Note that the last five values in `x` are samples of a parabola, so when `mode='interp'` (the default) is used with `polyorder=2`, the last three values are unchanged. Compare that to, for example, `mode='nearest'`:

```
>>> savgol_filter(x, 5, 2, mode='nearest')
array([ 1.74,  3.03,  3.54,  2.86,  0.66,  0.17,  1.  ,  4.6 ,  7.97])
```

`scipy.signal.deconvolve` (*signal, divisor*)

Deconvolves divisor out of signal.

Returns the quotient and remainder such that `signal = convolve(divisor, quotient) + remainder`

<b>Parameters</b>	<b>signal</b> : array_like	Signal data, typically a recorded signal
	<b>divisor</b> : array_like	Divisor data, typically an impulse response or filter that was applied to the original signal
<b>Returns</b>	<b>quotient</b> : ndarray	Quotient, typically the recovered original signal
	<b>remainder</b> : ndarray	Remainder

See also:

[`numpy.polydiv`](#)

performs polynomial division (same operation, but also accepts `poly1d` objects)

### Examples

Deconvolve a signal that's been filtered:

```
>>> from scipy import signal
>>> original = [0, 1, 0, 0, 1, 1, 0, 0]
>>> impulse_response = [2, 1]
>>> recorded = signal.convolve(impulse_response, original)
>>> recorded
array([0, 2, 1, 0, 2, 3, 1, 0])
>>> recovered, remainder = signal.deconvolve(recorded, impulse_response)
>>> recovered
array([ 0.,  1.,  0.,  0.,  1.,  1.,  0.,  0.])
```

`scipy.signal.sosfilt` (*sos*, *x*, *axis=-1*, *zi=None*)

Filter data along one dimension using cascaded second-order sections

Filter a data sequence, *x*, using a digital IIR filter defined by *sos*. This is implemented by performing `lfilter` for each second-order section. See `lfilter` for details.

**Parameters**

**sos** : array\_like  
Array of second-order filter coefficients, must have shape  $(n\_sections, 6)$ . Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

**x** : array\_like  
An N-dimensional input array.

**axis** : int, optional  
The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.

**zi** : array\_like, optional  
Initial conditions for the cascaded filter delays. It is a (at least 2D) vector of shape  $(n\_sections, \dots, 2, \dots)$ , where  $\dots, 2, \dots$  denotes the shape of *x*, but with `x.shape[axis]` replaced by 2. If *zi* is None or is not given then initial rest (i.e. all zeros) is assumed. Note that these initial conditions are *not* the same as the initial conditions given by `lfilter` or `lfilter_zi`.

**Returns**

**y** : ndarray  
The output of the digital filter.

**zf** : ndarray, optional  
If *zi* is None, this is not returned, otherwise, *zf* holds the final filter delay values.

**See also:**

`zpk2sos`, `sos2zpk`, `sosfilt_zi`, `sosfiltfilt`, `sosfreqz`

**Notes**

The filter function is implemented as a series of second-order filters with direct-form II transposed structure. It is designed to minimize numerical precision errors for high-order filters.

New in version 0.16.0.

**Examples**

Plot a 13th-order filter's impulse response using both `lfilter` and `sosfilt`, showing the instability that results from trying to do a 13th-order filter in a single stage (the numerical error pushes some poles outside of the unit circle):

```
>>> import matplotlib.pyplot as plt
>>> from scipy import signal
>>> b, a = signal.ellip(13, 0.009, 80, 0.05, output='ba')
>>> sos = signal.ellip(13, 0.009, 80, 0.05, output='sos')
>>> x = signal.unit_impulse(700)
>>> y_tf = signal.lfilter(b, a, x)
>>> y_sos = signal.sosfilt(sos, x)
>>> plt.plot(y_tf, 'r', label='TF')
>>> plt.plot(y_sos, 'k', label='SOS')
>>> plt.legend(loc='best')
>>> plt.show()
```

`scipy.signal.sosfilt_zi(sos)`

Compute an initial state  $zi$  for the `sosfilt` function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters** `sos` : array\_like  
Array of second-order filter coefficients, must have shape  $(n\_sections, 6)$ . See `sosfilt` for the SOS filter format specification.

**Returns** `zi` : ndarray  
Initial conditions suitable for use with `sosfilt`, shape  $(n\_sections, 2)$ .

**See also:**

`sosfilt`, `zpk2sos`

**Notes**

New in version 0.16.0.

**Examples**

Filter a rectangular pulse that begins at time 0, with and without the use of the  $zi$  argument of `scipy.signal.sosfilt`.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sos = signal.butter(9, 0.125, output='sos')
>>> zi = signal.sosfilt_zi(sos)
>>> x = (np.arange(250) < 100).astype(int)
>>> f1 = signal.sosfilt(sos, x)
>>> f2, zo = signal.sosfilt(sos, x, zi=zi)

>>> plt.plot(x, 'k--', label='x')
>>> plt.plot(f1, 'b', alpha=0.5, linewidth=2, label='filtered')
>>> plt.plot(f2, 'g', alpha=0.25, linewidth=4, label='filtered with zi')
```

```
>>> plt.legend(loc='best')
>>> plt.show()
```

`scipy.signal.sosfiltfilt` (*sos*, *x*, *axis=-1*, *padtype='odd'*, *padlen=None*)

A forward-backward filter using cascaded second-order sections.

See `filtfilt` for more complete information about this method.

**Parameters**    *sos* : array\_like

Array of second-order filter coefficients, must have shape (n\_sections, 6). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

*x* : array\_like

The array of data to be filtered.

*axis* : int, optional

The axis of *x* to which the filter is applied. Default is -1.

*padtype* : str or None, optional

Must be 'odd', 'even', 'constant', or None. This determines the type of extension to use for the padded signal to which the filter is applied. If *padtype* is None, no padding is used. The default is 'odd'.

*padlen* : int or None, optional

The number of elements by which to extend *x* at both ends of *axis* before applying the filter. This value must be less than `x.shape[axis] - 1`. `padlen=0` implies no padding. The default value is:

```
3 * (2 * len(sos) + 1 - min((sos[:, 2] == 0).sum(),
                             (sos[:, 5] == 0).sum()))
```

The extra subtraction at the end attempts to compensate for poles and zeros at the origin (e.g. for odd-order filters) to yield equivalent estimates of *padlen* to those of `filtfilt` for second-order section filters built with `scipy.signal` functions.

**Returns**        *y* : ndarray

The filtered output with the same shape as *x*.

**See also:**

`filtfilt`, `sosfilt`, `sosfilt_zi`, `sosfreqz`

**Notes**

New in version 0.18.0.

`scipy.signal.hilbert` ( $x$ ,  $N=None$ ,  $axis=-1$ )

Compute the analytic signal, using the Hilbert transform.

The transformation is done along the last axis by default.

**Parameters**

- x** : array\_like  
Signal data. Must be real.
- N** : int, optional  
Number of Fourier components. Default: `x.shape[axis]`
- axis** : int, optional  
Axis along which to do the transformation. Default: -1.

**Returns**

- xa** : ndarray  
Analytic signal of  $x$ , of each 1-D array along  $axis$

**See also:**

`scipy.fftpack.hilbert`

Return Hilbert transform of a periodic sequence  $x$ .

**Notes**

The analytic signal  $x_a(t)$  of signal  $x(t)$  is:

$$x_a = F^{-1}(F(x)2U) = x + iy$$

where  $F$  is the Fourier transform,  $U$  the unit step function, and  $y$  the Hilbert transform of  $x$ . [R235]

In other words, the negative half of the frequency spectrum is zeroed out, turning the real-valued signal into a complex signal. The Hilbert transformed signal can be obtained from `np.imag(hilbert(x))`, and the original signal from `np.real(hilbert(x))`.

**References**

[R235], [R236], [R237]

**Examples**

In this example we use the Hilbert transform to determine the amplitude envelope and instantaneous frequency of an amplitude-modulated signal.

```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import hilbert, chirp

>>> duration = 1.0
>>> fs = 400.0
>>> samples = int(fs*duration)
>>> t = np.arange(samples) / fs
```

We create a chirp of which the frequency increases from 20 Hz to 100 Hz and apply an amplitude modulation.

```
>>> signal = chirp(t, 20.0, t[-1], 100.0)
>>> signal *= (1.0 + 0.5 * np.sin(2.0*np.pi*3.0*t))
```

The amplitude envelope is given by magnitude of the analytic signal. The instantaneous frequency can be obtained by differentiating the instantaneous phase in respect to time. The instantaneous phase corresponds to the phase angle of the analytic signal.

```

>>> analytic_signal = hilbert(signal)
>>> amplitude_envelope = np.abs(analytic_signal)
>>> instantaneous_phase = np.unwrap(np.angle(analytic_signal))
>>> instantaneous_frequency = (np.diff(instantaneous_phase) /
...                             (2.0*np.pi) * fs)

>>> fig = plt.figure()
>>> ax0 = fig.add_subplot(211)
>>> ax0.plot(t, signal, label='signal')
>>> ax0.plot(t, amplitude_envelope, label='envelope')
>>> ax0.set_xlabel("time in seconds")
>>> ax0.legend()
>>> ax1 = fig.add_subplot(212)
>>> ax1.plot(t[1:], instantaneous_frequency)
>>> ax1.set_xlabel("time in seconds")
>>> ax1.set_ylim(0.0, 120.0)
    
```

`scipy.signal.hilbert2(x, N=None)`

Compute the '2-D' analytic signal of  $x$

**Parameters**

- x** : array\_like  
2-D signal data.
- N** : int or tuple of two ints, optional  
Number of Fourier components. Default is `x.shape`

**Returns**

- xa** : ndarray  
Analytic signal of  $x$  taken along axes (0,1).

### References

[R238]

`scipy.signal.decimate(x, q, n=None, ftype='iir', axis=-1, zero_phase=None)`

Downsample the signal after applying an anti-aliasing filter.

By default, an order 8 Chebyshev type I filter is used. A 30 point FIR filter with Hamming window is used if `ftype` is 'fir'.

**Parameters**

- x** : ndarray

**q** : int The signal to be downsampled, as an N-dimensional array.

The downsampling factor. For downsampling factors higher than 13, it is recommended to call `decimate` multiple times.

**n** : int, optional The order of the filter (1 less than the length for ‘fir’). Defaults to 8 for ‘iir’ and 30 for ‘fir’.

**ftype** : str {‘iir’, ‘fir’} or `dlti` instance, optional  
If ‘iir’ or ‘fir’, specifies the type of lowpass filter. If an instance of an `dlti` object, uses that object to filter before downsampling.

**axis** : int, optional The axis along which to decimate.

**zero\_phase** : bool, optional Prevent phase shift by filtering with `filtfilt` instead of `lfilter` when using an IIR filter, and shifting the outputs back by the filter’s group delay when using an FIR filter. A value of `True` is recommended, since a phase shift is generally not desired. Using `None` defaults to `False` for backwards compatibility. This default will change to `True` in a future release, so it is best to set this argument explicitly.

**Returns** **y** : ndarray New in version 0.18.0.  
The down-sampled signal.

**See also:**`resample` Resample up or down using the FFT method.`resample_poly`

Resample using polyphase filtering and an FIR filter.

**Notes**

The `zero_phase` keyword was added in 0.18.0. The possibility to use instances of `dlti` as `ftype` was added in 0.18.0.

`scipy.signal.detrend` (*data*, *axis=-1*, *type='linear'*, *bp=0*)

Remove linear trend along axis from data.

**Parameters** **data** : array\_like

The input data.

**axis** : int, optional

The axis along which to detrend the data. By default this is the last axis (-1).

**type** : {‘linear’, ‘constant’}, optionalThe type of detrending. If `type == 'linear'` (default), the result of a linear least-squares fit to *data* is subtracted from *data*. If `type == 'constant'`, only the mean of *data* is subtracted.**bp** : array\_like of ints, optionalA sequence of break points. If given, an individual linear fit is performed for each part of *data* between two break points. Break points are specified as indices into *data*.**Returns** **ret** : ndarray

The detrended input data.

**Examples**

```
>>> from scipy import signal
>>> randgen = np.random.RandomState(9)
```

```

>>> npoints = 1000
>>> noise = randgen.randn(npoints)
>>> x = 3 + 2*np.linspace(0, 1, npoints) + noise
>>> (signal.detrend(x) - noise).max() < 0.01
True
    
```

`scipy.signal.resample(x, num, t=None, axis=0, window=None)`

Resample  $x$  to  $num$  samples using Fourier method along the given axis.

The resampled signal starts at the same value as  $x$  but is sampled with a spacing of  $\text{len}(x) / num * (\text{spacing of } x)$ . Because a Fourier method is used, the signal is assumed to be periodic.

**Parameters**

- x** : array\_like  
The data to be resampled.
- num** : int  
The number of samples in the resampled signal.
- t** : array\_like, optional  
If  $t$  is given, it is assumed to be the sample positions associated with the signal data in  $x$ .
- axis** : int, optional  
The axis of  $x$  that is resampled. Default is 0.
- window** : array\_like, callable, string, float, or tuple, optional  
Specifies the window applied to the signal in the Fourier domain. See below for details.

**Returns**

- resampled\_x or (resampled\_x, resampled\_t)  
Either the resampled array, or, if  $t$  was given, a tuple containing the resampled array and the corresponding resampled positions.

**See also:**

[`decimate`](#) Downsample the signal after applying an FIR or IIR filter.

[`resample\_poly`](#)

Resample using polyphase filtering and an FIR filter.

### Notes

The argument *window* controls a Fourier-domain window that tapers the Fourier spectrum before zero-padding to alleviate ringing in the resampled values for sampled signals you didn't intend to be interpreted as band-limited.

If *window* is a function, then it is called with a vector of inputs indicating the frequency bins (i.e. `fft-freq(x.shape[axis])`).

If *window* is an array of the same length as  $x.\text{shape}[\text{axis}]$  it is assumed to be the window to be applied directly in the Fourier domain (with dc and low-frequency first).

For any other type of *window*, the function `scipy.signal.get_window` is called to generate the window.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from  $dx$  to  $dx * \text{len}(x) / num$ .

If  $t$  is not `None`, then it represents the old sample positions, and the new sample positions will be returned as well as the new samples.

As noted, `resample` uses FFT transformations, which can be very slow if the number of input or output samples is large and prime; see `scipy.fftpack.fft`.

### Examples

Note that the end of the resampled data rises to meet the first sample of the next cycle:

```

>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f = signal.resample(y, 100)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'go-', xnew, f, '-.', 10, y[0], 'ro')
>>> plt.legend(['data', 'resampled'], loc='best')
>>> plt.show()

```

`scipy.signal.resample_poly(x, up, down, axis=0, window=('kaiser', 5.0))`

Resample  $x$  along the given axis using polyphase filtering.

The signal  $x$  is upsampled by the factor  $up$ , a zero-phase low-pass FIR filter is applied, and then it is downsampled by the factor  $down$ . The resulting sample rate is  $up / down$  times the original sample rate. Values beyond the boundary of the signal are assumed to be zero during the filtering step.

<b>Parameters</b>	<b>x</b> : array_like	The data to be resampled.
	<b>up</b> : int	The upsampling factor.
	<b>down</b> : int	The downsampling factor.
	<b>axis</b> : int, optional	The axis of $x$ that is resampled. Default is 0.
	<b>window</b> : string, tuple, or array_like, optional	Desired window to use to design the low-pass filter, or the FIR filter coefficients to employ. See below for details.
<b>Returns</b>	<b>resampled_x</b> : array	The resampled array.

See also:

[`decimate`](#) Downsample the signal after applying an FIR or IIR filter.  
[`resample`](#) Resample up or down using the FFT method.

### Notes

This polyphase method will likely be faster than the Fourier method in `scipy.signal.resample` when the number of samples is large and prime, or when the number of samples is large and *up* and *down* share a large greatest common denominator. The length of the FIR filter used will depend on  $\max(\text{up}, \text{down}) // \text{gcd}(\text{up}, \text{down})$ , and the number of operations during polyphase filtering will depend on the filter length and *down* (see `scipy.signal.upfirdn` for details).

The argument *window* specifies the FIR low-pass filter design.

If *window* is an array\_like it is assumed to be the FIR filter coefficients. Note that the FIR filter is applied after the upsampling step, so it should be designed to operate on a signal at a sampling frequency higher than the original by a factor of  $\text{up} // \text{gcd}(\text{up}, \text{down})$ . This function's output will be centered with respect to this array, so it is best to pass a symmetric filter with an odd number of samples if, as is usually the case, a zero-phase filter is desired.

For any other type of *window*, the functions `scipy.signal.get_window` and `scipy.signal.firwin` are called to generate the appropriate filter coefficients.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from *dx* to  $\text{dx} * \text{up} / \text{float}(\text{down})$ .

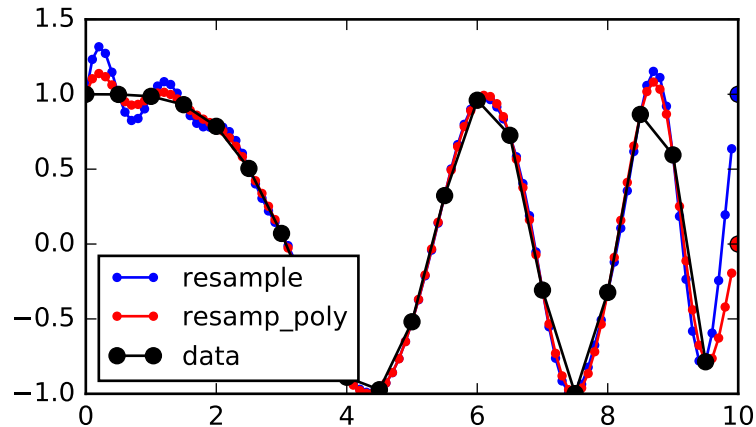

### Examples

Note that the end of the resampled data rises to meet the first sample of the next cycle for the FFT method, and gets closer to zero for the polyphase method:

```
>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f_fft = signal.resample(y, 100)
>>> f_poly = signal.resample_poly(y, 100, 20)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(xnew, f_fft, 'b.-', xnew, f_poly, 'r.-')
>>> plt.plot(x, y, 'ko-')
>>> plt.plot(10, y[0], 'bo', 10, 0., 'ro') # boundaries
>>> plt.legend(['resample', 'resamp_poly', 'data'], loc='best')
>>> plt.show()
```

`scipy.signal.upfirdn(h, x, up=1, down=1, axis=-1)`

Upsample, FIR filter, and downsample

**Parameters**

- h** : array\_like  
1-dimensional FIR (finite-impulse response) filter coefficients.
- x** : array\_like  
Input signal array.
- up** : int, optional  
Upsampling rate. Default is 1.
- down** : int, optional  
Downsampling rate. Default is 1.
- axis** : int, optional  
The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.

**Returns**

- y** : ndarray  
The output signal array. Dimensions will be the same as *x* except for along *axis*, which will change size according to the *h*, *up*, and *down* parameters.

### Notes

The algorithm is an implementation of the block diagram shown on page 129 of the Vaidyanathan text [R269] (Figure 4.3-8d).

The direct approach of upsampling by factor of *P* with zero insertion, FIR filtering of length *N*, and downsampling by factor of *Q* is  $O(N*Q)$  per output sample. The polyphase implementation used here is  $O(N/P)$ .

New in version 0.18.

### Examples

Simple operations:

```
>>> from scipy.signal import upfirdn
>>> upfirdn([1, 1, 1], [1, 1, 1]) # FIR filter
array([ 1.,  2.,  3.,  2.,  1.])
>>> upfirdn([1], [1, 2, 3], 3) # upsampling with zeros insertion
array([ 1.,  0.,  0.,  2.,  0.,  0.,  3.,  0.,  0.])
>>> upfirdn([1, 1, 1], [1, 2, 3], 3) # upsampling with sample-and-hold
array([ 1.,  1.,  1.,  2.,  2.,  2.,  3.,  3.,  3.])
```

```
>>> upfirdn([.5, 1, .5], [1, 1, 1], 2) # linear interpolation
array([ 0.5, 1. , 1. , 1. , 1. , 1. , 0.5, 0. ])
>>> upfirdn([1], np.arange(10), 1, 3) # decimation by 3
array([ 0., 3., 6., 9.])
>>> upfirdn([.5, 1, .5], np.arange(10), 2, 3) # linear interp, rate 2/3
array([ 0. , 1. , 2.5, 4. , 5.5, 7. , 8.5, 0. ])
```

Apply a single filter to multiple signals:

```
>>> x = np.reshape(np.arange(8), (4, 2))
>>> x
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7]])
```

Apply along the last dimension of x:

```
>>> h = [1, 1]
>>> upfirdn(h, x, 2)
array([[ 0., 0., 1., 1.],
       [ 2., 2., 3., 3.],
       [ 4., 4., 5., 5.],
       [ 6., 6., 7., 7.]])
```

Apply along the 0th dimension of x:

```
>>> upfirdn(h, x, 2, axis=0)
array([[ 0., 1.],
       [ 0., 1.],
       [ 2., 3.],
       [ 2., 3.],
       [ 4., 5.],
       [ 4., 5.],
       [ 6., 7.],
       [ 6., 7.]])
```

## 5.20.4 Filter design

<code>bilinear(b, a[, fs])</code>	Return a digital filter from an analog one using a bilinear transform.
<code>findfreqs(num, den, N[, kind])</code>	Find array of frequencies for computing the response of an analog filter.
<code>firls(numtaps, bands, desired[, weight, nyq])</code>	FIR filter design using least-squares error minimization.
<code>firwin(numtaps, cutoff[, width, window, ...])</code>	FIR filter design using the window method.
<code>firwin2(numtaps, freq, gain[, nfreqs, ...])</code>	FIR filter design using the window method.
<code>freqs(b, a[, worN, plot])</code>	Compute frequency response of analog filter.
<code>freqs_zpk(z, p, k[, worN])</code>	Compute frequency response of analog filter.
<code>freqz(b[, a, worN, whole, plot])</code>	Compute the frequency response of a digital filter.
<code>freqz_zpk(z, p, k[, worN, whole])</code>	Compute the frequency response of a digital filter in ZPK form.
<code>sosfreqz(sos[, worN, whole])</code>	Compute the frequency response of a digital filter in SOS format.
<code>group_delay(system[, w, whole])</code>	Compute the group delay of a digital filter.
<code>iirdesign(wp, ws, gpass, gstop[, analog, ...])</code>	Complete IIR digital and analog filter design.
<code>iirfilter(N, Wn[, rp, rs, btype, analog, ...])</code>	IIR digital and analog filter design given order and critical points.
<code>kaiser_atten(numtaps, width)</code>	Compute the attenuation of a Kaiser FIR filter.

Continued on next page

Table 5.128 – continued from previous page

<code>kaiser_beta(a)</code>	Compute the Kaiser parameter <i>beta</i> , given the attenuation <i>a</i> .
<code>kaiserord(ripple, width)</code>	Design a Kaiser window to limit ripple and width of transition region.
<code>minimum_phase(h[, method, n_fft])</code>	Convert a linear-phase FIR filter to minimum phase
<code>savgol_coeffs(window_length, polyorder[, ...])</code>	Compute the coefficients for a 1-d Savitzky-Golay FIR filter.
<code>remez(numtaps, bands, desired[, weight, Hz, ...])</code>	Calculate the minimax optimal filter using the Remez exchange algorithm.
<code>unique_roots(p[, tol, rtype])</code>	Determine unique roots and their multiplicities from a list of roots.
<code>residue(b, a[, tol, rtype])</code>	Compute partial-fraction expansion of $b(s) / a(s)$ .
<code>residuez(b, a[, tol, rtype])</code>	Compute partial-fraction expansion of $b(z) / a(z)$ .
<code>invres(r, p, k[, tol, rtype])</code>	Compute $b(s)$ and $a(s)$ from partial fraction expansion.
<code>invresz(r, p, k[, tol, rtype])</code>	Compute $b(z)$ and $a(z)$ from partial fraction expansion.
<code>BadCoefficients</code>	Warning about badly conditioned filter coefficients

`scipy.signal.bilinear` (*b, a, fs=1.0*)

Return a digital filter from an analog one using a bilinear transform.

The bilinear transform substitutes  $(z-1) / (z+1)$  for  $s$ .

`scipy.signal.findfreqs` (*num, den, N, kind='ba'*)

Find array of frequencies for computing the response of an analog filter.

**Parameters** `num, den` : array\_like, 1-D

The polynomial coefficients of the numerator and denominator of the transfer function of the filter or LTI system, where the coefficients are ordered from highest to lowest degree. Or, the roots of the transfer function numerator and denominator (i.e. zeroes and poles).

`N` : int

The length of the array to be computed.

`kind` : str {'ba', 'zp'}, optional

Specifies whether the numerator and denominator are specified by their polynomial coefficients ('ba'), or their roots ('zp').

**Returns** `w` : (N,) ndarray

A 1-D array of frequencies, logarithmically spaced.

### Examples

Find a set of nine frequencies that span the “interesting part” of the frequency response for the filter with the transfer function

$$H(s) = s / (s^2 + 8s + 25)$$

```
>>> from scipy import signal
>>> signal.findfreqs([1, 0], [1, 8, 25], N=9)
array([[ 1.00000000e-02,  3.16227766e-02,  1.00000000e-01,
         3.16227766e-01,  1.00000000e+00,  3.16227766e+00,
         1.00000000e+01,  3.16227766e+01,  1.00000000e+02]])
```

`scipy.signal.firls` (*numtaps, bands, desired, weight=None, nyq=1.0*)

FIR filter design using least-squares error minimization.

Calculate the filter coefficients for the linear-phase finite impulse response (FIR) filter which has the best approximation to the desired frequency response described by *bands* and *desired* in the least squares sense (i.e., the integral of the weighted mean-squared error within the specified bands is minimized).

**Parameters** `numtaps` : int

The number of taps in the FIR filter. *numtaps* must be odd.

`bands` : array\_like

A monotonic nondecreasing sequence containing the band edges in Hz. All elements must be non-negative and less than or equal to the Nyquist frequency given by *nyq*.

**desired** : array\_like  
 A sequence the same size as *bands* containing the desired gain at the start and end point of each band.

**weight** : array\_like, optional  
 A relative weighting to give to each band region when solving the least squares problem. *weight* has to be half the size of *bands*.

**nyq** : float, optional  
 Nyquist frequency. Each frequency in *bands* must be between 0 and *nyq* (inclusive).

**Returns** **coeffs** : ndarray  
 Coefficients of the optimal (in a least squares sense) FIR filter.

**See also:**

`firwin`, `firwin2`, `minimum_phase`, `remez`

**Notes**

This implementation follows the algorithm given in [R218]. As noted there, least squares design has multiple advantages:

1. Optimal in a least-squares sense.
2. Simple, non-iterative method.
3. The general solution can be obtained by solving a linear system of equations.
4. Allows the use of a frequency dependent weighting function.

This function constructs a Type I linear phase FIR filter, which contains an odd number of *coeffs* satisfying for  $n < numtaps$ :

$$coeffs(n) = coeffs(numtaps - 1 - n)$$

The odd number of coefficients and filter symmetry avoid boundary conditions that could otherwise occur at the Nyquist and 0 frequencies (e.g., for Type II, III, or IV variants).

New in version 0.18.

**References**

[R218]

**Examples**

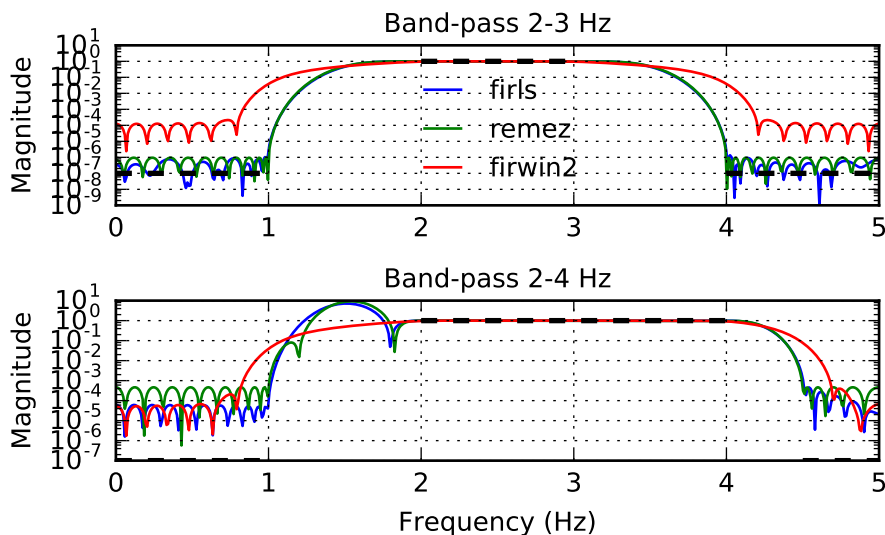

We want to construct a band-pass filter. Note that the behavior in the frequency ranges between our stop bands and pass bands is unspecified, and thus may overshoot depending on the parameters of our filter:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> fig, axs = plt.subplots(2)
>>> nyq = 5. # Hz
>>> desired = (0, 0, 1, 1, 0, 0)
>>> for bi, bands in enumerate(((0, 1, 2, 3, 4, 5), (0, 1, 2, 4, 4.5, 5))):
...     fir_firls = signal.firls(73, bands, desired, nyq=nyq)
...     fir_remez = signal.remez(73, bands, desired[::2], Hz=2 * nyq)
...     fir_firwin2 = signal.firwin2(73, bands, desired, nyq=nyq)
...     hs = list()
...     ax = axs[bi]
...     for fir in (fir_firls, fir_remez, fir_firwin2):
...         freq, response = signal.freqz(fir)
```

```

...     hs.append(ax.semilogy(nyq*freq/(np.pi), np.abs(response))[0])
...     for band, gains in zip(zip(bands[:,2], bands[1:,2]), zip(desired[:,2], desired[1:,2])):
...         ax.semilogy(band, np.maximum(gains, 1e-7), 'k--', linewidth=2)
...     if bi == 0:
...         ax.legend(hs, ('firls', 'remez', 'firwin2'), loc='lower center', frameon=False)
...     else:
...         ax.set_xlabel('Frequency (Hz)')
...     ax.grid(True)
...     ax.set(title='Band-pass %d-%d Hz' % bands[2:4], ylabel='Magnitude')
...
>>> fig.tight_layout()
>>> plt.show()

```

`scipy.signal.firwin` (*numtaps*, *cutoff*, *width=None*, *window='hamming'*, *pass\_zero=True*, *scale=True*, *nyq=1.0*)

FIR filter design using the window method.

This function computes the coefficients of a finite impulse response filter. The filter will have linear phase; it will be Type I if *numtaps* is odd and Type II if *numtaps* is even.

Type II filters always have zero response at the Nyquist rate, so a `ValueError` exception is raised if `firwin` is called with *numtaps* even and having a passband whose right end is at the Nyquist rate.

**Parameters** *numtaps* : int

Length of the filter (number of coefficients, i.e. the filter order + 1). *numtaps* must be even if a passband includes the Nyquist frequency.

**cutoff** : float or 1D array\_like

Cutoff frequency of filter (expressed in the same units as *nyq*) OR an array of cutoff frequencies (that is, band edges). In the latter case, the frequencies in *cutoff* should be positive and monotonically increasing between 0 and *nyq*. The values 0 and *nyq* must not be included in *cutoff*.

**width** : float or None, optional

If *width* is not None, then assume it is the approximate width of the transition region (expressed in the same units as *nyq*) for use in Kaiser FIR filter design. In this case, the *window* argument is ignored.

**window** : string or tuple of string and parameter values, optional

Desired window to use. See `scipy.signal.get_window` for a list of windows and required parameters.

**pass\_zero** : bool, optional

If True, the gain at the frequency 0 (i.e. the “DC gain”) is 1. Otherwise the DC gain is 0.

**scale** : bool, optional

Set to True to scale the coefficients so that the frequency response is exactly unity at a certain frequency. That frequency is either:

- 0 (DC) if the first passband starts at 0 (i.e. `pass_zero` is True)
- nyq* (the Nyquist rate) if the first passband ends at *nyq* (i.e. the filter is a single band highpass filter); center of first passband otherwise

**nyq** : float, optional

Nyquist frequency. Each frequency in *cutoff* must be between 0 and *nyq*.

**Returns**

**h** : (numtaps,) ndarray

**Raises**

**ValueError**

Coefficients of length *numtaps* FIR filter.

If any value in *cutoff* is less than or equal to 0 or greater than or equal to *nyq*, if the values in *cutoff* are not strictly monotonically increasing, or if *numtaps* is even but a passband includes the Nyquist frequency.

**See also:**

`firwin2`, `firls`, `minimum_phase`, `remez`

### Examples

Low-pass from 0 to f:

```
>>> from scipy import signal
>>> numtaps = 3
>>> f = 0.1
>>> signal.firwin(numtaps, f)
array([ 0.06799017,  0.86401967,  0.06799017])
```

Use a specific window function:

```
>>> signal.firwin(numtaps, f, window='nuttall')
array([ 3.56607041e-04,  9.99286786e-01,  3.56607041e-04])
```

High-pass (‘stop’ from 0 to f):

```
>>> signal.firwin(numtaps, f, pass_zero=False)
array([-0.00859313,  0.98281375, -0.00859313])
```

Band-pass:

```
>>> f1, f2 = 0.1, 0.2
>>> signal.firwin(numtaps, [f1, f2], pass_zero=False)
array([ 0.06301614,  0.88770441,  0.06301614])
```

Band-stop:

```
>>> signal.firwin(numtaps, [f1, f2])
array([-0.00801395,  1.0160279 , -0.00801395])
```

Multi-band (passbands are [0, f1], [f2, f3] and [f4, 1]):

```
>>> f3, f4 = 0.3, 0.4
>>> signal.firwin(numtaps, [f1, f2, f3, f4])
array([-0.01376344,  1.02752689, -0.01376344])
```

Multi-band (passbands are [f1, f2] and [f3,f4]):

```
>>> signal.firwin(numtaps, [f1, f2, f3, f4], pass_zero=False)
array([ 0.04890915,  0.91284326,  0.04890915])
```

`scipy.signal.firwin2` (*numtaps*, *freq*, *gain*, *nfreqs*=None, *window*='hamming', *nyq*=1.0, *antisymmetric*=False)

FIR filter design using the window method.

From the given frequencies *freq* and corresponding gains *gain*, this function constructs an FIR filter with linear phase and (approximately) the given frequency response.

<b>Parameters</b>	<b>numtaps</b> : int	The number of taps in the FIR filter. <i>numtaps</i> must be less than <i>nfreqs</i> .
	<b>freq</b> : array_like, 1D	The frequency sampling points. Typically 0.0 to 1.0 with 1.0 being Nyquist. The Nyquist frequency can be redefined with the argument <i>nyq</i> . The values in <i>freq</i> must be nondecreasing. A value can be repeated once to implement a discontinuity. The first value in <i>freq</i> must be 0, and the last value must be <i>nyq</i> .
	<b>gain</b> : array_like	The filter gains at the frequency sampling points. Certain constraints to gain values, depending on the filter type, are applied, see Notes for details.
	<b>nfreqs</b> : int, optional	The size of the interpolation mesh used to construct the filter. For most efficient behavior, this should be a power of 2 plus 1 (e.g, 129, 257, etc). The default is one more than the smallest power of 2 that is not less than <i>numtaps</i> . <i>nfreqs</i> must be greater than <i>numtaps</i> .
	<b>window</b> : string or (string, float) or float, or None, optional	Window function to use. Default is "hamming". See <a href="#">scipy.signal.get_window</a> for the complete list of possible values. If None, no window function is applied.
	<b>nyq</b> : float, optional	Nyquist frequency. Each frequency in <i>freq</i> must be between 0 and <i>nyq</i> (inclusive).
	<b>antisymmetric</b> : bool, optional	Whether resulting impulse response is symmetric/antisymmetric. See Notes for more details.
<b>Returns</b>	<b>taps</b> : ndarray	The filter coefficients of the FIR filter, as a 1-D array of length <i>numtaps</i> .

See also:

[firls](#), [firwin](#), [minimum\\_phase](#), [remez](#)

Notes

From the given set of frequencies and gains, the desired response is constructed in the frequency domain. The inverse FFT is applied to the desired response to create the associated convolution kernel, and the first *numtaps* coefficients of this kernel, scaled by *window*, are returned.

The FIR filter will have linear phase. The type of filter is determined by the value of 'numtaps' and *antisymmetric* flag. There are four possible combinations:

- odd *numtaps*, *antisymmetric* is False, type I filter is produced

- even *numtaps*, *antisymmetric* is False, type II filter is produced
  - odd *numtaps*, *antisymmetric* is True, type III filter is produced
  - even *numtaps*, *antisymmetric* is True, type IV filter is produced
- Magnitude response of all but type I filters are subjects to following constraints:

- type II – zero at the Nyquist frequency
- type III – zero at zero and Nyquist frequencies
- type IV – zero at zero frequency

New in version 0.9.0.

### References

[R219], [R220]

### Examples

A lowpass FIR filter with a response that is 1 on [0.0, 0.5], and that decreases linearly on [0.5, 1.0] from 1 to 0:

```
>>> from scipy import signal
>>> taps = signal.firwin2(150, [0.0, 0.5, 1.0], [1.0, 1.0, 0.0])
>>> print(taps[72:78])
[-0.02286961 -0.06362756  0.57310236  0.57310236 -0.06362756 -0.02286961]
```

`scipy.signal.freqs` (*b*, *a*, *worN=None*, *plot=None*)

Compute frequency response of analog filter.

Given the M-order numerator *b* and N-order denominator *a* of an analog filter, compute its frequency response:

$$H(w) = \frac{b[0]*(jw)**M + b[1]*(jw)**(M-1) + \dots + b[M]}{a[0]*(jw)**N + a[1]*(jw)**(N-1) + \dots + a[N]}$$

**Parameters**

- b** : array\_like  
Numerator of a linear filter.
- a** : array\_like  
Denominator of a linear filter.
- worN** : {None, int, array\_like}, optional  
If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g. rad/s) given in *worN*.
- plot** : callable, optional  
A callable that takes two arguments. If given, the return parameters *w* and *h* are passed to plot. Useful for plotting the frequency response inside `freqs`.

**Returns**

- w** : ndarray  
The angular frequencies at which *h* was computed.
- h** : ndarray  
The frequency response.

**See also:**

`freqz` Compute the frequency response of a digital filter.

### Notes

Using Matplotlib’s “plot” function as the callable for *plot* produces unexpected results, this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, abs(h))`.

**Examples**

```

>>> from scipy.signal import freqs, iirfilter

>>> b, a = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1')

>>> w, h = freqs(b, a, worN=np.logspace(-1, 2, 1000))

>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()

```

`scipy.signal.freqs_zpk` (*z*, *p*, *k*, *worN=None*)

Compute frequency response of analog filter.

Given the zeros *z*, poles *p*, and gain *k* of a filter, compute its frequency response:

$$H(\omega) = k * \frac{(j\omega - z[0]) * (j\omega - z[1]) * \dots * (j\omega - z[-1])}{(j\omega - p[0]) * (j\omega - p[1]) * \dots * (j\omega - p[-1])}$$

**Parameters** **z** : array\_like

Zeroes of a linear filter

**p** : array\_like

Poles of a linear filter

**k** : scalar

Gain of a linear filter

**worN** : {None, int, array\_like}, optional

If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g. rad/s) given in *worN*.

**Returns**

**w** : ndarray  
The angular frequencies at which *h* was computed.

**h** : ndarray  
The frequency response.

**See also:**

**freqs** Compute the frequency response of an analog filter in TF form  
**freqz** Compute the frequency response of a digital filter in TF form  
**freqz\_zpk** Compute the frequency response of a digital filter in ZPK form

**Notes**

**Examples**

```
>>> from scipy.signal import freqs_zpk, iirfilter

>>> z, p, k = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1',
...                 output='zpk')

>>> w, h = freqs_zpk(z, p, k, worN=np.logspace(-1, 2, 1000))

>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

`scipy.signal.freqz(b, a=1, worN=None, whole=False, plot=None)`  
 Compute the frequency response of a digital filter.

Given the *M*-order numerator *b* and *N*-order denominator *a* of a digital filter, compute its frequency response:

$$H(e^{j\omega}) = \frac{B(e^{j\omega})}{A(e^{j\omega})} = \frac{b[0] + b[1]e^{-j\omega} + \dots + b[M]e^{-j\omega M}}{a[0] + a[1]e^{-j\omega} + \dots + a[N]e^{-j\omega N}}$$

<b>Parameters</b>	<b>b</b> : array_like	numerator of a linear filter
	<b>a</b> : array_like	denominator of a linear filter
	<b>worN</b> : {None, int, array_like}, optional	If None (default), then compute at 512 frequencies equally spaced around the unit circle. If a single integer, then compute at that many frequencies. If an array_like, compute the response at the frequencies given (in radians/sample).
	<b>whole</b> : bool, optional	Normally, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If <i>whole</i> is True, compute frequencies from 0 to 2*pi radians/sample.
	<b>plot</b> : callable	A callable that takes two arguments. If given, the return parameters <i>w</i> and <i>h</i> are passed to plot. Useful for plotting the frequency response inside <code>freqz</code> .
<b>Returns</b>	<b>w</b> : ndarray	The normalized frequencies at which <i>h</i> was computed, in radians/sample.
	<b>h</b> : ndarray	The frequency response, as complex numbers.

**See also:**`sosfreqz`**Notes**

Using Matplotlib's "plot" function as the callable for *plot* produces unexpected results, this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, abs(h))`.

**Examples**

```
>>> from scipy import signal
>>> b = signal.firwin(80, 0.5, window='kaiser', 8)
>>> w, h = signal.freqz(b)

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.title('Digital filter frequency response')
>>> ax1 = fig.add_subplot(111)

>>> plt.plot(w, 20 * np.log10(abs(h)), 'b')
>>> plt.ylabel('Amplitude [dB]', color='b')
>>> plt.xlabel('Frequency [rad/sample]')

>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> plt.plot(w, angles, 'g')
>>> plt.ylabel('Angle (radians)', color='g')
```

```
>>> plt.grid()
>>> plt.axis('tight')
>>> plt.show()
```

`scipy.signal.freqz_zpk(z, p, k, worN=None, whole=False)`

Compute the frequency response of a digital filter in ZPK form.

Given the Zeros, Poles and Gain of a digital filter, compute its frequency response:

$$H(z) = k \prod_i (z - Z[i]) / \prod_j (z - P[j])$$

where  $k$  is the *gain*,  $Z$  are the *zeros* and  $P$  are the *poles*.

**Parameters**

- z** : array\_like  
Zeroes of a linear filter
- p** : array\_like  
Poles of a linear filter
- k** : scalar  
Gain of a linear filter
- worN** : {None, int, array\_like}, optional  
If None (default), then compute at 512 frequencies equally spaced around the unit circle. If a single integer, then compute at that many frequencies. If an array\_like, compute the response at the frequencies given (in radians/sample).
- whole** : bool, optional  
Normally, frequencies are computed from 0 to the Nyquist frequency,  $\pi$  radians/sample (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to  $2\pi$  radians/sample.

**Returns**

- w** : ndarray  
The normalized frequencies at which  $h$  was computed, in radians/sample.
- h** : ndarray  
The frequency response.

See also:

`freqs` Compute the frequency response of an analog filter in TF form  
`freqs_zpk` Compute the frequency response of an analog filter in ZPK form  
`freqz` Compute the frequency response of a digital filter in TF form

**Notes****Examples**

```

>>> from scipy import signal
>>> z, p, k = signal.butter(4, 0.2, output='zpk')
>>> w, h = signal.freqz_zpk(z, p, k)

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.title('Digital filter frequency response')
>>> ax1 = fig.add_subplot(111)

>>> plt.plot(w, 20 * np.log10(abs(h)), 'b')
>>> plt.ylabel('Amplitude [dB]', color='b')
>>> plt.xlabel('Frequency [rad/sample]')

>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> plt.plot(w, angles, 'g')
>>> plt.ylabel('Angle (radians)', color='g')
>>> plt.grid()
>>> plt.axis('tight')
>>> plt.show()

```

`scipy.signal.sosfreqz` (*sos*, *worN=None*, *whole=False*)

Compute the frequency response of a digital filter in SOS format.

Given *sos*, an array with shape (n, 6) of second order sections of a digital filter, compute the frequency response of the system function:

$$H(z) = \frac{B_0(z)}{A_0(z)} * \frac{B_1(z)}{A_1(z)} * \dots * \frac{B_{n-1}(z)}{A_{n-1}(z)}$$

for  $z = \exp(j\omega)$ , where  $B\{k\}(z)$  and  $A\{k\}(z)$  are numerator and denominator of the transfer function of the k-th second order section.

<b>Parameters</b>	<p><b>sos</b> : array_like Array of second-order filter coefficients, must have shape <math>(n\_sections, 6)</math>. Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.</p> <p><b>worN</b> : {None, int, array_like}, optional If None (default), then compute at 512 frequencies equally spaced around the unit circle. If a single integer, then compute at that many frequencies. If an array_like, compute the response at the frequencies given (in radians/sample).</p> <p><b>whole</b> : bool, optional Normally, frequencies are computed from 0 to the Nyquist frequency, <math>\pi</math> radians/sample (upper-half of unit-circle). If <i>whole</i> is True, compute frequencies from 0 to <math>2\pi</math> radians/sample.</p>
<b>Returns</b>	<p><b>w</b> : ndarray The normalized frequencies at which <i>h</i> was computed, in radians/sample.</p> <p><b>h</b> : ndarray The frequency response, as complex numbers.</p>

**See also:**

`freqz`, `sosfilt`

**Notes**

New in version 0.19.0.

**Examples**

Design a 15th-order bandpass filter in SOS format.

```
>>> from scipy import signal
>>> sos = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
...                       output='sos')
```

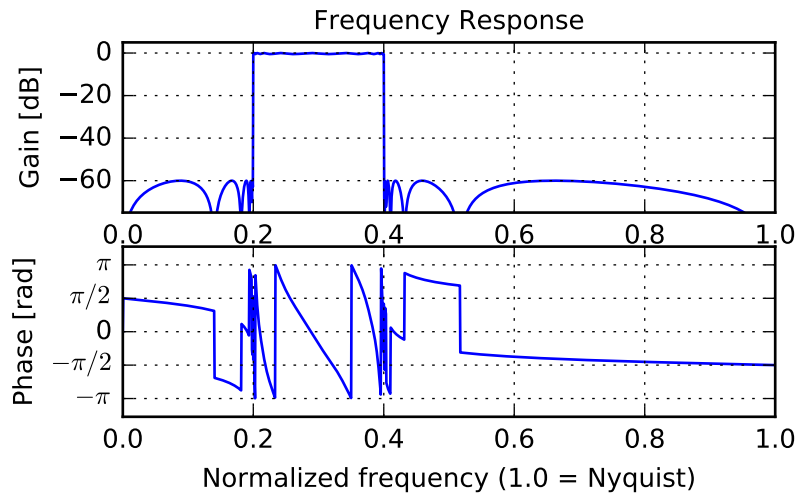

Compute the frequency response at 1500 points from DC to Nyquist.

```
>>> w, h = signal.sosfreqz(sos, worN=1500)
```

Plot the response.

```
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.abs(h))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([0, -20, -40, -60])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
...           [r'$-\pi$', r'$-\pi/2$', '0', r'\pi/2$', r'\pi$'])
>>> plt.ylabel('Phase [rad]')
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```

If the same filter is implemented as a single transfer function, numerical error corrupts the frequency response:

```
>>> b, a = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
...                   output='ba')
>>> w, h = signal.freqz(b, a, worN=1500)
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.abs(h))
>>> plt.plot(w/np.pi, db)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.show()
```

`scipy.signal.group_delay` (*system*, *w=None*, *whole=False*)  
 Compute the group delay of a digital filter.

