1) is dominated on its western side by the Carina OB1 association, at a distance of 2.35 kpc, while the eastern half includes three prominent H II regions: NGC 3576,

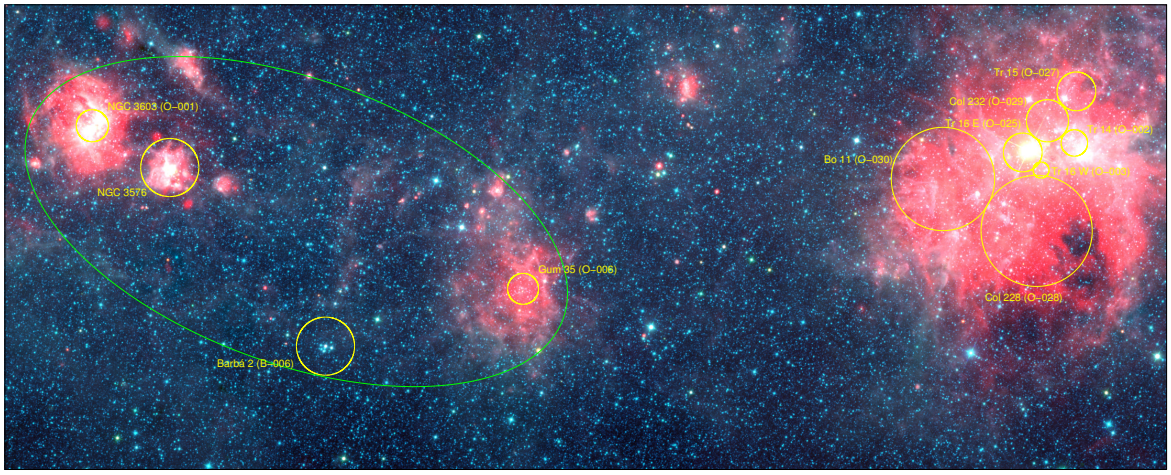

Figure 1: Three-color WISE W4 + W2 + W1 mosaic of the region with Galactic longitude between 287° and 292° (horizontal) and latitude between −2° and 0° (vertical). The intensity scale in each channel is logarithmic. Stellar groups are marked and labelled in yellow (with their Villafranca IDs in parentheses where relevant) and the proposed Carina distant OB association is marked in green.