The group delay measures by how many samples amplitude envelopes of various spectral components of a signal are delayed by a filter. It is formally defined as the derivative of continuous (unwrapped) phase:

$$D(\omega) = -\frac{d}{d\omega} \arg H(e^{j\omega})$$

**Parameters**

**system** : tuple of array\_like (b, a)  
 Numerator and denominator coefficients of a filter transfer function.

**w** : {None, int, array-like}, optional  
 If None (default), then compute at 512 frequencies equally spaced around the unit circle. If a single integer, then compute at that many frequencies. If array, compute the delay at the frequencies given (in radians/sample).

**whole** : bool, optional  
 Normally, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to 2\*pi radians/sample.

**Returns**

**w** : ndarray  
 The normalized frequencies at which the group delay was computed, in radians/sample.

**gd** : ndarray  
 The group delay.

**See also:**

[\*freqz\*](#) Frequency response of a digital filter

### Notes

The similar function in MATLAB is called *grpdelay*.

If the transfer function  $H(z)$  has zeros or poles on the unit circle, the group delay at corresponding frequencies is undefined. When such a case arises the warning is raised and the group delay is set to 0 at those frequencies.

For the details of numerical computation of the group delay refer to [R222].

### References

[R222]

### Examples

```
>>> from scipy import signal
>>> b, a = signal.iirdesign(0.1, 0.3, 5, 50, ftype='cheby1')
>>> w, gd = signal.group_delay((b, a))

>>> import matplotlib.pyplot as plt
>>> plt.title('Digital filter group delay')
>>> plt.plot(w, gd)
>>> plt.ylabel('Group delay [samples]')
>>> plt.xlabel('Frequency [rad/sample]')
>>> plt.show()
```

`scipy.signal.iirdesign` (*wp*, *ws*, *gpass*, *gstop*, *analog=False*, *ftype='ellip'*, *output='ba'*)

Complete IIR digital and analog filter design.

Given passband and stopband frequencies and gains, construct an analog or digital IIR filter of minimum order for a given basic type. Return the output in numerator, denominator ('ba'), pole-zero ('zpk') or second order sections ('sos') form.

**Parameters**    **wp, ws** : float

Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: *wp* = 0.2, *ws* = 0.3
- Highpass: *wp* = 0.3, *ws* = 0.2
- Bandpass: *wp* = [0.2, 0.5], *ws* = [0.4, 0.6]
- Bandstop: *wp* = [0.1, 0.6], *ws* = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g. rad/s).

**gpass** : float

The maximum loss in the passband (dB).

**gstop** : float

The minimum attenuation in the stopband (dB).

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**ftype** : str, optional

The type of IIR filter to design:

- Butterworth: 'butter'
- Chebyshev I: 'cheby1'
- Chebyshev II: 'cheby2'
- Cauchy/elliptic: 'ellip'
- Bessel/Thomson: 'bessel'

**output** : {'ba', 'zpk', 'sos'}, optional

Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

**b, a** : ndarray, ndarray

Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if *output='ba'*.

**z, p, k** : ndarray, ndarray, float

Zeros, poles, and system gain of the IIR filter transfer function. Only returned if *output='zpk'*.

**sos** : ndarray

Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

**butter** Filter design using order and critical points

`cheby1`, `cheby2`, `ellip`, `bessel`

**buttord** Find order and critical points from passband and stopband spec

`cheblord`, `cheb2ord`, `ellipord`

**iirfilter** General filter design using order and critical frequencies

**Notes**

The 'sos' output parameter was added in 0.16.0.

`scipy.signal.iirfilter` (*N*, *Wn*, *rp=None*, *rs=None*, *btype='band'*, *analog=False*, *ftype='butter'*, *output='ba'*)

IIR digital and analog filter design given order and critical points.

Design an Nth-order digital or analog filter and return the filter coefficients.

**Parameters** **N** : int

The order of the filter.

**Wn** : array\_like

A scalar or length-2 sequence giving the critical frequencies. For digital filters, *Wn* is normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*Wn* is thus in half-cycles / sample.) For analog filters, *Wn* is an angular frequency (e.g. rad/s).

**rp** : float, optional

For Chebyshev and elliptic filters, provides the maximum ripple in the passband. (dB)

**rs** : float, optional

For Chebyshev and elliptic filters, provides the minimum attenuation in the stop band. (dB)

**btype** : { 'bandpass', 'lowpass', 'highpass', 'bandstop' }, optional

The type of filter. Default is 'bandpass'.

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**ftype** : str, optional

The type of IIR filter to design:

- Butterworth: 'butter'
- Chebyshev I: 'cheby1'
- Chebyshev II: 'cheby2'
- Cauchy/elliptic: 'ellip'
- Bessel/Thomson: 'bessel'

**output** : { 'ba', 'zpk', 'sos' }, optional

Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

**b, a** : ndarray, ndarray

Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

**z, p, k** : ndarray, ndarray, float

Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

**sos** : ndarray

Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

**butter** Filter design using order and critical points

`cheby1`, `cheby2`, `ellip`, `bessel`

**buttord** Find order and critical points from passband and stopband spec

`cheblord`, `cheb2ord`, `ellipord`

**iirdesign** General filter design using passband and stopband spec

### Notes

The 'sos' output parameter was added in 0.16.0.

### Examples

Generate a 17th-order Chebyshev II bandpass filter and plot the frequency response:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.iirfilter(17, [50, 200], rs=60, btype='band',
...                        analog=True, ftype='cheby2')
>>> w, h = signal.freqs(b, a, 1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.semilogx(w, 20 * np.log10(abs(h)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [radians / second]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
>>> ax.grid(which='both', axis='both')
>>> plt.show()
```

`scipy.signal.kaiser_atten` (*numtaps*, *width*)

Compute the attenuation of a Kaiser FIR filter.

Given the number of taps  $N$  and the transition width  $width$ , compute the attenuation  $a$  in dB, given by Kaiser's formula:

$$a = 2.285 * (N - 1) * \pi * width + 7.95$$

**Parameters**

- numtaps** : int  
The number of taps in the FIR filter.
- width** : float  
The desired width of the transition region between passband and stopband (or, in general, at any discontinuity) for the filter.

**Returns**

- a** : float  
The attenuation of the ripple, in dB.

**See also:**

`kaiserord`, `kaiser_beta`

`scipy.signal.kaiser_beta` (*a*)

Compute the Kaiser parameter *beta*, given the attenuation *a*.

**Parameters**

- a** : float  
The desired attenuation in the stopband and maximum ripple in the passband, in dB. This should be a *positive* number.

**Returns**

- beta** : float  
The *beta* parameter to be used in the formula for a Kaiser window.

**References**

Oppenheim, Schafer, “Discrete-Time Signal Processing”, p.475-476.

`scipy.signal.kaiserord` (*ripple*, *width*)

Design a Kaiser window to limit ripple and width of transition region.

**Parameters**

- ripple** : float  
Positive number specifying maximum ripple in passband (dB) and minimum ripple in stopband.
- width** : float  
Width of transition region (normalized so that 1 corresponds to pi radians / sample).

**Returns**

- numtaps** : int  
The length of the kaiser window.
- beta** : float  
The beta parameter for the kaiser window.

**See also:**

`kaiser_beta`, `kaiser_atten`

**Notes**

There are several ways to obtain the Kaiser window:

- `signal.kaiser(numtaps, beta, sym=True)`
- `signal.get_window(beta, numtaps)`
- `signal.get_window('kaiser', beta), numtaps)`

The empirical equations discovered by Kaiser are used.

**References**

Oppenheim, Schafer, “Discrete-Time Signal Processing”, p.475-476.

`scipy.signal.minimum_phase` (*h*, *method='homomorphic'*, *n\_fft=None*)

Convert a linear-phase FIR filter to minimum phase

**Parameters**

- h** : array  
Linear-phase FIR filter coefficients.
- method** : { 'hilbert', 'homomorphic' }  
The method to use:

**'homomorphic' (default)**

This method [R253] [R254] works best with filters with an odd number of taps, and the resulting minimum phase filter will have a magnitude response that approximates the square root of the the original filter's magnitude response.

**'hilbert'**

This method [R250] is designed to be used with equiripple filters (e.g., from `remez`) with unity or zero gain regions.

**Returns**

`n_fft` : int  
The number of points to use for the FFT. Should be at least a few times larger than the signal length (see Notes).

`h_minimum` : array  
The minimum-phase version of the filter, with length  $(\text{length}(h) + 1) // 2$ .

**See also:**

`firwin`, `firwin2`, `remez`

**Notes**

Both the Hilbert [R250] or homomorphic [R253] [R254] methods require selection of an FFT length to estimate the complex cepstrum of the filter.

In the case of the Hilbert method, the deviation from the ideal spectrum `epsilon` is related to the number of stopband zeros `n_stop` and FFT length `n_fft` as:

```
epsilon = 2. * n_stop / n_fft
```

For example, with 100 stopband zeros and a FFT length of 2048, `epsilon = 0.0976`. If we conservatively assume that the number of stopband zeros is one less than the filter length, we can take the FFT length to be the next power of 2 that satisfies `epsilon=0.01` as:

```
n_fft = 2 ** int(np.ceil(np.log2(2 * (len(h) - 1) / 0.01)))
```

This gives reasonable results for both the Hilbert and homomorphic methods, and gives the value used when `n_fft=None`.

Alternative implementations exist for creating minimum-phase filters, including zero inversion [R251] and spectral factorization [R252] [R253]. For more information, see:

<http://dspguru.com/dsp/howtos/how-to-design-minimum-phase-fir-filters>

**References**

[R250], [R251], [R252], [R253], [R254]

**Examples**

Create an optimal linear-phase filter, then convert it to minimum phase:

```
>>> from scipy.signal import remez, minimum_phase, freqz, group_delay
>>> import matplotlib.pyplot as plt
>>> freq = [0, 0.2, 0.3, 1.0]
>>> desired = [1, 0]
>>> h_linear = remez(151, freq, desired, Hz=2.)
```

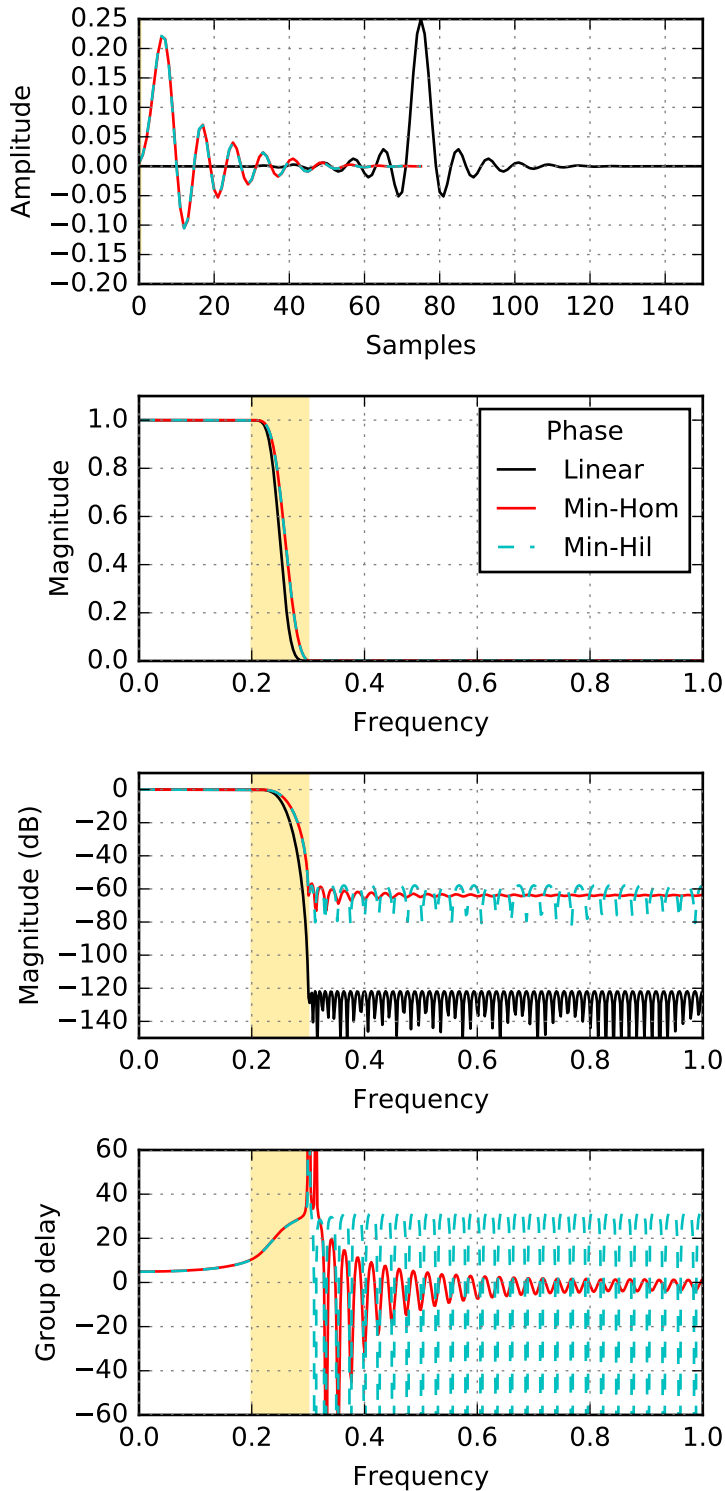

Convert it to minimum phase:

```
>>> h_min_hom = minimum_phase(h_linear, method='homomorphic')
>>> h_min_hil = minimum_phase(h_linear, method='hilbert')
```

Compare the three filters:

```
>>> fig, axs = plt.subplots(4, figsize=(4, 8))
>>> for h, style, color in zip((h_linear, h_min_hom, h_min_hil),
...                           ('-', '-', '--'), ('k', 'r', 'c')):
...     w, H = freqz(h)
...     w, gd = group_delay((h, 1))
...     w /= np.pi
...     axs[0].plot(h, color=color, linestyle=style)
...     axs[1].plot(w, np.abs(H), color=color, linestyle=style)
...     axs[2].plot(w, 20 * np.log10(np.abs(H)), color=color, linestyle=style)
...     axs[3].plot(w, gd, color=color, linestyle=style)
>>> for ax in axs:
...     ax.grid(True, color='0.5')
...     ax.fill_between(freq[1:3], *ax.get_ylim(), color='#ffeeaa', zorder=1)
>>> axs[0].set(xlim=[0, len(h_linear) - 1], ylabel='Amplitude', xlabel='Samples')
>>> axs[1].legend(['Linear', 'Min-Hom', 'Min-Hil'], title='Phase')
>>> for ax, ylim in zip(axs[1:], ([0, 1.1], [-150, 10], [-60, 60])):
...     ax.set(xlim=[0, 1], ylim=ylim, xlabel='Frequency')
>>> axs[1].set(ylabel='Magnitude')
>>> axs[2].set(ylabel='Magnitude (dB)')
>>> axs[3].set(ylabel='Group delay')
>>> plt.tight_layout()
```

`scipy.signal.savgol_coeffs`(*window\_length*, *polyorder*, *deriv*=0, *delta*=1.0, *pos*=None, *use*='conv')

Compute the coefficients for a 1-d Savitzky-Golay FIR filter.

**Parameters** `window_length`: int

The length of the filter window (i.e. the number of coefficients). *win-*

*dow\_length* must be an odd positive integer.

**polyorder** : int

The order of the polynomial used to fit the samples. *polyorder* must be less than *window\_length*.

**deriv** : int, optional

The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

**delta** : float, optional

The spacing of the samples to which the filter will be applied. This is only used if *deriv* > 0.

**pos** : int or None, optional

If *pos* is not None, it specifies evaluation position within the window. The default is the middle of the window.

**use** : str, optional

Either 'conv' or 'dot'. This argument chooses the order of the coefficients. The default is 'conv', which means that the coefficients are ordered to be used in a convolution. With *use*='dot', the order is reversed, so the filter is applied by dotting the coefficients with the data set.

**Returns**

**coeffs** : 1-d ndarray

The filter coefficients.

**See also:**

`savgol_filter`

**Notes**

New in version 0.14.0.

**References**

**Examples**

```
>>> from scipy.signal import savgol_coeffs
>>> savgol_coeffs(5, 2)
array([-0.08571429,  0.34285714,  0.48571429,  0.34285714, -0.08571429])
>>> savgol_coeffs(5, 2, deriv=1)
array([ 2.00000000e-01,  1.00000000e-01,  2.00607895e-16,
        -1.00000000e-01, -2.00000000e-01])
```

Note that *use*='dot' simply reverses the coefficients.

```
>>> savgol_coeffs(5, 2, pos=3)
array([ 0.25714286,  0.37142857,  0.34285714,  0.17142857, -0.14285714])
>>> savgol_coeffs(5, 2, pos=3, use='dot')
array([-0.14285714,  0.17142857,  0.34285714,  0.37142857,  0.25714286])
```

*x* contains data from the parabola  $x = t^2$ , sampled at  $t = -1, 0, 1, 2, 3$ . *c* holds the coefficients that will compute the derivative at the last position. When dotted with *x* the result should be 6.

```
>>> x = np.array([1, 0, 1, 4, 9])
>>> c = savgol_coeffs(5, 2, pos=4, deriv=1, use='dot')
>>> c.dot(x)
6.0000000000000018
```

```
scipy.signal.remez(numtaps, bands, desired, weight=None, Hz=1, type='bandpass', maxiter=25,
                  grid_density=16)
```

Calculate the minimax optimal filter using the Remez exchange algorithm.

Calculate the filter-coefficients for the finite impulse response (FIR) filter whose transfer function minimizes the maximum error between the desired gain and the realized gain in the specified frequency bands using the Remez exchange algorithm.

**Parameters** **numtaps** : int

The desired number of taps in the filter. The number of taps is the number of terms in the filter, or the filter order plus one.

**bands** : array\_like

A monotonic sequence containing the band edges in Hz. All elements must be non-negative and less than half the sampling frequency as given by *Hz*.

**desired** : array\_like

A sequence half the size of *bands* containing the desired gain in each of the specified bands.

**weight** : array\_like, optional

A relative weighting to give to each band region. The length of *weight* has to be half the length of *bands*.

**Hz** : scalar, optional

The sampling frequency in Hz. Default is 1.

**type** : {'bandpass', 'differentiator', 'hilbert'}, optional

The type of filter:

- 'bandpass' : flat response in bands. This is the default.
- 'differentiator' : frequency proportional response in bands.
- 'hilbert' : [filter with odd symmetry, that is, type III] (for even order) or type IV (for odd order) linear phase filters.

**maxiter** : int, optional

Maximum number of iterations of the algorithm. Default is 25.

**grid\_density** : int, optional

Grid density. The dense grid used in `remez` is of size  $(\text{numtaps} + 1) * \text{grid\_density}$ . Default is 16.

**Returns**

**out** : ndarray

A rank-1 array containing the coefficients of the optimal (in a minimax sense) filter.

**See also:**

`firls`, `firwin`, `firwin2`, `minimum_phase`

**References**

[R260], [R261]

**Examples**

We want to construct a filter with a passband at 0.2-0.4 Hz, and stop bands at 0-0.1 Hz and 0.45-0.5 Hz. Note that this means that the behavior in the frequency ranges between those bands is unspecified and may overshoot.

```
>>> from scipy import signal
>>> bpass = signal.remez(72, [0, 0.1, 0.2, 0.4, 0.45, 0.5], [0, 1, 0])
>>> freq, response = signal.freqz(bpass)
>>> ampl = np.abs(response)

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(111)
```

```
>>> ax1.semilogy(freq/(2*np.pi), ampl, 'b-') # freq in Hz
>>> plt.show()
```

```
scipy.signal.unique_roots(p, tol=0.001, rtype='min')
```

Determine unique roots and their multiplicities from a list of roots.

**Parameters**

- p** : array\_like  
The list of roots.
- tol** : float, optional  
The tolerance for two roots to be considered equal. Default is 1e-3.
- rtype** : {'max', 'min', 'avg'}, optional  
How to determine the returned root if multiple roots are within *tol* of each other.
  - 'max': pick the maximum of those roots.
  - 'min': pick the minimum of those roots.
  - 'avg': take the average of those roots.

**Returns**

- root** : ndarray  
The list of unique roots, sorted from low to high.
- mult** : ndarray  
The multiplicity of each root.

### Notes

This utility function is not specific to roots but can be used for any sequence of values for which uniqueness and multiplicity has to be determined. For a more general routine, see `numpy.unique`.

### Examples

```
>>> from scipy import signal
>>> vals = [0, 1.3, 1.31, 2.8, 1.25, 2.2, 10.3]
>>> uniq, mult = signal.unique_roots(vals, tol=2e-2, rtype='avg')
```

Check which roots have multiplicity larger than 1:

```
>>> uniq[mult > 1]
array([ 1.305])
```

`scipy.signal.residue(b, a, tol=0.001, rtype='avg')`

Compute partial-fraction expansion of  $b(s) / a(s)$ .

If  $M$  is the degree of numerator  $b$  and  $N$  the degree of denominator  $a$ :

$$H(s) = \frac{b(s)}{a(s)} = \frac{b[0] s^{**}(M) + b[1] s^{**}(M-1) + \dots + b[M]}{a[0] s^{**}(N) + a[1] s^{**}(N-1) + \dots + a[N]}$$

then the partial-fraction expansion  $H(s)$  is defined as:

$$= \frac{r[0]}{(s-p[0])} + \frac{r[1]}{(s-p[1])} + \dots + \frac{r[-1]}{(s-p[-1])} + k(s)$$

If there are any repeated roots (closer together than  $tol$ ), then  $H(s)$  has terms like:

$$\frac{r[i]}{(s-p[i])} + \frac{r[i+1]}{(s-p[i])**2} + \dots + \frac{r[i+n-1]}{(s-p[i])**n}$$

This function is used for polynomials in positive powers of  $s$  or  $z$ , such as analog filters or digital filters in controls engineering. For negative powers of  $z$  (typical for digital filters in DSP), use `residuez`.

**Parameters**

- b** : array\_like  
Numerator polynomial coefficients.
- a** : array\_like  
Denominator polynomial coefficients.

**Returns**

- r** : ndarray  
Residues.
- p** : ndarray  
Poles.
- k** : ndarray  
Coefficients of the direct polynomial term.

**See also:**

`invres`, `residuez`, `numpy.poly`, `unique_roots`

`scipy.signal.residuez(b, a, tol=0.001, rtype='avg')`

Compute partial-fraction expansion of  $b(z) / a(z)$ .

If  $M$  is the degree of numerator  $b$  and  $N$  the degree of denominator  $a$ :

$$H(z) = \frac{b(z)}{a(z)} = \frac{b[0] + b[1] z^{**}(-1) + \dots + b[M] z^{**}(-M)}{a[0] + a[1] z^{**}(-1) + \dots + a[N] z^{**}(-N)}$$

then the partial-fraction expansion  $H(z)$  is defined as:

$$= \frac{r[0]}{(1-p[0]z^{**}(-1))} + \dots + \frac{r[-1]}{(1-p[-1]z^{**}(-1))} + k[0] + k[1]z^{**}(-1) \dots$$

If there are any repeated roots (closer than  $tol$ ), then the partial fraction expansion has terms like:

$$\frac{r[i]}{(1-p[i]z^{**}(-1))} + \frac{r[i+1]}{(1-p[i]z^{**}(-1))**2} + \dots + \frac{r[i+n-1]}{(1-p[i]z^{**}(-1))**n}$$

This function is used for polynomials in negative powers of  $z$ , such as digital filters in DSP. For positive powers, use `residue`.

**Parameters**

- b** : array\_like  
Numerator polynomial coefficients.
- a** : array\_like  
Denominator polynomial coefficients.

**Returns**

- r** : ndarray  
Residues.
- p** : ndarray  
Poles.
- k** : ndarray  
Coefficients of the direct polynomial term.

**See also:**

`invresz`, `residue`, `unique_roots`

`scipy.signal.invres(r, p, k, tol=0.001, rtype='avg')`  
 Compute  $b(s)$  and  $a(s)$  from partial fraction expansion.

If  $M$  is the degree of numerator  $b$  and  $N$  the degree of denominator  $a$ :

$$H(s) = \frac{b(s)}{a(s)} = \frac{b[0] s^{**}(M) + b[1] s^{**}(M-1) + \dots + b[M]}{a[0] s^{**}(N) + a[1] s^{**}(N-1) + \dots + a[N]}$$

then the partial-fraction expansion  $H(s)$  is defined as:

$$= \frac{r[0]}{(s-p[0])} + \frac{r[1]}{(s-p[1])} + \dots + \frac{r[-1]}{(s-p[-1])} + k(s)$$

If there are any repeated roots (closer together than `tol`), then  $H(s)$  has terms like:

$$\frac{r[i]}{(s-p[i])} + \frac{r[i+1]}{(s-p[i])**2} + \dots + \frac{r[i+n-1]}{(s-p[i])**n}$$

This function is used for polynomials in positive powers of  $s$  or  $z$ , such as analog filters or digital filters in controls engineering. For negative powers of  $z$  (typical for digital filters in DSP), use `invresz`.

**Parameters**

- r** : array\_like  
Residues.
- p** : array\_like  
Poles.
- k** : array\_like  
Coefficients of the direct polynomial term.
- tol** : float, optional  
The tolerance for two roots to be considered equal. Default is 1e-3.
- rtype** : { 'max', 'min', 'avg' }, optional  
How to determine the returned root if multiple roots are within `tol` of each other.
  - 'max': pick the maximum of those roots.
  - 'min': pick the minimum of those roots.
  - 'avg': take the average of those roots.

**Returns**

- b** : ndarray  
Numerator polynomial coefficients.
- a** : ndarray  
Denominator polynomial coefficients.

**See also:**`residue, invresz, unique_roots``scipy.signal.invresz(r, p, k, tol=0.001, rtype='avg')`Compute  $b(z)$  and  $a(z)$  from partial fraction expansion.If  $M$  is the degree of numerator  $b$  and  $N$  the degree of denominator  $a$ :

$$H(z) = \frac{b(z)}{a(z)} = \frac{b[0] + b[1]z^{*-1} + \dots + b[M]z^{*-M}}{a[0] + a[1]z^{*-1} + \dots + a[N]z^{*-N}}$$

then the partial-fraction expansion  $H(z)$  is defined as:

$$= \frac{r[0]}{(1-p[0]z^{*-1})} + \dots + \frac{r[-1]}{(1-p[-1]z^{*-1})} + k[0] + k[1]z^{*-1} \dots$$

If there are any repeated roots (closer than  $tol$ ), then the partial fraction expansion has terms like:

$$\frac{r[i]}{(1-p[i]z^{*-1})} + \frac{r[i+1]}{(1-p[i]z^{*-1})^{*2}} + \dots + \frac{r[i+n-1]}{(1-p[i]z^{*-1})^{*n}}$$

This function is used for polynomials in negative powers of  $z$ , such as digital filters in DSP. For positive powers, use `invres`.

**Parameters**

- r** : array\_like  
Residues.
- p** : array\_like  
Poles.
- k** : array\_like  
Coefficients of the direct polynomial term.
- tol** : float, optional  
The tolerance for two roots to be considered equal. Default is 1e-3.
- rtype** : { 'max', 'min', 'avg' }, optional  
How to determine the returned root if multiple roots are within  $tol$  of each other.
  - 'max': pick the maximum of those roots.
  - 'min': pick the minimum of those roots.
  - 'avg': take the average of those roots.

**Returns**

- b** : ndarray  
Numerator polynomial coefficients.
- a** : ndarray  
Denominator polynomial coefficients.

Lower-level filter design functions:

<code>abcd_normalize([A, B, C, D])</code>	Check state-space matrices and ensure they are two-dimensional.
<code>band_stop_obj(wp, ind, passb, stopb, gpass, ...)</code>	Band Stop Objective Function for order minimization.
<code>besselap(N[, norm])</code>	Return (z,p,k) for analog prototype of an Nth-order Bessel filter.

Continued on next page

Table 5.129 – continued from previous page

<code>buttap(N)</code>	Return (z,p,k) for analog prototype of Nth-order Butterworth filter.
<code>cheb1ap(N, rp)</code>	Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.
<code>cheb2ap(N, rs)</code>	Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.
<code>cmplx_sort(p)</code>	Sort roots based on magnitude.
<code>ellipap(N, rp, rs)</code>	Return (z,p,k) of Nth-order elliptic analog lowpass filter.
<code>lp2bp(b, a[, wo, bw])</code>	Transform a lowpass filter prototype to a bandpass filter.
<code>lp2bs(b, a[, wo, bw])</code>	Transform a lowpass filter prototype to a bandstop filter.
<code>lp2hp(b, a[, wo])</code>	Transform a lowpass filter prototype to a highpass filter.
<code>lp2lp(b, a[, wo])</code>	Transform a lowpass filter prototype to a different frequency.
<code>normalize(b, a)</code>	Normalize numerator/denominator of a continuous-time transfer function.

`scipy.signal.abcd_normalize` (*A=None, B=None, C=None, D=None*)

Check state-space matrices and ensure they are two-dimensional.

If enough information on the system is provided, that is, enough properly-shaped arrays are passed to the function, the missing ones are built from this information, ensuring the correct number of rows and columns. Otherwise a `ValueError` is raised.

**Parameters** **A, B, C, D** : array\_like, optional  
State-space matrices. All of them are None (missing) by default. See `ss2tf` for format.

**Returns** **A, B, C, D** : array

**Raises** **ValueError** Properly shaped state-space matrices.  
If not enough information on the system was provided.

`scipy.signal.band_stop_obj` (*wp, ind, passb, stopb, gpass, gstop, type*)

Band Stop Objective Function for order minimization.

Returns the non-integer order for an analog band stop filter.

**Parameters** **wp** : scalar  
Edge of passband *passb*.

**ind** : int, {0, 1}  
Index specifying which *passb* edge to vary (0 or 1).

**passb** : ndarray  
Two element sequence of fixed passband edges.

**stopb** : ndarray  
Two element sequence of fixed stopband edges.

**gstop** : float  
Amount of attenuation in stopband in dB.

**gpass** : float  
Amount of ripple in the passband in dB.

**type** : {'butter', 'cheby', 'ellip'}

**Returns** **n** : scalar  
Type of filter.  
Filter order (possibly non-integer).

`scipy.signal.besselap` (*N, norm='phase'*)

Return (z,p,k) for analog prototype of an Nth-order Bessel filter.

**Parameters** **N** : int  
The order of the filter.

**norm** : {'phase', 'delay', 'mag'}, optional  
Frequency normalization:

	<b><i>phase</i></b>	The filter is normalized such that the phase response reaches its midpoint at an angular (e.g. rad/s) cutoff frequency of 1. This happens for both low-pass and high-pass filters, so this is the “phase-matched” case. [R199] The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of $Wn$ . This is the default, and matches MATLAB’s implementation.
	<b><i>delay</i></b>	The filter is normalized such that the group delay in the pass-band is 1 (e.g. 1 second). This is the “natural” type obtained by solving Bessel polynomials.
	<b><i>mag</i></b>	The filter is normalized such that the gain magnitude is -3 dB at angular frequency 1. This is called “frequency normalization” by Bond. [R194]
<b>Returns</b>	<b><i>z</i></b> : ndarray	New in version 0.18.0. Zeros of the transfer function. Is always an empty array.
	<b><i>p</i></b> : ndarray	Poles of the transfer function.
	<b><i>k</i></b> : scalar	Gain of the transfer function. For phase-normalized, this is always 1.

**See also:*****bessel*** Filter design function using this prototype**Notes**

To find the pole locations, approximate starting points are generated [R195] for the zeros of the ordinary Bessel polynomial [R196], then the Aberth-Ehrlich method [R197] [R198] is used on the  $K_v(x)$  Bessel function to calculate more accurate zeros, and these locations are then inverted about the unit circle.

`scipy.signal.buttap` ( $N$ )

Return (z,p,k) for analog prototype of Nth-order Butterworth filter.

The filter will have an angular (e.g. rad/s) cutoff frequency of 1.

**See also:*****butter*** Filter design function using this prototype`scipy.signal.cheb1ap` ( $N, rp$ )

Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.

The returned filter prototype has  $rp$  decibels of ripple in the passband.The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below  $-rp$ .**See also:*****cheby1*** Filter design function using this prototype`scipy.signal.cheb2ap` ( $N, rs$ )

Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.

The returned filter prototype has  $rs$  decibels of ripple in the stopband.The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first reaches  $-rs$ .

**See also:**

***cheby2*** Filter design function using this prototype

`scipy.signal.complex_sort(p)`

Sort roots based on magnitude.

**Parameters** **p** : array\_like  
 The roots to sort, as a 1-D array.

**Returns** **p\_sorted** : ndarray  
 Sorted roots.

**indx** : ndarray  
 Array of indices needed to sort the input *p*.

`scipy.signal.ellipap(N, rp, rs)`

Return (z,p,k) of Nth-order elliptic analog lowpass filter.

The filter is a normalized prototype that has *rp* decibels of ripple in the passband and a stopband *rs* decibels down.

The filter's angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below  $-rp$ .

**See also:**

***ellip*** Filter design function using this prototype

**References**

[R215]

`scipy.signal.lp2bp(b, a, wo=1.0, bw=1.0)`

Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency *wo* and bandwidth *bw* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

`scipy.signal.lp2bs(b, a, wo=1.0, bw=1.0)`

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency *wo* and bandwidth *bw* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

`scipy.signal.lp2hp(b, a, wo=1.0)`

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency *wo* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

`scipy.signal.lp2lp(b, a, wo=1.0)`

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency *wo* from an analog low-pass filter prototype with unity cutoff frequency, in transfer function ('ba') representation.

`scipy.signal.normalize(b, a)`

Normalize numerator/denominator of a continuous-time transfer function.

If values of *b* are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

**Parameters** **b**: array\_like  
 Numerator of the transfer function. Can be a 2d array to normalize multiple transfer functions.

**a**: array\_like

<b>Returns</b>	num: array	Denominator of the transfer function. At most 1d.
	den: 1d-array	The numerator of the normalized transfer function. At least a 1d array. A 2d-array if the input <i>num</i> is a 2d array. The denominator of the normalized transfer function.

**Notes**

Coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.,  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

**5.20.5 Matlab-style IIR filter design**

---

<code>butter(N, Wn[, btype, analog, output])</code>	Butterworth digital and analog filter design.
<code>buttord(wp, ws, gpass, gstop[, analog])</code>	Butterworth filter order selection.
<code>cheby1(N, rp, Wn[, btype, analog, output])</code>	Chebyshev type I digital and analog filter design.
<code>cheblord(wp, ws, gpass, gstop[, analog])</code>	Chebyshev type I filter order selection.
<code>cheby2(N, rs, Wn[, btype, analog, output])</code>	Chebyshev type II digital and analog filter design.
<code>cheb2ord(wp, ws, gpass, gstop[, analog])</code>	Chebyshev type II filter order selection.
<code>ellip(N, rp, rs, Wn[, btype, analog, output])</code>	Elliptic (Cauer) digital and analog filter design.
<code>ellipord(wp, ws, gpass, gstop[, analog])</code>	Elliptic (Cauer) filter order selection.
<code>bessel(N, Wn[, btype, analog, output, norm])</code>	Bessel/Thomson digital and analog filter design.
<code>iirnotch(w0, Q)</code>	Design second-order IIR notch digital filter.
<code>iirpeak(w0, Q)</code>	Design second-order IIR peak (resonant) digital filter.

---

`scipy.signal.butter(N, Wn, btype='low', analog=False, output='ba')`

Butterworth digital and analog filter design.

Design an Nth-order digital or analog Butterworth filter and return the filter coefficients.

**Parameters** **N** : int

The order of the filter.

**Wn** : array\_like

A scalar or length-2 sequence giving the critical frequencies. For a Butterworth filter, this is the point at which the gain drops to  $1/\sqrt{2}$  that of the passband (the “-3 dB point”). For digital filters, *Wn* is normalized from 0 to 1, where 1 is the Nyquist frequency,  $\pi$  radians/sample. (*Wn* is thus in half-cycles / sample.) For analog filters, *Wn* is an angular frequency (e.g. rad/s).

**btype** : { ‘lowpass’, ‘highpass’, ‘bandpass’, ‘bandstop’ }, optional

The type of filter. Default is ‘lowpass’.

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**output** : { ‘ba’, ‘zpk’, ‘sos’ }, optional

Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’.

**Returns**

**b, a** : ndarray, ndarray

Numerator (*b*) and denominator (*a*) polynomials of the IIR filter. Only returned if `output='ba'`.

**z, p, k** : ndarray, ndarray, float

Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

**sos** : ndarray

Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

`butterd`, `butterap`

**Notes**

The Butterworth filter has maximally flat frequency response in the passband.

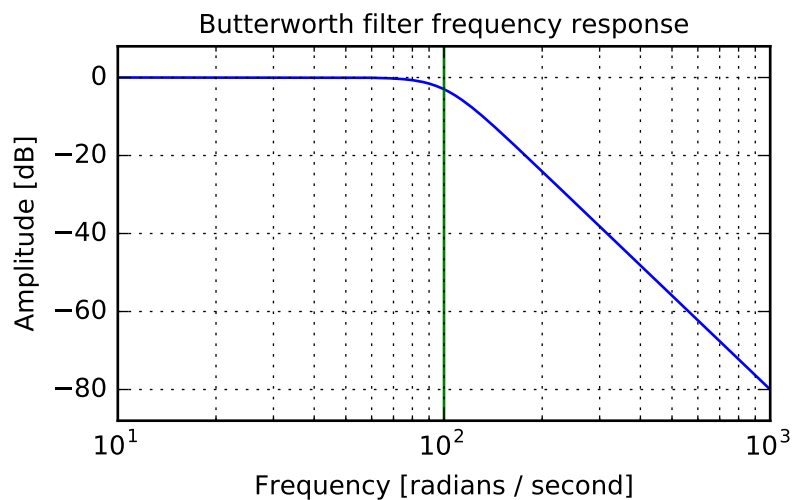

The `'sos'` output parameter was added in 0.16.0.

**Examples**

Plot the filter's frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.show()
```

`scipy.signal.buttord` (*wp*, *ws*, *gpass*, *gstop*, *analog=False*)  
Butterworth filter order selection.

Return the order of the lowest order digital or analog Butterworth filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

**Parameters** `wp, ws` : float

Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: *wp* = 0.2, *ws* = 0.3
- Highpass: *wp* = 0.3, *ws* = 0.2
- Bandpass: *wp* = [0.2, 0.5], *ws* = [0.1, 0.6]
- Bandstop: *wp* = [0.1, 0.6], *ws* = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g. rad/s).

<b>gpass</b> : float	The maximum loss in the passband (dB).
<b>gstop</b> : float	The minimum attenuation in the stopband (dB).
<b>analog</b> : bool, optional	When True, return an analog filter, otherwise a digital filter is returned.
<b>Returns</b>	
<b>ord</b> : int	The lowest order for a Butterworth filter which meets specs.
<b>wn</b> : ndarray or float	The Butterworth natural frequency (i.e. the “3dB frequency”). Should be used with <code>butter</code> to give filter results.

**`iirdesign`** General filter design using passband and stopband spec

#### Examples

Design an analog bandpass filter with passband within 3 dB from 20 to 50 rad/s, while rejecting at least -40 dB below 14 and above 60 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.buttord([20, 50], [14, 60], 3, 40, True)
>>> b, a = signal.butter(N, Wn, 'band', True)
>>> w, h = signal.freqs(b, a, np.logspace(1, 2, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth bandpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([1, 14, 14, 1], [-40, -40, 99, 99], '0.9', lw=0) # stop
>>> plt.fill([20, 20, 50, 50], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.fill([60, 60, 1e9, 1e9], [99, -40, -40, 99], '0.9', lw=0) # stop
>>> plt.axis([10, 100, -60, 3])
>>> plt.show()
```

`scipy.signal.cheby1(N, rp, Wn, btype='low', analog=False, output='ba')`  
Chebyshev type I digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type I filter and return the filter coefficients.

**Parameters**

- N** : int  
The order of the filter.
- rp** : float  
The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
- Wn** : array\_like  
A scalar or length-2 sequence giving the critical frequencies. For Type I filters, this is the point in the transition band at which the gain first drops below  $-rp$ . For digital filters,  $Wn$  is normalized from 0 to 1, where 1 is the Nyquist frequency,  $\pi$  radians/sample. ( $Wn$  is thus in half-cycles / sample.) For analog filters,  $Wn$  is an angular frequency (e.g. rad/s).
- btype** : {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional  
The type of filter. Default is 'lowpass'.
- analog** : bool, optional  
When True, return an analog filter, otherwise a digital filter is returned.
- output** : {'ba', 'zpk', 'sos'}, optional  
Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

- b, a** : ndarray, ndarray  
Numerator ( $b$ ) and denominator ( $a$ ) polynomials of the IIR filter. Only returned if `output='ba'`.
- z, p, k** : ndarray, ndarray, float  
Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.
- sos** : ndarray  
Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

`cheblord`, `cheblap`

### Notes

The Chebyshev type I filter maximizes the rate of cutoff between the frequency response's passband and stopband, at the expense of ripple in the passband and increased ringing in the step response.

Type I filters roll off faster than Type II (`cheby2`), but Type II filters do not have any ripple in the passband.

The equiripple passband has  $N$  maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or  $-rp$  dB for even-order filters.

The `'sos'` output parameter was added in 0.16.0.

### Examples

Plot the filter's frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby1(4, 5, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type I frequency response (rp=5)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

```
scipy.signal.cheblord(wp, ws, gpass, gstop, analog=False)
```

Chebyshev type I filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type I filter that loses no more than  $g_{pass}$  dB in the passband and has at least  $g_{stop}$  dB attenuation in the stopband.

**Parameters** `wp`, `ws` : float

Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. ( $wp$  and  $ws$  are thus in half-cycles / sample.) For example:

- Lowpass:  $wp = 0.2$ ,  $ws = 0.3$
- Highpass:  $wp = 0.3$ ,  $ws = 0.2$
- Bandpass:  $wp = [0.2, 0.5]$ ,  $ws = [0.1, 0.6]$
- Bandstop:  $wp = [0.1, 0.6]$ ,  $ws = [0.2, 0.5]$

For analog filters,  $wp$  and  $ws$  are angular frequencies (e.g. rad/s).

**gpass** : float

The maximum loss in the passband (dB).

**gstop** : float

The minimum attenuation in the stopband (dB).

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

**Returns**

**ord** : int

The lowest order for a Chebyshev type I filter that meets specs.

**wn** : ndarray or float

The Chebyshev natural frequency (the “3dB frequency”) for use with `cheby1` to give filter results.

**See also:**

`cheby1` Filter design using order and critical points

`buttord` Find order and critical points from passband and stopband spec

`cheb2ord`, `ellipord`

`iirfilter` General filter design using order and critical frequencies

`iirdesign` General filter design using passband and stopband spec

**Examples**

Design a digital lowpass filter such that the passband is within 3 dB up to  $0.2*(fs/2)$ , while rejecting at least -40 dB above  $0.3*(fs/2)$ . Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheblord(0.2, 0.3, 3, 40)
>>> b, a = signal.cheby1(N, 3, Wn, 'low')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev I lowpass filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([0.01, 0.2, 0.2, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([0.3, 0.3, 2, 2], [9, -40, -40, 9], '0.9', lw=0) # pass
>>> plt.axis([0.08, 1, -60, 3])
>>> plt.show()
```

`scipy.signal.cheby2(N, rs, Wn, btype='low', analog=False, output='ba')`  
 Chebyshev type II digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type II filter and return the filter coefficients.

**Parameters**

- N** : int  
The order of the filter.
- rs** : float  
The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- Wn** : array\_like  
A scalar or length-2 sequence giving the critical frequencies. For Type II filters, this is the point in the transition band at which the gain first reaches  $-rs$ . For digital filters,  $Wn$  is normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. ( $Wn$  is thus in half-cycles / sample.) For analog filters,  $Wn$  is an angular frequency (e.g. rad/s).
- btype** : {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional  
The type of filter. Default is 'lowpass'.
- analog** : bool, optional  
When True, return an analog filter, otherwise a digital filter is returned.
- output** : {'ba', 'zpk', 'sos'}, optional  
Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

- b, a** : ndarray, ndarray  
Numerator ( $b$ ) and denominator ( $a$ ) polynomials of the IIR filter. Only returned if `output='ba'`.
- z, p, k** : ndarray, ndarray, float  
Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.
- sos** : ndarray  
Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

See also:

[cheb2ord](#), [cheb2ap](#)

**Notes**

The Chebyshev type II filter maximizes the rate of cutoff between the frequency response's passband and stopband, at the expense of ripple in the stopband and increased ringing in the step response.

Type II filters do not roll off as fast as Type I (`cheby1`).

The `'sos'` output parameter was added in 0.16.0.

**Examples**

Plot the filter's frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby2(4, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type II frequency response (rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-40, color='green') # rs
>>> plt.show()
```

`scipy.signal.cheb2ord` (*wp, ws, gpass, gstop, analog=False*)  
Chebyshev type II filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type II filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

**Parameters** `wp, ws` : float

Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: `wp = 0.2, ws = 0.3`

- Highpass:  $w_p = 0.3$ ,  $w_s = 0.2$
- Bandpass:  $w_p = [0.2, 0.5]$ ,  $w_s = [0.1, 0.6]$
- Bandstop:  $w_p = [0.1, 0.6]$ ,  $w_s = [0.2, 0.5]$

For analog filters,  $w_p$  and  $w_s$  are angular frequencies (e.g. rad/s).

**gpass** : float

The maximum loss in the passband (dB).

**gstop** : float

The minimum attenuation in the stopband (dB).

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

#### Returns

**ord** : int

The lowest order for a Chebyshev type II filter that meets specs.

**wn** : ndarray or float

The Chebyshev natural frequency (the “3dB frequency”) for use with `cheby2` to give filter results.

#### See also:

`cheby2` Filter design using order and critical points

`buttord` Find order and critical points from passband and stopband spec

`iirfilter` General filter design using order and critical frequencies

`iirdesign` General filter design using passband and stopband spec

#### Examples

Design a digital bandstop filter which rejects -60 dB from  $0.2*(fs/2)$  to  $0.5*(fs/2)$ , while staying within 3 dB below  $0.1*(fs/2)$  or above  $0.6*(fs/2)$ . Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheb2ord([0.1, 0.6], [0.2, 0.5], 3, 60)
>>> b, a = signal.cheby2(N, 60, Wn, 'stop')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev II bandstop filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, .1, .1, .01], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([.2, .2, .5, .5], [ 9, -60, -60,  9], '0.9', lw=0) # pass
>>> plt.fill([.6, .6, 2, 2], [-99, -3, -3, -99], '0.9', lw=0) # stop
>>> plt.axis([0.06, 1, -80, 3])
>>> plt.show()
```

`scipy.signal.ellip` ( $N$ ,  $rp$ ,  $rs$ ,  $Wn$ ,  $btype='low'$ ,  $analog=False$ ,  $output='ba'$ )  
 Elliptic (Cauer) digital and analog filter design.

Design an Nth-order digital or analog elliptic filter and return the filter coefficients.

**Parameters**

- N** : int  
The order of the filter.
- rp** : float  
The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
- rs** : float  
The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- Wn** : array\_like  
A scalar or length-2 sequence giving the critical frequencies. For elliptic filters, this is the point in the transition band at which the gain first drops below  $-rp$ . For digital filters,  $Wn$  is normalized from 0 to 1, where 1 is the Nyquist frequency,  $\pi$  radians/sample. ( $Wn$  is thus in half-cycles / sample.) For analog filters,  $Wn$  is an angular frequency (e.g. rad/s).
- btype** : {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional  
The type of filter. Default is 'lowpass'.
- analog** : bool, optional  
When True, return an analog filter, otherwise a digital filter is returned.
- output** : {'ba', 'zpk', 'sos'}, optional  
Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

- b, a** : ndarray, ndarray  
Numerator ( $b$ ) and denominator ( $a$ ) polynomials of the IIR filter. Only returned if `output='ba'`.
- z, p, k** : ndarray, ndarray, float  
Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.
- sos** : ndarray  
Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

See also:

`ellipord`, `ellipap`

### Notes

Also known as Cauer or Zolotarev filters, the elliptical filter maximizes the rate of transition between the frequency response's passband and stopband, at the expense of ripple in both, and increased ringing in the step response.