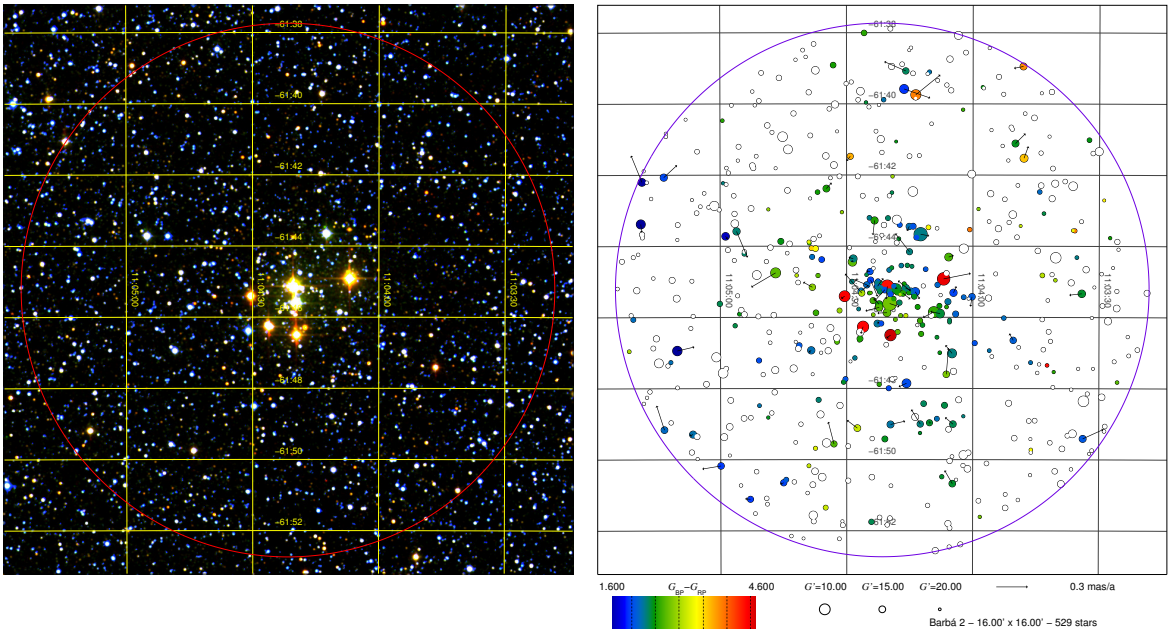

Figure 2: (left) Three-color $16' \times 16'$ 2MASS K + 2MASS J + DSS2 IR mosaic of Barbá 2. The outer circle has a radius of 7.5′. (right) *Gaia* DR3 chart of the proper-motion-selected sample of Barbá 2. Final cluster members are colored and non-members are empty. Symbol size represents G' magnitude, symbol color $G_{\rm BP} - G_{\rm RP}$, and arrows proper motion. Only proper motions for members with $G' < 17$ mag are shown and have the mean value for the cluster subtracted.

Table 1: Membership selection criteria.

α_c	=	166.090°
δ_c	=	−61.754°
r	=	7.5′
$\mu_{\alpha*,c}$	=	−5.89 mas/a
$\mu_{\delta,c}$	=	2.27 mas/a
r_μ	=	0.28 mas/a
C^*	<	0.40
RUWE	<	1.4
$\Delta(G_{BP} - G_{RP})$	>	−1.10 mag
$\lvert(\varpi_c - \varpi_g)/\sigma_{\varpi_g}\rvert$	<	3.0

Table 2: Membership and distance results.

N_*	529 first selection
	209 after isochrone cut
	204 final, norm. par. cut
t_ϖ	0.88
$t_{\mu_{\alpha*}}$	1.22
t_{μ_δ}	1.25
$\mu_{\alpha*,g}$	-5.893 ± 0.023 mas/a
$\mu_{\delta,g}$	2.271 ± 0.023 mas/a
ϖ_g	0.134 ± 0.011 mas
d	$7.39\ ^{+\ 0.65}_{-\ 0.55}$ kpc

at a distance similar to that of Carina OB1, and the more distant and richer NGC 3603 and Gum 35 (see Villafranca papers and Maíz Apellániz et al. 2025). All of them are in the Sagittarius arm and the overlap is caused by the proximity of the tangent (outside the field of view to the right). Rodolfo found Barbá 2 as a significant cluster between NGC 3603 and Gum 35 with seven bright stars and no warm dust associated. Based on their optical and NIR colors (Fig. 2), the cluster had a large extinction (the reason why it had not discovered before), with five of the bright stars likely being RSGs and the other two likely earlier-type SGs.

3 Membership selection with Gaia DR3

To select the Barbá 2 cluster members we follow a procedure similar to the one in Villafranca I+II. We first select based in proper motion (plus position and photometric and astrometric quality) using the criteria listed in the first block in Table 1. For the final selection we add a displaced isochrone cut and iteratively select the stars within 3 sigmas of the group

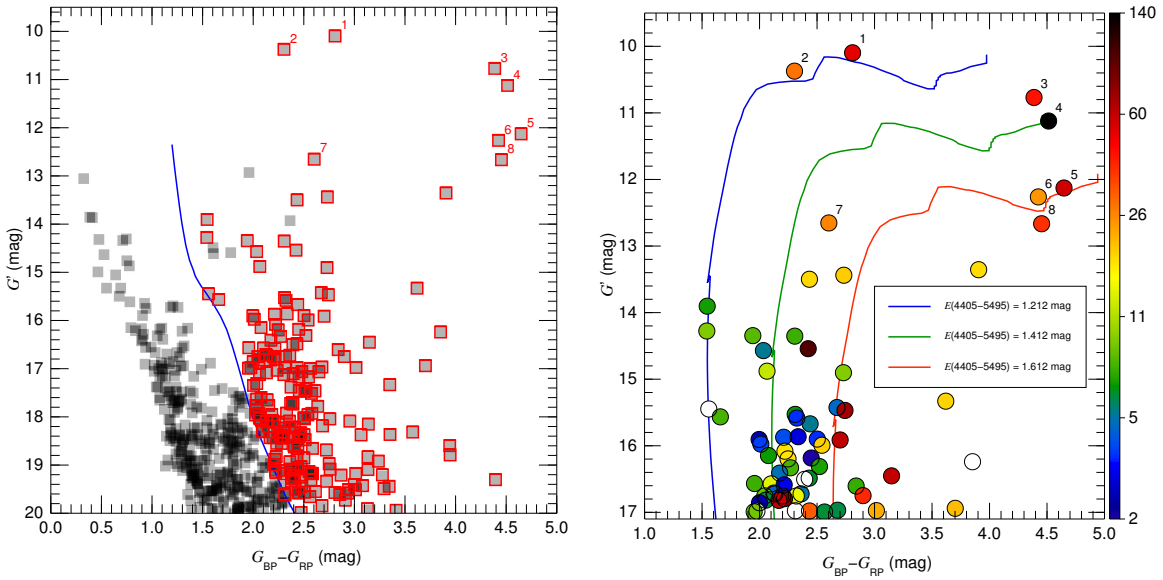

Figure 3: (left) *Gaia* DR3 CMD of Barbá 2 with both cluster and non-cluster members as filled gray squares and cluster members as unfilled red squares. The blue line shows the displaced isochrone used as one of the criteria to separate them. (right) Cluster-members CMD color-coded by σ_G from Maíz Apellániz et al. (2023) (color bar in mmag). The lines correspond to the 10 Ma isochrone with different values of $E(4405-5495)$, note the differential reddening. 2MASS J11041243−6143399 is located above its isochrone because of its $E(4405-5495) = 1.612 \pm 0.012$ mag. Empty symbols have no σ_G measured.

parallax. The selection criteria were iteratively chosen based on the observed *Gaia* values of the seven SGs and the surrounding objects. Results are shown in Figs. 2-4 and Table 2.

We apply the astrometric calibration of Maíz Apellániz et al. (2021b) and Maíz Apellániz (2022) for the parallaxes, the proper-motion corrections of Cantat-Gaudin & Anders (2020), and the photometric calibration of Maíz Apellániz & Weiler (2025). To calculate the distance we apply the prior of Maíz Apellániz (2001, 2005) with the parameters of Maíz Apellániz et al. (2008).

4 Membership results

We identify 201 cluster members and derive a distance of $7.39^{+0.65}_{-0.55}$ kpc. The cluster members are clearly concentrated near the core and the objects in the first sample excluded from the final sample are uniformly spread in the field (Fig. 2). The main criterion differentiating the cluster from the foreground population with a similar proper motion (which peaks at a distance about one half of the cluster, Fig. 4) is its higher extinction (Fig. 3). The normalized χ^2 test for the parallax, t_ϖ, is 0.88, indicating a well defined cluster with slightly overestimated uncertainties (Fig. 4).