As *rp* approaches 0, the elliptical filter becomes a Chebyshev type II filter (`cheby2`). As *rs* approaches 0, it becomes a Chebyshev type I filter (`cheby1`). As both approach 0, it becomes a Butterworth filter (`butter`).

The equiripple passband has *N* maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or -*rp* dB for even-order filters.

The '`sos`' output parameter was added in 0.16.0.

### Examples

Plot the filter's frequency response, showing the critical points:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.ellip(4, 5, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptic filter frequency response (rp=5, rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-40, color='green') # rs
>>> plt.axhline(-5, color='green') # rp
>>> plt.show()
```

`scipy.signal.ellipord` (*wp*, *ws*, *gpass*, *gstop*, *analog=False*)  
Elliptic (Cauer) filter order selection.

Return the order of the lowest order digital or analog elliptic filter that loses no more than *gpass* dB in the passband and has at least *gstop* dB attenuation in the stopband.

**Parameters**

**wp, ws** : float  
Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (*wp* and *ws* are thus in half-cycles / sample.) For example:

- Lowpass: *wp* = 0.2, *ws* = 0.3
- Highpass: *wp* = 0.3, *ws* = 0.2
- Bandpass: *wp* = [0.2, 0.5], *ws* = [0.1, 0.6]
- Bandstop: *wp* = [0.1, 0.6], *ws* = [0.2, 0.5]

For analog filters, *wp* and *ws* are angular frequencies (e.g. rad/s).

**gpass** : float  
The maximum loss in the passband (dB).

**gstop** : float  
The minimum attenuation in the stopband (dB).

**analog** : bool, optional  
When True, return an analog filter, otherwise a digital filter is returned.

**Returns**

**ord** : int  
The lowest order for an Elliptic (Cauer) filter that meets specs.

**wn** : ndarray or float  
The Chebyshev natural frequency (the “3dB frequency”) for use with `ellip` to give filter results.

`iirdesign` General filter design using passband and stopband spec

### Examples

Design an analog highpass filter such that the passband is within 3 dB above 30 rad/s, while rejecting -60 dB at 10 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.ellipord(30, 10, 3, 60, True)
>>> b, a = signal.ellip(N, 3, 60, Wn, 'high', True)
>>> w, h = signal.freqs(b, a, np.logspace(0, 3, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptical highpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.1, 10, 10, .1], [1e4, 1e4, -60, -60], '0.9', lw=0) # stop
>>> plt.fill([30, 30, 1e9, 1e9], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.axis([1, 300, -80, 3])
>>> plt.show()
```

`scipy.signal.bessel` ( $N$ ,  $Wn$ ,  $btype='low'$ ,  $analog=False$ ,  $output='ba'$ ,  $norm='phase'$ )  
Bessel/Thomson digital and analog filter design.

Design an  $N$ th-order digital or analog Bessel filter and return the filter coefficients.

**Parameters**  $N$  : int

The order of the filter.

$Wn$  : array\_like

A scalar or length-2 sequence giving the critical frequencies (defined by the *norm* parameter). For analog filters,  $Wn$  is an angular frequency (e.g. rad/s). For digital filters,  $Wn$  is normalized from 0 to 1, where 1 is the Nyquist frequency,  $\pi$  radians/sample. ( $Wn$  is thus in half-cycles / sample.)

**btype** : {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional

The type of filter. Default is 'lowpass'.

**analog** : bool, optional

When True, return an analog filter, otherwise a digital filter is returned. (See Notes.)

**output** : {'ba', 'zpk', 'sos'}, optional

Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**norm** : {'phase', 'delay', 'mag'}, optional

Critical frequency normalization:

**phase**

The filter is normalized such that the phase response reaches its midpoint at angular (e.g. rad/s) frequency  $Wn$ . This happens for both low-pass and high-pass filters, so this is the "phase-matched" case.

The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of  $Wn$ .

This is the default, and matches MATLAB's implementation.

**delay**

The filter is normalized such that the group delay in the pass-band is  $1/Wn$  (e.g. seconds). This is the "natural" type obtained by solving Bessel polynomials.

**mag**

The filter is normalized such that the gain magnitude is -3 dB at angular frequency  $Wn$ .

**Returns**  $b, a$  : ndarray, ndarray New in version 0.18.0.

Numerator ( $b$ ) and denominator ( $a$ ) polynomials of the IIR filter. Only returned if `output='ba'`.

**z, p, k** : ndarray, ndarray, float  
Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

**sos** : ndarray  
Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

### Notes

Also known as a Thomson filter, the analog Bessel filter has maximally flat group delay and maximally linear phase response, with very little ringing in the step response. [R193]

The Bessel is inherently an analog filter. This function generates digital Bessel filters using the bilinear transform, which does not preserve the phase response of the analog filter. As such, it is only approximately correct at frequencies below about  $fs/4$ . To get maximally-flat group delay at higher frequencies, the analog Bessel filter must be transformed using phase-preserving techniques.

See `besselap` for implementation details and references.

The `'sos'` output parameter was added in 0.16.0.

### References

[R193]

### Examples

Plot the phase-normalized frequency response, showing the relationship to the Butterworth's cutoff frequency (green):

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)), color='silver', ls='dashed')
>>> b, a = signal.bessel(4, 100, 'low', analog=True, norm='phase')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.title('Bessel filter magnitude response (with Butterworth)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.show()
```

and the phase midpoint:

```
>>> plt.figure()
>>> plt.semilogx(w, np.unwrap(np.angle(h)))
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.axhline(-np.pi, color='red') # phase midpoint
>>> plt.title('Bessel filter phase response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Phase [radians]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```

Plot the magnitude-normalized frequency response, showing the -3 dB cutoff:

```
>>> b, a = signal.bessel(3, 10, 'low', analog=True, norm='mag')
>>> w, h = signal.freqs(b, a)
```

```

>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.axhline(-3, color='red') # -3 dB magnitude
>>> plt.axvline(10, color='green') # cutoff frequency
>>> plt.title('Magnitude-normalized Bessel filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()

```

Plot the delay-normalized filter, showing the maximally-flat group delay at 0.1 seconds:

```

>>> b, a = signal.bessel(5, 1/0.1, 'low', analog=True, norm='delay')
>>> w, h = signal.freqs(b, a)
>>> plt.figure()
>>> plt.semilogx(w[1:], -np.diff(np.unwrap(np.angle(h)))/np.diff(w))
>>> plt.axhline(0.1, color='red') # 0.1 seconds group delay
>>> plt.title('Bessel filter group delay')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Group delay [seconds]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()

```

`scipy.signal.iirnotch(w0, Q)`

Design second-order IIR notch digital filter.

A notch filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

**Parameters** **w0** : float

Normalized frequency to remove from a signal. It is a scalar that must satisfy  $0 < w0 < 1$ , with  $w0 = 1$  corresponding to half of the sampling frequency.

**Q** : float

Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth  $bw$  relative to its center frequency,  $Q = w0/bw$ .

**Returns**

**b, a** : ndarray, ndarray  
 Numerator (b) and denominator (a) polynomials of the IIR filter.

**See also:**

`iirpeak`

**Notes**

**References**

[R239]

**Examples**

Design and plot filter to remove the 60Hz component from a signal sampled at 200Hz, using a quality factor  $Q = 30$

```
>>> from scipy import signal
>>> import numpy as np
>>> import matplotlib.pyplot as plt

>>> fs = 200.0 # Sample frequency (Hz)
>>> f0 = 60.0 # Frequency to be removed from signal (Hz)
>>> Q = 30.0 # Quality factor
>>> w0 = f0/(fs/2) # Normalized Frequency
```

```

>>> # Design notch filter
>>> b, a = signal.iirnotch(w0, Q)

>>> # Frequency response
>>> w, h = signal.freqz(b, a)
>>> # Generate frequency axis
>>> freq = w*fs/(2*np.pi)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-25, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()

```

`scipy.signal.iirpeak(w0, Q)`

Design second-order IIR peak (resonant) digital filter.

A peak filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a

narrow frequency band.

<b>Parameters</b>	<b>w0</b> : float	Normalized frequency to be retained in a signal. It is a scalar that must satisfy $0 < w0 < 1$ , with $w0 = 1$ corresponding to half of the sampling frequency.
	<b>Q</b> : float	Quality factor. Dimensionless parameter that characterizes peak filter -3 dB bandwidth $bw$ relative to its center frequency, $Q = w0/bw$ .
<b>Returns</b>	<b>b, a</b> : ndarray, ndarray	Numerator (b) and denominator (a) polynomials of the IIR filter.

**See also:**

`iirnotch`

**Notes**

**References**

[R240]

**Examples**

Design and plot filter to remove the frequencies other than the 300Hz component from a signal sampled at 1000Hz, using a quality factor  $Q = 30$

```
>>> from scipy import signal
>>> import numpy as np
>>> import matplotlib.pyplot as plt

>>> fs = 1000.0 # Sample frequency (Hz)
>>> f0 = 300.0 # Frequency to be retained (Hz)
>>> Q = 30.0 # Quality factor
>>> w0 = f0/(fs/2) # Normalized Frequency
>>> # Design peak filter
>>> b, a = signal.iirpeak(w0, Q)

>>> # Frequency response
>>> w, h = signal.freqz(b, a)
>>> # Generate frequency axis
>>> freq = w*fs/(2*np.pi)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-50, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

## 5.20.6 Continuous-Time Linear Systems

<code>lti(*system)</code>	Continuous-time linear time invariant system base class.
<code>StateSpace(*system, **kwargs)</code>	Linear Time Invariant system in state-space form.
<code>TransferFunction(*system, **kwargs)</code>	Linear Time Invariant system class in transfer function form.
<code>ZerosPolesGain(*system, **kwargs)</code>	Linear Time Invariant system class in zeros, poles, gain form.
<code>lsim(system, U, T[, X0, interp])</code>	Simulate output of a continuous-time linear system.
<code>lsim2(system[, U, T, X0])</code>	Simulate output of a continuous-time linear system, by using the ODE solver <code>scipy.integrate.odeint</code> .
<code>impulse(system[, X0, T, N])</code>	Impulse response of continuous-time system.
<code>impulse2(system[, X0, T, N])</code>	Impulse response of a single-input, continuous-time linear system.
<code>step(system[, X0, T, N])</code>	Step response of continuous-time system.
<code>step2(system[, X0, T, N])</code>	Step response of continuous-time system.
<code>freqresp(system[, w, n])</code>	Calculate the frequency response of a continuous-time system.
<code>bode(system[, w, n])</code>	Calculate Bode magnitude and phase data of a continuous-time system.

**class** `scipy.signal.lti(*system)`  
 Continuous-time linear time invariant system base class.

**Parameters** `*system` : arguments

The `lti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding continuous-time subclass that is created:

- 2: `TransferFunction`: (numerator, denominator)
- 3: `ZerosPolesGain`: (zeros, poles, gain)

•4: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

**See also:**

`ZerosPolesGain`, `StateSpace`, `TransferFunction`, `dlti`

**Notes**

`lti` instances do not exist directly. Instead, `lti` creates an instance of one of its subclasses: `StateSpace`, `TransferFunction` or `ZerosPolesGain`.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.,  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

Changing the value of properties that are not directly part of the current system representation (such as the `zeros` of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

**Examples**

```
>>> from scipy import signal

>>> signal.lti(1, 2, 3, 4)
StateSpaceContinuous(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: None
)

>>> signal.lti([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
array([1, 2]),
array([3, 4]),
5,
dt: None
)

>>> signal.lti([3, 4], [1, 2])
TransferFunctionContinuous(
array([ 3.,  4.]),
array([ 1.,  2.]),
dt: None
)
```

**Attributes**

A	State matrix of the <code>StateSpace</code> system.
B	Input matrix of the <code>StateSpace</code> system.
C	Output matrix of the <code>StateSpace</code> system.
D	Feedthrough matrix of the <code>StateSpace</code> system.
den	Denominator of the <code>TransferFunction</code> system.

Continued on next page

Table 5.132 – continued from previous page

<code>dt</code>	Return the sampling time of the system, <i>None</i> for <code>lti</code> systems.
<code>gain</code>	Gain of the <code>ZerosPolesGain</code> system.
<code>num</code>	Numerator of the <code>TransferFunction</code> system.
<code>poles</code>	Poles of the system.
<code>zeros</code>	Zeros of the system.

`lti.A`  
State matrix of the `StateSpace` system.

`lti.B`  
Input matrix of the `StateSpace` system.

`lti.C`  
Output matrix of the `StateSpace` system.

`lti.D`  
Feedthrough matrix of the `StateSpace` system.

`lti.den`  
Denominator of the `TransferFunction` system.

`lti.dt`  
Return the sampling time of the system, *None* for `lti` systems.

`lti.gain`  
Gain of the `ZerosPolesGain` system.

`lti.num`  
Numerator of the `TransferFunction` system.

`lti.poles`  
Poles of the system.

`lti.zeros`  
Zeros of the system.

### Methods

<code>bode([w, n])</code>	Calculate Bode magnitude and phase data of a continuous-time system.
<code>freqresp([w, n])</code>	Calculate the frequency response of a continuous-time system.
<code>impulse([X0, T, N])</code>	Return the impulse response of a continuous-time system.
<code>output(U, T[, X0])</code>	Return the response of a continuous-time system to input <i>U</i> .
<code>step([X0, T, N])</code>	Return the step response of a continuous-time system.
<code>to_discrete(dt[, method, alpha])</code>	Return a discretized version of the current system.

`lti.bode` (*w=None, n=100*)  
Calculate Bode magnitude and phase data of a continuous-time system.  
  
Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See `bode` for details.

### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

```

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = sys.bode()

>>> plt.figure()
>>> plt.semilogx(w, mag)      # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)   # Bode phase plot
>>> plt.show()

```

`lti.freqresp` ( $w=None, n=10000$ )

Calculate the frequency response of a continuous-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `freqresp` for details.

`lti.impulse` ( $X0=None, T=None, N=None$ )

Return the impulse response of a continuous-time system. See `impulse` for details.

`lti.output` (*U*, *T*, *X0=None*)  
 Return the response of a continuous-time system to input *U*. See `lsim` for details.

`lti.step` (*X0=None*, *T=None*, *N=None*)  
 Return the step response of a continuous-time system. See `step` for details.

`lti.to_discrete` (*dt*, *method='zoh'*, *alpha=None*)  
 Return a discretized version of the current system.

Parameters: See `cont2discrete` for details.

**Returns** sys: instance of `dlti`

**class** `scipy.signal.StateSpace` (*\*system*, *\*\*kwargs*)

Linear Time Invariant system in state-space form.

Represents the system as the continuous-time, first order differential equation  $\dot{x} = Ax + Bu$  or the discrete-time difference equation  $x[k+1] = Ax[k] + Bu[k]$ . `StateSpace` systems inherit additional functionality from the `lti`, respectively the `dlti` classes, depending on which system representation is used.

**Parameters** **\*system: arguments**

The `StateSpace` class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:

- 1: `lti` or `dlti` system: (`StateSpace`, `TransferFunction` or `ZerosPolesGain`)
- 4: array\_like: (A, B, C, D)

**dt: float, optional**

Sampling time [s] of the discrete-time systems. Defaults to `None` (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`TransferFunction`, `ZerosPolesGain`, `lti`, `dlti`, `ss2zpk`, `ss2tf`, `zpk2sos`

**Notes**

Changing the value of properties that are not part of the `StateSpace` system representation (such as `zeros` or `poles`) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

**Examples**

```
>>> from scipy import signal

>>> a = np.array([[0, 1], [0, 0]])
>>> b = np.array([[0], [1]])
>>> c = np.array([[1, 0]])
>>> d = np.array([[0]])

>>> sys = signal.StateSpace(a, b, c, d)
>>> print(sys)
StateSpaceContinuous(
array([[0, 1],
       [0, 0]]),
array([[0],
       [1]]),
array([[1, 0]]),
```

```

array([[0]]),
dt: None
)

>>> sys.to_discrete(0.1)
StateSpaceDiscrete(
array([[ 1. ,  0.1],
       [ 0. ,  1. ]]),
array([[ 0.005],
       [ 0.1  ]]),
array([[1, 0]]),
array([[0]]),
dt: 0.1
)

>>> a = np.array([[1, 0.1], [0, 1]])
>>> b = np.array([[0.005], [0.1]])

>>> signal.StateSpace(a, b, c, d, dt=0.1)
StateSpaceDiscrete(
array([[ 1. ,  0.1],
       [ 0. ,  1. ]]),
array([[ 0.005],
       [ 0.1  ]]),
array([[1, 0]]),
array([[0]]),
dt: 0.1
)

```

**Attributes**

---

<code>A</code>	State matrix of the <code>StateSpace</code> system.
<code>B</code>	Input matrix of the <code>StateSpace</code> system.
<code>C</code>	Output matrix of the <code>StateSpace</code> system.
<code>D</code>	Feedthrough matrix of the <code>StateSpace</code> system.
<code>den</code>	Denominator of the <code>TransferFunction</code> system.
<code>dt</code>	Return the sampling time of the system, <i>None</i> for <code>lti</code> systems.
<code>gain</code>	Gain of the <code>ZerosPolesGain</code> system.
<code>num</code>	Numerator of the <code>TransferFunction</code> system.
<code>poles</code>	Poles of the system.
<code>zeros</code>	Zeros of the system.

---

**StateSpace.A**

State matrix of the `StateSpace` system.

**StateSpace.B**

Input matrix of the `StateSpace` system.

**StateSpace.C**

Output matrix of the `StateSpace` system.

**StateSpace.D**

Feedthrough matrix of the `StateSpace` system.

**StateSpace.den**

Denominator of the `TransferFunction` system.

`StateSpace.dt`

Return the sampling time of the system, `None` for `lti` systems.

`StateSpace.gain`

Gain of the `ZerosPolesGain` system.

`StateSpace.num`

Numerator of the `TransferFunction` system.

`StateSpace.poles`

Poles of the system.

`StateSpace.zeros`

Zeros of the system.

**Methods**

<code>to_ss()</code>	Return a copy of the current <code>StateSpace</code> system.
<code>to_tf(**kwargs)</code>	Convert system representation to <code>TransferFunction</code> .
<code>to_zpk(**kwargs)</code>	Convert system representation to <code>ZerosPolesGain</code> .

`StateSpace.to_ss()`

Return a copy of the current `StateSpace` system.

**Returns** `sys` : instance of `StateSpace`  
The current system (copy)

`StateSpace.to_tf(**kwargs)`

Convert system representation to `TransferFunction`.

**Parameters** `kwargs` : dict, optional  
Additional keywords passed to `ss2zpk`  
**Returns** `sys` : instance of `TransferFunction`  
Transfer function of the current system

`StateSpace.to_zpk(**kwargs)`

Convert system representation to `ZerosPolesGain`.

**Parameters** `kwargs` : dict, optional  
Additional keywords passed to `ss2zpk`  
**Returns** `sys` : instance of `ZerosPolesGain`  
Zeros, poles, gain representation of the current system

**class** `scipy.signal.TransferFunction(*system, **kwargs)`

Linear Time Invariant system class in transfer function form.

Represents the system as the continuous-time transfer function  $H(s) = \sum_{i=0}^N b[N-i]s^i / \sum_{j=0}^M a[M-j]s^j$  or the discrete-time transfer function  $H(z) = \sum_{i=0}^N b[N-i]z^i / \sum_{j=0}^M a[M-j]z^j$ , where `b` are elements of the numerator `num`, `a` are elements of the denominator `den`, and `N == len(b) - 1`, `M == len(a) - 1`. `TransferFunction` systems inherit additional functionality from the `lti`, respectively the `dlti` classes, depending on which system representation is used.

**Parameters** `*system: arguments`  
The `TransferFunction` class can be instantiated with 1 or 2 arguments. The following gives the number of input arguments and their interpretation:

- 1: `lti` or `dlti` system: (`StateSpace`, `TransferFunction` or `ZerosPolesGain`)
- 2: `array_like`: (numerator, denominator)

**dt**: float, optional

Sampling time [s] of the discrete-time systems. Defaults to *None* (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`ZerosPolesGain`, `StateSpace`, `lti`, `dlti`, `tf2ss`, `tf2zpk`, `tf2sos`

**Notes**

Changing the value of properties that are not part of the `TransferFunction` system representation (such as the `A`, `B`, `C`, `D` state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the `A`, `B`, `C`, `D` system matrices.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  or  $z^2 + 3z + 5$  would be represented as `[1, 3, 5]`)

**Examples**

Construct the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> from scipy import signal
```

```
>>> num = [1, 3, 3]
```

```
>>> den = [1, 2, 1]
```

```
>>> signal.TransferFunction(num, den)
TransferFunctionContinuous(
array([ 1.,  3.,  3.]),
array([ 1.,  2.,  1.]),
dt: None
)
```

Construct the transfer function with a sampling time of 0.1 seconds:

$$H(z) = \frac{z^2 + 3z + 3}{z^2 + 2z + 1}$$

```
>>> signal.TransferFunction(num, den, dt=0.1)
TransferFunctionDiscrete(
array([ 1.,  3.,  3.]),
array([ 1.,  2.,  1.]),
dt: 0.1
)
```

Table 5.136 – continued from previous page

*Attributes*

---

<code>A</code>	State matrix of the <code>StateSpace</code> system.
<code>B</code>	Input matrix of the <code>StateSpace</code> system.
<code>C</code>	Output matrix of the <code>StateSpace</code> system.
<code>D</code>	Feedthrough matrix of the <code>StateSpace</code> system.
<code>den</code>	Denominator of the <code>TransferFunction</code> system.
<code>dt</code>	Return the sampling time of the system, <i>None</i> for <code>lti</code> systems.
<code>gain</code>	Gain of the <code>ZerosPolesGain</code> system.
<code>num</code>	Numerator of the <code>TransferFunction</code> system.
<code>poles</code>	Poles of the system.
<code>zeros</code>	Zeros of the system.

---

`TransferFunction.A`  
State matrix of the `StateSpace` system.

`TransferFunction.B`  
Input matrix of the `StateSpace` system.

`TransferFunction.C`  
Output matrix of the `StateSpace` system.

`TransferFunction.D`  
Feedthrough matrix of the `StateSpace` system.

`TransferFunction.den`  
Denominator of the `TransferFunction` system.

`TransferFunction.dt`  
Return the sampling time of the system, *None* for `lti` systems.

`TransferFunction.gain`  
Gain of the `ZerosPolesGain` system.

`TransferFunction.num`  
Numerator of the `TransferFunction` system.

`TransferFunction.poles`  
Poles of the system.

`TransferFunction.zeros`  
Zeros of the system.

*Methods*

---

<code>to_ss()</code>	Convert system representation to <code>StateSpace</code> .
<code>to_tf()</code>	Return a copy of the current <code>TransferFunction</code> system.
<code>to_zpk()</code>	Convert system representation to <code>ZerosPolesGain</code> .

---

`TransferFunction.to_ss()`  
Convert system representation to `StateSpace`.

**Returns** `sys` : instance of `StateSpace`  
State space model of the current system

`TransferFunction.to_tf()`

Return a copy of the current `TransferFunction` system.

**Returns** `sys` : instance of `TransferFunction`  
The current system (copy)

`TransferFunction.to_zpk()`

Convert system representation to `ZerosPolesGain`.

**Returns** `sys` : instance of `ZerosPolesGain`  
Zeros, poles, gain representation of the current system

**class** `scipy.signal.ZerosPolesGain(*system, **kwargs)`

Linear Time Invariant system class in zeros, poles, gain form.

Represents the system as the continuous- or discrete-time transfer function  $H(s) = k \prod_i (s - z[i]) / \prod_j (s - p[j])$ , where  $k$  is the `gain`,  $z$  are the `zeros` and  $p$  are the `poles`. `ZerosPolesGain` systems inherit additional functionality from the `lti`, respectively the `dlti` classes, depending on which system representation is used.

**Parameters** `*system` : arguments

The `ZerosPolesGain` class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:

- 1: `lti` or `dlti` system: (`StateSpace`, `TransferFunction` or `ZerosPolesGain`)
- 3: `array_like`: (`zeros`, `poles`, `gain`)

**dt**: float, optional

Sampling time [s] of the discrete-time systems. Defaults to `None` (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`TransferFunction`, `StateSpace`, `lti`, `dlti`, `zpk2ss`, `zpk2tf`, `zpk2sos`

**Notes**

Changing the value of properties that are not part of the `ZerosPolesGain` system representation (such as the `A`, `B`, `C`, `D` state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the `A`, `B`, `C`, `D` system matrices.

**Examples**

```
>>> from scipy import signal
```

Transfer function:  $H(s) = 5(s - 1)(s - 2) / (s - 3)(s - 4)$

```
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
  array([1, 2]),
  array([3, 4]),
  5,
  dt: None
)
```

Transfer function:  $H(z) = 5(z - 1)(z - 2) / (z - 3)(z - 4)$

```
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
  array([1, 2]),
  array([3, 4]),
```

```
5,
dt: 0.1
)
```

**Attributes**

---

<code>A</code>	State matrix of the <code>StateSpace</code> system.
<code>B</code>	Input matrix of the <code>StateSpace</code> system.
<code>C</code>	Output matrix of the <code>StateSpace</code> system.
<code>D</code>	Feedthrough matrix of the <code>StateSpace</code> system.
<code>den</code>	Denominator of the <code>TransferFunction</code> system.
<code>dt</code>	Return the sampling time of the system, <i>None</i> for <code>lti</code> systems.
<code>gain</code>	Gain of the <code>ZerosPolesGain</code> system.
<code>num</code>	Numerator of the <code>TransferFunction</code> system.
<code>poles</code>	Poles of the <code>ZerosPolesGain</code> system.
<code>zeros</code>	Zeros of the <code>ZerosPolesGain</code> system.

---

`ZerosPolesGain.A`  
State matrix of the `StateSpace` system.

`ZerosPolesGain.B`  
Input matrix of the `StateSpace` system.

`ZerosPolesGain.C`  
Output matrix of the `StateSpace` system.

`ZerosPolesGain.D`  
Feedthrough matrix of the `StateSpace` system.

`ZerosPolesGain.den`  
Denominator of the `TransferFunction` system.

`ZerosPolesGain.dt`  
Return the sampling time of the system, *None* for `lti` systems.

`ZerosPolesGain.gain`  
Gain of the `ZerosPolesGain` system.

`ZerosPolesGain.num`  
Numerator of the `TransferFunction` system.

`ZerosPolesGain.poles`  
Poles of the `ZerosPolesGain` system.

`ZerosPolesGain.zeros`  
Zeros of the `ZerosPolesGain` system.

**Methods**

---

<code>to_ss()</code>	Convert system representation to <code>StateSpace</code> .
<code>to_tf()</code>	Convert system representation to <code>TransferFunction</code> .
<code>to_zpk()</code>	Return a copy of the current 'ZerosPolesGain' system.

---

`ZerosPolesGain.to_ss()`  
Convert system representation to `StateSpace`.

**Returns** `sys` : instance of `StateSpace`

State space model of the current system

`ZerosPolesGain.to_tf()`

Convert system representation to `TransferFunction`.

**Returns** `sys` : instance of `TransferFunction`  
Transfer function of the current system

`ZerosPolesGain.to_zpk()`

Return a copy of the current ‘ZerosPolesGain’ system.

**Returns** `sys` : instance of `ZerosPolesGain`  
The current system (copy)

`scipy.signal.lsim(system, U, T, X0=None, interp=True)`

Simulate output of a continuous-time linear system.

**Parameters** `system` : an instance of the LTI class or a tuple describing the system.  
The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `lti`)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

`U` : array\_like

An input array describing the input at each time  $T$  (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input. If  $U = 0$  or `None`, a zero input is used.

`T` : array\_like

The time steps at which the input is defined and at which the output is desired. Must be nonnegative, increasing, and equally spaced.

`X0` : array\_like, optional

The initial conditions on the state vector (zero by default).

`interp` : bool, optional

Whether to use linear (`True`, the default) or zero-order-hold (`False`) interpolation for the input array.

**Returns** `T` : 1D ndarray

Time values for the output.

`yout` : 1D ndarray

System response.

`xout` : ndarray

Time evolution of the state vector.

### Notes

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

### Examples

Simulate a double integrator  $y'' = u$ , with a constant input  $u = 1$

```
>>> from scipy import signal
>>> system = signal.lti([[0., 1.], [0., 0.]], [[0.], [1.]], [[1., 0.]], 0.)
>>> t = np.linspace(0, 5)
>>> u = np.ones_like(t)
>>> tout, y, x = signal.lsim(system, u, t)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

`scipy.signal.lsim2` (*system*, *U=None*, *T=None*, *X0=None*, *\*\*kwargs*)

Simulate output of a continuous-time linear system, by using the ODE solver `scipy.integrate.odeint`.

**Parameters** **system** : an instance of the `lti` class or a tuple describing the system.  
The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `lti`)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

**U** : array\_like (1D or 2D), optional

An input array describing the input at each time *T*. Linear interpolation is used between given times. If there are multiple inputs, then each column of the rank-2 array represents an input. If *U* is not given, the input is assumed to be zero.

**T** : array\_like (1D or 2D), optional

The time steps at which the input is defined and at which the output is desired. The default is 101 evenly spaced points on the interval [0,10.0].

**X0** : array\_like (1D), optional

The initial condition of the state vector. If *X0* is not given, the initial conditions are assumed to be 0.

**kwargs** : dict

Additional keyword arguments are passed on to the function `odeint`. See the notes below for more details.

**Returns** **T** : 1D ndarray

The time values for the output.

**yout** : ndarray

The response of the system.

**xout** : ndarray

The time-evolution of the state-vector.

### Notes

This function uses `scipy.integrate.odeint` to solve the system's differential equations. Additional keyword arguments given to `lsim2` are passed on to `odeint`. See the documentation for `scipy.integrate.odeint` for the full list of arguments.

If (num, den) is passed in for *system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

`scipy.signal.impulse` (*system*, *X0=None*, *T=None*, *N=None*)

Impulse response of continuous-time system.

**Parameters**

- system** : an instance of the LTI class or a tuple of array\_like describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- X0** : array\_like, optional  
Initial state-vector. Defaults to zero.
- T** : array\_like, optional  
Time points. Computed if not given.
- N** : int, optional  
The number of time points to compute (if *T* is not given).

**Returns**

- T** : ndarray  
A 1-D array of time points.
- yout** : ndarray  
A 1-D array containing the impulse response of the system (except for singularities at zero).

#### Notes

If (num, den) is passed in for *system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

`scipy.signal.impulse2` (*system*, *X0=None*, *T=None*, *N=None*, **\*\*kwargs**)

Impulse response of a single-input, continuous-time linear system.

**Parameters**

- system** : an instance of the LTI class or a tuple of array\_like describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)
- X0** : 1-D array\_like, optional  
The initial condition of the state vector. Default: 0 (the zero vector).
- T** : 1-D array\_like, optional  
The time steps at which the input is defined and at which the output is desired. If *T* is not given, the function will generate a set of time samples automatically.
- N** : int, optional  
Number of time points to compute. Default: 100.
- kwargs** : various types  
Additional keyword arguments are passed on to the function `scipy.signal.lsim2`, which in turn passes them on to `scipy.integrate.odeint`; see the latter's documentation for information about these arguments.

**Returns**

- T** : ndarray  
The time values for the output.
- yout** : ndarray  
The output response of the system.

See also:

`impulse`, `lsim2`, `integrate.odeint`

**Notes**

The solution is generated by calling `scipy.signal.lsim2`, which uses the differential equation solver `scipy.integrate.odeint`.

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as `[1, 3, 5]`).

New in version 0.8.0.

**Examples**

Second order system with a repeated root:  $x''(t) + 2x'(t) + x(t) = u(t)$

```
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse2(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

`scipy.signal.step` (*system, X0=None, T=None, N=None*)

Step response of continuous-time system.

**Parameters** **system** : an instance of the LTI class or a tuple of array\_like describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of `lti`)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

**X0** : array\_like, optional  
Initial state-vector (default is zero).

**T** : array\_like, optional  
Time points (computed if not given).

**N** : int, optional  
Number of time points to compute if *T* is not given.

**Returns** **T** : 1D ndarray  
Output time points.

**yout** : 1D ndarray  
Step response of system.

**See also:**`scipy.signal.step2`**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

`scipy.signal.step2` (*system*, *X0=None*, *T=None*, *N=None*, *\*\*kwargs*)  
 Step response of continuous-time system.

This function is functionally the same as `scipy.signal.step`, but it uses the function `scipy.signal.lsim2` to compute the step response.

**Parameters** **system** : an instance of the LTI class or a tuple of array\_like describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of `lti`)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

**X0** : array\_like, optional  
 Initial state-vector (default is zero).

**T** : array\_like, optional  
 Time points (computed if not given).

**N** : int, optional  
 Number of time points to compute if *T* is not given.

**kwargs** : various types  
 Additional keyword arguments are passed on the function `scipy.signal.lsim2`, which in turn passes them on to `scipy.integrate.odeint`. See the documentation for `scipy.integrate.odeint` for information about these arguments.

**Returns** **T** : 1D ndarray  
 Output time points.

**yout** : 1D ndarray  
 Step response of system.

**See also:**`scipy.signal.step`**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

New in version 0.8.0.

`scipy.signal.freqresp` (*system*, *w=None*, *n=10000*)  
 Calculate the frequency response of a continuous-time system.

**Parameters** **system** : an instance of the `lti` class or a tuple describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of `lti`)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

**w** : array\_like, optional  
 Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given, a reasonable set will be calculated.

**n** : int, optional

**Returns**

- w** : 1D ndarray  
Number of frequency points to compute if  $w$  is not given. The  $n$  frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.
- H** : 1D ndarray  
Frequency array [rad/s]  
Array of complex magnitude values

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

**Examples**

Generating the Nyquist plot of a transfer function

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Transfer function:  $H(s) = 5 / (s-1)^3$

```
>>> s1 = signal.ZerosPolesGain([], [1, 1, 1], [5])
```

```
>>> w, H = signal.freqresp(s1)
```

```
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```

```
scipy.signal.bode(system, w=None, n=100)
```

Calculate Bode magnitude and phase data of a continuous-time system.

**Parameters**

- system** : an instance of the LTI class or a tuple describing the system.  
The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of `lti`)
- 2 (num, den)
- 3 (zeros, poles, gain)
- 4 (A, B, C, D)

**w** : array\_like, optional

Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

**n** : int, optional

Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

#### Returns

**w** : 1D ndarray

Frequency array [rad/s]

**mag** : 1D ndarray

Magnitude array [dB]

**phase** : 1D ndarray

Phase array [deg]

#### Notes

If (num, den) is passed in for *system*, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  would be represented as [1, 3, 5]).

New in version 0.11.0.

#### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = signal.bode(sys)

>>> plt.figure()
>>> plt.semilogx(w, mag)      # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)   # Bode phase plot
>>> plt.show()
```

## 5.20.7 Discrete-Time Linear Systems

---

<code>dlti(*system, **kwargs)</code>	Discrete-time linear time invariant system base class.
<code>StateSpace(*system, **kwargs)</code>	Linear Time Invariant system in state-space form.
<code>TransferFunction(*system, **kwargs)</code>	Linear Time Invariant system class in transfer function form.
<code>ZerosPolesGain(*system, **kwargs)</code>	Linear Time Invariant system class in zeros, poles, gain form.
<code>dlsim(system, u[, t, x0])</code>	Simulate output of a discrete-time linear system.
<code>dimpulse(system[, x0, t, n])</code>	Impulse response of discrete-time system.
<code>dstep(system[, x0, t, n])</code>	Step response of discrete-time system.
<code>dfreqresp(system[, w, n, whole])</code>	Calculate the frequency response of a discrete-time system.
<code>dbode(system[, w, n])</code>	Calculate Bode magnitude and phase data of a discrete-time system.

---

**class** `scipy.signal.dlti` (*\*system*, *\*\*kwargs*)  
 Discrete-time linear time invariant system base class.

**Parameters** *\*system*: arguments

The `dlti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding discrete-time subclass that is created:

- 2: `TransferFunction`: (numerator, denominator)
- 3: `ZerosPolesGain`: (zeros, poles, gain)
- 4: `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

**dt**: float, optional

Sampling time [s] of the discrete-time systems. Defaults to `True` (unspecified sampling time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`ZerosPolesGain`, `StateSpace`, `TransferFunction`, `lti`

**Notes**

`dlti` instances do not exist directly. Instead, `dlti` creates an instance of one of its subclasses: `StateSpace`, `TransferFunction` or `ZerosPolesGain`.

Changing the value of properties that are not directly part of the current system representation (such as the `zeros` of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.,  $z^2 + 3z + 5$  would be represented as `[1, 3, 5]`).

New in version 0.18.0.

### Examples

```
>>> from scipy import signal

>>> signal.dlti(1, 2, 3, 4)
StateSpaceDiscrete(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: True
)

>>> signal.dlti(1, 2, 3, 4, dt=0.1)
StateSpaceDiscrete(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: 0.1
)

>>> signal.dlti([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
array([1, 2]),
array([3, 4]),
5,
dt: 0.1
)

>>> signal.dlti([3, 4], [1, 2], dt=0.1)
TransferFunctionDiscrete(
array([ 3.,  4.]),
array([ 1.,  2.]),
dt: 0.1
)
```

### Attributes

A	State matrix of the <code>StateSpace</code> system.
B	Input matrix of the <code>StateSpace</code> system.
C	Output matrix of the <code>StateSpace</code> system.
D	Feedthrough matrix of the <code>StateSpace</code> system.

Continued on next page

Table 5.141 – continued from previous page

<code>den</code>	Denominator of the <code>TransferFunction</code> system.
<code>dt</code>	Return the sampling time of the system.
<code>gain</code>	Gain of the <code>ZerosPolesGain</code> system.
<code>num</code>	Numerator of the <code>TransferFunction</code> system.
<code>poles</code>	Poles of the system.
<code>zeros</code>	Zeros of the system.

- `dlti.A`  
State matrix of the `StateSpace` system.
- `dlti.B`  
Input matrix of the `StateSpace` system.
- `dlti.C`  
Output matrix of the `StateSpace` system.
- `dlti.D`  
Feedthrough matrix of the `StateSpace` system.
- `dlti.den`  
Denominator of the `TransferFunction` system.
- `dlti.dt`  
Return the sampling time of the system.
- `dlti.gain`  
Gain of the `ZerosPolesGain` system.
- `dlti.num`  
Numerator of the `TransferFunction` system.
- `dlti.poles`  
Poles of the system.
- `dlti.zeros`  
Zeros of the system.

**Methods**

<code>bode([w, n])</code>	Calculate Bode magnitude and phase data of a discrete-time system.
<code>freqresp([w, n, whole])</code>	Calculate the frequency response of a discrete-time system.
<code>impulse([x0, t, n])</code>	Return the impulse response of the discrete-time <code>dlti</code> system.
<code>output(u, t[, x0])</code>	Return the response of the discrete-time system to input <i>u</i> .
<code>step([x0, t, n])</code>	Return the step response of the discrete-time <code>dlti</code> system.

`dlti.bode` (*w=None, n=100*)  
 Calculate Bode magnitude and phase data of a discrete-time system.  
 Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See `dbode` for details.

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Transfer function:  $H(z) = 1 / (z^2 + 2z + 3)$  with sampling time 0.5s

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.5)
```

Equivalent: `signal.dbode(sys)`

```
>>> w, mag, phase = sys.bode()
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag)      # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)   # Bode phase plot
>>> plt.show()
```

`dlti.freqresp(w=None, n=10000, whole=False)`

Calculate the frequency response of a discrete-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `dfreqresp` for details.

`dlti.impulse` ( $x0=None, t=None, n=None$ )

Return the impulse response of the discrete-time `dlti` system. See `dimpulse` for details.

`dlti.output` ( $u, t, x0=None$ )

Return the response of the discrete-time system to input  $u$ . See `dlsim` for details.

`dlti.step` ( $x0=None, t=None, n=None$ )

Return the step response of the discrete-time `dlti` system. See `dstep` for details.

**class** `scipy.signal.StateSpace` (*\*system, \*\*kwargs*)

Linear Time Invariant system in state-space form.

Represents the system as the continuous-time, first order differential equation  $\dot{x} = Ax + Bu$  or the discrete-time difference equation  $x[k+1] = Ax[k] + Bu[k]$ . `StateSpace` systems inherit additional functionality from the `lti`, respectively the `dlti` classes, depending on which system representation is used.

**Parameters** **\*system: arguments**

The `StateSpace` class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:

- 1: `lti` or `dlti` system: (`StateSpace`, `TransferFunction` or `ZerosPolesGain`)
- 4: `array_like`: (A, B, C, D)

**dt: float, optional**

Sampling time [s] of the discrete-time systems. Defaults to `None` (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`TransferFunction`, `ZerosPolesGain`, `lti`, `dlti`, `ss2zpk`, `ss2tf`, `zpk2sos`

**Notes**

Changing the value of properties that are not part of the `StateSpace` system representation (such as `zeros` or `poles`) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

**Examples**

```
>>> from scipy import signal

>>> a = np.array([[0, 1], [0, 0]])
>>> b = np.array([[0], [1]])
>>> c = np.array([[1, 0]])
>>> d = np.array([[0]])

>>> sys = signal.StateSpace(a, b, c, d)
>>> print(sys)
StateSpaceContinuous(
array([[0, 1],
       [0, 0]]),
array([[0],
       [1]]),
array([[1, 0]]),
array([[0]]),
dt: None
)
```

```

>>> sys.to_discrete(0.1)
StateSpaceDiscrete(
array([[ 1. ,  0.1],
       [ 0. ,  1. ]]),
array([[ 0.005],
       [ 0.1 ]]),
array([[1, 0]]),
array([[0]]),
dt: 0.1
)

>>> a = np.array([[1, 0.1], [0, 1]])
>>> b = np.array([[0.005], [0.1]])

>>> signal.StateSpace(a, b, c, d, dt=0.1)
StateSpaceDiscrete(
array([[ 1. ,  0.1],
       [ 0. ,  1. ]]),
array([[ 0.005],
       [ 0.1 ]]),
array([[1, 0]]),
array([[0]]),
dt: 0.1
)

```

**Attributes**

---

<code>A</code>	State matrix of the <code>StateSpace</code> system.
<code>B</code>	Input matrix of the <code>StateSpace</code> system.
<code>C</code>	Output matrix of the <code>StateSpace</code> system.
<code>D</code>	Feedthrough matrix of the <code>StateSpace</code> system.
<code>den</code>	Denominator of the <code>TransferFunction</code> system.
<code>dt</code>	Return the sampling time of the system, <i>None</i> for <code>lti</code> systems.
<code>gain</code>	Gain of the <code>ZerosPolesGain</code> system.
<code>num</code>	Numerator of the <code>TransferFunction</code> system.
<code>poles</code>	Poles of the system.
<code>zeros</code>	Zeros of the system.

---

**StateSpace.A**

State matrix of the `StateSpace` system.

**StateSpace.B**

Input matrix of the `StateSpace` system.

**StateSpace.C**

Output matrix of the `StateSpace` system.

**StateSpace.D**

Feedthrough matrix of the `StateSpace` system.

**StateSpace.den**

Denominator of the `TransferFunction` system.

**StateSpace.dt**

Return the sampling time of the system, *None* for `lti` systems.

`StateSpace.gain`  
Gain of the `ZerosPolesGain` system.

`StateSpace.num`  
Numerator of the `TransferFunction` system.

`StateSpace.poles`  
Poles of the system.

`StateSpace.zeros`  
Zeros of the system.

**Methods**

<code>to_ss()</code>	Return a copy of the current <code>StateSpace</code> system.
<code>to_tf(**kwargs)</code>	Convert system representation to <code>TransferFunction</code> .
<code>to_zpk(**kwargs)</code>	Convert system representation to <code>ZerosPolesGain</code> .

`StateSpace.to_ss()`  
Return a copy of the current `StateSpace` system.

**Returns** `sys` : instance of `StateSpace`  
The current system (copy)

`StateSpace.to_tf(**kwargs)`  
Convert system representation to `TransferFunction`.

**Parameters** `kwargs` : dict, optional  
Additional keywords passed to `ss2zpk`

**Returns** `sys` : instance of `TransferFunction`  
Transfer function of the current system

`StateSpace.to_zpk(**kwargs)`  
Convert system representation to `ZerosPolesGain`.

**Parameters** `kwargs` : dict, optional  
Additional keywords passed to `ss2zpk`

**Returns** `sys` : instance of `ZerosPolesGain`  
Zeros, poles, gain representation of the current system

**class** `scipy.signal.TransferFunction(*system, **kwargs)`  
Linear Time Invariant system class in transfer function form.

Represents the system as the continuous-time transfer function  $H(s) = \sum_{i=0}^N b[N-i]s^i / \sum_{j=0}^M a[M-j]s^j$  or the discrete-time transfer function  $H(z) = \sum_{i=0}^N b[N-i]z^i / \sum_{j=0}^M a[M-j]z^j$ , where `b` are elements of the numerator `num`, `a` are elements of the denominator `den`, and  $N == \text{len}(b) - 1, M == \text{len}(a) - 1$ . `TransferFunction` systems inherit additional functionality from the `lti`, respectively the `dlti` classes, depending on which system representation is used.

**Parameters** `*system: arguments`  
The `TransferFunction` class can be instantiated with 1 or 2 arguments. The following gives the number of input arguments and their interpretation:

- 1: `lti` or `dlti` system: (`StateSpace`, `TransferFunction` or `ZerosPolesGain`)
- 2: `array_like`: (numerator, denominator)

**dt: float, optional**  
Sampling time [s] of the discrete-time systems. Defaults to `None` (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

ZerosPolesGain, StateSpace, lti, dlti, tf2ss, tf2zpk, tf2sos

**Notes**

Changing the value of properties that are not part of the `TransferFunction` system representation (such as the `A`, `B`, `C`, `D` state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the `A`, `B`, `C`, `D` system matrices.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $s^2 + 3s + 5$  or  $z^2 + 3z + 5$  would be represented as `[1, 3, 5]`)

**Examples**

Construct the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> from scipy import signal

>>> num = [1, 3, 3]
>>> den = [1, 2, 1]

>>> signal.TransferFunction(num, den)
TransferFunctionContinuous(
array([ 1.,  3.,  3.]),
array([ 1.,  2.,  1.]),
dt: None
)
```

Construct the transfer function with a sampling time of 0.1 seconds:

$$H(z) = \frac{z^2 + 3z + 3}{z^2 + 2z + 1}$$

```
>>> signal.TransferFunction(num, den, dt=0.1)
TransferFunctionDiscrete(
array([ 1.,  3.,  3.]),
array([ 1.,  2.,  1.]),
dt: 0.1
)
```

**Attributes**

<code>A</code>	State matrix of the <code>StateSpace</code> system.
<code>B</code>	Input matrix of the <code>StateSpace</code> system.
<code>C</code>	Output matrix of the <code>StateSpace</code> system.
<code>D</code>	Feedthrough matrix of the <code>StateSpace</code> system.
<code>den</code>	Denominator of the <code>TransferFunction</code> system.