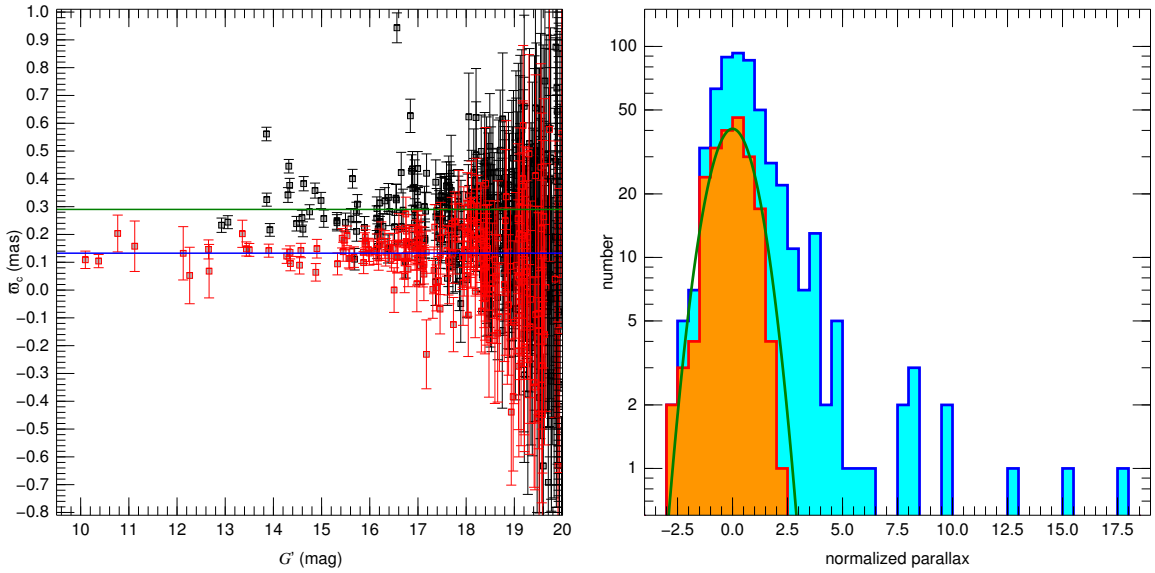

Figure 4: (left) *Gaia* DR3 G'-ϖ_c (corrected parallax) diagram of Barbá 2 with cluster and non-cluster members as filled gray squares, cluster members as unfilled red squares with error bars, and non-cluster members as unfilled black square with error bars. The blue line shows the group parallax ϖ_g for the cluster and the green line the weighted average parallax for the foreground population. (right) *Gaia* DR3 normalized parallax $[(\varpi_c - \varpi_g)/\sigma_{\varpi_g}]$ histogram of Barbá 2 for cluster (red-orange) and non-cluster (blue-cyan) members. The green curve shows the expected distribution for cluster members.

5 Results from FEROS spectroscopy

We obtained FEROS spectroscopy for seven of the brightest stars in Barbá 2. The spectra for the two bluest ones are shown in Fig. 5 and the results are given in Table 3. The brightest star is yellow supergiant and the other six are one blue osupergiant and five red supergiants.

6 Extinction analysis

We fitted the *Gaia* DR2+EDR3 G'_{BP}+G'+G'_{RP} + 2MASS $J + H + K$ photometry of 2MASS J11041243−6143399 using CHORIZOS (Maíz Apellániz 2004) to determine its luminosity class and its extinction parameters [$E(4405-5495)$ and R_{5495}, Fig. 6]. The value of R_{5495} indicates a dust grain size larger than average, but within the expected range for the value of $E(4405-5495)$ (Maíz Apellániz & Barbá 2018; Maíz Apellániz et al. 2021a). We also analyzed the behavior of the 7700 Å band (Maíz Apellániz et al. 2021a) for several likely B stars and established that its equivalent width increases with $G_{BP} - G_{RP}$ (an extinction proxy), indicating that there is differential extinction in Barbá 2 (Fig. 7).

Table 3: The eight brightest stars in $G_{\rm RP}$ in Barbá 2.

#	Name	*Gaia* DR3 ID	ST	LC

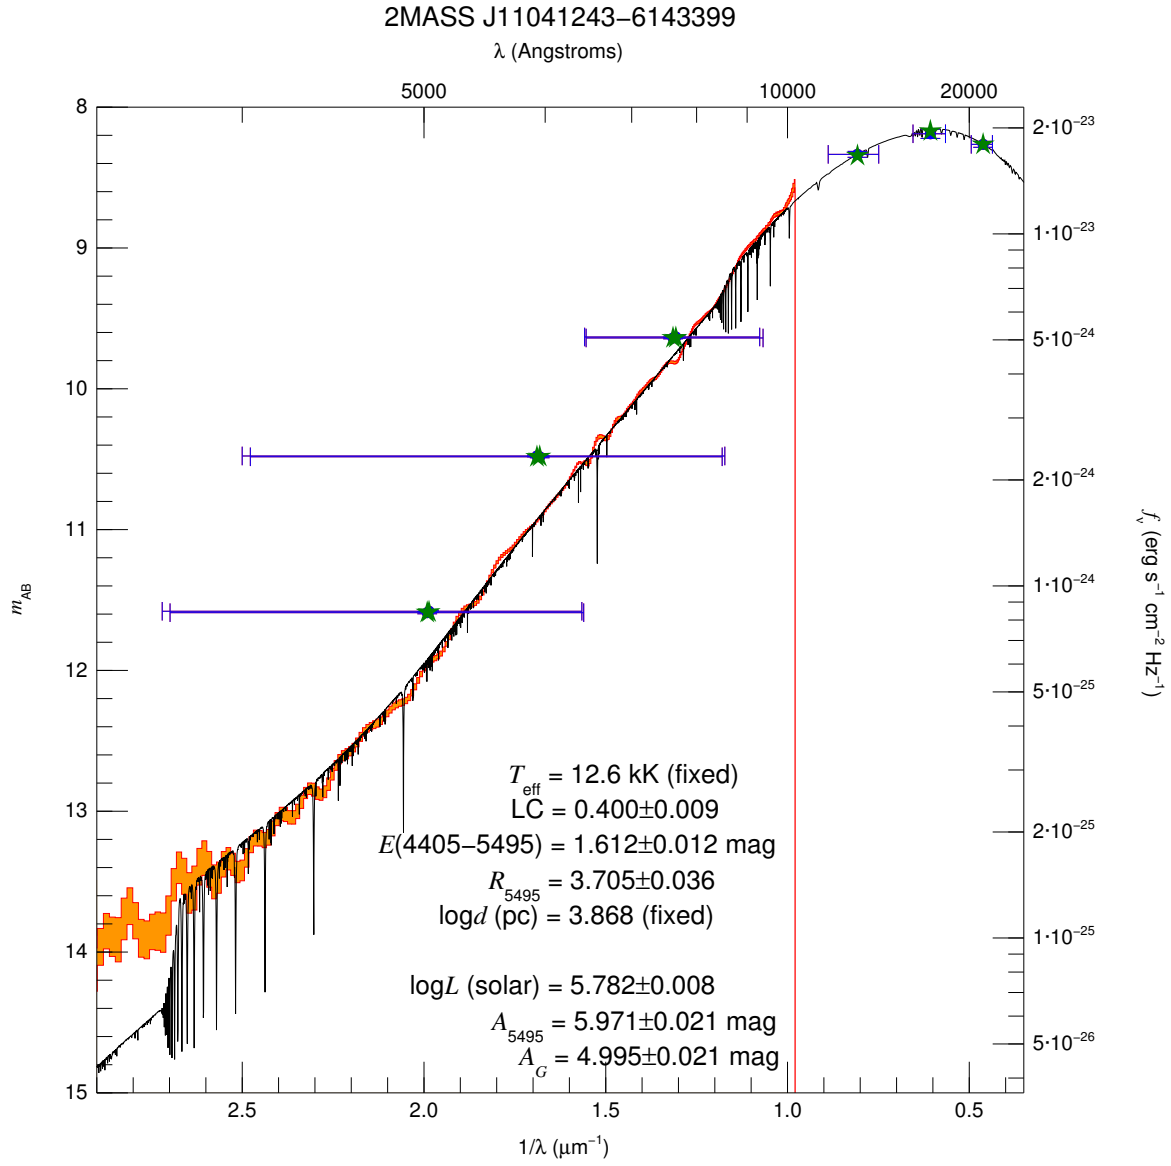

Figure 6: CHORIZOS fit and *Gaia* DR3 XP spectrophotometry (in orange) for comparison.