Continued on next page

Table 5.145 – continued from previous page

<code>dt</code>	Return the sampling time of the system, <i>None</i> for <code>lti</code> systems.
<code>gain</code>	Gain of the <code>ZerosPolesGain</code> system.
<code>num</code>	Numerator of the <code>TransferFunction</code> system.
<code>poles</code>	Poles of the system.
<code>zeros</code>	Zeros of the system.

`TransferFunction.A`  
State matrix of the `StateSpace` system.

`TransferFunction.B`  
Input matrix of the `StateSpace` system.

`TransferFunction.C`  
Output matrix of the `StateSpace` system.

`TransferFunction.D`  
Feedthrough matrix of the `StateSpace` system.

`TransferFunction.den`  
Denominator of the `TransferFunction` system.

`TransferFunction.dt`  
Return the sampling time of the system, *None* for `lti` systems.

`TransferFunction.gain`  
Gain of the `ZerosPolesGain` system.

`TransferFunction.num`  
Numerator of the `TransferFunction` system.

`TransferFunction.poles`  
Poles of the system.

`TransferFunction.zeros`  
Zeros of the system.

**Methods**

<code>to_ss()</code>	Convert system representation to <code>StateSpace</code> .
<code>to_tf()</code>	Return a copy of the current <code>TransferFunction</code> system.
<code>to_zpk()</code>	Convert system representation to <code>ZerosPolesGain</code> .

`TransferFunction.to_ss()`  
Convert system representation to `StateSpace`.  
**Returns** `sys` : instance of `StateSpace`  
State space model of the current system

`TransferFunction.to_tf()`  
Return a copy of the current `TransferFunction` system.  
**Returns** `sys` : instance of `TransferFunction`  
The current system (copy)

`TransferFunction.to_zpk()`  
Convert system representation to `ZerosPolesGain`.  
**Returns** `sys` : instance of `ZerosPolesGain`

Zeros, poles, gain representation of the current system

**class** `scipy.signal.ZerosPolesGain` (\*system, \*\*kwargs)  
 Linear Time Invariant system class in zeros, poles, gain form.

Represents the system as the continuous- or discrete-time transfer function  $H(s) = k \prod_i (s - z[i]) / \prod_j (s - p[j])$ , where  $k$  is the `gain`,  $z$  are the `zeros` and  $p$  are the `poles`. `ZerosPolesGain` systems inherit additional functionality from the `lti`, respectively the `dlti` classes, depending on which system representation is used.

**Parameters** \*system : arguments

The `ZerosPolesGain` class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:

- 1: `lti` or `dlti` system: (`StateSpace`, `TransferFunction` or `ZerosPolesGain`)
- 3: `array_like`: (`zeros`, `poles`, `gain`)

**dt: float, optional**

Sampling time [s] of the discrete-time systems. Defaults to `None` (continuous-time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

`TransferFunction`, `StateSpace`, `lti`, `dlti`, `zpk2ss`, `zpk2tf`, `zpk2sos`

**Notes**

Changing the value of properties that are not part of the `ZerosPolesGain` system representation (such as the `A`, `B`, `C`, `D` state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_ss()` before accessing/changing the `A`, `B`, `C`, `D` system matrices.

**Examples**

```
>>> from scipy import signal
```

Transfer function:  $H(s) = 5(s - 1)(s - 2) / (s - 3)(s - 4)$

```
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
array([1, 2]),
array([3, 4]),
5,
dt: None
)
```

Transfer function:  $H(z) = 5(z - 1)(z - 2) / (z - 3)(z - 4)$

```
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
array([1, 2]),
array([3, 4]),
5,
dt: 0.1
)
```

**Attributes**

A	State matrix of the <code>StateSpace</code> system.
---	---

Continued on next page
------------------------

Table 5.147 – continued from previous page

<code>B</code>	Input matrix of the <code>StateSpace</code> system.
<code>C</code>	Output matrix of the <code>StateSpace</code> system.
<code>D</code>	Feedthrough matrix of the <code>StateSpace</code> system.
<code>den</code>	Denominator of the <code>TransferFunction</code> system.
<code>dt</code>	Return the sampling time of the system, <code>None</code> for <code>lti</code> systems.
<code>gain</code>	Gain of the <code>ZerosPolesGain</code> system.
<code>num</code>	Numerator of the <code>TransferFunction</code> system.
<code>poles</code>	Poles of the <code>ZerosPolesGain</code> system.
<code>zeros</code>	Zeros of the <code>ZerosPolesGain</code> system.

`ZerosPolesGain.A`

State matrix of the `StateSpace` system.

`ZerosPolesGain.B`

Input matrix of the `StateSpace` system.

`ZerosPolesGain.C`

Output matrix of the `StateSpace` system.

`ZerosPolesGain.D`

Feedthrough matrix of the `StateSpace` system.

`ZerosPolesGain.den`

Denominator of the `TransferFunction` system.

`ZerosPolesGain.dt`

Return the sampling time of the system, `None` for `lti` systems.

`ZerosPolesGain.gain`

Gain of the `ZerosPolesGain` system.

`ZerosPolesGain.num`

Numerator of the `TransferFunction` system.

`ZerosPolesGain.poles`

Poles of the `ZerosPolesGain` system.

`ZerosPolesGain.zeros`

Zeros of the `ZerosPolesGain` system.

**Methods**

<code>to_ss()</code>	Convert system representation to <code>StateSpace</code> .
<code>to_tf()</code>	Convert system representation to <code>TransferFunction</code> .
<code>to_zpk()</code>	Return a copy of the current ‘ZerosPolesGain’ system.

`ZerosPolesGain.to_ss()`

Convert system representation to `StateSpace`.

**Returns** `sys` : instance of `StateSpace`  
State space model of the current system

`ZerosPolesGain.to_tf()`

Convert system representation to `TransferFunction`.

**Returns** `sys` : instance of `TransferFunction`  
Transfer function of the current system

`ZerosPolesGain.to_zpk()`

Return a copy of the current ‘ZerosPolesGain’ system.

**Returns** `sys` : instance of `ZerosPolesGain`  
The current system (copy)

`scipy.signal.dlsim(system, u, t=None, x0=None)`

Simulate output of a discrete-time linear system.

**Parameters** `system` : tuple of array\_like or instance of `dlti`  
A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `dlti`)
- 3: (num, den, dt)
- 4: (zeros, poles, gain, dt)
- 5: (A, B, C, D, dt)

`u` : array\_like  
An input array describing the input at each time  $t$  (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input.

`t` : array\_like, optional  
The time steps at which the input is defined. If  $t$  is given, it must be the same length as  $u$ , and the final value in  $t$  determines the number of steps returned in the output.

`x0` : array\_like, optional  
The initial conditions on the state vector (zero by default).

**Returns** `tout` : ndarray  
Time values for the output, as a 1-D array.

`yout` : ndarray  
System response, as a 1-D array.

`xout` : ndarray, optional  
Time-evolution of the state-vector. Only generated if the input is a `StateSpace` system.

**See also:**

`lsim`, `dstep`, `dimpulse`, `cont2discrete`

**Examples**

A simple integrator transfer function with a discrete time step of 1.0 could be implemented as:

```
>>> from scipy import signal
>>> tf = ([1.0,], [1.0, -1.0], 1.0)
>>> t_in = [0.0, 1.0, 2.0, 3.0]
>>> u = np.asarray([0.0, 0.0, 1.0, 1.0])
>>> t_out, y = signal.dlsim(tf, u, t=t_in)
>>> y.T
array([[ 0.,  0.,  0.,  1.]])
```

`scipy.signal.dimpulse(system, x0=None, t=None, n=None)`

Impulse response of discrete-time system.

**Parameters** `system` : tuple of array\_like or instance of `dlti`  
A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `dlti`)
- 3: (num, den, dt)
- 4: (zeros, poles, gain, dt)
- 5: (A, B, C, D, dt)

`x0` : array\_like, optional  
Initial state-vector. Defaults to zero.

**Returns**

**t** : array\_like, optional  
Time points. Computed if not given.

**n** : int, optional  
The number of time points to compute (if *t* is not given).

**tout** : ndarray  
Time values for the output, as a 1-D array.

**yout** : ndarray  
Impulse response of system. Each element of the tuple represents the output of the system based on an impulse in each input.

**See also:**

`impulse`, `dstep`, `dlsim`, `cont2discrete`

`scipy.signal.dstep` (*system*, *x0=None*, *t=None*, *n=None*)

Step response of discrete-time system.

**Parameters**

**system** : tuple of array\_like  
A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `dlti`)
- 2: (num, den, dt)
- 3: (zeros, poles, gain, dt)
- 4: (A, B, C, D, dt)

**x0** : array\_like, optional  
Initial state-vector. Defaults to zero.

**t** : array\_like, optional  
Time points. Computed if not given.

**n** : int, optional  
The number of time points to compute (if *t* is not given).

**Returns**

**tout** : ndarray  
Output time points, as a 1-D array.

**yout** : ndarray  
Step response of system. Each element of the tuple represents the output of the system based on a step response to each input.

**See also:**

`step`, `dimpulse`, `dlsim`, `cont2discrete`

`scipy.signal.dfreqresp` (*system*, *w=None*, *n=10000*, *whole=False*)

Calculate the frequency response of a discrete-time system.

**Parameters**

**system** : an instance of the `dlti` class or a tuple describing the system.  
The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of `dlti`).
- 2 (numerator, denominator, dt)
- 3 (zeros, poles, gain, dt)
- 4 (A, B, C, D, dt)

**w** : array\_like, optional  
Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

**n** : int, optional  
Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**whole** : bool, optional  
Normally, if 'w' is not given, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If *whole* is True, compute frequencies from 0 to 2\*pi radians/sample.

**Returns** **w** : 1D ndarray  
Frequency array [radians/sample]  
**H** : 1D ndarray  
Array of complex magnitude values

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $z^2 + 3z + 5$  would be represented as `[1, 3, 5]`).

New in version 0.18.0.

**Examples**

Generating the Nyquist plot of a transfer function

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Transfer function:  $H(z) = 1 / (z^2 + 2z + 3)$

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```

```
>>> w, H = signal.dfreqresp(sys)
```

```
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```

`scipy.signal.dbode` (*system*, *w=None*, *n=100*)

Calculate Bode magnitude and phase data of a discrete-time system.

**Parameters** **system** : an instance of the LTI class or a tuple describing the system.

The following gives the number of elements in the tuple and the interpretation:

- 1 (instance of `dlti`)
- 2 (num, den, dt)

`•3 (zeros, poles, gain, dt)`  
`•4 (A, B, C, D, dt)`

**w** : array\_like, optional  
 Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

**n** : int, optional  
 Number of frequency points to compute if *w* is not given. The *n* frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns**

**w** : 1D ndarray  
 Frequency array [rad/time\_unit]

**mag** : 1D ndarray  
 Magnitude array [dB]

**phase** : 1D ndarray  
 Phase array [deg]

**Notes**

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g.  $z^2 + 3z + 5$  would be represented as [1, 3, 5]).

New in version 0.18.0.

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Transfer function:  $H(z) = 1 / (z^2 + 2z + 3)$

```
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```

Equivalent: `sys.bode()`

```
>>> w, mag, phase = signal.dbode(sys)
```

```
>>> plt.figure()
>>> plt.semilogx(w, mag)      # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)   # Bode phase plot
>>> plt.show()
```

### 5.20.8 LTI Representations

<code>tf2zpk(b, a)</code>	Return zero, pole, gain (z, p, k) representation from a numerator, denominator
<code>tf2sos(b, a[, pairing])</code>	Return second-order sections from transfer function representation
<code>tf2ss(num, den)</code>	Transfer function to state-space representation.
<code>zpk2tf(z, p, k)</code>	Return polynomial transfer function representation from zeros and poles
<code>zpk2sos(z, p, k[, pairing])</code>	Return second-order sections from zeros, poles, and gain of a system
<code>zpk2ss(z, p, k)</code>	Zero-pole-gain representation to state-space representation
<code>ss2tf(A, B, C, D[, input])</code>	State-space to transfer function.
<code>ss2zpk(A, B, C, D[, input])</code>	State-space representation to zero-pole-gain representation.
<code>sos2zpk(sos)</code>	Return zeros, poles, and gain of a series of second-order sections
<code>sos2tf(sos)</code>	Return a single transfer function from a series of second-order sections
<code>cont2discrete(system, dt[, method, alpha])</code>	Transform a continuous to a discrete state-space system.
<code>place_poles(A, B, poles[, method, rtol, maxiter])</code>	Compute K such that eigenvalues $(A - \text{dot}(B, K)) = \text{poles}$ .

`scipy.signal.tf2zpk(b, a)`

Return zero, pole, gain (z, p, k) representation from a numerator, denominator representation of a linear filter.

<b>Parameters</b>	<b>b</b> : array_like	Numerator polynomial coefficients.
	<b>a</b> : array_like	Denominator polynomial coefficients.
<b>Returns</b>	<b>z</b> : ndarray	Zeros of the transfer function.
	<b>p</b> : ndarray	Poles of the transfer function.
	<b>k</b> : float	System gain.

#### Notes

If some values of  $b$  are too close to 0, they are removed. In that case, a `BadCoefficients` warning is emitted.

The  $b$  and  $a$  arrays are interpreted as coefficients for positive, descending powers of the transfer function variable. So the inputs  $b = [b_0, b_1, \dots, b_M]$  and  $a = [a_0, a_1, \dots, a_N]$  can represent an analog filter of the form:

$$H(s) = \frac{b_0 s^M + b_1 s^{(M-1)} + \dots + b_M}{a_0 s^N + a_1 s^{(N-1)} + \dots + a_N}$$

or a discrete-time filter of the form:

$$H(z) = \frac{b_0 z^M + b_1 z^{(M-1)} + \dots + b_M}{a_0 z^N + a_1 z^{(N-1)} + \dots + a_N}$$

This “positive powers” form is found more commonly in controls engineering. If  $M$  and  $N$  are equal (which is true for all filters generated by the bilinear transform), then this happens to be equivalent to the “negative powers” discrete-time form preferred in DSP:

$$H(z) = \frac{b_0 + b_1 z^{-1} + \dots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \dots + a_N z^{-N}}$$

Although this is true for common filters, remember that this is not true in the general case. If  $M$  and  $N$  are not equal, the discrete-time transfer function coefficients must first be converted to the “positive powers” form before finding the poles and zeros.

`scipy.signal.tf2sos(b, a, pairing='nearest')`

Return second-order sections from transfer function representation

<b>Parameters</b>	<b>b</b> : array_like	Numerator polynomial coefficients.
	<b>a</b> : array_like	Denominator polynomial coefficients.
	<b>pairing</b> : {'nearest', 'keep_odd'}, optional	The method to use to combine pairs of poles and zeros into sections. See <a href="#">zpk2sos</a> .
<b>Returns</b>	<b>sos</b> : ndarray	Array of second-order filter coefficients, with shape <code>(n_sections, 6)</code> . See <a href="#">sosfilt</a> for the SOS filter format specification.

See also:

[zpk2sos](#), [sosfilt](#)

**Notes**

It is generally discouraged to convert from TF to SOS format, since doing so usually will not improve numerical precision errors. Instead, consider designing filters in ZPK format and converting directly to SOS. TF is converted to SOS by first converting to ZPK format, then converting ZPK to SOS.

New in version 0.16.0.

`scipy.signal.tf2ss(num, den)`

Transfer function to state-space representation.

**Parameters** **num, den** : array\_like  
Sequences representing the coefficients of the numerator and denominator polynomials, in order of descending degree. The denominator needs to be at least as long as the numerator.

**Returns** **A, B, C, D** : ndarray  
State space representation of the system, in controller canonical form.

**Examples**

Convert the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

to the state-space representation:

$$\dot{\mathbf{x}}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \mathbf{u}(t)$$

$$\mathbf{y}(t) = [1 \quad 2] \mathbf{x}(t) + [1] \mathbf{u}(t)$$

```
>>> from scipy.signal import tf2ss
>>> A, B, C, D = tf2ss(num, den)
>>> A
array([[ -2.,  -1.],
       [  1.,   0.]])
>>> B
array([[ 1.],
       [ 0.]])
>>> C
array([[ 1.,  2.]])
>>> D
array([[ 1.]])
```

`scipy.signal.zpk2tf(z, p, k)`

Return polynomial transfer function representation from zeros and poles

**Parameters** **z** : array\_like  
Zeros of the transfer function.

**p** : array\_like  
Poles of the transfer function.

**k** : float  
System gain.

**Returns** **b** : ndarray

**a** : ndarray  
 Numerator polynomial coefficients.  
**b** : ndarray  
 Denominator polynomial coefficients.

`scipy.signal.zpk2sos(z, p, k, pairing='nearest')`

Return second-order sections from zeros, poles, and gain of a system

**Parameters**

- z** : array\_like  
Zeros of the transfer function.
- p** : array\_like  
Poles of the transfer function.
- k** : float  
System gain.
- pairing** : {'nearest', 'keep\_odd'}, optional  
The method to use to combine pairs of poles and zeros into sections. See Notes below.

**Returns**

- sos** : ndarray  
Array of second-order filter coefficients, with shape `(n_sections, 6)`. See `sosfilt` for the SOS filter format specification.

**See also:**

`sosfilt`

**Notes**

The algorithm used to convert ZPK to SOS format is designed to minimize errors due to numerical precision issues. The pairing algorithm attempts to minimize the peak gain of each biquadratic section. This is done by pairing poles with the nearest zeros, starting with the poles closest to the unit circle.

**Algorithms**

The current algorithms are designed specifically for use with digital filters. (The output coefficients are not correct for analog filters.)

The steps in the `pairing='nearest'` and `pairing='keep_odd'` algorithms are mostly shared. The `nearest` algorithm attempts to minimize the peak gain, while `'keep_odd'` minimizes peak gain under the constraint that odd-order systems should retain one section as first order. The algorithm steps and are as follows:

As a pre-processing step, add poles or zeros to the origin as necessary to obtain the same number of poles and zeros for pairing. If `pairing == 'nearest'` and there are an odd number of poles, add an additional pole and a zero at the origin.

The following steps are then iterated over until no more poles or zeros remain:

1. Take the (next remaining) pole (complex or real) closest to the unit circle to begin a new filter section.
2. If the pole is real and there are no other remaining real poles<sup>4</sup>, add the closest real zero to the section and leave it as a first order section. Note that after this step we are guaranteed to be left with an even number of real poles, complex poles, real zeros, and complex zeros for subsequent pairing iterations.
3. Else:
  - (a) If the pole is complex and the zero is the only remaining real zero\*, then pair the pole with the *next* closest zero (guaranteed to be complex). This is necessary to ensure that there will be a real zero remaining to eventually create a first-order section (thus keeping the odd order).
  - (b) Else pair the pole with the closest remaining zero (complex or real).
  - (c) Proceed to complete the second-order section by adding another pole and zero to the current pole and zero in the section:
    - i. If the current pole and zero are both complex, add their conjugates.
    - ii. Else if the pole is complex and the zero is real, add the conjugate pole and the next closest real zero.

---

<sup>4</sup> This conditional can only be met for specific odd-order inputs with the `pairing == 'keep_odd'` method.

- iii. Else if the pole is real and the zero is complex, add the conjugate zero and the real pole closest to those zeros.
- iv. Else (we must have a real pole and real zero) add the next real pole closest to the unit circle, and then add the real zero closest to that pole.

New in version 0.16.0.

### Examples

Design a 6th order low-pass elliptic digital filter for a system with a sampling rate of 8000 Hz that has a pass-band corner frequency of 1000 Hz. The ripple in the pass-band should not exceed 0.087 dB, and the attenuation in the stop-band should be at least 90 dB.

In the following call to `signal.ellip`, we could use `output='sos'`, but for this example, we'll use `output='zpk'`, and then convert to SOS format with `zpk2sos`:

```
>>> from scipy import signal
>>> z, p, k = signal.ellip(6, 0.087, 90, 1000/(0.5*8000), output='zpk')
```

Now convert to SOS format.

```
>>> sos = signal.zpk2sos(z, p, k)
```

The coefficients of the numerators of the sections:

```
>>> sos[:, :3]
array([[ 0.0014154 ,  0.00248707,  0.0014154 ],
       [ 1.          ,  0.72965193,  1.          ],
       [ 1.          ,  0.17594966,  1.          ]])
```

The symmetry in the coefficients occurs because all the zeros are on the unit circle.

The coefficients of the denominators of the sections:

```
>>> sos[:, 3:]
array([[ 1.          , -1.32543251,  0.46989499],
       [ 1.          , -1.26117915,  0.6262586 ],
       [ 1.          , -1.25707217,  0.86199667]])
```

The next example shows the effect of the `pairing` option. We have a system with three poles and three zeros, so the SOS array will have shape (2, 6). The means there is, in effect, an extra pole and an extra zero at the origin in the SOS representation.

```
>>> z1 = np.array([-1, -0.5-0.5j, -0.5+0.5j])
>>> p1 = np.array([0.75, 0.8+0.1j, 0.8-0.1j])
```

With `pairing='nearest'` (the default), we obtain

```
>>> signal.zpk2sos(z1, p1, 1)
array([[ 1. ,  1. ,  0.5 ,  1. , -0.75,  0. ],
       [ 1. ,  1. ,  0. ,  1. , -1.6 ,  0.65]])
```

The first section has the zeros  $\{-0.5-0.05j, -0.5+0.5j\}$  and the poles  $\{0, 0.75\}$ , and the second section has the zeros  $\{-1, 0\}$  and poles  $\{0.8+0.1j, 0.8-0.1j\}$ . Note that the extra pole and zero at the origin have been assigned to different sections.

With `pairing='keep_odd'`, we obtain:

```
>>> signal.zpk2sos(z1, p1, 1, pairing='keep_odd')
array([[ 1. ,  1. ,  0. ,  1. , -0.75,  0. ],
       [ 1. ,  1. ,  0.5,  1. , -1.6 ,  0.65]])
```

The extra pole and zero at the origin are in the same section. The first section is, in effect, a first-order section.

`scipy.signal.zpk2ss(z, p, k)`

Zero-pole-gain representation to state-space representation

**Parameters**

- z, p** : sequence  
Zeros and poles.
- k** : float  
System gain.

**Returns**

- A, B, C, D** : ndarray  
State space representation of the system, in controller canonical form.

`scipy.signal.ss2tf(A, B, C, D, input=0)`

State-space to transfer function.

A, B, C, D defines a linear state-space system with  $p$  inputs,  $q$  outputs, and  $n$  state variables.

**Parameters**

- A** : array\_like  
State (or system) matrix of shape  $(n, n)$
- B** : array\_like  
Input matrix of shape  $(n, p)$
- C** : array\_like  
Output matrix of shape  $(q, n)$
- D** : array\_like  
Feedthrough (or feedforward) matrix of shape  $(q, p)$
- input** : int, optional  
For multiple-input systems, the index of the input to use.

**Returns**

- num** : 2-D ndarray  
Numerator(s) of the resulting transfer function(s). *num* has one row for each of the system's outputs. Each row is a sequence representation of the numerator polynomial.
- den** : 1-D ndarray  
Denominator of the resulting transfer function(s). *den* is a sequence representation of the denominator polynomial.

### Examples

Convert the state-space representation:

$$\dot{\mathbf{x}}(t) = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \mathbf{u}(t)$$

$$\mathbf{y}(t) = \begin{bmatrix} 1 & 2 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 1 \end{bmatrix} \mathbf{u}(t)$$

```
>>> A = [[-2, -1], [1, 0]]
>>> B = [[1], [0]] # 2-dimensional column vector
>>> C = [[1, 2]] # 2-dimensional row vector
>>> D = 1
```

to the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```
>>> from scipy.signal import ss2tf
>>> ss2tf(A, B, C, D)
(array([[1, 3, 3]]), array([ 1.,  2.,  1.]))
```

`scipy.signal.ss2zpk(A, B, C, D, input=0)`  
State-space representation to zero-pole-gain representation.

A, B, C, D defines a linear state-space system with  $p$  inputs,  $q$  outputs, and  $n$  state variables.

**Parameters**

- A** : array\_like  
State (or system) matrix of shape  $(n, n)$
- B** : array\_like  
Input matrix of shape  $(n, p)$
- C** : array\_like  
Output matrix of shape  $(q, n)$
- D** : array\_like  
Feedthrough (or feedforward) matrix of shape  $(q, p)$
- input** : int, optional  
For multiple-input systems, the index of the input to use.

**Returns**

- z, p** : sequence  
Zeros and poles.
- k** : float  
System gain.

`scipy.signal.sos2zpk(sos)`  
Return zeros, poles, and gain of a series of second-order sections

**Parameters**

- sos** : array\_like  
Array of second-order filter coefficients, must have shape  $(n\_sections, 6)$ . See `sosfilt` for the SOS filter format specification.

**Returns**

- z** : ndarray  
Zeros of the transfer function.
- p** : ndarray  
Poles of the transfer function.
- k** : float  
System gain.

#### Notes

New in version 0.16.0.

`scipy.signal.sos2tf(sos)`  
Return a single transfer function from a series of second-order sections

**Parameters**

- sos** : array\_like  
Array of second-order filter coefficients, must have shape  $(n\_sections, 6)$ . See `sosfilt` for the SOS filter format specification.

**Returns**

- b** : ndarray  
Numerator polynomial coefficients.
- a** : ndarray  
Denominator polynomial coefficients.

#### Notes

New in version 0.16.0.

`scipy.signal.cont2discrete(system, dt, method='zoh', alpha=None)`  
Transform a continuous to a discrete state-space system.

**Parameters**

- system** : a tuple describing the system or an instance of `lti`

The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `lti`)
- 2: (num, den)
- 3: (zeros, poles, gain)
- 4: (A, B, C, D)

**dt** : float

The discretization time step.

**method** : {"gbt", "bilinear", "euler", "backward\_diff", "zoh"}, optional

Which method to use:

- gbt: generalized bilinear transformation
- bilinear: Tustin's approximation ("gbt" with `alpha=0.5`)
- euler: Euler (or forward differencing) method ("gbt" with `alpha=0`)
- backward\_diff: Backwards differencing ("gbt" with `alpha=1.0`)
- zoh: zero-order hold (default)

**alpha** : float within [0, 1], optional

The generalized bilinear transformation weighting parameter, which should only be specified with `method="gbt"`, and is ignored otherwise

**Returns**

**sysd** : tuple containing the discrete system

Based on the input type, the output will be of the form

- (num, den, dt) for transfer function input.
- (zeros, poles, gain, dt) for zeros-poles-gain input
- (A, B, C, D, dt) for state-space input

### Notes

By default, the routine uses a Zero-Order Hold (zoh) method to perform the transformation. Alternatively, a generalized bilinear transformation may be used, which includes the common Tustin's bilinear approximation, an Euler's method technique, or a backwards differencing technique.

The Zero-Order Hold (zoh) method is based on [R210], the generalized bilinear approximation is based on [R211] and [R212].

### References

[R210], [R211], [R212]

`scipy.signal.place_poles(A, B, poles, method='YT', rtol=0.001, maxiter=30)`

Compute K such that eigenvalues (A - dot(B, K))=poles.

K is the gain matrix such as the plant described by the linear system AX+BU will have its closed-loop poles, i.e the eigenvalues A - B\*K, as close as possible to those asked for in poles.

SISO, MISO and MIMO systems are supported.

**Parameters** **A, B** : ndarray

State-space representation of linear system AX + BU.

**poles** : array\_like

Desired real poles and/or complex conjugates poles. Complex poles are only supported with `method="YT"` (default).

**method**: {'YT', 'KNV0'}, optional

Which method to choose to find the gain matrix K. One of:

- 'YT': Yang Tits
- 'KNV0': Kautsky, Nichols, Van Dooren update method 0

See References and Notes for details on the algorithms.

**rtol**: float, optional

After each iteration the determinant of the eigenvectors of A - B\*K is compared to its previous value, when the relative error between these two values becomes lower than `rtol` the algorithm stops. Default is 1e-3.

**maxiter**: int, optional

Maximum number of iterations to compute the gain matrix. Default is 30.

**Returns**

**full\_state\_feedback** : Bunch object

*full\_state\_feedback* is composed of:

<b>gain_matrix</b>	[1-D ndarray] The closed loop matrix $K$ such as the eigenvalues of $A-BK$ are as close as possible to the requested poles.
<b>computed_poles</b>	[1-D ndarray] The poles corresponding to $A-BK$ sorted as first the real poles in increasing order, then the complex conjugates in lexicographic order.
<b>requested_poles</b>	[1-D ndarray] The poles the algorithm was asked to place sorted as above, they may differ from what was achieved.
<b>X</b>	[2-D ndarray] The transfer matrix such as $X * \text{diag}(\text{poles}) = (A - B*K) * X$ (see Notes)
<b>rtol</b>	[float] The relative tolerance achieved on $\det(X)$ (see Notes). <i>rtol</i> will be NaN if it is possible to solve the system $\text{diag}(\text{poles}) = (A - B*K)$ , or 0 when the optimization algorithms can't do anything i.e when $B.\text{shape}[1] == 1$ .
<b>nb_iter</b>	[int] The number of iterations performed before converging. <i>nb_iter</i> will be NaN if it is possible to solve the system $\text{diag}(\text{poles}) = (A - B*K)$ , or 0 when the optimization algorithms can't do anything i.e when $B.\text{shape}[1] == 1$ .

### Notes

The Tits and Yang (YT), [R259] paper is an update of the original Kautsky et al. (KNV) paper [R258]. KNV relies on rank-1 updates to find the transfer matrix  $X$  such that  $X * \text{diag}(\text{poles}) = (A - B*K) * X$ , whereas YT uses rank-2 updates. This yields on average more robust solutions (see [R259] pp 21-22), furthermore the YT algorithm supports complex poles whereas KNV does not in its original version. Only update method 0 proposed by KNV has been implemented here, hence the name 'KNV0'.

KNV extended to complex poles is used in Matlab's `place` function, YT is distributed under a non-free licence by Slicot under the name `robpole`. It is unclear and undocumented how KNV0 has been extended to complex poles (Tits and Yang claim on page 14 of their paper that their method can not be used to extend KNV to complex poles), therefore only YT supports them in this implementation.

As the solution to the problem of pole placement is not unique for MIMO systems, both methods start with a tentative transfer matrix which is altered in various way to increase its determinant. Both methods have been proven to converge to a stable solution, however depending on the way the initial transfer matrix is chosen they will converge to different solutions and therefore there is absolutely no guarantee that using 'KNV0' will yield results similar to Matlab's or any other implementation of these algorithms.

Using the default method 'YT' should be fine in most cases; 'KNV0' is only provided because it is needed by 'YT' in some specific cases. Furthermore 'YT' gives on average more robust results than 'KNV0' when  $\text{abs}(\det(X))$  is used as a robustness indicator.

[R259] is available as a technical report on the following URL: <http://drum.lib.umd.edu/handle/1903/5598>

## References

[R258], [R259]

## Examples

A simple example demonstrating real pole placement using both KNV and YT algorithms. This is example number 1 from section 4 of the reference KNV publication ([R258]):

```

>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> A = np.array([[ 1.380,  -0.2077,  6.715,  -5.676  ],
...             [-0.5814, -4.290,   0,      0.6750  ],
...             [ 1.067,   4.273, -6.654,  5.893  ],
...             [ 0.0480,  4.273,  1.343, -2.104  ]])
>>> B = np.array([[ 0,    5.679 ],
...             [ 1.136, 1.136 ],
...             [ 0,    0,    ],
...             [-3.146, 0    ]])
>>> P = np.array([-0.2, -0.5, -5.0566, -8.6659])

```

Now compute  $K$  with KNV method 0, with the default YT method and with the YT method while forcing 100 iterations of the algorithm and print some results after each call.

```

>>> fsf1 = signal.place_poles(A, B, P, method='KNV0')
>>> fsf1.gain_matrix
array([[ 0.20071427, -0.96665799,  0.24066128, -0.10279785],
       [ 0.50587268,  0.57779091,  0.51795763, -0.41991442]])

>>> fsf2 = signal.place_poles(A, B, P) # uses YT method
>>> fsf2.computed_poles
array([-8.6659, -5.0566, -0.5, -0.2])

>>> fsf3 = signal.place_poles(A, B, P, rtol=-1, maxiter=100)
>>> fsf3.X
array([[ 0.52072442+0.j, -0.08409372+0.j, -0.56847937+0.j,  0.74823657+0.j],
       [-0.04977751+0.j, -0.80872954+0.j,  0.13566234+0.j, -0.29322906+0.j],
       [-0.82266932+0.j, -0.19168026+0.j, -0.56348322+0.j, -0.43815060+0.j],
       [ 0.22267347+0.j,  0.54967577+0.j, -0.58387806+0.j, -0.40271926+0.j]])

```

The absolute value of the determinant of  $X$  is a good indicator to check the robustness of the results, both 'KNV0' and 'YT' aim at maximizing it. Below a comparison of the robustness of the results above:

```

>>> abs(np.linalg.det(fsf1.X)) < abs(np.linalg.det(fsf2.X))
True
>>> abs(np.linalg.det(fsf2.X)) < abs(np.linalg.det(fsf3.X))
True

```

Now a simple example for complex poles:

```

>>> A = np.array([[ 0,  7/3.,  0,  0  ],
...             [ 0,  0,  0,  7/9. ],
...             [ 0,  0,  0,  0  ],
...             [ 0,  0,  0,  0  ]])
>>> B = np.array([[ 0,  0 ]],

```

```

...         [ 0,  0 ],
...         [ 1,  0 ],
...         [ 0,  1 ]])
>>> P = np.array([-3, -1, -2-1j, -2+1j]) / 3.
>>> fsf = signal.place_poles(A, B, P, method='YT')

```

We can plot the desired and computed poles in the complex plane:

```

>>> t = np.linspace(0, 2*np.pi, 401)
>>> plt.plot(np.cos(t), np.sin(t), 'k--') # unit circle
>>> plt.plot(fsf.requested_poles.real, fsf.requested_poles.imag,
...         'wo', label='Desired')
>>> plt.plot(fsf.computed_poles.real, fsf.computed_poles.imag, 'bx',
...         label='Placed')
>>> plt.grid()
>>> plt.axis('image')
>>> plt.axis([-1.1, 1.1, -1.1, 1.1])
>>> plt.legend(bbox_to_anchor=(1.05, 1), loc=2, numpoints=1)

```

### 5.20.9 Waveforms

<code>chirp(t, f0, t1, f1[, method, phi, vertex_zero])</code>	Frequency-swept cosine generator.
<code>gausspulse(t[, fc, bw, bwr, tpr, retquad, ...])</code>	Return a Gaussian modulated sinusoid:
<code>max_len_seq(nbits[, state, length, taps])</code>	Maximum length sequence (MLS) generator.
<code>sawtooth(t[, width])</code>	Return a periodic sawtooth or triangle waveform.
<code>square(t[, duty])</code>	Return a periodic square-wave waveform.
<code>sweep_poly(t, poly[, phi])</code>	Frequency-swept cosine generator, with a time-dependent frequency.
<code>unit_impulse(shape[, idx, dtype])</code>	Unit impulse signal (discrete delta function) or unit basis vector.

`scipy.signal.chirp(t, f0, t1, f1, method='linear', phi=0, vertex_zero=True)`  
 Frequency-swept cosine generator.

In the following, ‘Hz’ should be interpreted as ‘cycles per unit’; there is no requirement here that the unit is one second. The important distinction is that the units of rotation are cycles, not radians. Likewise,  $t$  could be a

measurement of space instead of time.

**Parameters**

- t** : array\_like  
Times at which to evaluate the waveform.
- f0** : float  
Frequency (e.g. Hz) at time  $t=0$ .
- t1** : float  
Time at which  $f1$  is specified.
- f1** : float  
Frequency (e.g. Hz) of the waveform at time  $t1$ .
- method** : { 'linear', 'quadratic', 'logarithmic', 'hyperbolic' }, optional  
Kind of frequency sweep. If not given, *linear* is assumed. See Notes below for more details.
- phi** : float, optional  
Phase offset, in degrees. Default is 0.
- vertex\_zero** : bool, optional  
This parameter is only used when *method* is 'quadratic'. It determines whether the vertex of the parabola that is the graph of the frequency is at  $t=0$  or  $t=t1$ .

**Returns**

- y** : ndarray  
A numpy array containing the signal evaluated at  $t$  with the requested time-varying frequency. More precisely, the function returns  $\cos(\text{phase} + (\text{pi}/180) * \text{phi})$  where *phase* is the integral (from 0 to  $t$ ) of  $2 * \text{pi} * f(t)$ .  $f(t)$  is defined below.

**See also:**

[sweep\\_poly](#)

#### Notes

There are four options for the *method*. The following formulas give the instantaneous frequency (in Hz) of the signal generated by *chirp()*. For convenience, the shorter names shown below may also be used.

linear, lin, li:

$$f(t) = f0 + (f1 - f0) * t / t1$$

quadratic, quad, q:

The graph of the frequency  $f(t)$  is a parabola through  $(0, f0)$  and  $(t1, f1)$ . By default, the vertex of the parabola is at  $(0, f0)$ . If *vertex\_zero* is False, then the vertex is at  $(t1, f1)$ . The formula is:

if *vertex\_zero* is True:

$$f(t) = f0 + (f1 - f0) * t**2 / t1**2$$

else:

$$f(t) = f1 - (f1 - f0) * (t1 - t)**2 / t1**2$$

To use a more general quadratic function, or an arbitrary polynomial, use the function `scipy.signal.waveforms.sweep_poly`.

logarithmic, log, lo:

$$f(t) = f0 * (f1/f0)**(t/t1)$$

$f0$  and  $f1$  must be nonzero and have the same sign.

This signal is also known as a geometric or exponential chirp.

hyperbolic, hyp:

$$f(t) = f0 * f1 * t1 / ((f0 - f1) * t + f1 * t1)$$

$f0$  and  $f1$  must be nonzero.

`scipy.signal.gausspulse` (*t*, *fc*=1000, *bw*=0.5, *bwr*=-6, *tpr*=-60, *retquad*=False, *retenv*=False)

Return a Gaussian modulated sinusoid:

$$\exp(-a t^2) \exp(1j*2*\pi*fc*t).$$

If *retquad* is True, then return the real and imaginary parts (in-phase and quadrature). If *retenv* is True, then return the envelope (unmodulated signal). Otherwise, return the real part of the modulated sinusoid.

**Parameters**

- t** : ndarray or the string 'cutoff'  
Input array.
- fc** : int, optional  
Center frequency (e.g. Hz). Default is 1000.
- bw** : float, optional  
Fractional bandwidth in frequency domain of pulse (e.g. Hz). Default is 0.5.
- bwr** : float, optional  
Reference level at which fractional bandwidth is calculated (dB). Default is -6.
- tpr** : float, optional  
If *t* is 'cutoff', then the function returns the cutoff time for when the pulse amplitude falls below *tpr* (in dB). Default is -60.
- retquad** : bool, optional  
If True, return the quadrature (imaginary) as well as the real part of the signal. Default is False.
- retenv** : bool, optional  
If True, return the envelope of the signal. Default is False.

**Returns**

- yI** : ndarray  
Real part of signal. Always returned.
- yQ** : ndarray  
Imaginary part of signal. Only returned if *retquad* is True.
- yenv** : ndarray  
Envelope of signal. Only returned if *retenv* is True.

**See also:**

`scipy.signal.morlet`

**Examples**

Plot real component, imaginary component, and envelope for a 5 Hz pulse, sampled at 100 Hz for 2 seconds:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 2 * 100, endpoint=False)
>>> i, q, e = signal.gausspulse(t, fc=5, retquad=True, retenv=True)
>>> plt.plot(t, i, t, q, t, e, '--')
```

`scipy.signal.max_len_seq` (*nbits*, *state=None*, *length=None*, *taps=None*)  
 Maximum length sequence (MLS) generator.

**Parameters**    **nbits** : int

Number of bits to use. Length of the resulting sequence will be  $(2^{**nbits}) - 1$ . Note that generating long sequences (e.g., greater than `nbits == 16`) can take a long time.

**state** : array\_like, optional

If array, must be of length `nbits`, and will be cast to binary (bool) representation. If `None`, a seed of ones will be used, producing a repeatable representation. If `state` is all zeros, an error is raised as this is invalid. Default: `None`.

**length** : int, optional

Number of samples to compute. If `None`, the entire length  $(2^{**nbits}) - 1$  is computed.

**taps** : array\_like, optional

Polynomial taps to use (e.g., `[7, 6, 1]` for an 8-bit sequence). If `None`, taps will be automatically selected (for up to `nbits == 32`).

**Returns**

**seq** : array

Resulting MLS sequence of 0's and 1's.

**state** : array

The final state of the shift register.

### Notes

The algorithm for MLS generation is generically described in:

[https://en.wikipedia.org/wiki/Maximum\\_length\\_sequence](https://en.wikipedia.org/wiki/Maximum_length_sequence)

The default values for `taps` are specifically taken from the first option listed for each value of `nbits` in:

[http://www.newwaveinstruments.com/resources/articles/m\\_sequence\\_linear\\_feedback\\_shift\\_register\\_lfsr.htm](http://www.newwaveinstruments.com/resources/articles/m_sequence_linear_feedback_shift_register_lfsr.htm)

New in version 0.15.0.

### Examples

MLS uses binary convention:

```
>>> from scipy.signal import max_len_seq
>>> max_len_seq(4)[0]
array([1, 1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0], dtype=int8)
```

MLS has a white spectrum (except for DC):

```
>>> import matplotlib.pyplot as plt
>>> from numpy.fft import fft, ifft, fftshift, fftfreq
>>> seq = max_len_seq(6)[0]*2-1 # +1 and -1
>>> spec = fft(seq)
>>> N = len(seq)
>>> plt.plot(fftshift(fftfreq(N)), fftshift(np.abs(spec)), '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

Circular autocorrelation of MLS is an impulse:

```
>>> acorrirc = ifft(spec * np.conj(spec)).real
>>> plt.figure()
>>> plt.plot(np.arange(-N/2+1, N/2+1), fftshift(acorrirc), '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

Linear autocorrelation of MLS is approximately an impulse:

```
>>> acorr = np.correlate(seq, seq, 'full')
>>> plt.figure()
>>> plt.plot(np.arange(-N+1, N), acorr, '-.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

`scipy.signal.sawtooth`(*t*, *width*=1)

Return a periodic sawtooth or triangle waveform.

The sawtooth waveform has a period  $2\pi$ , rises from -1 to 1 on the interval 0 to  $\text{width} \cdot 2\pi$ , then drops from 1 to -1 on the interval  $\text{width} \cdot 2\pi$  to  $2\pi$ . *width* must be in the interval [0, 1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

**Parameters** *t*: array\_like

Time.

**width** : array\_like, optional  
Width of the rising ramp as a proportion of the total cycle. Default is 1, producing a rising ramp, while 0 produces a falling ramp. *width* = 0.5 produces a triangle wave. If an array, causes wave shape to change over time, and must be the same length as *t*.

**Returns** **y** : ndarray  
Output array containing the sawtooth waveform.

### Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500)
>>> plt.plot(t, signal.sawtooth(2 * np.pi * 5 * t))
```

`scipy.signal.square(t, duty=0.5)`

Return a periodic square-wave waveform.

The square wave has a period  $2\pi$ , has value +1 from 0 to  $2\pi \cdot \text{duty}$  and -1 from  $2\pi \cdot \text{duty}$  to  $2\pi$ . *duty* must be in the interval [0,1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

**Parameters** **t** : array\_like  
The input time array.

**duty** : array\_like, optional  
Duty cycle. Default is 0.5 (50% duty cycle). If an array, causes wave shape to change over time, and must be the same length as *t*.