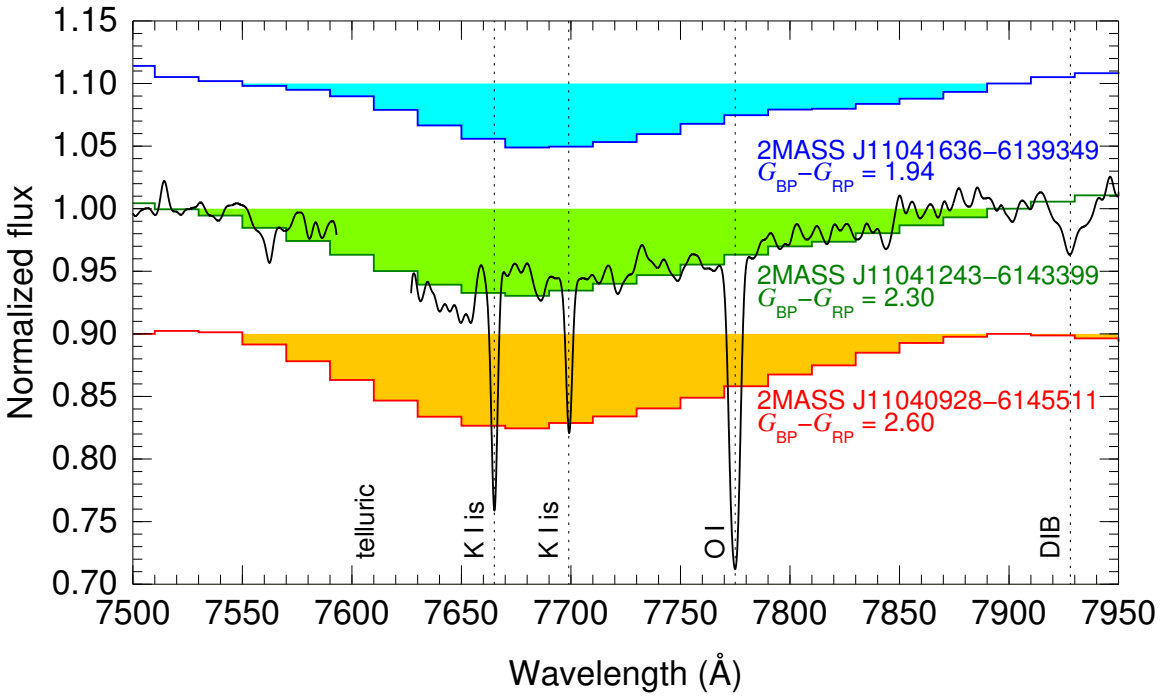

Figure 7: Rectified spectra of the 7700 Å region (Maíz Apellániz et al. 2021a) for three likely B-type stars in Barbá 2 sorted by color (as a proxy for extinction). The colored lines show the *Gaia* XP spectra and the black line the FEROS spectrum for the second star.

7 Age and variability

The presence of RSGs shows that Barbá 2 has a minimum age of ∼10 Ma (Fig. 3). Differential extinction manifests in a broadened MS and for that reason in Fig. 3 we plot three different values of $E(4405-5495)$ (all with R_{5495}= 3.705). The location of the RSGs in the CMD is consistent with an age of 10 Ma plus differential extinction. 2MASS J11041243−6143399 (with known extinction) is clearly above its corresponding isochrone (middle one), so it is likely a post-RSG object. Tyc 8958-00479-1 either has a low extinction or (more likely) is also a post-RSG object.

We plot in Fig. 3 the σ_G variability values from Maíz Apellániz et al. (2023). The RSGs are highly variable but so are the two possible post-RSG objects. Stars near the MS have, in general, low variability. The exceptions are likely eclipsing binaries or Be stars. For four bright stars with *Gaia* DR3 epoch photometry we show in Fig. 8 their variability plots.

8 Cluster structure

Barbá 2 has values of $t_{\mu_{\alpha*}}$ and t_{μ_δ} just over 1.0. This indicates that Barbá 2 does not show strong internal motions in the plane of the sky and is not expanding or includes a

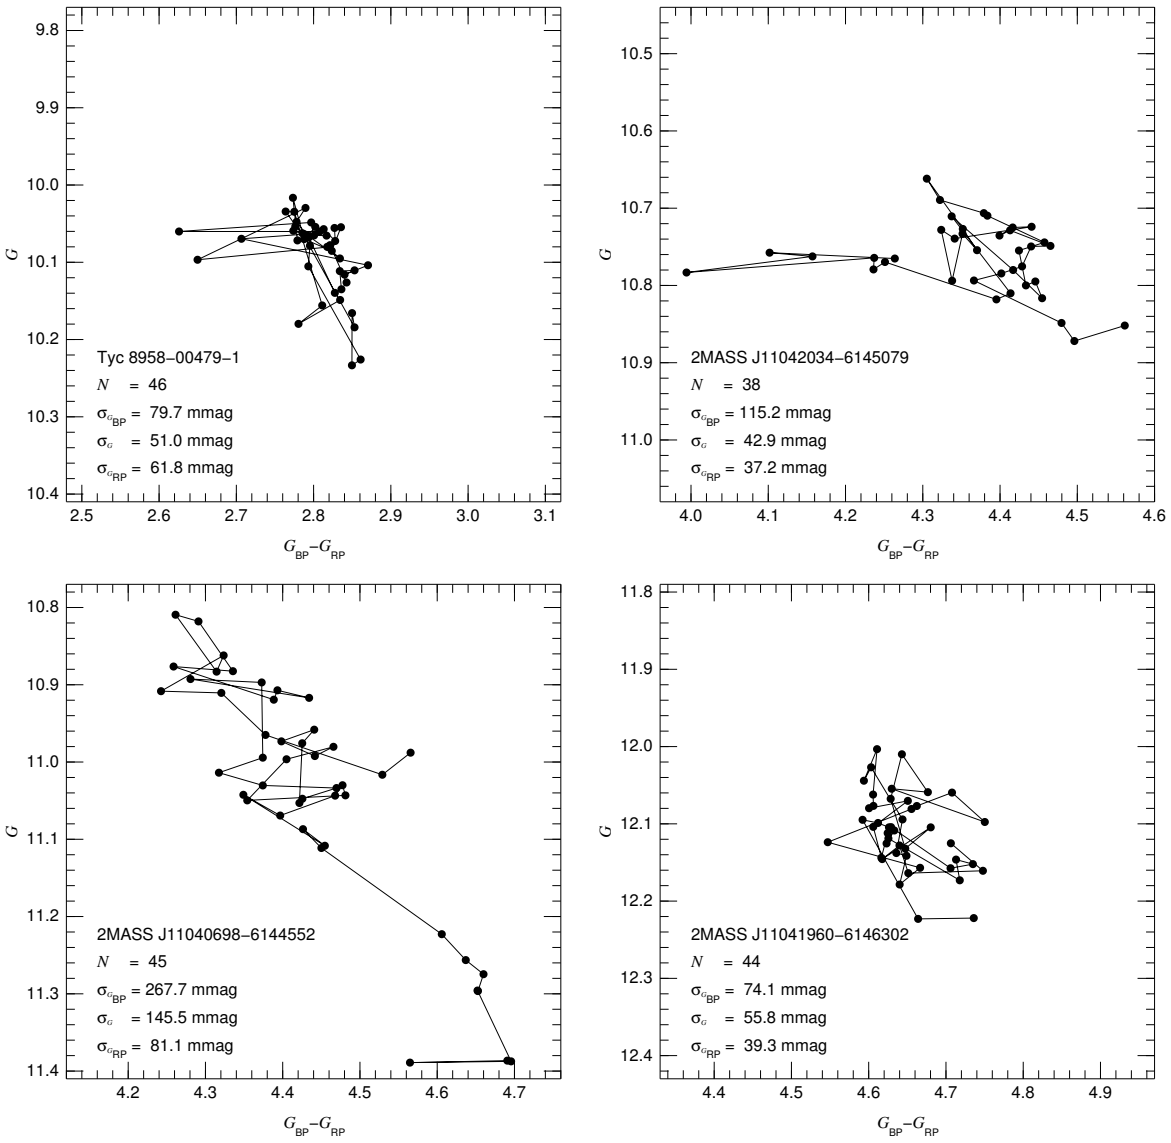

Figure 8: *Gaia* DR3 epoch variability plots (see Fig. 11 in Eyer et al. 2019) for four bright stars in Barbá 2. All panels have the same range in both axes (0.64 mag).