**Returns** **y** : ndarray  
Output array containing the square waveform.

### Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500, endpoint=False)
>>> plt.plot(t, signal.square(2 * np.pi * 5 * t))
>>> plt.ylim(-2, 2)
```

A pulse-width modulated sine wave:

```
>>> plt.figure()
>>> sig = np.sin(2 * np.pi * t)
>>> pwm = signal.square(2 * np.pi * 30 * t, duty=(sig + 1)/2)
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, sig)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, pwm)
>>> plt.ylim(-1.5, 1.5)
```

`scipy.signal.sweep_poly(t, poly, phi=0)`

Frequency-swept cosine generator, with a time-dependent frequency.

This function generates a sinusoidal function whose instantaneous frequency varies with time. The frequency at time  $t$  is given by the polynomial  $poly$ .

**Parameters** `t` : ndarray

Times at which to evaluate the waveform.

`poly` : 1-D array\_like or instance of `numpy.poly1d`

The desired frequency expressed as a polynomial. If  $poly$  is a list or ndarray of length  $n$ , then the elements of  $poly$  are the coefficients of the polynomial, and the instantaneous frequency is

$$f(t) = poly[0]*t^{n-1} + poly[1]*t^{n-2} + \dots + poly[n-1]$$

If  $poly$  is an instance of `numpy.poly1d`, then the instantaneous frequency is

$$f(t) = poly(t)$$

`phi` : float, optional

Phase offset, in degrees, Default: 0.

**Returns**

`sweep_poly` : ndarray

A numpy array containing the signal evaluated at  $t$  with the requested time-varying frequency. More precisely, the function returns  $\cos(\text{phase} + (\pi/180)*\text{phi})$ , where  $phase$  is the integral (from 0 to  $t$ ) of  $2 * \pi * f(t)$ ;  $f(t)$  is defined above.

**See also:**

[chirp](#)

**Notes**

New in version 0.8.0.

If  $poly$  is a list or ndarray of length  $n$ , then the elements of  $poly$  are the coefficients of the polynomial, and the instantaneous frequency is:

$$f(t) = poly[0]*t^{n-1} + poly[1]*t^{n-2} + \dots + poly[n-1]$$

If  $poly$  is an instance of `numpy.poly1d`, then the instantaneous frequency is:

$$f(t) = poly(t)$$

Finally, the output  $s$  is:

$$\cos(\text{phase} + (\pi/180)*\text{phi})$$

where  $phase$  is the integral from 0 to  $t$  of  $2 * \pi * f(t)$ ,  $f(t)$  as defined above.

`scipy.signal.unit_impulse(shape, idx=None, dtype=<type 'float'>)`

Unit impulse signal (discrete delta function) or unit basis vector.

**Parameters** `shape` : int or tuple of int

Number of samples in the output (1-D), or a tuple that represents the shape of the output (N-D).

`idx` : None or int or tuple of int or 'mid', optional

Index at which the value is 1. If None, defaults to the 0th element. If `idx='mid'`, the impulse will be centered at `shape // 2` in all dimensions. If an int, the impulse will be at `idx` in all dimensions.

`dtype` : data-type, optional

The desired data-type for the array, e.g., `numpy.int8`. Default is `numpy.float64`.

**Returns**

`y` : ndarray

Output array containing an impulse signal.

### Notes

The 1D case is also known as the Kronecker delta.

New in version 0.19.0.

### Examples

An impulse at the 0th element ( $\delta[n]$ ):

```
>>> from scipy import signal
>>> signal.unit_impulse(8)
array([ 1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.])
```

Impulse offset by 2 samples ( $\delta[n - 2]$ ):

```
>>> signal.unit_impulse(7, 2)
array([ 0.,  0.,  1.,  0.,  0.,  0.,  0.])
```

2-dimensional impulse, centered:

```
>>> signal.unit_impulse((3, 3), 'mid')
array([[ 0.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  0.]])
```

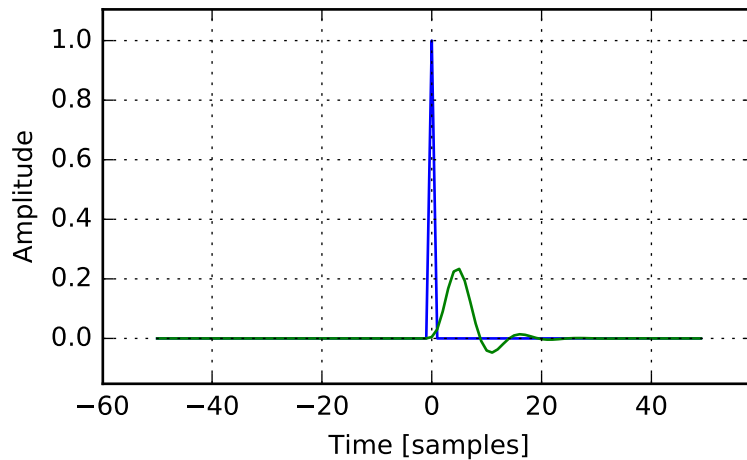

Impulse at (2, 2), using broadcasting:

```
>>> signal.unit_impulse((4, 4), 2)
array([[ 0.,  0.,  0.,  0.],
       [ 0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.],
       [ 0.,  0.,  0.,  0.]])
```

Plot the impulse response of a 4th-order Butterworth lowpass filter:

```
>>> imp = signal.unit_impulse(100, 'mid')
>>> b, a = signal.butter(4, 0.2)
>>> response = signal.lfilter(b, a, imp)

>>> import matplotlib.pyplot as plt
>>> plt.plot(np.arange(-50, 50), imp)
>>> plt.plot(np.arange(-50, 50), response)
>>> plt.margins(0.1, 0.1)
>>> plt.xlabel('Time [samples]')
>>> plt.ylabel('Amplitude')
>>> plt.grid(True)
>>> plt.show()
```

### 5.20.10 Window functions

---

<code>get_window(window, Nx[, fftbins])</code>	Return a window.
<code>barthann(M[, sym])</code>	Return a modified Bartlett-Hann window.
<code>bartlett(M[, sym])</code>	Return a Bartlett window.
<code>blackman(M[, sym])</code>	Return a Blackman window.
<code>blackmanharris(M[, sym])</code>	Return a minimum 4-term Blackman-Harris window.
<code>bohman(M[, sym])</code>	Return a Bohman window.
<code>boxcar(M[, sym])</code>	Return a boxcar or rectangular window.
<code>chebwin(M, at[, sym])</code>	Return a Dolph-Chebyshev window.
<code>cosine(M[, sym])</code>	Return a window with a simple cosine shape.
<code>exponential(M[, center, tau, sym])</code>	Return an exponential (or Poisson) window.
<code>flattop(M[, sym])</code>	Return a flat top window.
<code>gaussian(M, std[, sym])</code>	Return a Gaussian window.
<code>general_gaussian(M, p, sig[, sym])</code>	Return a window with a generalized Gaussian shape.
<code>hamming(M[, sym])</code>	Return a Hamming window.
<code>hann(M[, sym])</code>	Return a Hann window.
<code>hanning(M[, sym])</code>	Return a Hann window.
<code>kaiser(M, beta[, sym])</code>	Return a Kaiser window.
<code>nuttall(M[, sym])</code>	Return a minimum 4-term Blackman-Harris window according to Nuttall.
<code>parzen(M[, sym])</code>	Return a Parzen window.
<code>slepian(M, width[, sym])</code>	Return a digital Slepian (DPSS) window.
<code>triang(M[, sym])</code>	Return a triangular window.
<code>tukey(M[, alpha, sym])</code>	Return a Tukey window, also known as a tapered cosine window.

---

`scipy.signal.get_window(window, Nx, fftbins=True)`

Return a window.

**Parameters**

- window** : string, float, or tuple  
The type of window to create. See below for more details.
- Nx** : int  
The number of samples in the window.
- fftbins** : bool, optional

**Returns** `get_window` : ndarray  
 If True (default), create a “periodic” window, ready to use with *fftshift* and be multiplied by the result of an FFT (see also *fftpack.fftfreq*). If False, create a “symmetric” window, for use in filter design.  
 Returns a window of length  $Nx$  and type *window*

**Notes**

Window types:

`boxcar`, `triang`, `blackman`, `hamming`, `hann`, `bartlett`, `flattop`, `parzen`, `bohman`, `blackmanharris`, `nuttall`, `barthann`, `kaiser` (needs beta), `gaussian` (needs standard deviation), `general_gaussian` (needs power, width), `slepian` (needs width), `chebwin` (needs attenuation), `exponential` (needs decay scale), `tukey` (needs taper fraction)

If the window requires no parameters, then *window* can be a string.

If the window requires parameters, then *window* must be a tuple with the first argument the string name of the window, and the next arguments the needed parameters.

If *window* is a floating point number, it is interpreted as the beta parameter of the `kaiser` window.

Each of the window types listed above is also the name of a function that can be called directly to create a window of that type.

**Examples**

```
>>> from scipy import signal
>>> signal.get_window('triang', 7)
array([ 0.125,  0.375,  0.625,  0.875,  0.875,  0.625,  0.375])
>>> signal.get_window(('kaiser', 4.0), 9)
array([ 0.08848053,  0.29425961,  0.56437221,  0.82160913,  0.97885093,
        0.97885093,  0.82160913,  0.56437221,  0.29425961])
>>> signal.get_window(4.0, 9)
array([ 0.08848053,  0.29425961,  0.56437221,  0.82160913,  0.97885093,
        0.97885093,  0.82160913,  0.56437221,  0.29425961])
```

`scipy.signal.barthann` ( $M$ , *sym*=True)  
 Return a modified Bartlett-Hann window.

**Parameters** `M` : int  
 Number of points in the output window. If zero or less, an empty array is returned.  
`sym` : bool, optional  
 When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.  
**Returns** `w` : ndarray  
 The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and *sym* is True).

**Examples**

Plot the window and its frequency response:

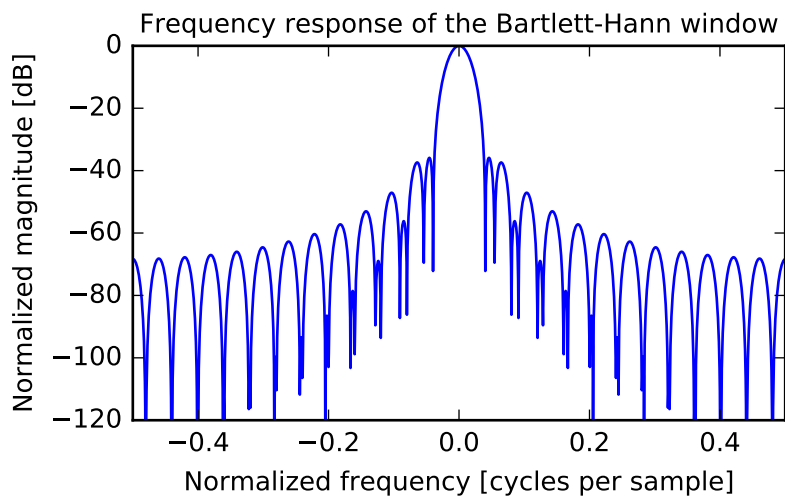

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```

>>> window = signal.bartlett(51)
>>> plt.plot(window)
>>> plt.title("Bartlett-Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Bartlett-Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")

```

`scipy.signal.bartlett` ( $M$ ,  $sym=True$ )

Return a Bartlett window.

The Bartlett window is very similar to a triangular window, except that the end points are at zero. It is often used in signal processing for tapering a signal, without generating too much ripple in the frequency domain.

**Parameters**

- M** : int  
Number of points in the output window. If zero or less, an empty array is returned.
- sym** : bool, optional  
When True (default), generates a symmetric window, for use in filter design.  
When False, generates a periodic window, for use in spectral analysis.

**Returns**

- w** : ndarray  
The triangular window, with the first and last samples equal to zero and the maximum value normalized to 1 (though the value 1 does not appear if *M* is even and *sym* is True).

**See also:**

[\*triang\*](#) A triangular window that does not touch zero at the ends

**Notes**

The Bartlett window is defined as

$$w(n) = \frac{2}{M-1} \left( \frac{M-1}{2} - \left| n - \frac{M-1}{2} \right| \right)$$

Most references to the Bartlett window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. Note that convolution with this window produces linear interpolation. It is also known as an apodization (which means "removing the foot", i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function. The Fourier transform of the Bartlett is the product of two sinc functions. Note the excellent discussion in Kanasewich. [R189]

**References**

[R188], [R189], [R190], [R191], [R192]

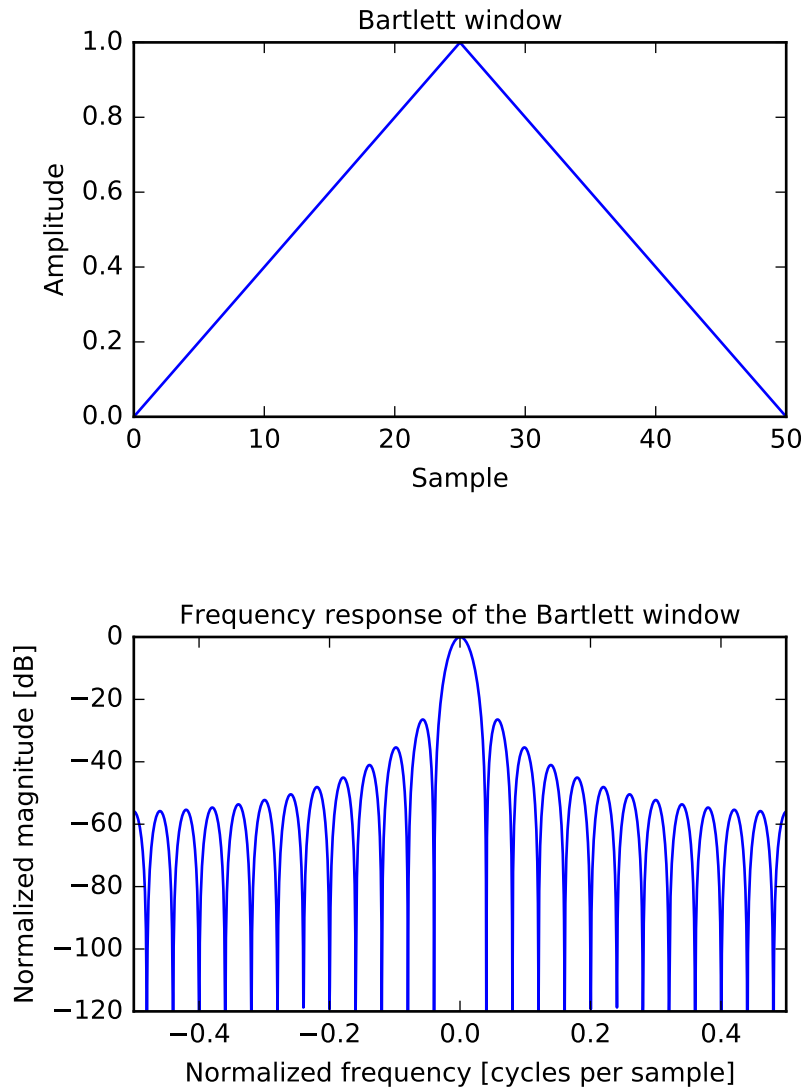

**Examples**

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.bartlett(51)
>>> plt.plot(window)
>>> plt.title("Bartlett window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Bartlett window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.blackman` ( $M$ ,  $sym=True$ )

Return a Blackman window.

The Blackman window is a taper formed by using the first three terms of a summation of cosines. It was designed to have close to the minimal leakage possible. It is close to optimal, only slightly worse than a Kaiser window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

The Blackman window is defined as

$$w(n) = 0.42 - 0.5 \cos(2\pi n/M) + 0.08 \cos(4\pi n/M)$$

The “exact Blackman” window was designed to null out the third and fourth sidelobes, but has discontinuities at the boundaries, resulting in a 6 dB/oct fall-off. This window is an approximation of the “exact” window, which does not null the sidelobes as well, but is smooth at the edges, improving the fall-off rate to 18 dB/oct. [R202]

Most references to the Blackman window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function. It is known as a “near optimal” tapering function, almost as good (by some measures) as the Kaiser window.

### References

[R200], [R201], [R202]

### Examples

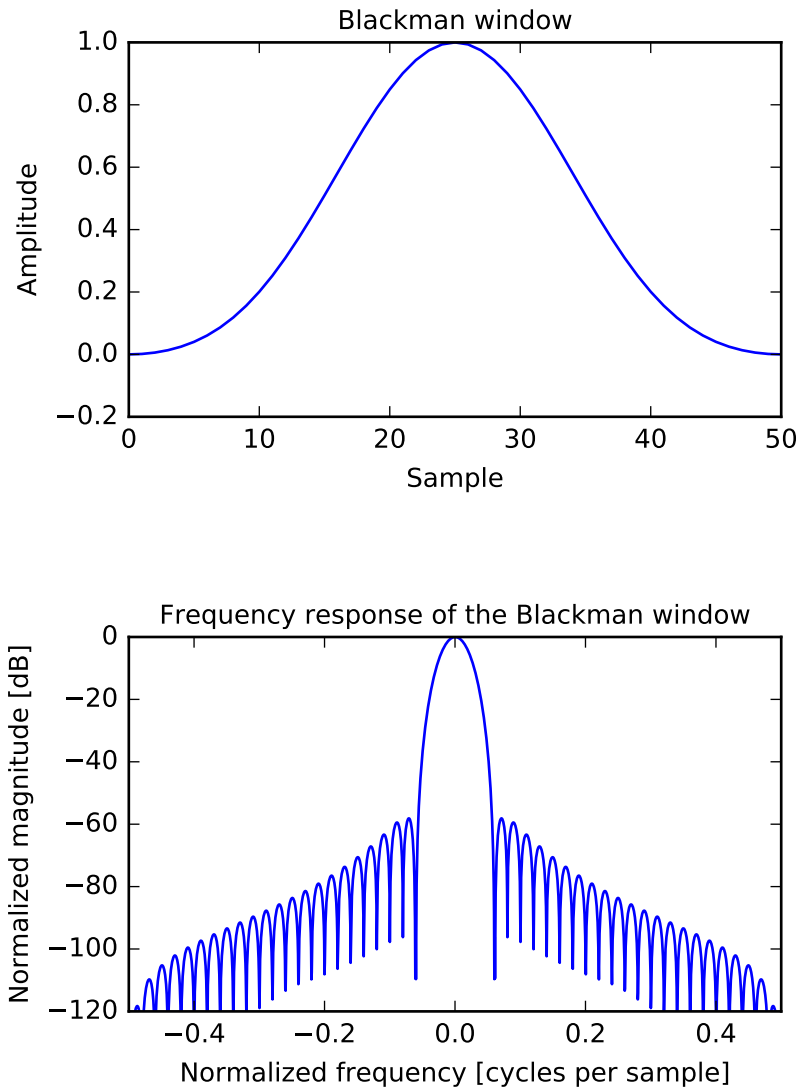

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.blackman(51)
>>> plt.plot(window)
>>> plt.title("Blackman window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Blackman window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.blackmanharris` ( $M$ ,  $sym=True$ )  
 Return a minimum 4-term Blackman-Harris window.

**Parameters**     $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**         $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.blackmanharris(51)
>>> plt.plot(window)
>>> plt.title("Blackman-Harris window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Blackman-Harris window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.bohman` ( $M$ ,  $sym=True$ )

Return a Bohman window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.bohman(51)
>>> plt.plot(window)
>>> plt.title("Bohman window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Bohman window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.boxcar` ( $M$ ,  $sym=True$ )

Return a boxcar or rectangular window.

Also known as a rectangular window or Dirichlet window, this is equivalent to no window at all.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

Whether the window is symmetric. (Has no effect for boxcar.)

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1.

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.boxcar(51)
>>> plt.plot(window)
>>> plt.title("Boxcar window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the boxcar window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.chebwin` ( $M$ ,  $at$ ,  $sym=True$ )

Return a Dolph-Chebyshev window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$at$  : float

Attenuation (in dB).

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value always normalized to 1

### Notes

This window optimizes for the narrowest main lobe width for a given order  $M$  and sidelobe equiripple attenuation  $at$ , using Chebyshev polynomials. It was originally developed by Dolph to optimize the directionality of radio antenna arrays.

Unlike most windows, the Dolph-Chebyshev is defined in terms of its frequency response:

$$W(k) = \frac{\cos\{M \cos^{-1}[\beta \cos(\frac{\pi k}{M})]\}}{\cosh[M \cosh^{-1}(\beta)]}$$

where

$$\beta = \cosh \left[ \frac{1}{M} \cosh^{-1}(10^{\frac{A}{20}}) \right]$$

and  $0 \leq \text{abs}(k) \leq M-1$ .  $A$  is the attenuation in decibels ( $at$ ).

The time domain window is then generated using the IFFT, so power-of-two  $M$  are the fastest to generate, and prime number  $M$  are the slowest.

The equiripple condition in the frequency domain creates impulses in the time domain, which appear at the ends of the window.

### References

*Examples*

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.chebwin(51, at=100)
>>> plt.plot(window)
>>> plt.title("Dolph-Chebyshev window (100 dB)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max()))))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Dolph-Chebyshev window (100 dB)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.cosine` ( $M$ ,  $sym=True$ )

Return a window with a simple cosine shape.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

New in version 0.13.0.

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.cosine(51)
>>> plt.plot(window)
>>> plt.title("Cosine window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
```

```

>>> plt.title("Frequency response of the cosine window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
>>> plt.show()

```

`scipy.signal.exponential` ( $M$ , *center=None*, *tau=1.0*, *sym=True*)

Return an exponential (or Poisson) window.

**Parameters** **M** : int

Number of points in the output window. If zero or less, an empty array is returned.

**center** : float, optional

Parameter defining the center location of the window function. The default value if not given is  $\text{center} = (M-1) / 2$ . This parameter must take its default value for symmetric windows.

**tau** : float, optional

Parameter defining the decay. For `center = 0` use `tau = -(M-1) / ln(x)` if `x` is the fraction of the window remaining at the end.

**sym** : bool, optional  
 When True (default), generates a symmetric window, for use in filter design.  
 When False, generates a periodic window, for use in spectral analysis.

**Returns** `w` : ndarray  
 The window, with the maximum value normalized to 1 (though the value 1 does not appear if `M` is even and `sym` is True).

### Notes

The Exponential window is defined as

$$w(n) = e^{-|n-center|/\tau}$$

### References

S. Gade and H. Herlufsen, “Windows to FFT analysis (Part I)”, Technical Review 3, Bruel & Kjaer, 1987.

### Examples

Plot the symmetric window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> M = 51
>>> tau = 3.0
>>> window = signal.exponential(M, tau=tau)
>>> plt.plot(window)
>>> plt.title("Exponential Window (tau=3.0)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -35, 0])
>>> plt.title("Frequency response of the Exponential window (tau=3.0)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

This function can also generate non-symmetric windows:

```
>>> tau2 = -(M-1) / np.log(0.01)
>>> window2 = signal.exponential(M, 0, tau2, False)
>>> plt.figure()
>>> plt.plot(window2)
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

`scipy.signal.flattop` ( $M$ ,  $sym=True$ )

Return a flat top window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

Flat top windows are used for taking accurate measurements of signal amplitude in the frequency domain, with minimal scalloping error from the center of a frequency bin to its edges, compared to others. This is a 5th-order cosine window, with the 5 terms optimized to make the main lobe maximally flat. [R221]

### References

[R221]

### Examples

Plot the window and its frequency response:

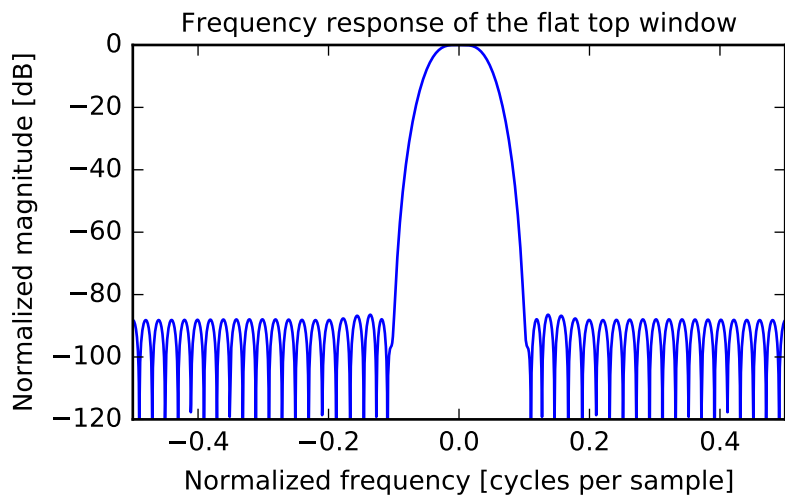

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.flattop(51)
>>> plt.plot(window)
>>> plt.title("Flat top window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```

```

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the flat top window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")

```

`scipy.signal.gaussian` ( $M$ ,  $std$ ,  $sym=True$ )

Return a Gaussian window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$std$  : float

The standard deviation, sigma.  
**sym** : bool, optional  
 When True (default), generates a symmetric window, for use in filter design.  
 When False, generates a periodic window, for use in spectral analysis.  
**Returns**     **w** : ndarray  
 The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and *sym* is True).

### Notes

The Gaussian window is defined as

$$w(n) = e^{-\frac{1}{2}\left(\frac{n}{\sigma}\right)^2}$$

### Examples

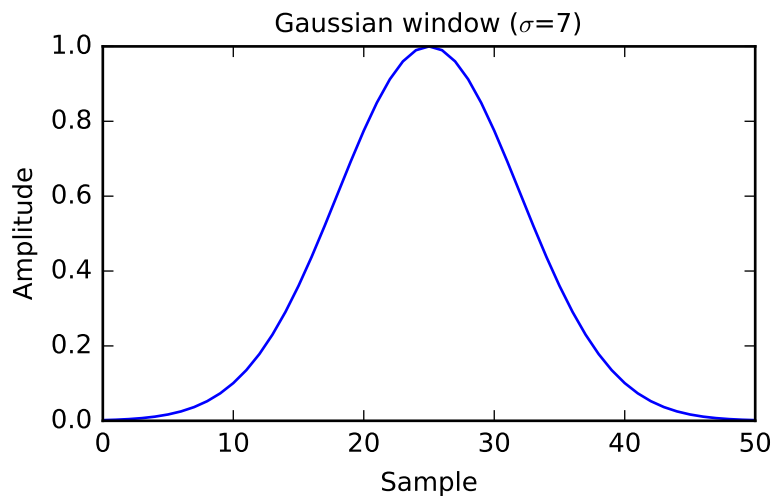

Plot the window and its frequency response:

```

>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.gaussian(51, std=7)
>>> plt.plot(window)
>>> plt.title(r"Gaussian window (\sigma=7)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title(r"Frequency response of the Gaussian window (\sigma=7)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
    
```

`scipy.signal.general_gaussian` ( $M, p, sig, sym=True$ )

Return a window with a generalized Gaussian shape.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$p$  : float

Shape parameter.  $p = 1$  is identical to `gaussian`,  $p = 0.5$  is the same shape as the Laplace distribution.

$sig$  : float

The standard deviation, sigma.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**

$w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

The generalized Gaussian window is defined as

$$w(n) = e^{-\frac{1}{2} \left| \frac{n}{\sigma} \right|^{2p}}$$

the half-power point is at

$$(2 \log(2))^{1/(2p)} \sigma$$

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```

>>> window = signal.general_gaussian(51, p=1.5, sig=7)
>>> plt.plot(window)
>>> plt.title(r"Generalized Gaussian window (p=1.5,  $\sigma=7$ )")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max()))))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title(r"Freq. resp. of the gen. Gaussian "
...         "window (p=1.5,  $\sigma=7$ )")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
    
```

`scipy.signal.hamming` ( $M$ ,  $sym=True$ )

Return a Hamming window.

The Hamming window is a taper formed by using a raised cosine with non-zero endpoints, optimized to minimize the nearest side lobe.

**Parameters**

- $M$**  : int  
Number of points in the output window. If zero or less, an empty array is returned.
- $sym$**  : bool, optional  
When True (default), generates a symmetric window, for use in filter design.  
When False, generates a periodic window, for use in spectral analysis.

**Returns**

- $w$**  : ndarray  
The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

The Hamming window is defined as

$$w(n) = 0.54 - 0.46 \cos\left(\frac{2\pi n}{M-1}\right) \quad 0 \leq n \leq M-1$$

The Hamming was named for R. W. Hamming, an associate of J. W. Tukey and is described in Blackman and Tukey. It was recommended for smoothing the truncated autocovariance function in the time domain. Most references to the Hamming window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

### References

[R223], [R224], [R225], [R226]

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.hamming(51)
>>> plt.plot(window)
>>> plt.title("Hamming window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hamming window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.hann` ( $M$ ,  $sym=True$ )

Return a Hann window.

The Hann window is a taper formed by using a raised cosine or sine-squared with ends that touch zero.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

The Hann window is defined as

$$w(n) = 0.5 - 0.5 \cos\left(\frac{2\pi n}{M-1}\right) \quad 0 \leq n \leq M-1$$

The window was named for Julius von Hann, an Austrian meteorologist. It is also known as the Cosine Bell. It is sometimes erroneously referred to as the “Hanning” window, from the use of “hann” as a verb in the original paper and confusion with the very similar Hamming window.

Most references to the Hann window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

### References

[R227], [R228], [R229], [R230]

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.hann(51)
>>> plt.plot(window)
>>> plt.title("Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.hanning` ( $M$ ,  $sym=True$ )

Return a Hann window.

The Hann window is a taper formed by using a raised cosine or sine-squared with ends that touch zero.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### Notes

The Hann window is defined as

$$w(n) = 0.5 - 0.5 \cos\left(\frac{2\pi n}{M-1}\right) \quad 0 \leq n \leq M-1$$

The window was named for Julius von Hann, an Austrian meteorologist. It is also known as the Cosine Bell. It is sometimes erroneously referred to as the “Hanning” window, from the use of “hann” as a verb in the original paper and confusion with the very similar Hamming window.

Most references to the Hann window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

### References

[R231], [R232], [R233], [R234]

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.hann(51)
>>> plt.plot(window)
>>> plt.title("Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.kaiser` ( $M$ ,  $\beta$ ,  $\text{sym}=\text{True}$ )

Return a Kaiser window.

The Kaiser window is a taper formed by using a Bessel function.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$\beta$  : float

Shape parameter, determines trade-off between main-lobe width and side lobe level. As  $\beta$  gets large, the window narrows.

$\text{sym}$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $\text{sym}$  is True).

### Notes

The Kaiser window is defined as

$$w(n) = I_0 \left( \beta \sqrt{1 - \frac{4n^2}{(M-1)^2}} \right) / I_0(\beta)$$

with

$$-\frac{M-1}{2} \leq n \leq \frac{M-1}{2},$$

where  $I_0$  is the modified zeroth-order Bessel function.

The Kaiser was named for Jim Kaiser, who discovered a simple approximation to the DPSS window based on Bessel functions. The Kaiser window is a very good approximation to the Digital Prolate Spheroidal Sequence, or Slepian window, which is the transform which maximizes the energy in the main lobe of the window relative to total energy.

The Kaiser can approximate other windows by varying the beta parameter. (Some literature uses alpha = beta/pi.) [R246]

beta	Window shape
0	Rectangular
5	Similar to a Hamming
6	Similar to a Hann
8.6	Similar to a Blackman

A beta value of 14 is probably a good starting point. Note that as beta gets large, the window narrows, and so the number of samples needs to be large enough to sample the increasingly narrow spike, otherwise NaNs will be returned.

Most references to the Kaiser window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

### References

[R243], [R244], [R245], [R246]

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.kaiser(51, beta=14)
>>> plt.plot(window)
>>> plt.title(r"Kaiser window (\beta=14)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
```

```
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title(r"Frequency response of the Kaiser window ( $\beta=14$ )")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.nuttall` ( $M$ ,  $sym=True$ )

Return a minimum 4-term Blackman-Harris window according to Nuttall.

This variation is called “Nuttall4c” by Heinzel. [R256]

**Parameters**    **M** : int

Number of points in the output window. If zero or less, an empty array is returned.

**sym** : bool, optional

When True (default), generates a symmetric window, for use in filter design.

When False, generates a periodic window, for use in spectral analysis.

**Returns**        **w** : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### References

[R255], [R256]

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.nuttall(51)
>>> plt.plot(window)
>>> plt.title("Nuttall window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Nuttall window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.parzen` ( $M$ ,  $sym=True$ )

Return a Parzen window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

### References

[R257]

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.parzen(51)
>>> plt.plot(window)
>>> plt.title("Parzen window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
```

```
>>> plt.title("Frequency response of the Parzen window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.slepian` ( $M$ ,  $width$ ,  $sym=True$ )

Return a digital Slepian (DPSS) window.

Used to maximize the energy concentration in the main lobe. Also called the digital prolate spheroidal sequence (DPSS).

**Parameters** **M** : int

Number of points in the output window. If zero or less, an empty array is returned.

**width** : float

Bandwidth

**sym** : bool, optional

When True (default), generates a symmetric window, for use in filter design.  
When False, generates a periodic window, for use in spectral analysis.

**Returns** `w` : ndarray

The window, with the maximum value always normalized to 1

### References

[R262], [R263]

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.slepian(51, width=0.3)
>>> plt.plot(window)
>>> plt.title("Slepian (DPSS) window (BW=0.3)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Slepian window (BW=0.3)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.triang` ( $M$ ,  $sym=True$ )

Return a triangular window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

$sym$  : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**  $w$  : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and  $sym$  is True).

**See also:**

`bartlett` A triangular window that touches zero

**Examples**

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.triang(51)
>>> plt.plot(window)
>>> plt.title("Triangular window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the triangular window")
```

```
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

`scipy.signal.tukey` ( $M$ ,  $\alpha=0.5$ ,  $\text{sym}=\text{True}$ )

Return a Tukey window, also known as a tapered cosine window.

**Parameters**  $M$  : int

Number of points in the output window. If zero or less, an empty array is returned.

**alpha** : float, optional

Shape parameter of the Tukey window, representing the fraction of the window inside the cosine tapered region. If zero, the Tukey window is equivalent to a rectangular window. If one, the Tukey window is equivalent to a Hann window.

**sym** : bool, optional

When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns** `w` : ndarray

The window, with the maximum value normalized to 1 (though the value 1 does not appear if  $M$  is even and *sym* is True).

### References

[R267], [R268]

### Examples

Plot the window and its frequency response:

```
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.tukey(51)
>>> plt.plot(window)
>>> plt.title("Tukey window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
>>> plt.ylim([0, 1.1])

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Tukey window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

## 5.20.11 Wavelets

<code>cascade(hk[, J])</code>	Return (x, phi, psi) at dyadic points $K/2^{**J}$ from filter coefficients.
<code>daub(p)</code>	The coefficients for the FIR low-pass filter producing Daubechies wavelets.
<code>morlet(M[, w, s, complete])</code>	Complex Morlet wavelet.
<code>qmf(hk)</code>	Return high-pass qmf filter from low-pass
<code>ricker(points, a)</code>	Return a Ricker wavelet, also known as the “Mexican hat wavelet”.
<code>cwt(data, wavelet, widths)</code>	Continuous wavelet transform.

`scipy.signal.cascade(hk, J=7)`

Return (x, phi, psi) at dyadic points  $K/2^{**J}$  from filter coefficients.

**Parameters** `hk` : array\_like

Coefficients of low-pass filter.

`J` : int, optional

Values will be computed at grid points  $K/2^{**J}$ . Default is 7.

**Returns**

`x` : ndarray

The dyadic points  $K/2^{**J}$  for  $K=0 \dots N * (2^{**J}) - 1$  where  $\text{len}(hk) = \text{len}(gk) = N + 1$ .

`phi` : ndarray

The scaling function  $\phi(x)$  at  $x$ :  $\phi(x) = \sum(hk * \phi(2x - k))$ , where  $k$  is from 0 to  $N$ .

`psi` : ndarray, optional

The wavelet function  $\psi(x)$  at  $x$ :  $\psi(x) = \sum(gk * \phi(2x - k))$ , where  $k$  is from 0 to  $N$ .  $\psi$  is only returned if  $gk$  is not None.

### Notes

The algorithm uses the vector cascade algorithm described by Strang and Nguyen in “Wavelets and Filter Banks”. It builds a dictionary of values and slices for quick reuse. Then inserts vectors into final vector at the end.

`scipy.signal.daub(p)`

The coefficients for the FIR low-pass filter producing Daubechies wavelets.

$p \geq 1$  gives the order of the zero at  $f=1/2$ . There are  $2p$  filter coefficients.

**Parameters** **p** : int  
Order of the zero at  $f=1/2$ , can have values from 1 to 34.

**Returns** **daub** : ndarray  
Return

`scipy.signal.morlet` ( $M, w=5.0, s=1.0, complete=True$ )

Complex Morlet wavelet.

**Parameters** **M** : int  
Length of the wavelet.

**w** : float, optional  
Omega0. Default is 5

**s** : float, optional  
Scaling factor, windowed from  $-s*2*\pi$  to  $+s*2*\pi$ . Default is 1.

**complete** : bool, optional  
Whether to use the complete or the standard version.

**Returns** **morlet** : (M,) ndarray

**See also:**

`scipy.signal.gausspulse`

**Notes**

The standard version:

$$\pi^{-0.25} * \exp(1j*w*x) * \exp(-0.5*(x**2))$$

This commonly used wavelet is often referred to simply as the Morlet wavelet. Note that this simplified version can cause admissibility problems at low values of  $w$ .

The complete version:

$$\pi^{-0.25} * (\exp(1j*w*x) - \exp(-0.5*(w**2))) * \exp(-0.5*(x**2))$$

This version has a correction term to improve admissibility. For  $w$  greater than 5, the correction term is negligible.

Note that the energy of the return wavelet is not normalised according to  $s$ .

The fundamental frequency of this wavelet in Hz is given by  $f = 2*s*w*r / M$  where  $r$  is the sampling rate.

Note: This function was created before `cwt` and is not compatible with it.

`scipy.signal.qmf` ( $hk$ )

Return high-pass qmf filter from low-pass

**Parameters** **hk** : array\_like  
Coefficients of high-pass filter.

`scipy.signal.ricker` ( $points, a$ )

Return a Ricker wavelet, also known as the ‘‘Mexican hat wavelet’’.

It models the function:

$$A (1 - x^2/a^2) \exp(-x^2/2 a^2),$$

where  $A = 2/\sqrt{3a} \pi^{1/4}$ .

**Parameters** **points** : int  
Number of points in *vector*. Will be centered around 0.

**Returns** **a** : scalar  
           **vector** : (N,) ndarray  
                     Width parameter of the wavelet.  
                     Array of length *points* in shape of ricker curve.

### Examples

```

>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> points = 100
>>> a = 4.0
>>> vec2 = signal.ricker(points, a)
>>> print(len(vec2))
100
>>> plt.plot(vec2)
>>> plt.show()
    
```

`scipy.signal.cwt` (*data*, *wavelet*, *widths*)

Continuous wavelet transform.

Performs a continuous wavelet transform on *data*, using the *wavelet* function. A CWT performs a convolution with *data* using the *wavelet* function, which is characterized by a width parameter and length parameter.

**Parameters** **data** : (N,) ndarray  
                     data on which to perform the transform.  
**wavelet** : function  
                     Wavelet function, which should take 2 arguments. The first argument is the number of points that the returned vector will have (`len(wavelet(length,width)) == length`). The second is a width parameter, defining the size of the wavelet (e.g. standard deviation of a gaussian). See `ricker`, which satisfies these requirements.  
**widths** : (M,) sequence  
                     Widths to use for transform.

**Returns** **cwt**: (M, N) ndarray  
                     Will have shape of `(len(widths), len(data))`.

### Notes

```
length = min(10 * width[ii], len(data))
cwt[ii,:] = signal.convolve(data, wavelet(length,
                                         width[ii]), mode='same')
```

### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 200, endpoint=False)
>>> sig = np.cos(2 * np.pi * 7 * t) + signal.gausspulse(t - 0.4, fc=2)
>>> widths = np.arange(1, 31)
>>> cwtmatr = signal.cwt(sig, signal.ricker, widths)
>>> plt.imshow(cwtmatr, extent=[-1, 1, 31, 1], cmap='PRGn', aspect='auto',
...           vmax=abs(cwtmatr).max(), vmin=-abs(cwtmatr).max())
>>> plt.show()
```

## 5.20.12 Peak finding

<code>find_peaks_cwt(vector, widths[, wavelet, ...])</code>	Attempt to find the peaks in a 1-D array.
<code>argrelmin(data[, axis, order, mode])</code>	Calculate the relative minima of <i>data</i> .
<code>argrelmax(data[, axis, order, mode])</code>	Calculate the relative maxima of <i>data</i> .
<code>argrelextrema(data, comparator[, axis, ...])</code>	Calculate the relative extrema of <i>data</i> .

`scipy.signal.find_peaks_cwt` (*vector*, *widths*, *wavelet=None*, *max\_distances=None*, *gap\_thresh=None*, *min\_length=None*, *min\_snr=1*, *noise\_perc=10*)  
 Attempt to find the peaks in a 1-D array.

The general approach is to smooth *vector* by convolving it with *wavelet(width)* for each width in *widths*. Relative maxima which appear at enough length scales, and with sufficiently high SNR, are accepted.

**Parameters** **vector** : ndarray  
 1-D array in which to find the peaks.

**widths** : sequence  
 1-D array of widths to use for calculating the CWT matrix. In general, this range should cover the expected width of peaks of interest.

**wavelet** : callable, optional  
 Should take two parameters and return a 1-D array to convolve with *vector*. The first parameter determines the number of points of the returned wavelet array, the second parameter is the scale (*width*) of the wavelet. Should be normalized and symmetric. Default is the ricker wavelet.

**max\_distances** : ndarray, optional  
 At each row, a ridge line is only connected if the relative max at row[n] is within `max_distances[n]` from the relative max at row[n+1]. Default value is `widths/4`.

**gap\_thresh** : float, optional  
 If a relative maximum is not found within *max\_distances*, there will be a gap. A ridge line is discontinued if there are more than *gap\_thresh* points without connecting a new relative maximum. Default is 2.

**min\_length** : int, optional  
 Minimum length a ridge line needs to be acceptable. Default is `cwt.shape[0] / 4`, ie 1/4-th the number of widths.

**min\_snr** : float, optional  
 Minimum SNR ratio. Default 1. The signal is the value of the cwt matrix at the shortest length scale (`cwt[0, loc]`), the noise is the *noise\_perc*'th percentile of datapoints contained within a window of *window\_size* around `cwt[0, loc]`.

**noise\_perc** : float, optional  
 When calculating the noise floor, percentile of data points examined below which to consider noise. Calculated using *stats.scoreatpercentile*. Default is 10.

**Returns** **peaks\_indices** : ndarray  
 Indices of the locations in the *vector* where peaks were found. The list is sorted.

**See also:**

`cwt`

**Notes**

This approach was designed for finding sharp peaks among noisy data, however with proper parameter selection it should function well for different peak shapes.

*The algorithm is as follows:*

1. Perform a continuous wavelet transform on *vector*, for the supplied *widths*. This is a convolution of *vector* with *wavelet(width)* for each width in *widths*. See `cwt`
2. Identify “ridge lines” in the cwt matrix. These are relative maxima at each row, connected across adjacent rows. See `identify_ridge_lines`
3. Filter the `ridge_lines` using `filter_ridge_lines`.

New in version 0.11.0.

**References**

[R217]

**Examples**

```
>>> from scipy import signal
>>> xs = np.arange(0, np.pi, 0.05)
```

```
>>> data = np.sin(xs)
>>> peakind = signal.find_peaks_cwt(data, np.arange(1,10))
>>> peakind, xs[peakind], data[peakind]
([32], array([ 1.6]), array([ 0.9995736]))
```

`scipy.signal.argrelmin` (*data*, *axis=0*, *order=1*, *mode='clip'*)

Calculate the relative minima of *data*.

<b>Parameters</b>	<p><b>data</b> : ndarray Array in which to find the relative minima.</p> <p><b>axis</b> : int, optional Axis over which to select from <i>data</i>. Default is 0.</p> <p><b>order</b> : int, optional How many points on each side to use for the comparison to consider <code>comparator(n, n+x)</code> to be True.</p> <p><b>mode</b> : str, optional How the edges of the vector are treated. Available options are 'wrap' (wrap around) or 'clip' (treat overflow as the same as the last (or first) element). Default 'clip'. See <code>numpy.take</code></p>
<b>Returns</b>	<p><b>extrema</b> : tuple of ndarrays Indices of the minima in arrays of integers. <code>extrema[k]</code> is the array of indices of axis <i>k</i> of <i>data</i>. Note that the return value is a tuple even when <i>data</i> is one-dimensional.</p>

See also:

`argrelextrema`, `argrelmax`

**Notes**

This function uses `argrelextrema` with `np.less` as comparator.

New in version 0.11.0.

**Examples**

```
>>> from scipy.signal import argrelmin
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmin(x)
(array([1, 5]),)
>>> y = np.array([[1, 2, 1, 2],
...              [2, 2, 0, 0],
...              [5, 3, 4, 4]])
...
>>> argrelmin(y, axis=1)
(array([0, 2]), array([2, 1]))
```

`scipy.signal.argrelmax` (*data*, *axis=0*, *order=1*, *mode='clip'*)

Calculate the relative maxima of *data*.

<b>Parameters</b>	<p><b>data</b> : ndarray Array in which to find the relative maxima.</p> <p><b>axis</b> : int, optional Axis over which to select from <i>data</i>. Default is 0.</p> <p><b>order</b> : int, optional How many points on each side to use for the comparison to consider <code>comparator(n, n+x)</code> to be True.</p> <p><b>mode</b> : str, optional</p>
-------------------	---

**Returns** **extrema** : tuple of ndarrays

How the edges of the vector are treated. Available options are ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default ‘clip’. See `numpy.take`.

Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis *k* of *data*. Note that the return value is a tuple even when *data* is one-dimensional.

**See also:**

`argrelextrema`, `argrelmin`

**Notes**

This function uses `argrelextrema` with `np.greater` as comparator.

New in version 0.11.0.

**Examples**

```
>>> from scipy.signal import argrelmax
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmax(x)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
...              [2, 2, 0, 0],
...              [5, 3, 4, 4]])
...
>>> argrelmax(y, axis=1)
(array([0]), array([1]))
```

`scipy.signal.argrelextrema` (*data*, *comparator*, *axis=0*, *order=1*, *mode='clip'*)  
 Calculate the relative extrema of *data*.

**Parameters**

- data** : ndarray  
 Array in which to find the relative extrema.
- comparator** : callable  
 Function to use to compare two data points. Should take two arrays as arguments.
- axis** : int, optional  
 Axis over which to select from *data*. Default is 0.
- order** : int, optional  
 How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.
- mode** : str, optional  
 How the edges of the vector are treated. ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default is ‘clip’.

**Returns** **extrema** : tuple of ndarrays

See `numpy.take`.

Indices of the maxima in arrays of integers. `extrema[k]` is the array of indices of axis *k* of *data*. Note that the return value is a tuple even when *data* is one-dimensional.

**See also:**

`argrelmin`, `argrelmax`

**Notes**

New in version 0.11.0.

**Examples**

```

>>> from scipy.signal import argrelextrema
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelextrema(x, np.greater)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
...               [2, 2, 0, 0],
...               [5, 3, 4, 4]])
...
>>> argrelextrema(y, np.less, axis=1)
(array([0, 2]), array([2, 1]))

```

**5.20.13 Spectral Analysis**

---

<code>periodogram(x[, fs, window, nfft, detrend, ...])</code>	Estimate power spectral density using a periodogram.
<code>welch(x[, fs, window, nperseg, noverlap, ...])</code>	Estimate power spectral density using Welch's method.
<code>csd(x, y[, fs, window, nperseg, noverlap, ...])</code>	Estimate the cross power spectral density, $P_{xy}$ , using Welch's method.
<code>coherence(x, y[, fs, window, nperseg, ...])</code>	Estimate the magnitude squared coherence estimate, $C_{xy}$ , of discrete-time signals.
<code>spectrogram(x[, fs, window, nperseg, ...])</code>	Compute a spectrogram with consecutive Fourier transforms.
<code>lombscargle(x, y, freqs)</code>	Computes the Lomb-Scargle periodogram.
<code>vectorstrength(events, period)</code>	Determine the vector strength of the events corresponding to the given period.
<code>stft(x[, fs, window, nperseg, noverlap, ...])</code>	Compute the Short Time Fourier Transform (STFT).
<code>istft(Zxx[, fs, window, nperseg, noverlap, ...])</code>	Perform the inverse Short Time Fourier transform (iSTFT).
<code>check_COLA(window, nperseg, noverlap[, tol])</code>	Check whether the Constant OverLap Add (COLA) constraint is met

---

`scipy.signal.periodogram(x, fs=1.0, window='boxcar', nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)`

Estimate power spectral density using a periodogram.

**Parameters** `x` : array\_like

Time series of measurement values

`fs` : float, optional

Sampling frequency of the  $x$  time series. Defaults to 1.0.

`window` : str or tuple or array\_like, optional

Desired window to use. See `get_window` for a list of windows and required parameters. If `window` is array\_like it will be used directly as the window and its length must be `nperseg`. Defaults to 'boxcar'.

`nfft` : int, optional

Length of the FFT used. If *None* the length of  $x$  will be used.

`detrend` : str or function or *False*, optional

Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is *False*, no detrending is done. Defaults to 'constant'.

`return_onesided` : bool, optional

If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.

`scaling` : { 'density', 'spectrum' }, optional

Selects between computing the power spectral density ('density') where  $P_{xx}$  has units of  $V^{**2}/Hz$  and computing the power spectrum ('spectrum')

where  $P_{xx}$  has units of  $V^{**2}$ , if  $x$  is measured in  $V$  and  $fs$  is measured in  $Hz$ . Defaults to 'density'

**Returns**

- axis** : int, optional  
Axis along which the periodogram is computed; the default is over the last axis (i.e. `axis=-1`).
- f** : ndarray  
Array of sample frequencies.
- Pxx** : ndarray  
Power spectral density or power spectrum of  $x$ .

**See also:**

[`welch`](#) Estimate power spectral density using Welch's method

[`lombscargle`](#) Lomb-Scargle periodogram for unevenly sampled data

**Notes**

New in version 0.12.0.

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)
```

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001  $V^{**2}/Hz$  of white noise sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```

Compute and plot the power spectral density.

```
>>> f, Pxx_den = signal.periodogram(x, fs)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([1e-7, 1e2])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```
>>> np.mean(Pxx_den[256:])
0.0018156616014838548
```

Now compute and plot the power spectrum.

```
>>> f, Pxx_spec = signal.periodogram(x, fs, 'flattop', scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.ylim([1e-4, 1e1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

The peak height in the power spectrum is an estimate of the RMS amplitude.

```
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

`scipy.signal.welch(x, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)`  
 Estimate power spectral density using Welch's method.

Welch's method [R270] computes an estimate of the power spectral density by dividing the data into overlapping segments, computing a modified periodogram for each segment and averaging the periodograms.

**Parameters**

- x** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be `nperseg`. Defaults to a Hann window.
- nperseg** : int, optional  
Length of each segment. Defaults to `None`, but if *window* is str or tuple, is set to 256, and if *window* is array\_like, is set to the length of the window.
- noverlap** : int, optional  
Number of points to overlap between segments. If `None`, `noverlap = nperseg // 2`. Defaults to `None`.
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If `None`, the FFT length is `nperseg`. Defaults to `None`.
- detrend** : str or function or `False`, optional  
Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is `False`, no detrending is done. Defaults to 'constant'.
- return\_onesided** : bool, optional  
If `True`, return a one-sided spectrum for real data. If `False` return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.
- scaling** : { 'density', 'spectrum' }, optional  
Selects between computing the power spectral density ('density') where *Pxx* has units of  $V^{**2}/\text{Hz}$  and computing the power spectrum ('spectrum') where *Pxx* has units of  $V^{**2}$ , if *x* is measured in V and *fs* is measured in Hz. Defaults to 'density'
- axis** : int, optional  
Axis along which the periodogram is computed; the default is over the last axis (i.e. `axis=-1`).

**Returns**

- f** : ndarray  
Array of sample frequencies.
- Pxx** : ndarray  
Power spectral density or power spectrum of *x*.

See also:

[\*periodogram\*](#)

Simple, optionally modified periodogram

[\*lombscargle\*](#)

Lomb-Scargle periodogram for unevenly sampled data

**Notes**

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default ‘hann’ window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

If *noverlap* is 0, this method is equivalent to Bartlett’s method [R271].

New in version 0.12.0.

**References**

[R270], [R271]

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)
```

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V\*\*2/Hz of white noise sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```

Compute and plot the power spectral density.

```
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```

If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```
>>> np.mean(Pxx_den[256:])
0.0009924865443739191
```

Now compute and plot the power spectrum.

```
>>> f, Pxx_spec = signal.welch(x, fs, 'flattop', 1024, scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

The peak height in the power spectrum is an estimate of the RMS amplitude.

```
>>> np.sqrt(Pxx_spec.max())
2.0077340678640727
```

`scipy.signal.csd(x, y, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)`  
 Estimate the cross power spectral density, Pxy, using Welch's method.

**Parameters**

- x** : array\_like  
Time series of measurement values
- y** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* and *y* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Hann window.
- nperseg** : int, optional  
Length of each segment. Defaults to None, but if *window* is str or tuple, is set to 256, and if *window* is array\_like, is set to the length of the window.
- noverlap** : int, optional  
Number of points to overlap between segments. If None, *noverlap* = *nperseg* // 2. Defaults to None.
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is *nperseg*. Defaults to None.
- detrend** : str or function or False, optional  
Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is False, no detrending is done. Defaults to 'constant'.
- return\_onesided** : bool, optional  
If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.
- scaling** : { 'density', 'spectrum' }, optional  
Selects between computing the cross spectral density ('density') where *Pxy* has units of V\*\*2/Hz and computing the cross spectrum ('spectrum') where *Pxy* has units of V\*\*2, if *x* and *y* are measured in V and *fs* is measured in Hz. Defaults to 'density'
- axis** : int, optional  
Axis along which the CSD is computed for both inputs; the default is over the last axis (i.e. *axis*=-1).

**Returns**

- f** : ndarray  
Array of sample frequencies.
- Pxy** : ndarray  
Cross spectral density or cross power spectrum of *x,y*.

[`lombscargle`](#)

Lomb-Scargle periodogram for unevenly sampled data

[`welch`](#)

Power spectral density by Welch's method. [Equivalent to `csd(x,x)`]

[`coherence`](#)

Magnitude squared coherence by Welch's method.

**Notes**

By convention,  $P_{xy}$  is computed with the conjugate FFT of  $X$  multiplied by the FFT of  $Y$ .

If the input series differ in length, the shorter series will be zero-padded to match.

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default 'hann' window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

New in version 0.16.0.

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate two test signals with some common features.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the magnitude of the cross spectral density.

```
>>> f, Pxy = signal.csd(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, np.abs(Pxy))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('CSD [V**2/Hz]')
>>> plt.show()
```

`scipy.signal.coherence` (*x*, *y*, *fs*=1.0, *window*='hann', *nperseg*=None, *noverlap*=None, *nfft*=None, *detrend*='constant', *axis*=-1)

Estimate the magnitude squared coherence estimate,  $C_{xy}$ , of discrete-time signals *X* and *Y* using Welch's method.

$C_{xy} = \text{abs}(P_{xy}) ** 2 / (P_{xx} * P_{yy})$ , where  $P_{xx}$  and  $P_{yy}$  are power spectral density estimates of *X* and *Y*, and  $P_{xy}$  is the cross spectral density estimate of *X* and *Y*.

**Parameters**

- x** : array\_like  
Time series of measurement values
- y** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* and *y* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Hann window.
- nperseg** : int, optional  
Length of each segment. Defaults to None, but if *window* is str or tuple, is set to 256, and if *window* is array\_like, is set to the length of the window.
- noverlap** : int, optional  
Number of points to overlap between segments. If None, *noverlap* = *nperseg* // 2. Defaults to None.
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is *nperseg*. Defaults to None.
- detrend** : str or function or False, optional  
Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is False, no detrending is done. Defaults to 'constant'.
- axis** : int, optional  
Axis along which the coherence is computed for both inputs; the default is over the last axis (i.e. *axis*=-1).

**Returns**

- f** : ndarray  
Array of sample frequencies.

**Cxy** : ndarray  
Magnitude squared coherence of x and y.

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate two test signals with some common features.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)
```

Compute and plot the coherence.

```
>>> f, Cxy = signal.coherence(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, Cxy)
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Coherence')
>>> plt.show()
```

```
scipy.signal.spectrogram(x, fs=1.0, window=('tukey', 0.25), nperseg=None, noverlap=None,
                        nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, mode='psd')
```

Compute a spectrogram with consecutive Fourier transforms.

Spectrograms can be used as a way of visualizing the change of a nonstationary signal's frequency content over time.

**Parameters**

- x** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Tukey window with shape parameter of 0.25.
- nperseg** : int, optional  
Length of each segment. Defaults to *None*, but if *window* is str or tuple, is set to 256, and if *window* is array\_like, is set to the length of the window.
- noverlap** : int, optional  
Number of points to overlap between segments. If *None*, `noverlap = nperseg // 8`. Defaults to *None*.
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.
- detrend** : str or function or *False*, optional  
Specifies how to detrend each segment. If `detrend` is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is *False*, no detrending is done. Defaults to 'constant'.
- return\_onesided** : bool, optional  
If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.
- scaling** : { 'density', 'spectrum' }, optional

Selects between computing the power spectral density ('density') where  $S_{xx}$  has units of  $V^{**2}/\text{Hz}$  and computing the power spectrum ('spectrum') where  $S_{xx}$  has units of  $V^{**2}$ , if  $x$  is measured in  $V$  and  $fs$  is measured in  $\text{Hz}$ . Defaults to 'density'.

**axis** : int, optional

Axis along which the spectrogram is computed; the default is over the last axis (i.e. `axis=-1`).

**mode** : str, optional

Defines what kind of return values are expected. Options are ['psd', 'complex', 'magnitude', 'angle', 'phase']. 'complex' is equivalent to the output of `stft` with no padding or boundary extension. 'magnitude' returns the absolute magnitude of the STFT. 'angle' and 'phase' return the complex angle of the STFT, with and without unwrapping, respectively.

#### Returns

**f** : ndarray

Array of sample frequencies.

**t** : ndarray

Array of segment times.

**Sxx** : ndarray

Spectrogram of  $x$ . By default, the last axis of  $S_{xx}$  corresponds to the segment times.

#### See also:

##### *periodogram*

Simple, optionally modified periodogram

##### *lombscargle*

Lomb-Scargle periodogram for unevenly sampled data

##### *welch*

Power spectral density by Welch's method.

##### *csd*

Cross spectral density by Welch's method.

#### Notes

An appropriate amount of overlap will depend on the choice of window and on your requirements. In contrast to `welch`'s method, where the entire data stream is averaged over, one may wish to use a smaller overlap (or perhaps none at all) when computing a spectrogram, to maintain some statistical independence between individual segments. It is for this reason that the default window is a Tukey window with 1/8th of a window's length overlap at each end.

New in version 0.16.0.

#### References

[R264]

#### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500*np.cos(2*np.pi*0.25*time)
```

```
>>> carrier = amp * np.sin(2*np.pi*3e3*time + mod)
>>> noise = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the spectrogram.

```
>>> f, t, Sxx = signal.spectrogram(x, fs)
>>> plt.pcolormesh(t, f, Sxx)
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

`scipy.signal.lombscargle(x, y, freqs)`

Computes the Lomb-Scargle periodogram.

The Lomb-Scargle periodogram was developed by Lomb [R247] and further extended by Scargle [R248] to find, and test the significance of weak periodic signals with uneven temporal sampling.

The computed periodogram is unnormalized, it takes the value  $(A**2) * N/4$  for a harmonic signal with amplitude  $A$  for sufficiently large  $N$ .

**Parameters**

- x** : array\_like  
Sample times.
- y** : array\_like  
Measurement values.
- freqs** : array\_like  
Angular frequencies for output periodogram.

**Returns**

- pgram** : array\_like  
Lomb-Scargle periodogram.

**Raises**

- ValueError**  
If the input arrays  $x$  and  $y$  do not have the same shape.

#### Notes

This subroutine calculates the periodogram using a slightly modified algorithm due to Townsend [R249] which allows the periodogram to be calculated using only a single pass through the input arrays for each frequency.

The algorithm running time scales roughly as  $O(x * \text{freqs})$  or  $O(N^2)$  for a large number of samples and frequencies.

### References

[R247], [R248], [R249]

### Examples

```
>>> import scipy.signal
>>> import matplotlib.pyplot as plt
```

First define some input parameters for the signal:

```
>>> A = 2.
>>> w = 1.
>>> phi = 0.5 * np.pi
>>> nin = 1000
>>> nout = 100000
>>> frac_points = 0.9 # Fraction of points to select
```

Randomly select a fraction of an array with timesteps:

```
>>> r = np.random.rand(nin)
>>> x = np.linspace(0.01, 10*np.pi, nin)
>>> x = x[r >= frac_points]
>>> normval = x.shape[0] # For normalization of the periodogram
```

Plot a sine wave for the selected times:

```
>>> y = A * np.sin(w*x+phi)
```

Define the array of frequencies for which to compute the periodogram:

```
>>> f = np.linspace(0.01, 10, nout)
```

Calculate Lomb-Scargle periodogram:

```
>>> import scipy.signal as signal
>>> pgram = signal.lombscargle(x, y, f)
```

Now make a plot of the input data:

```
>>> plt.subplot(2, 1, 1)
<matplotlib.axes.AxesSubplot object at 0x102154f50>
>>> plt.plot(x, y, 'b+')
[<matplotlib.lines.Line2D object at 0x102154a10>]
```

Then plot the normalized periodogram:

```
>>> plt.subplot(2, 1, 2)
<matplotlib.axes.AxesSubplot object at 0x104b0a990>
>>> plt.plot(f, np.sqrt(4*(pgram/normval)))
[<matplotlib.lines.Line2D object at 0x104b2f910>]
>>> plt.show()
```

`scipy.signal.vectorstrength(events, period)`

Determine the vector strength of the events corresponding to the given period.

The vector strength is a measure of phase synchrony, how well the timing of the events is synchronized to a single period of a periodic signal.

If multiple periods are used, calculate the vector strength of each. This is called the “resonating vector strength”.

**Parameters** **events** : 1D array\_like

An array of time points containing the timing of the events.

**period** : float or array\_like

The period of the signal that the events should synchronize to. The period is in the same units as *events*. It can also be an array of periods, in which case the outputs are arrays of the same length.

**Returns** **strength** : float or 1D array

The strength of the synchronization. 1.0 is perfect synchronization and 0.0 is no synchronization. If *period* is an array, this is also an array with each element containing the vector strength at the corresponding period.

**phase** : float or array

The phase that the events are most strongly synchronized to in radians. If *period* is an array, this is also an array with each element containing the phase for the corresponding period.

`scipy.signal.stft(x, fs=1.0, window='hann', nperseg=256, noverlap=None, nfft=None, detrend=False, return_onesided=True, boundary='zeros', padded=True, axis=-1)`  
 Compute the Short Time Fourier Transform (STFT).

STFTs can be used as a way of quantifying the change of a nonstationary signal's frequency and phase content over time.

**Parameters**

- x** : array\_like  
Time series of measurement values
- fs** : float, optional  
Sampling frequency of the *x* time series. Defaults to 1.0.
- window** : str or tuple or array\_like, optional  
Desired window to use. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Hann window.
- nperseg** : int, optional  
Length of each segment. Defaults to 256.
- noverlap** : int, optional  
Number of points to overlap between segments. If *None*, `noverlap = nperseg // 2`. Defaults to *None*. When specified, the COLA constraint must be met (see Notes below).
- nfft** : int, optional  
Length of the FFT used, if a zero padded FFT is desired. If *None*, the FFT length is *nperseg*. Defaults to *None*.
- detrend** : str or function or *False*, optional  
Specifies how to detrend each segment. If *detrend* is a string, it is passed as the *type* argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If *detrend* is *False*, no detrending is done. Defaults to *False*.
- return\_onesided** : bool, optional  
If *True*, return a one-sided spectrum for real data. If *False* return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned. Defaults to *True*.
- boundary** : str or *None*, optional  
Specifies whether the input signal is extended at both ends, and how to generate the new values, in order to center the first windowed segment on the first input point. This has the benefit of enabling reconstruction of the first input point when the employed window function starts at zero. Valid options are [*'even'*, *'odd'*, *'constant'*, *'zeros'*, *None*]. Defaults to *'zeros'*, for zero padding extension. I.e. `[1, 2, 3, 4]` is extended to `[0, 1, 2, 3, 4, 0]` for `nperseg=3`.
- padded** : bool, optional  
Specifies whether the input signal is zero-padded at the end to make the signal fit exactly into an integer number of window segments, so that all of the signal is included in the output. Defaults to *True*. Padding occurs after boundary extension, if *boundary* is not *None*, and *padded* is *True*, as is the default.
- axis** : int, optional  
Axis along which the STFT is computed; the default is over the last axis (i.e. `axis=-1`).

**Returns**

- f** : ndarray  
Array of sample frequencies.
- t** : ndarray  
Array of segment times.
- Zxx** : ndarray  
STFT of *x*. By default, the last axis of *Zxx* corresponds to the segment times.

**See also:**

**`istft`** Inverse Short Time Fourier Transform  
**`check_COLA`** Check whether the Constant OverLap Add (COLA) constraint is met  
**`welch`** Power spectral density by Welch's method.  
**`spectrogram`**  
 Spectrogram by Welch's method.  
**`csd`** Cross spectral density by Welch's method.  
**`lombscargle`**  
 Lomb-Scargle periodogram for unevenly sampled data

**Notes**

In order to enable inversion of an STFT via the inverse STFT in `istft`, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA), and the input signal must have complete windowing coverage (i.e.  $(x.shape[axis] - nperseg) \% (nperseg - noverlap) == 0$ ). The *padded* argument may be used to accomplish this.

The COLA constraint ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction. Whether a choice of *window*, *nperseg*, and *noverlap* satisfy this constraint can be tested with `check_COLA`.

New in version 0.19.0.

**Examples**

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500 * np.cos(2 * np.pi * 0.25 * time)
>>> carrier = amp * np.sin(2 * np.pi * 3e3 * time + mod)
>>> noise = np.random.normal(scale=np.sqrt(noise_power),
...                          size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the STFT's magnitude.

```
>>> f, t, Zxx = signal.stft(x, fs, nperseg=1000)
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp)
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

`scipy.signal.istft` (*Zxx*, *fs*=1.0, *window*='hann', *nperseg*=None, *noverlap*=None, *nfft*=None, *input\_onesided*=True, *boundary*=True, *time\_axis*=-1, *freq\_axis*=-2)

Perform the inverse Short Time Fourier transform (iSTFT).

**Parameters** *Zxx* : array\_like

STFT of the signal to be reconstructed. If a purely real array is passed, it will be cast to a complex data type.

*fs* : float, optional

Sampling frequency of the time series. Defaults to 1.0.

**window** : str or tuple or array\_like, optional

Desired window to use. See `get_window` for a list of windows and required parameters. If *window* is array\_like it will be used directly as the window and its length must be *nperseg*. Defaults to a Hann window. Must match the window used to generate the STFT for faithful inversion.

**nperseg** : int, optional

Number of data points corresponding to each STFT segment. This parameter must be specified if the number of data points per segment is odd, or if the STFT was padded via `nfft > nperseg`. If *None*, the value depends on the shape of *Zxx* and *input\_onesided*. If *input\_onesided* is True, `nperseg=2*(Zxx.shape[freq_axis] - 1)`. Otherwise, `nperseg=Zxx.shape[freq_axis]`. Defaults to *None*.

**noverlap** : int, optional

Number of points to overlap between segments. If *None*, half of the segment length. Defaults to *None*. When specified, the COLA constraint must be met (see Notes below), and should match the parameter used to generate the STFT. Defaults to *None*.

**nfft** : int, optional

Number of FFT points corresponding to each STFT segment. This parameter must be specified if the STFT was padded via `nfft > nperseg`. If *None*, the default values are the same as for *nperseg*, detailed above, with one exception: if *input\_onesided* is True and `nperseg==2*Zxx.shape[freq_axis] - 1`, *nfft* also takes on that value. This case allows the proper inversion of an odd-length unpadded STFT using `nfft=None`. Defaults to *None*.

**input\_onesided** : bool, optional

If *True*, interpret the input array as one-sided FFTs, such as is returned by `stft` with `return_onesided=True` and `numpy.fft.rfft`. If *False*, interpret the input as a two-sided FFT. Defaults to *True*.

**boundary** : bool, optional

Specifies whether the input signal was extended at its boundaries by supplying a non-*None* boundary argument to `stft`. Defaults to *True*.

**time\_axis** : int, optional

Where the time segments of the STFT is located; the default is the last axis (i.e. `axis=-1`).

**freq\_axis** : int, optional

Where the frequency axis of the STFT is located; the default is the penultimate axis (i.e. `axis=-2`).

#### Returns

**t** : ndarray

Array of output data times.

**x** : ndarray

iSTFT of  $Z_{xx}$ .

#### See also:

[`stft`](#) Short Time Fourier Transform

[`check\_COLA`](#) Check whether the Constant OverLap Add (COLA) constraint is met

#### Notes

In order to enable inversion of an STFT via the inverse STFT with `istft`, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction. Whether a choice of *window*, *nperseg*, and *noverlap* satisfy this constraint can be tested with `check_COLA`, by using `nperseg = Zxx.shape[freq_axis]`.

An STFT which has been modified (via masking or otherwise) is not guaranteed to correspond to a exactly realizable signal. This function implements the iSTFT via the least-squares estimation algorithm detailed in [R242], which produces a signal that minimizes the mean squared error between the STFT of the returned signal and the modified STFT.

New in version 0.19.0.

#### References

[R241], [R242]

#### Examples

```
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate a test signal, a 2 Vrms sine wave at 50Hz corrupted by 0.001 V\*\*2/Hz of white noise sampled at 1024 Hz.

```
>>> fs = 1024
>>> N = 10*fs
>>> nperseg = 512
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> carrier = amp * np.sin(2*np.pi*50*time)
>>> noise = np.random.normal(scale=np.sqrt(noise_power),
```

```
...                                     size=time.shape)
>>> x = carrier + noise
```

Compute the STFT, and plot its magnitude

```
>>> f, t, Zxx = signal.stft(x, fs=fs, nperseg=nperseg)
>>> plt.figure()
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp)
>>> plt.ylim([f[1], f[-1]])
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.yscale('log')
>>> plt.show()
```

Zero the components that are 10% or less of the carrier magnitude, then convert back to a time series via inverse STFT

```
>>> Zxx = np.where(np.abs(Zxx) >= amp/10, Zxx, 0)
>>> _, xrec = signal.istft(Zxx, fs)
```

Compare the cleaned signal with the original and true carrier signals.

```
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([2, 2.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

Note that the cleaned signal does not start as abruptly as the original, since some of the coefficients of the transient were also removed:

```
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([0, 0.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

```
scipy.signal.check_COLA(window, nperseg, noverlap, tol=1e-10)
```

Check whether the Constant OverLap Add (COLA) constraint is met

**Parameters** **window** : str or tuple or array\_like

Desired window to use. See `get_window` for a list of windows and required parameters. If `window` is array\_like it will be used directly as the window and its length must be `nperseg`.

**npersg** : int  
 Length of each segment.

**noverlap** : int  
 Number of points to overlap between segments.

**tol** : float, optional  
 The allowed variance of a bin's weighted sum from the median bin sum.

**Returns** **verdict** : bool  
*True* if chosen combination satisfies COLA within *tol*, *False* otherwise

**See also:**

*stft* Short Time Fourier Transform  
*istft* Inverse Short Time Fourier Transform

**Notes**

In order to enable inversion of an STFT via the inverse STFT in *istft*, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction.

**Some examples of windows that satisfy COLA:**

- Rectangular window at overlap of 0, 1/2, 2/3, 3/4, ...
- Bartlett window at overlap of 1/2, 3/4, 5/6, ...
- Hann window at 1/2, 2/3, 3/4, ...
- Any Blackman family window at 2/3 overlap
- Any window with `noverlap = npersg-1`

A very comprehensive list of other windows may be found in [R207], wherein the COLA condition is satisfied when the “Amplitude Flatness” is unity.

New in version 0.19.0.

**References**

[R206], [R207]

**Examples**

```
>>> from scipy import signal
```

Confirm COLA condition for rectangular window of 75% (3/4) overlap:

```
>>> signal.check_COLA(signal.boxcar(100), 100, 75)
True
```

COLA is not true for 25% (1/4) overlap, though:

```
>>> signal.check_COLA(signal.boxcar(100), 100, 25)
False
```

“Symmetrical” Hann window (for filter design) is not COLA:

```
>>> signal.check_COLA(signal.hann(120, sym=True), 120, 60)
False
```

“Periodic” or “DFT-even” Hann window (for FFT analysis) is COLA for overlap of 1/2, 2/3, 3/4, etc.:

```
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 60)
True
```

```
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 80)
True
```

```
>>> signal.check_COLA(signal.hann(120, sym=False), 120, 90)
True
```

## 5.21 Sparse matrices (`scipy.sparse`)

SciPy 2-D sparse matrix package for numeric data.

### 5.21.1 Contents

#### Sparse matrix classes

---

<code>bsr_matrix</code> (arg1[, shape, dtype, copy, blocksize])	Block Sparse Row matrix
<code>coo_matrix</code> (arg1[, shape, dtype, copy])	A sparse matrix in COOrdinate format.
<code>csc_matrix</code> (arg1[, shape, dtype, copy])	Compressed Sparse Column matrix
<code>csr_matrix</code> (arg1[, shape, dtype, copy])	Compressed Sparse Row matrix
<code>dia_matrix</code> (arg1[, shape, dtype, copy])	Sparse matrix with DIAgonal storage
<code>dok_matrix</code> (arg1[, shape, dtype, copy])	Dictionary Of Keys based sparse matrix.
<code>lil_matrix</code> (arg1[, shape, dtype, copy])	Row-based linked list sparse matrix
<code>spmatrix</code> ([maxprint])	This class provides a base class for all sparse matrices.

---

**class** `scipy.sparse.bsr_matrix`(arg1, shape=None, dtype=None, copy=False, blocksize=None)

Block Sparse Row matrix

*This can be instantiated in several ways:*

*`bsr_matrix(D, [blocksize=(R,C)])`*

where D is a dense matrix or 2-D ndarray.

*`bsr_matrix(S, [blocksize=(R,C)])`*

with another sparse matrix S (equivalent to `S.tobsr()`)

*`bsr_matrix((M, N), [blocksize=(R,C), dtype])`*

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to `dtype='d'`.

*`bsr_matrix((data, ij), [blocksize=(R,C), shape=(M, N)])`*

where data and ij satisfy `a[ij[0, k], ij[1, k]] = data[k]`

*`bsr_matrix((data, indices, indptr), [shape=(M, N)])`*

is the standard BSR representation where the block column indices for row i are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding block values are stored in `data[indptr[i]:indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

#### Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

#### Summary of BSR format

The Block Compressed Row (BSR) format is very similar to the Compressed Sparse Row (CSR) format. BSR is appropriate for sparse matrices with dense sub matrices like the last example below. Block matrices often arise in vector-valued finite element discretizations. In such cases, BSR is considerably more efficient than CSR and CSC for many sparse arithmetic operations.

### Blocksize

The blocksize (R,C) must evenly divide the shape of the matrix (M,N). That is, R and C must satisfy the relationship  $M \% R = 0$  and  $N \% C = 0$ .

If no blocksize is specified, a simple heuristic is applied to determine an appropriate blocksize.

### Examples

```
>>> from scipy.sparse import bsr_matrix
>>> bsr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> bsr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6]).repeat(4).reshape(6, 2, 2)
>>> bsr_matrix((data, indices, indptr), shape=(6, 6)).toarray()
array([[1, 1, 0, 0, 2, 2],
       [1, 1, 0, 0, 2, 2],
       [0, 0, 0, 0, 3, 3],
       [0, 0, 0, 0, 3, 3],
       [4, 4, 5, 5, 6, 6],
       [4, 4, 5, 5, 6, 6]])
```

### Attributes

<code>shape</code>	Get shape of a matrix.
<code>nnz</code>	Number of stored values, including explicit zeros.
<code>has_sorted_indices</code>	Determine whether the matrix has sorted indices

`bsr_matrix.shape`  
Get shape of a matrix.

`bsr_matrix.nnz`  
Number of stored values, including explicit zeros.

#### See also:

`count_nonzero`  
Number of non-zero entries

`bsr_matrix.has_sorted_indices`

Determine whether the matrix has sorted indices

**Returns**

- True: if the indices of the matrix are in sorted order
- False: otherwise

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	Data array of the matrix
<code>indices</code>	BSR format index array
<code>indptr</code>	BSR format index pointer array
<code>blocksize</code>	Block size of the matrix

**Methods**

---

<code>arcsin()</code>	Element-wise arcsin.
<code>arcsinh()</code>	Element-wise arcsinh.
<code>arctan()</code>	Element-wise arctan.
<code>arctanh()</code>	Element-wise arctanh.
<code>argmax([axis, out])</code>	Return indices of minimum elements along an axis.
<code>argmin([axis, out])</code>	Return indices of minimum elements along an axis.
<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(t)</code>	Cast the matrix elements to a specified type.
<code>ceil()</code>	Element-wise ceil.
<code>check_format([full_check])</code>	check whether the matrix format is valid
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>deg2rad()</code>	Element-wise deg2rad.
<code>diagonal()</code>	Returns the main diagonal of the matrix
<code>dot(other)</code>	Ordinary dot product
<code>eliminate_zeros()</code>	Remove zero elements in-place.
<code>expm1()</code>	Element-wise expm1.
<code>floor()</code>	Element-wise floor.
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(j)</code>	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
<code>log1p()</code>	Element-wise log1p.
<code>matmat(*args, **kwds)</code>	<code>matmat</code> is deprecated!
<code>matvec(*args, **kwds)</code>	<code>matvec</code> is deprecated!
<code>max([axis, out])</code>	Return the maximum of the matrix or maximum along an axis.
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>min([axis, out])</code>	Return the minimum of the matrix or maximum along an axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix, vector, or scalar.
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>prune()</code>	Remove empty space after all non-zero elements.

Continued on next page

Table 5.157 – continued from previous page

<code>rad2deg()</code>	Element-wise <code>rad2deg</code> .
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise <code>rint</code> .
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise <code>sign</code> .
<code>sin()</code>	Element-wise <code>sin</code> .
<code>sinh()</code>	Element-wise <code>sinh</code> .
<code>sort_indices()</code>	Sort the indices of this matrix <i>in place</i>
<code>sorted_indices()</code>	Return a copy of this matrix with sorted indices
<code>sqrt()</code>	Element-wise <code>sqrt</code> .
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>sum_duplicates()</code>	Eliminate duplicate matrix entries by adding them together
<code>tan()</code>	Element-wise <code>tan</code> .
<code>tanh()</code>	Element-wise <code>tanh</code> .
<code>toarray([order, out])</code>	See the docstring for <code>spmatrix.toarray</code> .
<code>tobsr([blocksize, copy])</code>	Convert this matrix into Block Sparse Row Format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise <code>trunc</code> .

`bsr_matrix.arcsin()`  
Element-wise `arcsin`.

See `numpy.arcsin` for more information.

`bsr_matrix.arcsinh()`  
Element-wise `arcsinh`.

See `numpy.arcsinh` for more information.

`bsr_matrix.arctan()`  
Element-wise `arctan`.

See `numpy.arctan` for more information.

`bsr_matrix.arctanh()`  
Element-wise `arctanh`.

See `numpy.arctanh` for more information.

`bsr_matrix.argmax(axis=None, out=None)`  
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters** `axis` : {-2, -1, 0, 1, None}, optional  
Axis along which the `argmax` is computed. If None (default), index of the maximum element in the flattened data is returned.

`out` : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of maximum elements. If matrix, its size along *axis* is 1.

`bsr_matrix.argmax` (*axis=None, out=None*)  
 Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
 Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of minimum elements. If matrix, its size along *axis* is 1.

`bsr_matrix.asformat` (*format*)  
 Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for csr\_matrix format
- “csc” for csc\_matrix format
- “lil” for lil\_matrix format
- “dok” for dok\_matrix format and so on

`bsr_matrix.asfptype` ()  
 Upcast matrix to a floating point format (if necessary)

`bsr_matrix.astype` (*t*)  
 Cast the matrix elements to a specified type.  
 The data will be copied.

**Parameters** **t** : string or numpy dtype  
 Typecode or data-type to which to cast the data.

`bsr_matrix.ceil` ()  
 Element-wise ceil.

See `numpy.ceil` for more information.

`bsr_matrix.check_format` (*full\_check=True*)  
 check whether the matrix format is valid

**Parameters:**  
**full\_check**: True - rigorous check, O(N) operations : default False - basic check, O(1) operations

`bsr_matrix.conj` ()  
 Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`bsr_matrix.conjugate()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`bsr_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`bsr_matrix.count_nonzero()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`bsr_matrix.deg2rad()`

Element-wise `deg2rad`.

See `numpy.deg2rad` for more information.

`bsr_matrix.diagonal()`

Returns the main diagonal of the matrix

`bsr_matrix.dot(other)`

Ordinary dot product

### Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`bsr_matrix.eliminate_zeros()`

Remove zero elements in-place.

`bsr_matrix.expm1()`

Element-wise `expm1`.

See `numpy.expm1` for more information.

`bsr_matrix.floor()`

Element-wise floor.

See `numpy.floor` for more information.

`bsr_matrix.getH()`

Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**

NumPy's implementation of `getH` for matrices

`bsr_matrix.get_shape()`

Get shape of a matrix.

`bsr_matrix.getcol(j)`

Returns a copy of column `j` of the matrix, as an  $(m \times 1)$  sparse matrix (column vector).

`bsr_matrix.getformat()`

Format of a matrix representation as a string.

`bsr_matrix.getmaxprint()`

Maximum number of elements to display when printed.

`bsr_matrix.getnnz(axis=None)`

Number of stored values, including explicit zeros.

**Parameters** `axis` : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

`count_nonzero`

Number of non-zero entries

`bsr_matrix.getrow(i)`

Returns a copy of row *i* of the matrix, as a (1 x n) sparse matrix (row vector).

`bsr_matrix.log1p()`

Element-wise log1p.

See `numpy.log1p` for more information.

`bsr_matrix.matmat(*args, **kwargs)`

`matmat` is deprecated! BSR `matmat` is deprecated in `scipy 0.19.0`. Use `*` operator instead.

Multiply this sparse matrix by other matrix.

`bsr_matrix.matvec(*args, **kwargs)`

`matvec` is deprecated! BSR `matvec` is deprecated in `scipy 0.19.0`. Use `*` operator instead.

Multiply matrix by vector.

`bsr_matrix.max(axis=None, out=None)`

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** `axis` : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. `axis = None`).

`out` : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** `amax` : `coo_matrix` or scalar

Maximum of *a*. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

`min` The minimum value of a sparse matrix along a given axis.

`np.matrix.max`

NumPy's implementation of 'max' for matrices

`bsr_matrix.maximum(other)`

Element-wise maximum between this and another matrix.

`bsr_matrix.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional  
 Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional  
 Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : np.matrix, optional  
 Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`bsr_matrix.min` (*axis=None, out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional  
 Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. *axis = None*).

**out** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amin** : `coo_matrix` or scalar  
 Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse `coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**`max`** The maximum value of a sparse matrix along a given axis.

**`np.matrix.min`**

NumPy's implementation of 'min' for matrices

`bsr_matrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

`bsr_matrix.multiply` (*other*)

Point-wise multiplication by another matrix, vector, or scalar.

`bsr_matrix.nonzero` ()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`bsr_matrix.power` (*n*, *dtype=None*)

This function performs element-wise power.

**Parameters**

- n** : n is a scalar
- dtype** : If dtype is not specified, the current dtype will be preserved.

`bsr_matrix.prune` ()

Remove empty space after all non-zero elements.

`bsr_matrix.rad2deg` ()

Element-wise rad2deg.

See `numpy.rad2deg` for more information.

`bsr_matrix.reshape` (*shape*, *order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- shape** : length-2 tuple of ints  
The new shape should be compatible with the original shape.
- order** : 'C', optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** `reshaped_matrix` : *self* with the new dimensions of `shape`

See also:

**`np.matrix.reshape`**

NumPy's implementation of 'reshape' for matrices

`bsr_matrix.rint` ()

Element-wise rint.

See `numpy.rint` for more information.

`bsr_matrix.set_shape` (*shape*)

See `reshape`.

`bsr_matrix.setdiag` (*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

**Parameters**

- values** : array\_like  
New values of the diagonal elements.  
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.  
If a scalar value is given, all of the diagonal is set to it.
- k** : int, optional  
Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`bsr_matrix.sign` ()

Element-wise sign.

See `numpy.sign` for more information.

`bsr_matrix.sin` ()

Element-wise sin.

See `numpy.sin` for more information.

`bsr_matrix.sinh` ()

Element-wise sinh.

See `numpy.sinh` for more information.

`bsr_matrix.sort_indices()`  
Sort the indices of this matrix *in place*

`bsr_matrix.sorted_indices()`  
Return a copy of this matrix with sorted indices

`bsr_matrix.sqrt()`  
Element-wise sqrt.

See `numpy.sqrt` for more information.

`bsr_matrix.sum(axis=None, dtype=None, out=None)`  
Sum the matrix elements over a given axis.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).
- dtype** : dtype, optional  
The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
- out** : np.matrix, optional  
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

**sum\_along\_axis** : np.matrix  
A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

`np.matrix.sum`  
NumPy's implementation of 'sum' for matrices

`bsr_matrix.sum_duplicates()`  
Eliminate duplicate matrix entries by adding them together  
The is an *in place* operation

`bsr_matrix.tan()`  
Element-wise tan.  
See `numpy.tan` for more information.

`bsr_matrix.tanh()`  
Element-wise tanh.  
See `numpy.tanh` for more information.

`bsr_matrix.toarray(order=None, out=None)`  
See the docstring for `spmatrix.toarray`.

`bsr_matrix.tobsr(blocksize=None, copy=False)`  
Convert this matrix into Block Sparse Row Format.  
With `copy=False`, the `data/indices` may be shared between this matrix and the resultant `bsr_matrix`.  
If `blocksize=(R, C)` is provided, it will be used for determining block size of the `bsr_matrix`.

`bsr_matrix.tocoo` (*copy=True*)

Convert this matrix to COOrdinate format.

When *copy=False* the data array will be shared between this matrix and the resultant `coo_matrix`.

`bsr_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`bsr_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`bsr_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters**    **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are

**Returns**        **arr** : `numpy.matrix`, 2-dimensional

calling the method.  
A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`bsr_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`bsr_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`bsr_matrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`bsr_matrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters**    **axes** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**        **p** : *self* with the dimensions reversed.

See also:

**`np.matrix.transpose`**

NumPy's implementation of 'transpose' for matrices

`bsr_matrix.trunc()`

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.coo_matrix` (*arg1*, *shape=None*, *dtype=None*, *copy=False*)

A sparse matrix in COOrdinate format.

Also known as the 'ijv' or 'triplet' format.

*This can be instantiated in several ways:*

**`coo_matrix(D)`**

with a dense matrix D

**`coo_matrix(S)`** with another sparse matrix S (equivalent to `S.tocoo()`)

**`coo_matrix((M, N), [dtype])`**

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

**`coo_matrix((data, (i, j)), [shape=(M, N)])`**

*to construct from three arrays:*

1.`data[:]` the entries of the matrix, in any order

2.`i[:]` the row indices of the matrix entries

3.`j[:]` the column indices of the matrix entries

Where  $A[i[k], j[k]] = data[k]$ . When shape is not specified, it is inferred from the index arrays

### Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

### Advantages of the COO format

- facilitates fast conversion among sparse formats
- permits duplicate entries (see example)
- very fast conversion to and from CSR/CSC formats

### Disadvantages of the COO format

•*does not directly support:*

–arithmetic operations

–slicing

### Intended Usage

- COO is a fast format for constructing sparse matrices
- Once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
- By default when converting to CSR or CSC format, duplicate (i,j) entries will be summed together. This facilitates efficient construction of finite element matrices and the like. (see example)

**Examples**

```
>>> from scipy.sparse import coo_matrix
>>> coo_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 3, 1, 0])
>>> col = np.array([0, 3, 1, 2])
>>> data = np.array([4, 5, 7, 9])
>>> coo_matrix((data, (row, col)), shape=(4, 4)).toarray()
array([[4, 0, 9, 0],
       [0, 7, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 5]])

>>> # example with duplicates
>>> row = np.array([0, 0, 1, 3, 1, 0, 0])
>>> col = np.array([0, 2, 1, 3, 1, 0, 0])
>>> data = np.array([1, 1, 1, 1, 1, 1, 1])
>>> coo_matrix((data, (row, col)), shape=(4, 4)).toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

**Attributes**

---

<code>shape</code>	Get shape of a matrix.
<code>nnz</code>	Number of stored values, including explicit zeros.

---

`coo_matrix.shape`  
Get shape of a matrix.

`coo_matrix.nnz`  
Number of stored values, including explicit zeros.

**See also:**

`count_nonzero`  
Number of non-zero entries

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	COO format data array of the matrix
<code>row</code>	COO format row index array of the matrix
<code>col</code>	COO format column index array of the matrix

**Methods**

---

<code>arcsin()</code>	Element-wise arcsin.
<code>arcsinh()</code>	Element-wise arcsinh.
<code>arctan()</code>	Element-wise arctan.
<code>arctanh()</code>	Element-wise arctanh.

Continued on next page

Table 5.159 – continued from previous page

<code>argmax([axis, out])</code>	Return indices of minimum elements along an axis.
<code>argmin([axis, out])</code>	Return indices of minimum elements along an axis.
<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(t)</code>	Cast the matrix elements to a specified type.
<code>ceil()</code>	Element-wise ceil.
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>deg2rad()</code>	Element-wise deg2rad.
<code>diagonal()</code>	Returns the main diagonal of the matrix
<code>dot(other)</code>	Ordinary dot product
<code>eliminate_zeros()</code>	Remove zero entries from the matrix
<code>expm1()</code>	Element-wise expm1.
<code>floor()</code>	Element-wise floor.
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(j)</code>	Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
<code>log1p()</code>	Element-wise log1p.
<code>max([axis, out])</code>	Return the maximum of the matrix or maximum along an axis.
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>min([axis, out])</code>	Return the minimum of the matrix or maximum along an axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>rad2deg()</code>	Element-wise rad2deg.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise rint.
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise sign.
<code>sin()</code>	Element-wise sin.
<code>sinh()</code>	Element-wise sinh.
<code>sqrt()</code>	Element-wise sqrt.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>sum_duplicates()</code>	Eliminate duplicate matrix entries by adding them together
<code>tan()</code>	Element-wise tan.
<code>tanh()</code>	Element-wise tanh.
<code>toarray([order, out])</code>	See the docstring for <code>spmatrix.toarray</code> .
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.

Continued on next page

Table 5.159 – continued from previous page

---

<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise trunc.

---

`coo_matrix.arcsin()`  
Element-wise arcsin.

See `numpy.arcsin` for more information.

`coo_matrix.arcsinh()`  
Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`coo_matrix.arctan()`  
Element-wise arctan.

See `numpy.arctan` for more information.

`coo_matrix.arctanh()`  
Element-wise arctanh.

See `numpy.arctanh` for more information.

`coo_matrix.argmax(axis=None, out=None)`  
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

**out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
Indices of maximum elements. If matrix, its size along *axis* is 1.

`coo_matrix.argmin(axis=None, out=None)`  
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

**out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
Indices of minimum elements. If matrix, its size along *axis* is 1.

`coo_matrix.asformat(format)`  
Return this matrix in a given sparse format

**Parameters** **format** : {string, None}

*desired sparse matrix format*

- None for no format conversion
- “csr” for csr\_matrix format
- “csc” for csc\_matrix format
- “lil” for lil\_matrix format
- “dok” for dok\_matrix format and so on

`coo_matrix.asfptype()`

Upcast matrix to a floating point format (if necessary)

`coo_matrix.astype(t)`

Cast the matrix elements to a specified type.

The data will be copied.

**Parameters** `t`: string or numpy dtype  
Typecode or data-type to which to cast the data.

`coo_matrix.ceil()`

Element-wise ceil.

See `numpy.ceil` for more information.

`coo_matrix.conj()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`coo_matrix.conjugate()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`coo_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`coo_matrix.count_nonzero()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`coo_matrix.deg2rad()`

Element-wise `deg2rad`.

See `numpy.deg2rad` for more information.

`coo_matrix.diagonal()`

Returns the main diagonal of the matrix

`coo_matrix.dot(other)`

Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
```

```
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`coo_matrix.eliminate_zeros()`  
Remove zero entries from the matrix

This is an *in place* operation

`coo_matrix.expm1()`  
Element-wise `expm1`.

See `numpy.expm1` for more information.

`coo_matrix.floor()`  
Element-wise floor.

See `numpy.floor` for more information.

`coo_matrix.getH()`  
Return the Hermitian transpose of this matrix.

**See also:**

`np.matrix.getH`  
NumPy's implementation of `getH` for matrices

`coo_matrix.get_shape()`  
Get shape of a matrix.

`coo_matrix.getcol(j)`  
Returns a copy of column `j` of the matrix, as an  $(m \times 1)$  sparse matrix (column vector).

`coo_matrix.getformat()`  
Format of a matrix representation as a string.

`coo_matrix.getmaxprint()`  
Maximum number of elements to display when printed.

`coo_matrix.getnnz(axis=None)`  
Number of stored values, including explicit zeros.

**Parameters** `axis` : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

`count_nonzero`  
Number of non-zero entries

`coo_matrix.getrow(i)`  
Returns a copy of row `i` of the matrix, as a  $(1 \times n)$  sparse matrix (row vector).

`coo_matrix.log1p()`  
Element-wise `log1p`.

See `numpy.log1p` for more information.

`coo_matrix.max(axis=None, out=None)`  
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** `axis` : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. *axis = None*).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

**amax** : `coo_matrix` or scalar

Maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

`min` The minimum value of a sparse matrix along a given axis.

`np.matrix.max`

NumPy's implementation of 'max' for matrices

`coo_matrix.maximum` (*other*)

Element-wise maximum between this and another matrix.

`coo_matrix.mean` (*axis=None, dtype=None, out=None*)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : `np.matrix`, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

**m** : `np.matrix`

**See also:**

`np.matrix.mean`

NumPy's implementation of 'mean' for matrices

`coo_matrix.min` (*axis=None, out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. *axis = None*).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

**amin** : `coo_matrix` or scalar

Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

**max** The maximum value of a sparse matrix along a given axis.  
**np.matrix.min**  
 NumPy's implementation of 'min' for matrices

`coo_matrix.minimum (other)`  
 Element-wise minimum between this and another matrix.

`coo_matrix.multiply (other)`  
 Point-wise multiplication by another matrix

`coo_matrix.nonzero ()`  
 nonzero indices  
 Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

### Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`coo_matrix.power (n, dtype=None)`  
 This function performs element-wise power.

**Parameters** **n** : n is a scalar  
**dtype** : If dtype is not specified, the current dtype will be preserved.

`coo_matrix.rad2deg ()`  
 Element-wise rad2deg.

See `numpy.rad2deg` for more information.

`coo_matrix.reshape (shape, order='C')`  
 Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints  
 The new shape should be compatible with the original shape.  
**order** : 'C', optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.  
**Returns** **reshaped\_matrix** : *self* with the new dimensions of `shape`

### See also:

**np.matrix.reshape**  
 NumPy's implementation of 'reshape' for matrices

`coo_matrix.rint ()`  
 Element-wise rint.

See `numpy.rint` for more information.

`coo_matrix.set_shape (shape)`  
 See `reshape`.

`coo_matrix.setdiag (values, k=0)`  
 Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like

New values of the diagonal elements.

Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.

If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional

Which off-diagonal to set, corresponding to elements  $a[i,i+k]$ . Default: 0 (the main diagonal).

`coo_matrix.sign()`

Element-wise sign.

See `numpy.sign` for more information.

`coo_matrix.sin()`

Element-wise sin.

See `numpy.sin` for more information.

`coo_matrix.sinh()`

Element-wise sinh.

See `numpy.sinh` for more information.

`coo_matrix.sqrt()`

Element-wise sqrt.

See `numpy.sqrt` for more information.

`coo_matrix.sum(axis=None, dtype=None, out=None)`

Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **sum\_along\_axis** : np.matrix

A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

**`np.matrix.sum`**

NumPy's implementation of 'sum' for matrices

`coo_matrix.sum_duplicates()`

Eliminate duplicate matrix entries by adding them together

This is an *in place* operation

`coo_matrix.tan()`

Element-wise tan.

See `numpy.tan` for more information.

`coo_matrix.tanh()`  
Element-wise tanh.

See `numpy.tanh` for more information.

`coo_matrix.toarray` (*order=None, out=None*)  
See the docstring for `spmatrix.toarray`.

`coo_matrix.tobsr` (*blocksize=None, copy=False*)  
Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`coo_matrix.tocoo` (*copy=False*)  
Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`coo_matrix.tocsc` (*copy=False*)  
Convert this matrix to Compressed Sparse Column format

Duplicate entries will be summed together.

### Examples

```
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsc()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

`coo_matrix.tocsr` (*copy=False*)  
Convert this matrix to Compressed Sparse Row format

Duplicate entries will be summed together.