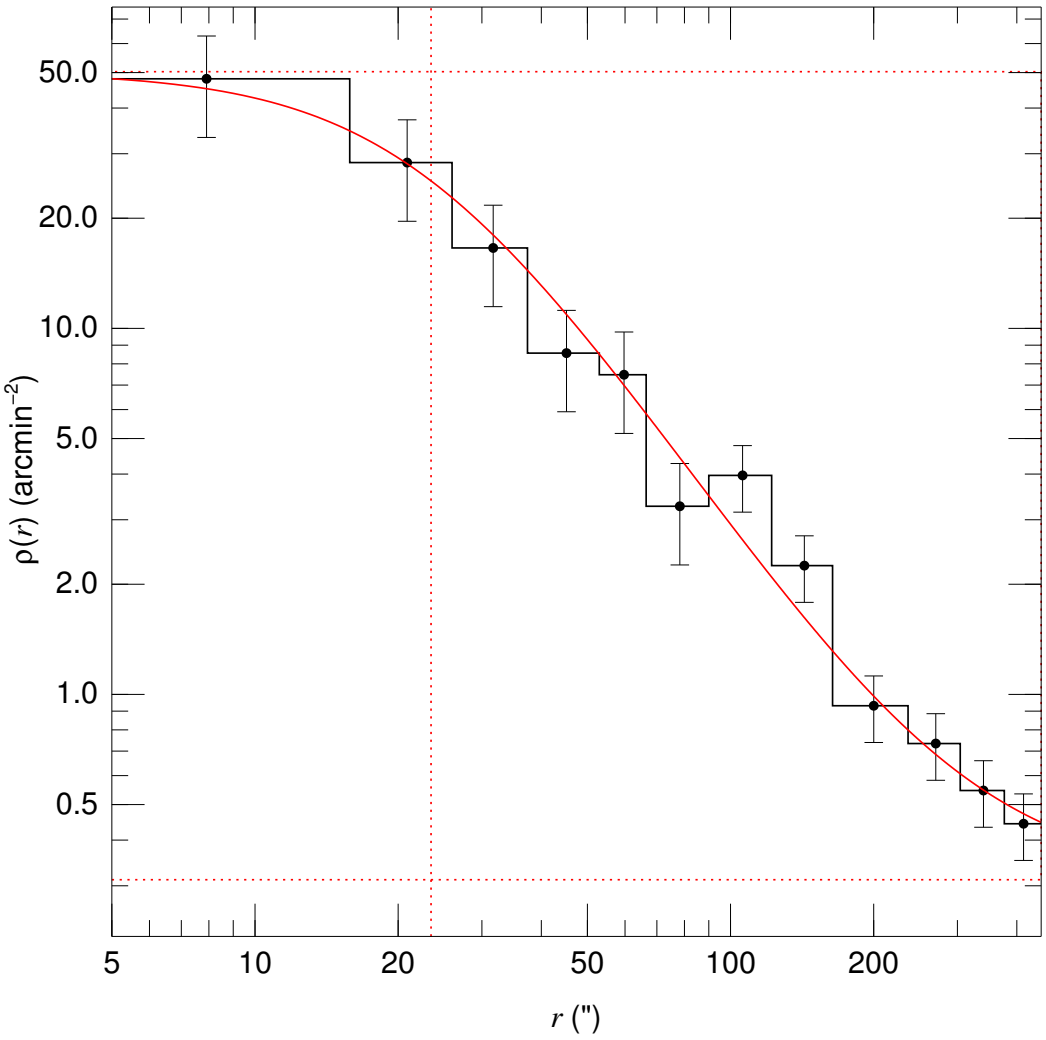

Figure 9: King profile fitting to the Barbá 2 *Gaia* sample. $r_c = 23.5 \pm 5.3'' = 0.84 \pm 0.19$ pc, $f_0 = 50 \pm 14$ stars/arcmin^2, $f_b = 0.3 \pm 0.1$ stars/arcmin^2

significant number of walkaway/runaway stars in the field. We have fitted a King profile:

$$\rho(r) = f_{\rm b} + \frac{f_0}{1 + (r/r_{\rm c})^2} \quad (1)$$

to the cluster members selected above (Fig. 9). We obtain a core radius of 0.84 ± 0.19 pc, compact for open clusters in general but relatively common for a young one. The value of $f_{\rm b}$ indicates that 53 ± 18 of the selected cluster members ($26 \pm 9\%$) are contaminants or belong to an extended population.