### Examples

```
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsr()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

`coo_matrix.todense` (*order=None, out=None*)  
Return a dense matrix representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional  
 Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional  
 If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns** **arr** : `numpy.matrix`, 2-dimensional  
 A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`coo_matrix.todia (copy=False)`

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`coo_matrix.todok (copy=False)`

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`coo_matrix.tolil (copy=False)`

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`coo_matrix.ttranspose (axes=None, copy=False)`

Reverses the dimensions of the sparse matrix.

**Parameters** **axes** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** **p** : *self* with the dimensions reversed.

**See also:**

`np.matrix.transpose`

NumPy's implementation of 'transpose' for matrices

`coo_matrix.trunc()`

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.csc_matrix (arg1, shape=None, dtype=None, copy=False)`

Compressed Sparse Column matrix

This can be instantiated in several ways:

`csc_matrix(D)` with a dense matrix or rank-2 ndarray *D*  
`csc_matrix(S)` with another sparse matrix *S* (equivalent to `S.tocsc()`)

`csc_matrix((M, N), [dtype])`

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.  
`csc_matrix((data, (row_ind, col_ind)), [shape=(M, N)])`

where data, row\_ind and col\_ind satisfy the relationship  $a[\text{row\_ind}[k],$

`csc_matrix((data, indices, indptr), [shape=(M, N)])`  
 $\text{col\_ind}[k]] = \text{data}[k]$

is the standard CSC representation where the row indices for column  $i$  are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding values are stored in `data[indptr[i]:indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.

### Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

#### Advantages of the CSC format

- efficient arithmetic operations CSC + CSC, CSC \* CSC, etc.
- efficient column slicing
- fast matrix vector products (CSR, BSR may be faster)

#### Disadvantages of the CSC format

- slow row slicing operations (consider CSR)
- changes to the sparsity structure are expensive (consider LIL or DOK)

### Examples

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix
>>> csc_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 2, 2, 0, 1, 2])
>>> col = np.array([0, 0, 1, 2, 2, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

### Attributes

<code>shape</code>	Get shape of a matrix.
<code>nnz</code>	Number of stored values, including explicit zeros.
<code>has_sorted_indices</code>	Determine whether the matrix has sorted indices

`csc_matrix.shape`  
Get shape of a matrix.

`csc_matrix.nnz`  
Number of stored values, including explicit zeros.

**See also:**

`count_nonzero`  
Number of non-zero entries

`csc_matrix.has_sorted_indices`  
Determine whether the matrix has sorted indices

**Returns**

- True: if the indices of the matrix are in sorted order
- False: otherwise

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	Data array of the matrix
<code>indices</code>	CSC format index array
<code>indptr</code>	CSC format index pointer array

**Methods**

---

<code>arcsin()</code>	Element-wise arcsin.
<code>arcsinh()</code>	Element-wise arcsinh.
<code>arctan()</code>	Element-wise arctan.
<code>arctanh()</code>	Element-wise arctanh.
<code>argmax([axis, out])</code>	Return indices of minimum elements along an axis.
<code>argmin([axis, out])</code>	Return indices of minimum elements along an axis.
<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(t)</code>	Cast the matrix elements to a specified type.
<code>ceil()</code>	Element-wise ceil.
<code>check_format([full_check])</code>	check whether the matrix format is valid
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>deg2rad()</code>	Element-wise deg2rad.
<code>diagonal()</code>	Returns the main diagonal of the matrix
<code>dot(other)</code>	Ordinary dot product
<code>eliminate_zeros()</code>	Remove zero entries from the matrix
<code>expm1()</code>	Element-wise expm1.
<code>floor()</code>	Element-wise floor.
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(i)</code>	Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
<code>log1p()</code>	Element-wise log1p.
<code>max([axis, out])</code>	Return the maximum of the matrix or maximum along an axis.
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.

Continued on next page

Table 5.161 – continued from previous page

---

<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>min([axis, out])</code>	Return the minimum of the matrix or maximum along an axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix, vector, or scalar.
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>prune()</code>	Remove empty space after all non-zero elements.
<code>rad2deg()</code>	Element-wise rad2deg.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise rint.
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise sign.
<code>sin()</code>	Element-wise sin.
<code>sinh()</code>	Element-wise sinh.
<code>sort_indices()</code>	Sort the indices of this matrix <i>in place</i>
<code>sorted_indices()</code>	Return a copy of this matrix with sorted indices
<code>sqrt()</code>	Element-wise sqrt.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>sum_duplicates()</code>	Eliminate duplicate matrix entries by adding them together
<code>tan()</code>	Element-wise tan.
<code>tanh()</code>	Element-wise tanh.
<code>toarray([order, out])</code>	See the docstring for <code>spmatrix.toarray</code> .
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise trunc.

---

`csc_matrix.arcsin()`

Element-wise arcsin.

See `numpy.arcsin` for more information.

`csc_matrix.arcsinh()`

Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`csc_matrix.arctan()`

Element-wise arctan.

See `numpy.arctan` for more information.

`csc_matrix.arctanh()`

Element-wise arctanh.

See `numpy.arctanh` for more information.

`csc_matrix.argmax(axis=None, out=None)`

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
 Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

**out** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of maximum elements. If matrix, its size along *axis* is 1.

`csc_matrix.argmax` (*axis=None, out=None*)

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
 Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

**out** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of minimum elements. If matrix, its size along *axis* is 1.

`csc_matrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for csr\_matrix format
- “csc” for csc\_matrix format
- “lil” for lil\_matrix format
- “dok” for dok\_matrix format and so on

`csc_matrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`csc_matrix.astype` (*t*)

Cast the matrix elements to a specified type.

The data will be copied.

**Parameters** **t** : string or numpy dtype  
 Typecode or data-type to which to cast the data.

`csc_matrix.ceil` ()

Element-wise ceil.

See `numpy.ceil` for more information.

`csc_matrix.check_format` (*full\_check=True*)

check whether the matrix format is valid

**Parameters** **full\_check** : bool, optional

If *True*, rigorous check,  $O(N)$  operations. Otherwise basic check,  $O(1)$  operations (default *True*).

`csc_matrix.conj()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`csc_matrix.conjugate()`

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`csc_matrix.copy()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`csc_matrix.count_nonzero()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`csc_matrix.deg2rad()`

Element-wise `deg2rad`.

See `numpy.deg2rad` for more information.

`csc_matrix.diagonal()`

Returns the main diagonal of the matrix

`csc_matrix.dot(other)`

Ordinary dot product

### Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`csc_matrix.eliminate_zeros()`

Remove zero entries from the matrix

This is an *in place* operation

`csc_matrix.expm1()`

Element-wise `expm1`.

See `numpy.expm1` for more information.

`csc_matrix.floor()`

Element-wise floor.

See `numpy.floor` for more information.

`csc_matrix.getH()`

Return the Hermitian transpose of this matrix.

See also:

`np.matrix.getH`  
 NumPy's implementation of `getH` for matrices

`csc_matrix.get_shape()`  
 Get shape of a matrix.

`csc_matrix.getcol(i)`  
 Returns a copy of column *i* of the matrix, as a (m x 1) CSC matrix (column vector).

`csc_matrix.getformat()`  
 Format of a matrix representation as a string.

`csc_matrix.getmaxprint()`  
 Maximum number of elements to display when printed.

`csc_matrix.getnnz(axis=None)`  
 Number of stored values, including explicit zeros.

**Parameters** `axis` : None, 0, or 1  
 Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

`count_nonzero`  
 Number of non-zero entries

`csc_matrix.getrow(i)`  
 Returns a copy of row *i* of the matrix, as a (1 x n) CSR matrix (row vector).

`csc_matrix.log1p()`  
 Element-wise `log1p`.  
 See `numpy.log1p` for more information.

`csc_matrix.max(axis=None, out=None)`  
 Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** `axis` : {-2, -1, 0, 1, None} optional  
 Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. `axis = None`).

`out` : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** `amax` : `coo_matrix` or scalar  
 Maximum of *a*. If `axis` is None, the result is a scalar value. If `axis` is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

`min` The minimum value of a sparse matrix along a given axis.

`np.matrix.max`  
 NumPy's implementation of 'max' for matrices

`csc_matrix.maximum(other)`  
 Element-wise maximum between this and another matrix.

`csc_matrix.mean(axis=None, dtype=None, out=None)`  
 Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).
- dtype** : data-type, optional  
Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.
- out** : np.matrix, optional  
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

- m** : np.matrix

See also:

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`csc_matrix.min` (*axis=None, out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. *axis = None*).
- out** : None, optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- amin** : `coo_matrix` or scalar  
Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a sparse `coo_matrix` of dimension `a.ndim - 1`.

See also:

**`max`** The maximum value of a sparse matrix along a given axis.

**`np.matrix.min`**

NumPy's implementation of 'min' for matrices

`csc_matrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

`csc_matrix.multiply` (*other*)

Point-wise multiplication by another matrix, vector, or scalar.

`csc_matrix.nonzero` ()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`csc_matrix.power` (*n*, *dtype=None*)

This function performs element-wise power.

**Parameters** **n** : n is a scalar  
**dtype** : If dtype is not specified, the current dtype will be preserved.

`csc_matrix.prune` ()

Remove empty space after all non-zero elements.

`csc_matrix.rad2deg` ()

Element-wise rad2deg.

See `numpy.rad2deg` for more information.

`csc_matrix.reshape` (*shape*, *order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints  
 The new shape should be compatible with the original shape.  
**order** : 'C', optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **reshaped\_matrix** : *self* with the new dimensions of `shape`

**See also:**

**`np.matrix.reshape`**  
 NumPy's implementation of 'reshape' for matrices

`csc_matrix.rint` ()

Element-wise rint.

See `numpy.rint` for more information.

`csc_matrix.set_shape` (*shape*)

See `reshape`.

`csc_matrix.setdiag` (*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : `array_like`  
 New values of the diagonal elements.  
 Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.  
 If a scalar value is given, all of the diagonal is set to it.  
**k** : int, optional  
 Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`csc_matrix.sign` ()

Element-wise sign.

See `numpy.sign` for more information.

`csc_matrix.sin` ()

Element-wise sin.

See `numpy.sin` for more information.

`csc_matrix.sinh` ()

Element-wise sinh.

See `numpy.sinh` for more information.

`csc_matrix.sort_indices()`  
Sort the indices of this matrix *in place*

`csc_matrix.sorted_indices()`  
Return a copy of this matrix with sorted indices

`csc_matrix.sqrt()`  
Element-wise sqrt.

See `numpy.sqrt` for more information.

`csc_matrix.sum(axis=None, dtype=None, out=None)`  
Sum the matrix elements over a given axis.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).
- dtype** : dtype, optional  
The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
- out** : np.matrix, optional  
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

**sum\_along\_axis** : np.matrix  
A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

**`np.matrix.sum`**  
NumPy's implementation of 'sum' for matrices

`csc_matrix.sum_duplicates()`  
Eliminate duplicate matrix entries by adding them together  
This is an *in place* operation

`csc_matrix.tan()`  
Element-wise tan.

See `numpy.tan` for more information.

`csc_matrix.tanh()`  
Element-wise tanh.

See `numpy.tanh` for more information.

`csc_matrix.toarray(order=None, out=None)`  
See the docstring for `spmatrix.toarray`.

`csc_matrix.tobsr(blocksize=None, copy=False)`  
Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`csc_matrix.tocoo` (*copy=True*)

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`csc_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`csc_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`csc_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters**    **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are

**Returns**        **arr** : `numpy.matrix`, 2-dimensional

calling the method.  
A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`csc_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`csc_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`csc_matrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`csc_matrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters**    **axes** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional

Indicates whether or not attributes of `self` should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**        **p** : `self` with the dimensions reversed.

**See also:****`np.matrix.transpose`**

NumPy's implementation of 'transpose' for matrices

`csc_matrix.trunc()`

Element-wise trunc.

See `numpy.trunc` for more information.**class** `scipy.sparse.csr_matrix` (*arg1*, *shape=None*, *dtype=None*, *copy=False*)

Compressed Sparse Row matrix

*This can be instantiated in several ways:**csr\_matrix(D)* with a dense matrix or rank-2 ndarray D*csr\_matrix(S)* with another sparse matrix S (equivalent to `S.tocsr()`)*csr\_matrix((M, N), [dtype])*

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

*csr\_matrix((data, (row\_ind, col\_ind)), [shape=(M, N)])*where `data`, `row_ind` and `col_ind` satisfy the relationship `a[row_ind[k], col_ind[k]] = data[k]`.*csr\_matrix((data, indices, indptr), [shape=(M, N)])*is the standard CSR representation where the column indices for row `i` are stored in `indices[indptr[i]:indptr[i+1]]` and their corresponding values are stored in `data[indptr[i]:indptr[i+1]]`. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

**Advantages of the CSR format**

- efficient arithmetic operations CSR + CSR, CSR \* CSR, etc.
- efficient row slicing
- fast matrix vector products

**Disadvantages of the CSR format**

- slow column slicing operations (consider CSC)
- changes to the sparsity structure are expensive (consider LIL or DOK)

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> csr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
```

```

[0, 0, 3],
[4, 5, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])

```

As an example of how to construct a CSR matrix incrementally, the following snippet builds a term-document matrix from texts:

```

>>> docs = [["hello", "world", "hello"], ["goodbye", "cruel", "world"]]
>>> indptr = [0]
>>> indices = []
>>> data = []
>>> vocabulary = {}
>>> for d in docs:
...     for term in d:
...         index = vocabulary.setdefault(term, len(vocabulary))
...         indices.append(index)
...         data.append(1)
...         indptr.append(len(indices))
...
>>> csr_matrix((data, indices, indptr), dtype=int).toarray()
array([[2, 1, 0, 0],
       [0, 1, 1, 1]])

```

### Attributes

<code>shape</code>	Get shape of a matrix.
<code>nnz</code>	Number of stored values, including explicit zeros.
<code>has_sorted_indices</code>	Determine whether the matrix has sorted indices

`csr_matrix.shape`  
Get shape of a matrix.

`csr_matrix.nnz`  
Number of stored values, including explicit zeros.

**See also:**

`count_nonzero`  
Number of non-zero entries

`csr_matrix.has_sorted_indices`  
Determine whether the matrix has sorted indices

**Returns**

- True: if the indices of the matrix are in sorted order
- False: otherwise

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	CSR format data array of the matrix
<code>indices</code>	CSR format index array of the matrix
<code>indptr</code>	CSR format index pointer array of the matrix

*Methods*

---

<code>arcsin()</code>	Element-wise arcsin.
<code>arcsinh()</code>	Element-wise arcsinh.
<code>arctan()</code>	Element-wise arctan.
<code>arctanh()</code>	Element-wise arctanh.
<code>argmax([axis, out])</code>	Return indices of minimum elements along an axis.
<code>argmin([axis, out])</code>	Return indices of minimum elements along an axis.
<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(t)</code>	Cast the matrix elements to a specified type.
<code>ceil()</code>	Element-wise ceil.
<code>check_format([full_check])</code>	check whether the matrix format is valid
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>deg2rad()</code>	Element-wise deg2rad.
<code>diagonal()</code>	Returns the main diagonal of the matrix
<code>dot(other)</code>	Ordinary dot product
<code>eliminate_zeros()</code>	Remove zero entries from the matrix
<code>expm1()</code>	Element-wise expm1.
<code>floor()</code>	Element-wise floor.
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(i)</code>	Returns a copy of column i of the matrix, as a (m x 1) CSR matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
<code>log1p()</code>	Element-wise log1p.
<code>max([axis, out])</code>	Return the maximum of the matrix or maximum along an axis.
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>min([axis, out])</code>	Return the minimum of the matrix or maximum along an axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix, vector, or scalar.
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>prune()</code>	Remove empty space after all non-zero elements.
<code>rad2deg()</code>	Element-wise rad2deg.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise rint.
<code>set_shape(shape)</code>	See <a href="#">reshape</a> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise sign.
<code>sin()</code>	Element-wise sin.

---

Continued on next page

Table 5.163 – continued from previous page

<code>sinh()</code>	Element-wise sinh.
<code>sort_indices()</code>	Sort the indices of this matrix <i>in place</i>
<code>sorted_indices()</code>	Return a copy of this matrix with sorted indices
<code>sqrt()</code>	Element-wise sqrt.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>sum_duplicates()</code>	Eliminate duplicate matrix entries by adding them together
<code>tan()</code>	Element-wise tan.
<code>tanh()</code>	Element-wise tanh.
<code>toarray([order, out])</code>	See the docstring for <code>spmatrix.toarray</code> .
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise trunc.

`csr_matrix.arcsin()`  
Element-wise arcsin.

See `numpy.arcsin` for more information.

`csr_matrix.arcsinh()`  
Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`csr_matrix.arctan()`  
Element-wise arctan.

See `numpy.arctan` for more information.

`csr_matrix.arctanh()`  
Element-wise arctanh.

See `numpy.arctanh` for more information.

`csr_matrix.argmax(axis=None, out=None)`  
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional

Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix of int

Indices of maximum elements. If matrix, its size along *axis* is 1.

`csr_matrix.argmin(axis=None, out=None)`  
Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters** **axis** : {-2, -1, 0, 1, None}, optional  
 Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

**out** : None, optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **ind** : np.matrix or int  
 Indices of minimum elements. If matrix, its size along *axis* is 1.

`csr_matrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for csr\_matrix format
- “csc” for csc\_matrix format
- “lil” for lil\_matrix format
- “dok” for dok\_matrix format and so on

`csr_matrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`csr_matrix.astype` (*t*)

Cast the matrix elements to a specified type.

The data will be copied.

**Parameters** **t** : string or numpy dtype  
 Typecode or data-type to which to cast the data.

`csr_matrix.ceil` ()

Element-wise ceil.

See `numpy.ceil` for more information.

`csr_matrix.check_format` (*full\_check=True*)

check whether the matrix format is valid

**Parameters** **full\_check** : bool, optional  
 If *True*, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default *True*).

`csr_matrix.conj` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`csr_matrix.conjugate` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`csr_matrix.copy` ()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`csr_matrix.count_nonzero()`  
 Number of non-zero entries, equivalent to  
`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`csr_matrix.deg2rad()`  
 Element-wise `deg2rad`.  
 See `numpy.deg2rad` for more information.

`csr_matrix.diagonal()`  
 Returns the main diagonal of the matrix

`csr_matrix.dot(other)`  
 Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`csr_matrix.eliminate_zeros()`  
 Remove zero entries from the matrix  
 This is an *in place* operation

`csr_matrix.expm1()`  
 Element-wise `expm1`.  
 See `numpy.expm1` for more information.

`csr_matrix.floor()`  
 Element-wise `floor`.  
 See `numpy.floor` for more information.

`csr_matrix.getH()`  
 Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**  
 NumPy's implementation of `getH` for matrices

`csr_matrix.get_shape()`  
 Get shape of a matrix.

`csr_matrix.getcol(i)`  
 Returns a copy of column `i` of the matrix, as a  $(m \times 1)$  CSR matrix (column vector).

`csr_matrix.getformat()`  
 Format of a matrix representation as a string.

`csr_matrix.getmaxprint()`  
 Maximum number of elements to display when printed.

`csr_matrix.getnnz` (*axis=None*)

Number of stored values, including explicit zeros.

**Parameters** **axis** : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

`count_nonzero`

Number of non-zero entries

`csr_matrix.getrow` (*i*)

Returns a copy of row *i* of the matrix, as a (1 x *n*) CSR matrix (row vector).

`csr_matrix.log1p` ()

Element-wise log1p.

See `numpy.log1p` for more information.

`csr_matrix.max` (*axis=None, out=None*)

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. *axis = None*).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amax** : `coo_matrix` or scalar

Maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

**See also:**

`min` The minimum value of a sparse matrix along a given axis.

`np.matrix.max`

NumPy's implementation of 'max' for matrices

`csr_matrix.maximum` (*other*)

Element-wise maximum between this and another matrix.

`csr_matrix.mean` (*axis=None, dtype=None, out=None*)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.

**out** : `np.matrix`, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : `np.matrix`

See also:

`np.matrix.mean`

NumPy's implementation of 'mean' for matrices

`csr_matrix.min` (*axis=None, out=None*)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. *axis = None*).

**out** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **amin** : `coo_matrix` or scalar

Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is a `sparse.coo_matrix` of dimension `a.ndim - 1`.

See also:

`max` The maximum value of a sparse matrix along a given axis.

`np.matrix.min`

NumPy's implementation of 'min' for matrices

`csr_matrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

`csr_matrix.multiply` (*other*)

Point-wise multiplication by another matrix, vector, or scalar.

`csr_matrix.nonzero` ()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

### Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`csr_matrix.power` (*n, dtype=None*)

This function performs element-wise power.

**Parameters** **n** : n is a scalar

**dtype** : If dtype is not specified, the current dtype will be preserved.

`csr_matrix.prune` ()

Remove empty space after all non-zero elements.

`csr_matrix.rad2deg` ()

Element-wise rad2deg.

See `numpy.rad2deg` for more information.

`csr_matrix.reshape` (*shape, order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints  
 The new shape should be compatible with the original shape.  
**order** : 'C', optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.  
**Returns** **reshaped\_matrix** : *self* with the new dimensions of **shape**

**See also:**

**`np.matrix.reshape`**

NumPy's implementation of 'reshape' for matrices

`csr_matrix.rint()`

Element-wise rint.

See `numpy rint` for more information.

`csr_matrix.set_shape(shape)`

See `reshape`.

`csr_matrix.setdiag(values, k=0)`

Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like

New values of the diagonal elements.

Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.

If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional

Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`csr_matrix.sign()`

Element-wise sign.

See `numpy.sign` for more information.

`csr_matrix.sin()`

Element-wise sin.

See `numpy.sin` for more information.

`csr_matrix.sinh()`

Element-wise sinh.

See `numpy.sinh` for more information.

`csr_matrix.sort_indices()`

Sort the indices of this matrix *in place*

`csr_matrix.sorted_indices()`

Return a copy of this matrix with sorted indices

`csr_matrix.sqrt()`

Element-wise sqrt.

See `numpy.sqrt` for more information.

`csr_matrix.sum(axis=None, dtype=None, out=None)`

Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

**sum\_along\_axis** : np.matrix

A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

***np.matrix.sum***

NumPy's implementation of 'sum' for matrices

`csr_matrix.sum_duplicates()`

Eliminate duplicate matrix entries by adding them together

The is an *in place* operation

`csr_matrix.tan()`

Element-wise tan.

See `numpy.tan` for more information.

`csr_matrix.tanh()`

Element-wise tanh.

See `numpy.tanh` for more information.

`csr_matrix.toarray (order=None, out=None)`

See the docstring for `spmatrix.toarray`.

`csr_matrix.tobsr (blocksize=None, copy=True)`

Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`csr_matrix.tocoo (copy=True)`

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`csr_matrix.tocsc (copy=False)`

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`csr_matrix.tocsr (copy=False)`

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`csr_matrix.todense (order=None, out=None)`

Return a dense matrix representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional  
Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional  
If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns** **arr** : `numpy.matrix`, 2-dimensional  
A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`csr_matrix.todia (copy=False)`

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`csr_matrix.todok (copy=False)`

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`csr_matrix.tolil (copy=False)`

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`csr_matrix.ttranspose (axes=None, copy=False)`

Reverses the dimensions of the sparse matrix.

**Parameters** **axes** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** **p** : *self* with the dimensions reversed.

**See also:**

`np.matrix.transpose`

NumPy's implementation of 'transpose' for matrices

`csr_matrix.trunc()`

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.dia_matrix (arg1, shape=None, dtype=None, copy=False)`

Sparse matrix with DIAgonal storage

*This can be instantiated in several ways:*

`dia_matrix(D)` with a dense matrix

`dia_matrix(S)` with another sparse matrix *S* (equivalent to `S.todia()`)

*dia\_matrix*((*M*, *N*), [*dtype*])

to construct an empty matrix with shape (*M*, *N*), *dtype* is optional, defaulting to *dtype*='d'.

*dia\_matrix*((*data*, *offsets*), *shape*=(*M*, *N*))

where the *data*[*k*, :] stores the diagonal entries for diagonal *offsets*[*k*]  
(See example below)

### Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

### Examples

```
>>> import numpy as np
>>> from scipy.sparse import dia_matrix
>>> dia_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> data = np.array([[1, 2, 3, 4]]).repeat(3, axis=0)
>>> offsets = np.array([0, -1, 2])
>>> dia_matrix((data, offsets), shape=(4, 4)).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

### Attributes

---

<i>shape</i>	Get shape of a matrix.
<i>nnz</i>	Number of stored values, including explicit zeros.

---

*dia\_matrix*.**shape**

Get shape of a matrix.

*dia\_matrix*.**nnz**

Number of stored values, including explicit zeros.

**See also:**

*count\_nonzero*

Number of non-zero entries

<i>dtype</i>	(dtype) Data type of the matrix
<i>ndim</i>	(int) Number of dimensions (this is always 2)
<i>data</i>	DIA format data array of the matrix
<i>offsets</i>	DIA format offset array of the matrix

### Methods

---

<i>arcsin</i> ()	Element-wise arcsin.
<i>arcsinh</i> ()	Element-wise arcsinh.
<i>arctan</i> ()	Element-wise arctan.

---

Continued on next page

Table 5.165 – continued from previous page

---

<code>arctanh()</code>	Element-wise arctanh.
<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(t)</code>	Cast the matrix elements to a specified type.
<code>ceil()</code>	Element-wise ceil.
<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>deg2rad()</code>	Element-wise deg2rad.
<code>diagonal()</code>	Returns the main diagonal of the matrix
<code>dot(other)</code>	Ordinary dot product
<code>expm1()</code>	Element-wise expm1.
<code>floor()</code>	Element-wise floor.
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(j)</code>	Returns a copy of column <i>j</i> of the matrix, as an ( <i>m</i> x 1) sparse matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row <i>i</i> of the matrix, as a (1 x <i>n</i> ) sparse matrix (row vector).
<code>log1p()</code>	Element-wise log1p.
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	This function performs element-wise power.
<code>rad2deg()</code>	Element-wise rad2deg.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>rint()</code>	Element-wise rint.
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sign()</code>	Element-wise sign.
<code>sin()</code>	Element-wise sin.
<code>sinh()</code>	Element-wise sinh.
<code>sqrt()</code>	Element-wise sqrt.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>tan()</code>	Element-wise tan.
<code>tanh()</code>	Element-wise tanh.
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>trunc()</code>	Element-wise trunc.

---

`dia_matrix.arcsin()`  
Element-wise arcsin.

See `numpy.arcsin` for more information.

`dia_matrix.arcsinh()`  
Element-wise arcsinh.

See `numpy.arcsinh` for more information.

`dia_matrix.arctan()`  
Element-wise arctan.

See `numpy.arctan` for more information.

`dia_matrix.arctanh()`  
Element-wise arctanh.

See `numpy.arctanh` for more information.

`dia_matrix.asformat(format)`  
Return this matrix in a given sparse format

**Parameters** `format` : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for `csr_matrix` format
- “csc” for `csc_matrix` format
- “lil” for `lil_matrix` format
- “dok” for `dok_matrix` format and so on

`dia_matrix.asfptype()`  
Upcast matrix to a floating point format (if necessary)

`dia_matrix.astype(t)`  
Cast the matrix elements to a specified type.

The data will be copied.

**Parameters** `t` : string or numpy dtype  
Typecode or data-type to which to cast the data.

`dia_matrix.ceil()`  
Element-wise ceil.

See `numpy.ceil` for more information.

`dia_matrix.conj()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`dia_matrix.conjugate()`  
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`dia_matrix.copy()`  
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`dia_matrix.count_nonzero()`  
 Number of non-zero entries, equivalent to  
`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`dia_matrix.deg2rad()`  
 Element-wise `deg2rad`.  
 See `numpy.deg2rad` for more information.

`dia_matrix.diagonal()`  
 Returns the main diagonal of the matrix

`dia_matrix.dot(other)`  
 Ordinary dot product

### Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`dia_matrix.expm1()`  
 Element-wise `expm1`.  
 See `numpy.expm1` for more information.

`dia_matrix.floor()`  
 Element-wise `floor`.  
 See `numpy.floor` for more information.

`dia_matrix.getH()`  
 Return the Hermitian transpose of this matrix.

### See also:

**`np.matrix.getH`**  
 NumPy's implementation of `getH` for matrices

`dia_matrix.get_shape()`  
 Get shape of a matrix.

`dia_matrix.getcol(j)`  
 Returns a copy of column `j` of the matrix, as an  $(m \times 1)$  sparse matrix (column vector).

`dia_matrix.getformat()`  
 Format of a matrix representation as a string.

`dia_matrix.getmaxprint()`  
 Maximum number of elements to display when printed.

`dia_matrix.getnnz(axis=None)`  
 Number of stored values, including explicit zeros.

**Parameters** `axis` : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

`count_nonzero`

Number of non-zero entries

`dia_matrix.getrow(i)`

Returns a copy of row *i* of the matrix, as a (1 x *n*) sparse matrix (row vector).

`dia_matrix.log1p()`

Element-wise log1p.

See `numpy.log1p` for more information.

`dia_matrix.maximum(other)`

Element-wise maximum between this and another matrix.

`dia_matrix.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

`np.matrix.mean`

NumPy's implementation of 'mean' for matrices

`dia_matrix.minimum(other)`

Element-wise minimum between this and another matrix.

`dia_matrix.multiply(other)`

Point-wise multiplication by another matrix

`dia_matrix.nonzero()`

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`dia_matrix.power(n, dtype=None)`

This function performs element-wise power.

**Parameters** **n** : *n* is a scalar

**dtype** : If dtype is not specified, the current dtype will be preserved.

`dia_matrix.rad2deg()`  
Element-wise rad2deg.

See `numpy.rad2deg` for more information.

`dia_matrix.reshape(shape, order='C')`  
Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- shape** : length-2 tuple of ints  
The new shape should be compatible with the original shape.
- order** : 'C', optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** `reshaped_matrix` : *self* with the new dimensions of `shape`

**See also:**

**`np.matrix.reshape`**  
NumPy's implementation of 'reshape' for matrices

`dia_matrix.rint()`  
Element-wise rint.

See `numpy.rint` for more information.

`dia_matrix.set_shape(shape)`  
See `reshape`.

`dia_matrix.setdiag(values, k=0)`  
Set diagonal or off-diagonal elements of the array.

**Parameters**

- values** : array\_like  
New values of the diagonal elements.  
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.  
If a scalar value is given, all of the diagonal is set to it.
- k** : int, optional  
Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`dia_matrix.sign()`  
Element-wise sign.

See `numpy.sign` for more information.

`dia_matrix.sin()`  
Element-wise sin.

See `numpy.sin` for more information.

`dia_matrix.sinh()`  
Element-wise sinh.

See `numpy.sinh` for more information.

`dia_matrix.sqrt()`  
Element-wise sqrt.

See `numpy.sqrt` for more information.

`dia_matrix.sum(axis=None, dtype=None, out=None)`  
Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional  
 Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional  
 The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional  
 Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **sum\_along\_axis** : np.matrix  
 A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

**`np.matrix.sum`**

NumPy's implementation of 'sum' for matrices

`dia_matrix.tan()`  
 Element-wise tan.

See `numpy.tan` for more information.

`dia_matrix.tanh()`  
 Element-wise tanh.

See `numpy.tanh` for more information.

`dia_matrix.toarray (order=None, out=None)`  
 Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional  
 Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional  
 If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** **arr** : ndarray, 2-dimensional  
 An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`dia_matrix.tobsr (blocksize=None, copy=False)`  
 Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`dia_matrix.tocoo (copy=False)`  
 Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`dia_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`dia_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`dia_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters** `order` : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

`out` : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns** `arr` : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`dia_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`dia_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`dia_matrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`dia_matrix.ttranspose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters** `axes` : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

`copy` : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** `p` : *self* with the dimensions reversed.

**See also:**

**`np.matrix.transpose`**

NumPy's implementation of 'transpose' for matrices

`dia_matrix.trunc()`

Element-wise trunc.

See `numpy.trunc` for more information.

**class** `scipy.sparse.dok_matrix` (*arg1*, *shape=None*, *dtype=None*, *copy=False*)

Dictionary Of Keys based sparse matrix.

This is an efficient structure for constructing sparse matrices incrementally.

*This can be instantiated in several ways:*

**`dok_matrix(D)`**

with a dense matrix, D

**`dok_matrix(S)`** with a sparse matrix, S

**`dok_matrix((M,N), [dtype])`**

create the matrix with initial shape (M,N) dtype is optional, defaulting to dtype='d'

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Allows for efficient O(1) access of individual elements. Duplicates are not allowed. Can be efficiently converted to a `coo_matrix` once constructed.

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import dok_matrix
>>> S = dok_matrix((5, 5), dtype=np.float32)
>>> for i in range(5):
...     for j in range(5):
...         S[i, j] = i + j      # Update element
```

**Attributes**

---

<code>shape</code>	Get shape of a matrix.
<code>nnz</code>	Number of stored values, including explicit zeros.

---

`dok_matrix.shape`

Get shape of a matrix.

`dok_matrix.nnz`

Number of stored values, including explicit zeros.

**See also:**

`count_nonzero`

Number of non-zero entries

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)

**Methods**

<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(t)</code>	Cast the matrix elements to a specified type.
<code>clear()</code> -> None. Remove all items from D.)	
<code>conj()</code>	Element-wise complex conjugation.
<code>conjtransp()</code>	Return the conjugate transpose
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>diagonal()</code>	Returns the main diagonal of the matrix
<code>dot(other)</code>	Ordinary dot product
<code>fromkeys(...)</code>	v defaults to None.
<code>get(key[, default])</code>	This overrides the dict.get method, providing type checking but otherwise equivalent
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(j)</code>	Returns a copy of column j of the matrix as a (m x 1) DOK matrix.
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of row i of the matrix as a (1 x n) DOK matrix.
<code>has_key(k)</code> -> True if D has a key k, else False)	
<code>items()</code> -> list of D's (key, value) pairs, ...)	
<code>iteritems()</code> -> an iterator over the (key, ...)	
<code>iterkeys()</code> -> an iterator over the keys of D)	
<code>itervalues(...)</code>	
<code>keys()</code> -> list of D's keys)	
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix
<code>nonzero()</code>	nonzero indices
<code>pop((k[,d]) -&gt; v, ...)</code>	If key is not found, d is returned if given, otherwise KeyError is raised
<code>popitem()</code> -> (k, v), ...)	2-tuple; but raise KeyError if D is empty.
<code>power(n[, dtype])</code>	Element-wise power.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>resize(shape)</code>	Resize the matrix in-place to dimensions given by 'shape'.
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdefault((k[,d]) -&gt; D.get(k,d), ...)</code>	
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>toarray([order, out])</code>	Return a dense ndarray representation of this matrix.
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.
<code>update([E, ...)</code>	If E present and has a .keys() method, does: for k in E: D[k] = E[k]
<code>values()</code> -> list of D's values)

`dok_matrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** **format** : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for `csr_matrix` format
- “csc” for `csc_matrix` format
- “lil” for `lil_matrix` format
- “dok” for `dok_matrix` format and so on

`dok_matrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`dok_matrix.astype` (*t*)

Cast the matrix elements to a specified type.

The data will be copied.

**Parameters** **t** : string or numpy dtype  
Typecode or data-type to which to cast the data.

`dok_matrix.clear` () → None. Remove all items from D.

`dok_matrix.conj` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`dok_matrix.conjtransp` ()

Return the conjugate transpose

`dok_matrix.conjugate` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`dok_matrix.copy` ()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`dok_matrix.count_nonzero` ()

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`dok_matrix.diagonal` ()

Returns the main diagonal of the matrix

`dok_matrix.dot` (*other*)

Ordinary dot product

*Examples*

```

>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)

```

**static** `dok_matrix.fromkeys(S[, v])` → New dict with keys from S and values equal to v.  
v defaults to None.

`dok_matrix.get(key, default=0.0)`  
This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

`dok_matrix.getH()`  
Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**  
NumPy's implementation of `getH` for matrices

`dok_matrix.get_shape()`  
Get shape of a matrix.

`dok_matrix.getcol(j)`  
Returns a copy of column j of the matrix as a (m x 1) DOK matrix.

`dok_matrix.getformat()`  
Format of a matrix representation as a string.

`dok_matrix.getmaxprint()`  
Maximum number of elements to display when printed.

`dok_matrix.getnnz(axis=None)`  
Number of stored values, including explicit zeros.

**Parameters** `axis` : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

**`count_nonzero`**  
Number of non-zero entries

`dok_matrix.getrow(i)`  
Returns a copy of row i of the matrix as a (1 x n) DOK matrix.

`dok_matrix.has_key(k)` → True if D has a key k, else False

`dok_matrix.items()` → list of D's (key, value) pairs, as 2-tuples

`dok_matrix.iteritems()` → an iterator over the (key, value) items of D

`dok_matrix.iterkeys()` → an iterator over the keys of D

`dok_matrix.itervalues()` → an iterator over the values of D

`dok_matrix.keys()` → list of D's keys

`dok_matrix.maximum(other)`

Element-wise maximum between this and another matrix.

`dok_matrix.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`dok_matrix.minimum(other)`

Element-wise minimum between this and another matrix.

`dok_matrix.multiply(other)`

Point-wise multiplication by another matrix

`dok_matrix.nonzero()`

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`dok_matrix.pop(k[, d])` → v, remove specified key and return the corresponding value.

If key is not found, d is returned if given, otherwise `KeyError` is raised

`dok_matrix.popitem()` → (k, v), remove and return some (key, value) pair as a

2-tuple; but raise `KeyError` if D is empty.

`dok_matrix.power(n, dtype=None)`

Element-wise power.

`dok_matrix.reshape(shape, order='C')`

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints  
 The new shape should be compatible with the original shape.  
**order** : 'C', optional  
 This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.  
**Returns** **reshaped\_matrix** : *self* with the new dimensions of **shape**

See also:

**np.matrix.reshape**  
 NumPy's implementation of 'reshape' for matrices

**dok\_matrix.resize** (*shape*)  
 Resize the matrix in-place to dimensions given by 'shape'.  
 Any non-zero elements that lie outside the new shape are removed.

**dok\_matrix.set\_shape** (*shape*)  
 See **reshape**.

**dok\_matrix.setdefault** (*k*[, *d*]) → *D.get(k,d)*, also set *D[k]=d* if *k* not in *D*

**dok\_matrix.setdiag** (*values*, *k=0*)  
 Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like  
 New values of the diagonal elements.  
 Values may have any length. If the diagonal is longer than *values*, then the remaining diagonal entries will not be set. If *values* is longer than the diagonal, then the remaining values are ignored.  
 If a scalar value is given, all of the diagonal is set to it.  
**k** : int, optional  
 Which off-diagonal to set, corresponding to elements *a[i,i+k]*. Default: 0 (the main diagonal).

**dok\_matrix.sum** (*axis=None*, *dtype=None*, *out=None*)  
 Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional  
 Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).  
**dtype** : dtype, optional  
 The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.  
**out** : np.matrix, optional  
 Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
**Returns** **sum\_along\_axis** : np.matrix  
 A matrix with the same shape as *self*, with the specified axis removed.

See also:

**np.matrix.sum**  
 NumPy's implementation of 'sum' for matrices

`dok_matrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** **arr** : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`dok_matrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When *blocksize=(R, C)* is provided, it will be used for construction of the `bsr_matrix`.

`dok_matrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`dok_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`dok_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`dok_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns** **arr** : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and

returned wrapped in a `numpy.matrix` object that shares the same memory.

`dok_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`dok_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`dok_matrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`dok_matrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters** `axes` : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

`copy` : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** `p` : *self* with the dimensions reversed.

**See also:**

**`np.matrix.transpose`**

NumPy's implementation of 'transpose' for matrices

`dok_matrix.update` (`[E]`, `**F`) → None. Update D from dict/iterable E and F.

If E present and has a `.keys()` method, does: for k in E: D[k] = E[k] If E present and lacks `.keys()` method, does: for (k, v) in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

`dok_matrix.values` () → list of D's values

`dok_matrix.viewitems` () → a set-like object providing a view on D's items

`dok_matrix.viewkeys` () → a set-like object providing a view on D's keys

`dok_matrix.viewvalues` () → an object providing a view on D's values

**class** `scipy.sparse.lil_matrix` (*arg1, shape=None, dtype=None, copy=False*)

Row-based linked list sparse matrix

This is a structure for constructing sparse matrices incrementally. Note that inserting a single item can take linear time in the worst case; to construct a matrix efficiently, make sure the items are pre-sorted by index, per row.

*This can be instantiated in several ways:*

`lil_matrix(D)` with a dense matrix or rank-2 ndarray D

`lil_matrix(S)` with another sparse matrix S (equivalent to `S.tolil()`)

`lil_matrix((M, N), [dtype])`

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

*Notes*

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

*Advantages of the LIL format*

- supports flexible slicing
- changes to the matrix sparsity structure are efficient

*Disadvantages of the LIL format*

- arithmetic operations LIL + LIL are slow (consider CSR or CSC)
- slow column slicing (consider CSC)
- slow matrix vector products (consider CSR or CSC)

*Intended Usage*

- LIL is a convenient format for constructing sparse matrices
- once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
- consider using the COO format when constructing large matrices

*Data Structure*

- An array (`self.rows`) of rows, each of which is a sorted list of column indices of non-zero elements.
- The corresponding nonzero values are stored in similar fashion in `self.data`.

*Attributes*

---

<code>shape</code>	Get shape of a matrix.
<code>nnz</code>	Number of stored values, including explicit zeros.

---

`lil_matrix.shape`

Get shape of a matrix.

`lil_matrix.nnz`

Number of stored values, including explicit zeros.

**See also:**

`count_nonzero`

Number of non-zero entries

<code>dtype</code>	(dtype) Data type of the matrix
<code>ndim</code>	(int) Number of dimensions (this is always 2)
<code>data</code>	LIL format data array of the matrix
<code>rows</code>	LIL format row index array of the matrix

*Methods*

---

<code>asformat(format)</code>	Return this matrix in a given sparse format
<code>asfptype()</code>	Upcast matrix to a floating point format (if necessary)
<code>astype(t)</code>	Cast the matrix elements to a specified type.

---

Continued on next page

Table 5.169 – continued from previous page

<code>conj()</code>	Element-wise complex conjugation.
<code>conjugate()</code>	Element-wise complex conjugation.
<code>copy()</code>	Returns a copy of this matrix.
<code>count_nonzero()</code>	Number of non-zero entries, equivalent to
<code>diagonal()</code>	Returns the main diagonal of the matrix
<code>dot(other)</code>	Ordinary dot product
<code>getH()</code>	Return the Hermitian transpose of this matrix.
<code>get_shape()</code>	Get shape of a matrix.
<code>getcol(j)</code>	Returns a copy of column <i>j</i> of the matrix, as an ( <i>m</i> x 1) sparse matrix (column vector).
<code>getformat()</code>	Format of a matrix representation as a string.
<code>getmaxprint()</code>	Maximum number of elements to display when printed.
<code>getnnz([axis])</code>	Number of stored values, including explicit zeros.
<code>getrow(i)</code>	Returns a copy of the ‘ <i>i</i> ’th row.
<code>getrowview(i)</code>	Returns a view of the ‘ <i>i</i> ’th row (without copying).
<code>maximum(other)</code>	Element-wise maximum between this and another matrix.
<code>mean([axis, dtype, out])</code>	Compute the arithmetic mean along the specified axis.
<code>minimum(other)</code>	Element-wise minimum between this and another matrix.
<code>multiply(other)</code>	Point-wise multiplication by another matrix
<code>nonzero()</code>	nonzero indices
<code>power(n[, dtype])</code>	Element-wise power.
<code>reshape(shape[, order])</code>	Gives a new shape to a sparse matrix without changing its data.
<code>set_shape(shape)</code>	See <code>reshape</code> .
<code>setdiag(values[, k])</code>	Set diagonal or off-diagonal elements of the array.
<code>sum([axis, dtype, out])</code>	Sum the matrix elements over a given axis.
<code>toarray([order, out])</code>	See the docstring for <code>spmatrix.toarray</code> .
<code>tobsr([blocksize, copy])</code>	Convert this matrix to Block Sparse Row format.
<code>tocoo([copy])</code>	Convert this matrix to COOrdinate format.
<code>tocsc([copy])</code>	Convert this matrix to Compressed Sparse Column format.
<code>tocsr([copy])</code>	Convert this matrix to Compressed Sparse Row format.
<code>todense([order, out])</code>	Return a dense matrix representation of this matrix.
<code>todia([copy])</code>	Convert this matrix to sparse DIAgonal format.
<code>todok([copy])</code>	Convert this matrix to Dictionary Of Keys format.
<code>tolil([copy])</code>	Convert this matrix to LInked List format.
<code>transpose([axes, copy])</code>	Reverses the dimensions of the sparse matrix.

`lil_matrix.asformat(format)`

Return this matrix in a given sparse format

**Parameters** `format` : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for `csr_matrix` format
- “csc” for `csc_matrix` format
- “lil” for `lil_matrix` format
- “dok” for `dok_matrix` format and so on

`lil_matrix.asfptype()`

Upcast matrix to a floating point format (if necessary)

`lil_matrix.astype(t)`

Cast the matrix elements to a specified type.

The data will be copied.

**Parameters** `t`: string or numpy dtype  
Typecode or data-type to which to cast the data.

- `lil_matrix.conj()`  
Element-wise complex conjugation.  
If the matrix is of non-complex data type, then this method does nothing and the data is not copied.
- `lil_matrix.conjugate()`  
Element-wise complex conjugation.  
If the matrix is of non-complex data type, then this method does nothing and the data is not copied.
- `lil_matrix.copy()`  
Returns a copy of this matrix.  
No data/indices will be shared between the returned value and current matrix.
- `lil_matrix.count_nonzero()`  
Number of non-zero entries, equivalent to  
`np.count_nonzero(a.toarray())`  
Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.
- `lil_matrix.diagonal()`  
Returns the main diagonal of the matrix
- `lil_matrix.dot(other)`  
Ordinary dot product
- Examples**
- ```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```
- `lil_matrix.getH()`  
Return the Hermitian transpose of this matrix.
- See also:**
- `np.matrix.getH`  
NumPy's implementation of `getH` for matrices
- `lil_matrix.get_shape()`  
Get shape of a matrix.
- `lil_matrix.getcol(j)`  
Returns a copy of column `j` of the matrix, as an  $(m \times 1)$  sparse matrix (column vector).
- `lil_matrix.getformat()`  
Format of a matrix representation as a string.
- `lil_matrix.getmaxprint()`  
Maximum number of elements to display when printed.
- `lil_matrix.getnnz(axis=None)`  
Number of stored values, including explicit zeros.

**Parameters** **axis** : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

`count_nonzero`

Number of non-zero entries

`lil_matrix.getrow(i)`

Returns a copy of the 'i'th row.

`lil_matrix.getrowview(i)`

Returns a view of the 'i'th row (without copying).

`lil_matrix.maximum(other)`

Element-wise maximum between this and another matrix.

`lil_matrix.mean(axis=None, dtype=None, out=None)`

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

`np.matrix.mean`

NumPy's implementation of 'mean' for matrices

`lil_matrix.minimum(other)`

Element-wise minimum between this and another matrix.

`lil_matrix.multiply(other)`

Point-wise multiplication by another matrix

`lil_matrix.nonzero()`

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`lil_matrix.power(n, dtype=None)`

Element-wise power.

`lil_matrix.reshape` (*shape*, *order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- shape** : length-2 tuple of ints  
The new shape should be compatible with the original shape.
- order** : 'C', optional  
This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **reshaped\_matrix** : *self* with the new dimensions of `shape`

See also:

**`np.matrix.reshape`**

NumPy's implementation of 'reshape' for matrices

`lil_matrix.set_shape` (*shape*)

See `reshape`.

`lil_matrix.setdiag` (*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

**Parameters**

- values** : array\_like  
New values of the diagonal elements.  
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.  
If a scalar value is given, all of the diagonal is set to it.
- k** : int, optional  
Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

`lil_matrix.sum` (*axis=None*, *dtype=None*, *out=None*)

Sum the matrix elements over a given axis.

**Parameters**

- axis** : {-2, -1, 0, 1, None} optional  
Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).
- dtype** : dtype, optional  
The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.
- out** : np.matrix, optional  
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **sum\_along\_axis** : np.matrix  
A matrix with the same shape as *self*, with the specified axis removed.

See also:

**`np.matrix.sum`**

NumPy's implementation of 'sum' for matrices

`lil_matrix.toarray` (*order=None*, *out=None*)

See the docstring for `spmatrix.toarray`.

`lil_matrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `bsr_matrix`.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`lil_matrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`lil_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`lil_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`lil_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters**    **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**        **arr** : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`lil_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`lil_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`lil_matrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`lil_matrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters**    **axes** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** `p` : *self* with the dimensions reversed.

**See also:**

`np.matrix.transpose`

NumPy's implementation of 'transpose' for matrices

**class** `scipy.sparse.spmatrix` (*maxprint=50*)

This class provides a base class for all sparse matrices. It cannot be instantiated. Most of the work is provided by subclasses.

**Attributes**

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <code>nnz</code>   | Number of stored values, including explicit zeros. |
| <code>shape</code> | Get shape of a matrix.                             |

`spmatrix.nnz`

Number of stored values, including explicit zeros.

**See also:**

`count_nonzero`

Number of non-zero entries

`spmatrix.shape`

Get shape of a matrix.

**Methods**

|                                       |                                                                                                       |
|---------------------------------------|-------------------------------------------------------------------------------------------------------|
| <code>asformat(format)</code>         | Return this matrix in a given sparse format                                                           |
| <code>asfptype()</code>               | Upcast matrix to a floating point format (if necessary)                                               |
| <code>astype(t)</code>                | Cast the matrix elements to a specified type.                                                         |
| <code>conj()</code>                   | Element-wise complex conjugation.                                                                     |
| <code>conjugate()</code>              | Element-wise complex conjugation.                                                                     |
| <code>copy()</code>                   | Returns a copy of this matrix.                                                                        |
| <code>count_nonzero()</code>          | Number of non-zero entries, equivalent to                                                             |
| <code>diagonal()</code>               | Returns the main diagonal of the matrix                                                               |
| <code>dot(other)</code>               | Ordinary dot product                                                                                  |
| <code>getH()</code>                   | Return the Hermitian transpose of this matrix.                                                        |
| <code>get_shape()</code>              | Get shape of a matrix.                                                                                |
| <code>getcol(j)</code>                | Returns a copy of column <i>j</i> of the matrix, as an ( <i>m</i> x 1) sparse matrix (column vector). |
| <code>getformat()</code>              | Format of a matrix representation as a string.                                                        |
| <code>getmaxprint()</code>            | Maximum number of elements to display when printed.                                                   |
| <code>getnnz([axis])</code>           | Number of stored values, including explicit zeros.                                                    |
| <code>getrow(i)</code>                | Returns a copy of row <i>i</i> of the matrix, as a (1 x <i>n</i> ) sparse matrix (row vector).        |
| <code>maximum(other)</code>           | Element-wise maximum between this and another matrix.                                                 |
| <code>mean([axis, dtype, out])</code> | Compute the arithmetic mean along the specified axis.                                                 |
| <code>minimum(other)</code>           | Element-wise minimum between this and another matrix.                                                 |
| <code>multiply(other)</code>          | Point-wise multiplication by another matrix                                                           |
| <code>nonzero()</code>                | nonzero indices                                                                                       |

| <code>tocsc([copy])</code>            | Convert this matrix to Compressed Sparse Column format.         |
| <code>tocsr([copy])</code>            | Convert this matrix to Compressed Sparse Row format.            |
| <code>todense([order, out])</code>    | Return a dense matrix representation of this matrix.            |
| <code>todia([copy])</code>            | Convert this matrix to sparse DIAgonal format.                  |
| <code>todok([copy])</code>            | Convert this matrix to Dictionary Of Keys format.               |
| <code>tolil([copy])</code>            | Convert this matrix to LInked List format.                      |
| <code>transpose([axes, copy])</code>  | Reverses the dimensions of the sparse matrix.                   |

`spmatrix.asformat` (*format*)

Return this matrix in a given sparse format

**Parameters** `format` : {string, None}  
*desired sparse matrix format*

- None for no format conversion
- “csr” for `csr_matrix` format
- “csc” for `csc_matrix` format
- “lil” for `lil_matrix` format
- “dok” for `dok_matrix` format and so on

`spmatrix.asfptype` ()

Upcast matrix to a floating point format (if necessary)

`spmatrix.astype` (*t*)

Cast the matrix elements to a specified type.

The data will be copied.

**Parameters** `t` : string or numpy dtype  
 Typecode or data-type to which to cast the data.

`spmatrix.conj` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`spmatrix.conjugate` ()

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

`spmatrix.copy` ()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

`spmatrix.count_nonzero` ()

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`spmatrix.diagonal()`  
Returns the main diagonal of the matrix

`spmatrix.dot(other)`  
Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

`spmatrix.getH()`  
Return the Hermitian transpose of this matrix.

**See also:**

**`np.matrix.getH`**  
NumPy's implementation of `getH` for matrices

`spmatrix.get_shape()`  
Get shape of a matrix.

`spmatrix.getcol(j)`  
Returns a copy of column `j` of the matrix, as an  $(m \times 1)$  sparse matrix (column vector).

`spmatrix.getformat()`  
Format of a matrix representation as a string.

`spmatrix.getmaxprint()`  
Maximum number of elements to display when printed.

`spmatrix.getnnz(axis=None)`  
Number of stored values, including explicit zeros.

**Parameters** `axis` : None, 0, or 1  
Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**

**`count_nonzero`**  
Number of non-zero entries

`spmatrix.getrow(i)`  
Returns a copy of row `i` of the matrix, as a  $(1 \times n)$  sparse matrix (row vector).

`spmatrix.maximum(other)`  
Element-wise maximum between this and another matrix.

`spmatrix.mean(axis=None, dtype=None, out=None)`  
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. `float64` intermediate and return values are used for integer inputs.

**Parameters** `axis` : {-2, -1, 0, 1, None} optional

Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. *axis = None*).

**dtype** : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **m** : np.matrix

**See also:**

**`np.matrix.mean`**

NumPy's implementation of 'mean' for matrices

`spmatrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

`spmatrix.multiply` (*other*)

Point-wise multiplication by another matrix

`spmatrix.nonzero` ()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

`spmatrix.power` (*n*, *dtype=None*)

Element-wise power.

`spmatrix.reshape` (*shape*, *order='C'*)

Gives a new shape to a sparse matrix without changing its data.

**Parameters** **shape** : length-2 tuple of ints

The new shape should be compatible with the original shape.

**order** : 'C', optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns** **reshaped\_matrix** : *self* with the new dimensions of *shape*

**See also:**

**`np.matrix.reshape`**

NumPy's implementation of 'reshape' for matrices

`spmatrix.set_shape` (*shape*)

See `reshape`.

`spmatrix.setdiag` (*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

**Parameters** **values** : array\_like

New values of the diagonal elements.

Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values is longer than the diagonal, then the remaining values are ignored.

If a scalar value is given, all of the diagonal is set to it.

**k** : int, optional

Which off-diagonal to set, corresponding to elements  $a[i,i+k]$ . Default: 0 (the main diagonal).

`spmatrix.sum` (*axis=None, dtype=None, out=None*)

Sum the matrix elements over a given axis.

**Parameters** **axis** : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. *axis = None*).

**dtype** : dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out** : np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns** **sum\_along\_axis** : np.matrix

A matrix with the same shape as *self*, with the specified axis removed.

See also:

`np.matrix.sum`

NumPy's implementation of 'sum' for matrices

`spmatrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters** **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns** **arr** : ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

`spmatrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the *data/indices* may be shared between this matrix and the resultant *bsr\_matrix*.

When `blocksize=(R, C)` is provided, it will be used for construction of the `bsr_matrix`.

`spmatrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.

`spmatrix.tocsf` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

`spmatrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

`spmatrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters**    **order** : {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** : ndarray, 2-dimensional, optional

If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**        **arr** : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

`spmatrix.todia` (*copy=False*)

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

`spmatrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

`spmatrix.tolil` (*copy=False*)

Convert this matrix to LInked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

`spmatrix.ttranspose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters**    **axes** : None, optional

This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.

**copy** : bool, optional

Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns** `p` : *self* with the dimensions reversed.

**See also:**

`np.matrix.transpose`

NumPy's implementation of 'transpose' for matrices

## Functions

Building sparse matrices:

|                                                                |                                                                                             |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <code>eye(m[, n, k, dtype, format])</code>                     | Sparse matrix with ones on diagonal                                                         |
| <code>identity(n[, dtype, format])</code>                      | Identity matrix in sparse format                                                            |
| <code>kron(A, B[, format])</code>                              | kronecker product of sparse matrices A and B                                                |
| <code>kronsum(A, B[, format])</code>                           | kronecker sum of sparse matrices A and B                                                    |
| <code>diags(diagonals[, offsets, shape, format, dtype])</code> | Construct a sparse matrix from diagonals.                                                   |
| <code>spdiags(data, diags, m, n[, format])</code>              | Return a sparse matrix from diagonals.                                                      |
| <code>block_diag(mats[, format, dtype])</code>                 | Build a block diagonal sparse matrix from provided matrices.                                |
| <code>tril(A[, k, format])</code>                              | Return the lower triangular portion of a matrix in sparse format                            |
| <code>triu(A[, k, format])</code>                              | Return the upper triangular portion of a matrix in sparse format                            |
| <code>bmat(blocks[, format, dtype])</code>                     | Build a sparse matrix from sparse sub-blocks                                                |
| <code>hstack(blocks[, format, dtype])</code>                   | Stack sparse matrices horizontally (column wise)                                            |
| <code>vstack(blocks[, format, dtype])</code>                   | Stack sparse matrices vertically (row wise)                                                 |
| <code>rand(m, n[, density, format, dtype, ...])</code>         | Generate a sparse matrix of the given shape and density with uniformly distributed elements |
| <code>random(m, n[, density, format, dtype, ...])</code>       | Generate a sparse matrix of the given shape and density with randomly distributed elements  |

`scipy.sparse.eye` (*m*, *n=None*, *k=0*, *dtype=<type 'float'>*, *format=None*)

Sparse matrix with ones on diagonal

Returns a sparse (*m* x *n*) matrix where the *k*-th diagonal is all ones and everything else is zeros.

**Parameters** `m` : int

Number of rows in the matrix.

`n` : int, optional

Number of columns. Default: *m*.

`k` : int, optional

Diagonal to place ones on. Default: 0 (main diagonal).

**dtype** : dtype, optional

Data type of the matrix.

**format** : str, optional

Sparse format of the result, e.g. `format="csr"`, etc.

### Examples

```
>>> from scipy import sparse
>>> sparse.eye(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> sparse.eye(3, dtype=np.int8)
<3x3 sparse matrix of type '<type 'numpy.int8''>'
with 3 stored elements (1 diagonals) in DIAgonal format>
```

`scipy.sparse.identity(n, dtype='d', format=None)`

Identity matrix in sparse format

Returns an identity matrix with shape (n,n) using a given sparse format and dtype.

**Parameters**

- n** : int  
Shape of the identity matrix.
- dtype** : dtype, optional  
Data type of the matrix
- format** : str, optional  
Sparse format of the result, e.g. format="csr", etc.

### Examples

```
>>> from scipy.sparse import identity
>>> identity(3).toarray()
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> identity(3, dtype='int8', format='dia')
<3x3 sparse matrix of type '<type 'numpy.int8'>'
  with 3 stored elements (1 diagonals) in DIAgonal format>
```

`scipy.sparse.kron(A, B, format=None)`

Kronecker product of sparse matrices A and B

**Parameters**

- A** : sparse or dense matrix  
first matrix of the product
- B** : sparse or dense matrix  
second matrix of the product
- format** : str, optional  
format of the result (e.g. "csr")

**Returns** Kronecker product in a sparse matrix format

### Examples

```
>>> from scipy import sparse
>>> A = sparse.csr_matrix(np.array([[0, 2], [5, 0]]))
>>> B = sparse.csr_matrix(np.array([[1, 2], [3, 4]]))
>>> sparse.kron(A, B).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])

>>> sparse.kron(A, [[1, 2], [3, 4]]).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])
```

`scipy.sparse.kronsum(A, B, format=None)`

Kronecker sum of sparse matrices A and B

Kronecker sum of two sparse matrices is a sum of two Kronecker products  $\text{kron}(I_n, A) + \text{kron}(B, I_m)$  where A has shape (m,m) and B has shape (n,n) and  $I_m$  and  $I_n$  are identity matrices of shape (m,m) and (n,n) respectively.

**Parameters** A

**B** square matrix

**format** : str square matrix format of the result (e.g. "csr")

**Returns** kronecker sum in a sparse matrix format

`scipy.sparse.diags` (*diagonals*, *offsets=0*, *shape=None*, *format=None*, *dtype=None*)  
 Construct a sparse matrix from diagonals.

**Parameters**

**diagonals** : sequence of array\_like  
 Sequence of arrays containing the matrix diagonals, corresponding to *offsets*.

**offsets** : sequence of int or an int, optional

**Diagonals to set:**

- k = 0 the main diagonal (default)
- k > 0 the k-th upper diagonal
- k < 0 the k-th lower diagonal

**shape** : tuple of int, optional  
 Shape of the result. If omitted, a square matrix large enough to contain the diagonals is returned.

**format** : {"dia", "csr", "csc", "lil", ...}, optional  
 Matrix format of the result. By default (*format=None*) an appropriate sparse matrix format is returned. This choice is subject to change.

**dtype** : dtype, optional  
 Data type of the matrix.

**See also:**

`spdiags` construct matrix from diagonals

**Notes**

This function differs from `spdiags` in the way it handles off-diagonals.

The result from `diags` is the sparse equivalent of:

```
np.diag(diagonals[0], offsets[0])
+ ...
+ np.diag(diagonals[k], offsets[k])
```

Repeated diagonal offsets are disallowed.

New in version 0.11.

**Examples**

```
>>> from scipy.sparse import diags
>>> diagonals = [[1, 2, 3, 4], [1, 2, 3], [1, 2]]
>>> diags(diagonals, [0, -1, 2]).toarray()
array([[1, 0, 1, 0],
       [1, 2, 0, 2],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

Broadcasting of scalars is supported (but *shape* needs to be specified):

```
>>> diags([1, -2, 1], [-1, 0, 1], shape=(4, 4)).toarray()
array([[ -2.,  1.,  0.,  0.],
       [  1., -2.,  1.,  0.],
       [  0.,  1., -2.,  1.],
       [  0.,  0.,  1., -2.]])
```

If only one diagonal is wanted (as in `numpy.diag`), the following works as well:

```
>>> diags([1, 2, 3], 1).toarray()
array([[ 0.,  1.,  0.,  0.],
       [ 0.,  0.,  2.,  0.],
       [ 0.,  0.,  0.,  3.],
       [ 0.,  0.,  0.,  0.]])
```

`scipy.sparse.spdiags` (*data*, *diags*, *m*, *n*, *format=None*)

Return a sparse matrix from diagonals.

**Parameters**

- data** : array\_like  
matrix diagonals stored row-wise
- diags** : diagonals to set
  - $k = 0$  the main diagonal
  - $k > 0$  the  $k$ -th upper diagonal
  - $k < 0$  the  $k$ -th lower diagonal
- m, n** : int  
shape of the result
- format** : str, optional  
Format of the result. By default (*format=None*) an appropriate sparse matrix format is returned. This choice is subject to change.

See also:

[`diags`](#) more convenient form of this function

[`dia\_matrix`](#) the sparse DIAgonal format.

**Examples**

```
>>> from scipy.sparse import spdiags
>>> data = np.array([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4]])
>>> diags = np.array([0, -1, 2])
>>> spdiags(data, diags, 4, 4).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

`scipy.sparse.block_diag` (*mats*, *format=None*, *dtype=None*)

Build a block diagonal sparse matrix from provided matrices.

**Parameters**

- mats** : sequence of matrices  
Input matrices.
- format** : str, optional  
The sparse format of the result (e.g. “csr”). If not given, the matrix is returned in “coo” format.
- dtype** : dtype specifier, optional  
The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**Returns**

- res** : sparse matrix

**See also:**

`bmat`, `diags`

**Notes**

New in version 0.11.0.

**Examples**

```
>>> from scipy.sparse import coo_matrix, block_diag
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> block_diag((A, B, C)).toarray()
array([[1, 2, 0, 0],
       [3, 4, 0, 0],
       [0, 0, 5, 0],
       [0, 0, 6, 0],
       [0, 0, 0, 7]])
```

`scipy.sparse.tril(A, k=0, format=None)`

Return the lower triangular portion of a matrix in sparse format

**Returns the elements on or below the *k*-th diagonal of the matrix *A*.**

- *k* = 0 corresponds to the main diagonal
- *k* > 0 is above the main diagonal
- *k* < 0 is below the main diagonal

**Parameters**

- A** : dense or sparse matrix  
Matrix whose lower triangular portion is desired.
- k** : integer  
The top-most diagonal of the lower triangle.
- format** : string  
Sparse format of the result, e.g. `format="csr"`, etc.

**Returns**

- L** : sparse matrix  
Lower triangular portion of *A* in sparse format.

**See also:**

`triu` upper triangle in sparse format

**Examples**

```
>>> from scipy.sparse import csr_matrix, tril
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
...               dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> tril(A).toarray()
array([[1, 0, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 0, 0]])
>>> tril(A).nnz
4
>>> tril(A, k=1).toarray()
```

```

array([[1, 2, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 9, 0]])
>>> tril(A, k=-1).toarray()
array([[0, 0, 0, 0, 0],
       [4, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])
>>> tril(A, format='csc')
<3x5 sparse matrix of type '<type 'numpy.int32'>'
  with 4 stored elements in Compressed Sparse Column format>

```

`scipy.sparse.triu(A, k=0, format=None)`

Return the upper triangular portion of a matrix in sparse format

*Returns the elements on or above the  $k$ -th diagonal of the matrix  $A$ .*

- $k = 0$  corresponds to the main diagonal
- $k > 0$  is above the main diagonal
- $k < 0$  is below the main diagonal

**Parameters**

- A** : dense or sparse matrix  
Matrix whose upper triangular portion is desired.
- k** : integer  
The bottom-most diagonal of the upper triangle.
- format** : string  
Sparse format of the result, e.g. `format="csr"`, etc.

**Returns**

- L** : sparse matrix  
Upper triangular portion of  $A$  in sparse format.

**See also:**

`tril` lower triangle in sparse format

**Examples**

```

>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
...                dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 2, 0, 0, 3],
       [0, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).nnz
8
>>> triu(A, k=1).toarray()
array([[0, 2, 0, 0, 3],
       [0, 0, 0, 6, 7],
       [0, 0, 0, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A, format='csc')

```

```
<3x5 sparse matrix of type '<type 'numpy.int32'>'
  with 8 stored elements in Compressed Sparse Column format>
```

`scipy.sparse.bmat` (*blocks*, *format=None*, *dtype=None*)

Build a sparse matrix from sparse sub-blocks

**Parameters**

- blocks** : array\_like  
Grid of sparse matrices with compatible shapes. An entry of None implies an all-zero matrix.
- format** : {'bsr', 'coo', 'csc', 'csr', 'dia', 'dok', 'lil'}, optional  
The sparse format of the result (e.g. "csr"). By default an appropriate sparse matrix format is returned. This choice is subject to change.
- dtype** : dtype, optional  
The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**Returns**

- bmat** : sparse matrix

**See also:**

`block_diag`, `diags`

**Examples**

```
>>> from scipy.sparse import coo_matrix, bmat
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> bmat([[A, B], [None, C]]).toarray()
array([[1, 2, 5],
       [3, 4, 6],
       [0, 0, 7]])

>>> bmat([[A, None], [None, C]]).toarray()
array([[1, 2, 0],
       [3, 4, 0],
       [0, 0, 7]])
```

`scipy.sparse.hstack` (*blocks*, *format=None*, *dtype=None*)

Stack sparse matrices horizontally (column wise)

**Parameters**

- blocks**  
sequence of sparse matrices with compatible shapes
- format** : str  
sparse format of the result (e.g. "csr") by default an appropriate sparse matrix format is returned. This choice is subject to change.
- dtype** : dtype, optional  
The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**See also:**

`vstack` stack sparse matrices vertically (row wise)

**Examples**

```
>>> from scipy.sparse import coo_matrix, hstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
```

```
>>> hstack([A,B]).toarray()
array([[1, 2, 5],
       [3, 4, 6]])
```

`scipy.sparse.vstack` (*blocks*, *format=None*, *dtype=None*)  
Stack sparse matrices vertically (row wise)

**Parameters**

- blocks**: sequence of sparse matrices with compatible shapes
- format**: str, optional  
sparse format of the result (e.g. “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.
- dtype**: dtype, optional  
The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

**See also:**

[`hstack`](#) stack sparse matrices horizontally (column wise)

**Examples**

```
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5, 6]])
>>> vstack([A, B]).toarray()
array([[1, 2],
       [3, 4],
       [5, 6]])
```

`scipy.sparse.rand` (*m*, *n*, *density=0.01*, *format='coo'*, *dtype=None*, *random\_state=None*)  
Generate a sparse matrix of the given shape and density with uniformly distributed values.

**Parameters**

- m, n**: int  
shape of the matrix
- density**: real, optional  
density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.
- format**: str, optional  
sparse matrix format.
- dtype**: dtype, optional  
type of the returned matrix values.
- random\_state**: {numpy.random.RandomState, int}, optional  
Random number generator or random seed. If not given, the singleton `numpy.random` will be used.

**Notes**

Only float types are supported for now.

`scipy.sparse.random` (*m*, *n*, *density=0.01*, *format='coo'*, *dtype=None*, *random\_state=None*, *data\_rvs=None*)

Generate a sparse matrix of the given shape and density with randomly distributed values.

**Parameters**

- m, n**: int  
shape of the matrix
- density**: real, optional  
density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.

**format** : str, optional  
 sparse matrix format.

**dtype** : dtype, optional  
 type of the returned matrix values.

**random\_state** : {numpy.random.RandomState, int}, optional  
 Random number generator or random seed. If not given, the singleton numpy.random will be used. This random state will be used for sampling the sparsity structure, but not necessarily for sampling the values of the structurally nonzero entries of the matrix.

**data\_rvs** : callable, optional  
 Samples a requested number of random values. This function should take a single argument specifying the length of the ndarray that it will return. The structurally nonzero entries of the sparse random matrix will be taken from the array sampled by this function. By default, uniform [0, 1) random values will be sampled using the same random state as is used for sampling the sparsity structure.

**Notes**

Only float types are supported for now.

**Examples**

```
>>> from scipy.sparse import random
>>> from scipy import stats
>>> class CustomRandomState(object):
...     def randint(self, k):
...         i = np.random.randint(k)
...         return i - i % 2
>>> rs = CustomRandomState()
>>> rvs = stats.poisson(25, loc=10).rvs
>>> S = random(3, 4, density=0.25, random_state=rs, data_rvs=rvs)
>>> S.A
array([[ 36.,   0.,  33.,   0.], # random
       [  0.,   0.,   0.,   0.],
       [  0.,   0.,  36.,   0.]])
```

Save and load sparse matrices:

|                                                   |                                                     |
|---------------------------------------------------|-----------------------------------------------------|
| <code>save_npz(file, matrix[, compressed])</code> | Save a sparse matrix to a file using .npz format.   |
| <code>load_npz(file)</code>                       | Load a sparse matrix from a file using .npz format. |

`scipy.sparse.save_npz(file, matrix, compressed=True)`

Save a sparse matrix to a file using .npz format.

**Parameters** **file** : str or file-like object  
 Either the file name (string) or an open file (file-like object) where the data will be saved. If file is a string, the .npz extension will be appended to the file name if it is not already there.

**matrix: spmatrix (format: “csc“, “csr“, “bsr“, “dia“ or coo“)**  
 The sparse matrix to save.

**compressed** : bool, optional  
 Allow compressing the file. Default: True

See also:

***scipy.sparse.load\_npz***

Load a sparse matrix from a file using `.npz` format.

***numpy.savez***

Save several arrays into a `.npz` archive.

***numpy.savez\_compressed***

Save several arrays into a compressed `.npz` archive.

**Examples**

Store sparse matrix to disk, and load it again:

```
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<type 'numpy.int64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)

>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')

>>> sparse_matrix
<2x3 sparse matrix of type '<type 'numpy.int64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

***scipy.sparse.load\_npz*** (*file*)

Load a sparse matrix from a file using `.npz` format.

|                   |                                                                                                                                                  |                                                                                                 |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>file</b> : str or file-like object                                                                                                            | Either the file name (string) or an open file (file-like object) where the data will be loaded. |
| <b>Returns</b>    | <b>result</b> : <code>csc_matrix</code> , <code>csr_matrix</code> , <code>bsr_matrix</code> , <code>dia_matrix</code> or <code>coo_matrix</code> | A sparse matrix containing the loaded data.                                                     |
| <b>Raises</b>     | <b>IOError</b>                                                                                                                                   | If the input file does not exist or cannot be read.                                             |

**See also:*****scipy.sparse.save\_npz***

Save a sparse matrix to a file using `.npz` format.

***numpy.load*** Load several arrays from a `.npz` archive.

Sparse matrix tools:

---

`find(A)` Return the indices and values of the nonzero elements of a matrix

---

***scipy.sparse.find*** (*A*)

Return the indices and values of the nonzero elements of a matrix

|                   |                                   |                                                                        |
|-------------------|-----------------------------------|------------------------------------------------------------------------|
| <b>Parameters</b> | <b>A</b> : dense or sparse matrix | Matrix whose nonzero elements are desired.                             |
| <b>Returns</b>    | <b>(I,J,V)</b> : tuple of arrays  | I, J, and V contain the row indices, column indices, and values of the |

nonzero matrix entries.

### Examples

```
>>> from scipy.sparse import csr_matrix, find
>>> A = csr_matrix([[7.0, 8.0, 0],[0, 0, 9.0]])
>>> find(A)
(array([0, 0, 1], dtype=int32), array([0, 1, 2], dtype=int32), array([ 7.,  8.,  9.]))
```

Identifying sparse matrices:

| <code>maximum_bipartite_matching(graph[, perm_type])</code>   | Returns an array of row or column permutations that makes the diagonal of a matrix |
| <code>structural_rank(graph)</code>                           | Compute the structural rank of a graph (matrix) with a given sparsity pattern      |
| <code>NegativeCycleError</code>                               |                                                                                    |

## Contents

`scipy.sparse.csgraph.connected_components` (*csgraph*, *directed=True*, *connection='weak'*, *return\_labels=True*)

Analyze the connected components of a sparse graph

New in version 0.11.0.

**Parameters**

- csgraph** : array\_like or sparse matrix  
The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- connection** : str, optional  
['weak'|'strong']. For directed graphs, the type of connection to use. Nodes i and j are strongly connected if a path exists both from i to j and from j to i. Nodes i and j are weakly connected if only one of these paths exists. If directed == False, this keyword is not referenced.
- return\_labels** : bool, optional  
If True (default), then return the labels for each of the connected components.

**Returns**

- n\_components: int  
The number of connected components.
- labels: ndarray  
The length-N array of labels of the connected components.

## References

[R14]

`scipy.sparse.csgraph.laplacian` (*csgraph*, *normed=False*, *return\_diag=False*, *use\_out\_degree=False*)

Return the Laplacian matrix of a directed graph.

**Parameters**

- csgraph** : array\_like or sparse matrix, 2 dimensions  
compressed-sparse graph, with shape (N, N).
- normed** : bool, optional

If True, then compute normalized Laplacian.

**return\_diag** : bool, optional  
If True, then also return an array related to vertex degrees.

**use\_out\_degree** : bool, optional  
If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns** **lap** : ndarray or sparse matrix  
The N x N laplacian matrix of csgraph. It will be a numpy array (dense) if the input was dense, or a sparse matrix otherwise.

**diag** : ndarray, optional  
The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

### Notes

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

### Examples

```
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```

`scipy.sparse.csgraph.shortest_path(csgraph, method='auto', directed=True, return_predecessors=False, unweighted=False, overwrite=False, indices=None)`

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters** **csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.

**method** : string ['auto'|'FW'|'D'], optional  
Algorithm to use for shortest paths. Options are:

- 'auto'** – (default) select the best among 'FW', 'D', 'BF', or 'J' based on the input data.
- 'FW'** – *Floyd-Warshall algorithm. Computational cost is approximately  $O[N^3]$ . The input csgraph will be converted to a dense representation.*
- 'D'** – *Dijkstra's algorithm with Fibonacci heaps. Computational cost is approximately  $O[N(N*k + N*\log(N))]$ , where k is the average*

number of connected edges per node. The input csgraph will be converted to a csr representation.

**‘BF’ – Bellman-Ford algorithm.** *This algorithm can be used when*

*weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately  $O[N(N^2 k)]$ , where  $k$  is the average number of connected edges per node. The input csgraph will be converted to a csr representation.*

**‘J’ – Johnson’s algorithm.** *Like the Bellman-Ford algorithm,*

*Johnson’s algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra’s algorithm for faster computation.*

**directed** : bool, optional

If True (default), then find the shortest path on a directed graph: only move from point  $i$  to point  $j$  along paths  $csgraph[i, j]$ . If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along  $csgraph[i, j]$  or  $csgraph[j, i]$

**return\_predecessors** : bool, optional

If True, return the size  $(N, N)$  predecessor matrix

**unweighted** : bool, optional

If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**overwrite** : bool, optional

If True, overwrite csgraph with the result. This applies only if method == ‘FW’ and csgraph is a dense,  $c$ -ordered array with dtype=float64.

**indices** : array\_like or int, optional

If specified, only compute the paths for the points at the given indices. Incompatible with method == ‘FW’.

**Returns**

**dist\_matrix** : ndarray

The  $N \times N$  matrix of distances between graph nodes.  $dist\_matrix[i,j]$  gives the shortest distance from point  $i$  to point  $j$  along the graph.

**predecessors** : ndarray

Returned only if return\_predecessors == True. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry predecessors[ $i, j$ ] gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then predecessors[ $i, j$ ] = -9999

**Raises**

**NegativeCycleError:**

if there are negative cycles in the graph

### Notes

As currently implemented, Dijkstra’s algorithm and Johnson’s algorithm do not work for graphs with direction-dependent distances when directed == False. i.e., if  $csgraph[i,j]$  and  $csgraph[j,i]$  are non-equal edges, method=‘D’ may yield an incorrect result.

`scipy.sparse.csgraph.dijkstra(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False, limit=np.inf)`

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

**Parameters**

- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of non-negative distances representing the input graph.
- directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.
- return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
- unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- limit** : float, optional  
The maximum distance to calculate, must be  $\geq 0$ . Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance  $> \text{limit}$ . For such pairs, the distance will be equal to `np.inf` (i.e., not connected).

**Returns**

- dist\_matrix** : ndarray  
New in version 0.14.0.  
The matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.
- predecessors** : ndarray  
Returned only if `return_predecessors == True`. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

### Notes

As currently implemented, Dijkstra's algorithm does not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are not equal and both are nonzero, setting `directed=False` will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford's algorithm or Johnson's algorithm.

`scipy.sparse.csgraph.floyd_warshall` (*csgraph*, *directed=True*, *return\_predecessors=False*, *unweighted=False*, *overwrite=False*)

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

**Parameters**

- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
- directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix

**unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**overwrite** : bool, optional  
If True, overwrite `csgraph` with the result. This applies only if `csgraph` is a dense, `C`-ordered array with `dtype=float64`.

**Returns** **dist\_matrix** : ndarray  
The  $N \times N$  matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point `i` to point `j` along the graph.

**predecessors** : ndarray  
Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row `i` of the predecessor matrix contains information on the shortest paths from point `i`: each entry `predecessors[i, j]` gives the index of the previous node in the path from point `i` to point `j`. If no path exists between point `i` and `j`, then `predecessors[i, j] = -9999`.

**Raises** **NegativeCycleError**:  
if there are negative cycles in the graph

`scipy.sparse.csgraph.bellman_ford(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)`

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra's algorithm may be faster.

New in version 0.11.0.

**Parameters** **csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The  $N \times N$  array of distances representing the input graph.

**directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point `i` to point `j` along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point `i` to `j` along `csgraph[i, j]` or `csgraph[j, i]`

**indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.

**return\_predecessors** : bool, optional  
If True, return the size  $(N, N)$  predecessor matrix

**unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns** **dist\_matrix** : ndarray  
The  $N \times N$  matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point `i` to point `j` along the graph.

**predecessors** : ndarray  
Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row `i` of the predecessor matrix contains information on the shortest paths from point `i`: each entry `predecessors[i, j]` gives the index of the previous node in the path from point `i` to point `j`. If no path exists between point `i` and `j`, then `predecessors[i, j] = -9999`.

**Raises** **NegativeCycleError**:  
if there are negative cycles in the graph

*Notes*

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

`scipy.sparse.csgraph.johnson` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using Johnson's algorithm.

Johnson's algorithm combines the Bellman-Ford algorithm and Dijkstra's algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, `dijkstra()` may be faster.

New in version 0.11.0.

- Parameters**
- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
  - directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`
  - indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.
  - return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
  - unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- Returns**
- dist\_matrix** : ndarray  
The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.
  - predecessors** : ndarray  
Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`
- Raises**
- NegativeCycleError**:  
if there are negative cycles in the graph

*Notes*

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

`scipy.sparse.csgraph.breadth_first_order` (*csgraph*, *i\_start*, *directed=True*, *return\_predecessors=True*)

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

- Parameters**
- csgraph** : array\_like or sparse matrix  
The N x N compressed sparse graph. The input `csgraph` will be converted to csr format for the calculation.
  - i\_start** : int

The index of starting node.

**directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.

**return\_predecessors** : bool, optional  
If True (default), then return the predecessor array (see below).

**Returns** **node\_array** : ndarray, one dimension  
The breadth-first list of nodes, starting with specified node. The length of `node_array` is the number of nodes reachable from the specified node.

**predecessors** : ndarray, one dimension  
Returned only if `return_predecessors` is True. The length-*N* list of predecessors of each node in a breadth-first tree. If node *i* is in the tree, then its parent is given by `predecessors[i]`. If node *i* is not in the tree (and for the parent node) then `predecessors[i] = -9999`.

```
scipy.sparse.csgraph.depth_first_order(csgraph, i_start, directed=True,
                                     return_predecessors=True)
```

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
The *N* x *N* compressed sparse graph. The input `csgraph` will be converted to csr format for the calculation.

**i\_start** : int  
The index of starting node.

**directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.

**return\_predecessors** : bool, optional  
If True (default), then return the predecessor array (see below).

**Returns** **node\_array** : ndarray, one dimension  
The breadth-first list of nodes, starting with specified node. The length of `node_array` is the number of nodes reachable from the specified node.

**predecessors** : ndarray, one dimension  
Returned only if `return_predecessors` is True. The length-*N* list of predecessors of each node in a breadth-first tree. If node *i* is in the tree, then its parent is given by `predecessors[i]`. If node *i* is not in the tree (and for the parent node) then `predecessors[i] = -9999`.

```
scipy.sparse.csgraph.breadth_first_tree(csgraph, i_start, directed=True)
```

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
The *N* x *N* matrix representing the compressed sparse graph. The input `csgraph` will be converted to csr format for the calculation.

**i\_start** : int  
The index of starting node.

**directed** : bool, optional  
 If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.

**Returns** **cstree** : csr matrix  
 The *N* x *N* directed compressed-sparse representation of the breadth-first tree drawn from `csgraph`, starting at the specified node.

### Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
    
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.

`scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)`

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
 The *N* x *N* matrix representing the compressed sparse graph. The input `csgraph` will be converted to `csr` format for the calculation.

**i\_start** : int  
 The index of starting node.

**directed** : bool, optional

**Returns** `cstree` : csr matrix  
 If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.  
 The N x N directed compressed-sparse representation of the depth- first tree drawn from `csgraph`, starting at the specified node.

**Examples**

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])
    
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

`scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)`

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

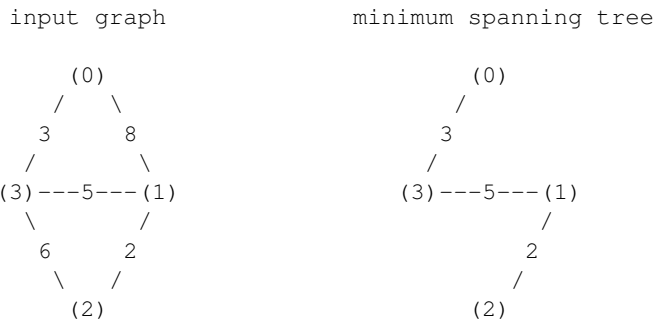

**Parameters** `csgraph` : array\_like or sparse matrix, 2 dimensions  
 The N x N matrix representing an undirected graph over N nodes (see notes below).  
`overwrite` : bool, optional  
 if true, then parts of the input graph will be overwritten for efficiency.  
**Returns** `span_tree` : csr matrix  
 The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

### Notes

This routine uses undirected graphs as input and output. That is, if `graph[i, j]` and `graph[j, i]` are both zero, then nodes `i` and `j` do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

### Examples

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

`scipy.sparse.csgraph.reverse_cuthill_mckee` (*graph*, *symmetric\_mode=False*)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix `A+A.T`. If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

**Parameters**

- graph** : sparse matrix  
Input sparse in CSC or CSR sparse matrix format.
- symmetric\_mode** : bool, optional  
Is input matrix guaranteed to be symmetric.

**Returns**

- perm** : ndarray  
Array of permuted row and column indices.

### Notes

New in version 0.15.0.

**References**

E. Cuthill and J. McKee, “Reducing the Bandwidth of Sparse Symmetric Matrices”, ACM ‘69 Proceedings of the 1969 24th national conference, (1969).

`scipy.sparse.csgraph.maximum_bipartite_matching` (*graph*, *perm\_type*='row')

Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.

Such a permutation is always possible provided that the matrix is nonsingular. This function looks at the structure of the matrix only. The input matrix will be converted to CSC matrix format if necessary.

**Parameters**    **graph** : sparse matrix  
                                 Input sparse in CSC format  
                                 **perm\_type** : str, {'row', 'column'}  
                                 Type of permutation to generate.  
**Returns**        **perm** : ndarray  
                                 Array of row or column permutations.

**Notes**

This function relies on a maximum cardinality bipartite matching algorithm based on a breadth-first search (BFS) of the underlying graph.

New in version 0.15.0.

**References**

`scipy.sparse.csgraph.structural_rank` (*graph*)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

**Parameters**    **graph** : sparse matrix  
                                 Input sparse matrix.  
**Returns**        **rank** : int  
                                 The structural rank of the sparse graph.  
                                 New in version 0.19.0.

`scipy.sparse.csgraph.construct_dist_matrix` (*graph*, *predecessors*, *directed*=True, *null\_value*=np.inf)

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

**Parameters**

- graph** : array\_like or sparse  
The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.
- predecessors** : array\_like  
The N x N matrix of predecessors of each node (see Notes below).
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- null\_value** : bool, optional  
value to use for distances between unconnected nodes. Default is `np.inf`

**Returns**

- dist\_matrix** : ndarray  
The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

**Notes**

The predecessor matrix is of the form returned by `graph_shortest_path`. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

`scipy.sparse.csgraph.csgraph_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*)

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

**Parameters**

- graph** : array\_like  
Input graph. Shape should be (n\_nodes, n\_nodes).
- null\_value** : float or None (optional)  
Value that denotes non-edges in the graph. Default is zero.
- infinity\_null** : bool  
If True (default), then infinite entries (both positive and negative) are treated as null edges.
- nan\_null** : bool  
If True (default), then NaN entries are treated as non-edges

**Returns**

- csgraph** : csr\_matrix  
Compressed sparse representation of graph,

`scipy.sparse.csgraph.csgraph_from_masked` (*graph*)

Construct a CSR-format graph from a masked array.

New in version 0.11.0.

**Parameters**

- graph** : MaskedArray  
Input graph. Shape should be (n\_nodes, n\_nodes).

**Returns**

- csgraph** : csr\_matrix  
Compressed sparse representation of graph,

`scipy.sparse.csgraph.csgraph_masked_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*, *copy=True*)

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

**Parameters**

- graph** : array\_like

Input graph. Shape should be (n\_nodes, n\_nodes).

**null\_value** : float or None (optional)  
Value that denotes non-edges in the graph. Default is zero.

**infinity\_null** : bool  
If True (default), then infinite entries (both positive and negative) are treated as null edges.

**nan\_null** : bool  
If True (default), then NaN entries are treated as non-edges

**Returns** **csgraph** : MaskedArray  
masked array representation of graph

`scipy.sparse.csgraph.csgraph_to_dense(csgraph, null_value=0)`  
Convert a sparse graph representation to a dense representation

New in version 0.11.0.

**Parameters** **csgraph** : csr\_matrix, csc\_matrix, or lil\_matrix  
Sparse representation of a graph.

**null\_value** : float, optional  
The value used to indicate null edges in the dense representation. Default is 0.

**Returns** **graph** : ndarray  
The dense representation of the sparse graph.

### Notes

For normal sparse graph representations, calling `csgraph_to_dense` with `null_value=0` produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in `scipy.sparse` will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default `scipy.sparse` behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
```

```
[0, 0])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[ inf,  0.],
       [ inf,  inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

`scipy.sparse.csgraph.csgraph_to_masked(csgraph)`  
 Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

**Parameters** **csgraph** : csr\_matrix, csc\_matrix, or lil\_matrix  
 Sparse representation of a graph.  
**Returns** **graph** : MaskedArray  
 The masked dense representation of the sparse graph.

`scipy.sparse.csgraph.reconstruct_path(csgraph, predecessors, directed=True)`  
 Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

**Parameters** **csgraph** : array\_like or sparse matrix  
 The N x N matrix representing the directed or undirected graph from which the predecessors are drawn.  
**predecessors** : array\_like, one dimension  
 The length-N array of indices of predecessors for the tree. The index of the parent of node i is given by predecessors[i].  
**directed** : bool, optional  
 If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].  
**Returns** **cstree** : csr matrix  
 The N x N directed compressed-sparse representation of the tree drawn from csgraph which is encoded by the predecessor list.

**Graph Representations** This module uses graphs which are stored in a matrix format. A graph with N nodes can be represented by an (N x N) adjacency matrix G. If there is a connection from node i to node j, then  $G[i, j] = w$ , where w is the weight of the connection. For nodes i and j which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by  $G[i, j] = 0$ , infinity, or NaN.
- for dense masked representations (of type `np.ma.MaskedArray`), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```
>>> G_dense = np.array([[0, 2, 1],
...                    [2, 0, 0],
...                    [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```
>>> G2_data = np.array([[np.inf, 2, 0 ],
...                    [2, np.inf, np.inf],
...                    [0, np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2.,  0.,  2.,  0.]
```

Here we have used a utility routine from the `csgraph` submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

**Directed vs. Undirected** Matrices may represent either directed or undirected graphs. This is specified throughout the `csgraph` module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node  $i$  to node  $j$  can be accomplished over the edge  $G[i, j]$ , but not the edge  $G[j, i]$ . In a non-directed graph, traversal from node  $i$  to node  $j$  can be accomplished over either  $G[i, j]$  or  $G[j, i]$ . If both edges are not null, and the two have unequal weights, then the smaller of the two is used. Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to True or False. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either `scipy.sparse` representations (`csr`, `csc`, or `lil` format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

### Functions

|                                                              |                                                                     |
|--------------------------------------------------------------|---------------------------------------------------------------------|
| <code>bellman_ford(csgraph[, directed, indices, ...])</code> | Compute the shortest path lengths using the Bellman-Ford algorithm. |
| <code>breadth_first_order(csgraph, i_start[, ...])</code>    | Return a breadth-first ordering starting with specified node.       |

**Sparse linear algebra (`scipy.sparse.linalg`)**

|                                           |                                                        |
|-------------------------------------------|--------------------------------------------------------|
| <code>LinearOperator(dtype, shape)</code> | Common interface for performing matrix vector products |
| <code>aslinearoperator(A)</code>          | Return A as a <code>LinearOperator</code> .            |

**Abstract linear operators**

**class** `scipy.sparse.linalg.LinearOperator` (*dtype, shape*)

Common interface for performing matrix vector products

Many iterative methods (e.g. `cg`, `gmres`) do not need to know the individual entries of a matrix to solve a linear system  $Ax=b$ . Such solvers only require the computation of matrix vector products,  $A*v$  where  $v$  is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete `LinearOperator`, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods `_matvec` and `_matmat`, and the attributes/properties `shape` (pair of integers) and `dtype` (may be `None`). It may call the `__init__` on this class to have these attributes validated. Implementing `_matvec` automatically implements `_matmat` (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement `_rmatvec` or `_adjoint` to implement the Hermitian adjoint (conjugate transpose). As with `_matvec` and `_matmat`, implementing either `_rmatvec` or `_adjoint` implements the other automatically. Implementing `_adjoint` is preferable; `_rmatvec` is mostly there for backwards compatibility.

**Parameters**

- shape** : tuple  
Matrix dimensions (M,N).
- matvec** : callable f(v)  
Returns returns  $A * v$ .
- rmatvec** : callable f(v)  
Returns  $A^H * v$ , where  $A^H$  is the conjugate transpose of A.
- matmat** : callable f(V)  
Returns  $A * V$ , where V is a dense matrix with dimensions (N,K).
- dtype** : dtype  
Data type of the matrix.

Construct LinearOperators

### Notes

The user-defined `matvec()` function must properly handle the case where `v` has shape `(N,)` as well as the `(N,1)` case. The shape of the return type is handled internally by `LinearOperator`.

`LinearOperator` instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite `LinearOperator`, that defers linear operations to the original operators and combines the results.

### Examples

```
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([ 2.,  3.])
>>> A * np.ones(2)
array([ 2.,  3.])
```

### Attributes

|      |                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------|
| args | (tuple) For linear operators describing products etc. of other linear operators, the operands of the binary operation. |
|------|------------------------------------------------------------------------------------------------------------------------|

### Methods

|                          |                                                |
|--------------------------|------------------------------------------------|
| <code>__call__(x)</code> |                                                |
| <code>adjoint()</code>   | Hermitian adjoint.                             |
| <code>dot(x)</code>      | Matrix-matrix or matrix-vector multiplication. |
| <code>matmat(X)</code>   | Matrix-matrix multiplication.                  |
| <code>matvec(x)</code>   | Matrix-vector multiplication.                  |

Table 5.183 – continued from previous page

|                          |                                       |
|--------------------------|---------------------------------------|
| <code>rmatvec(x)</code>  | Adjoint matrix-vector multiplication. |
| <code>transpose()</code> | Transpose this linear operator.       |

`LinearOperator.__call__(x)`

`LinearOperator.adjoint()`

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

**Returns** **A\_H**: LinearOperator  
Hermitian adjoint of self.

`LinearOperator.dot(x)`

Matrix-matrix or matrix-vector multiplication.

**Parameters** **x**: array\_like

**Returns** **Ax**: array 1-d or 2-d array, representing a vector or matrix.

1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

`LinearOperator.matmat(X)`

Matrix-matrix multiplication.

Performs the operation  $y=A*X$  where A is an  $M \times N$  linear operator and X dense  $N \times K$  matrix or ndarray.

**Parameters** **X**: {matrix, ndarray}

**Returns** **Y**: {matrix, ndarray} An array with shape (N,K).

A matrix or ndarray with shape (M,K) depending on the type of the X argument.

**Notes**

This matmat wraps any user-specified matmat routine or overridden `_matmat` method to ensure that y has the correct type.

`LinearOperator.matvec(x)`

Matrix-vector multiplication.

Performs the operation  $y=A*x$  where A is an  $M \times N$  linear operator and x is a column vector or 1-d array.

**Parameters** **x**: {matrix, ndarray}

**Returns** **y**: {matrix, ndarray} An array with shape (N,) or (N,1).

A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

**Notes**

This matvec wraps the user-specified matvec routine or overridden `_matvec` method to ensure that y has the correct shape and type.

`LinearOperator.rmatvec(x)`

Adjoint matrix-vector multiplication.

Performs the operation  $y = A^H * x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array.

**Parameters**  $x$  : {matrix, ndarray}

**Returns**  $y$  : {matrix, ndarray} An array with shape (M,) or (M,1).

A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the  $x$  argument.

**Notes**

This rmatvec wraps the user-specified rmatvec routine or overridden `_rmatvec` method to ensure that  $y$  has the correct shape and type.

`LinearOperator.transpose()`

Transpose this linear operator.

Returns a `LinearOperator` that represents the transpose of this one. Can be abbreviated `self.T` instead of `self.transpose()`.

`scipy.sparse.linalg.aslinearoperator(A)`

Return  $A$  as a `LinearOperator`.

' $A$ ' may be any of the following types:

- ndarray
- matrix
- sparse matrix (e.g. `csr_matrix`, `lil_matrix`, etc.)
- `LinearOperator`
- An object with `.shape` and `.matvec` attributes

See the `LinearOperator` documentation for additional information.

**Examples**

```
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1,2,3],[4,5,6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

---

|                                                                |                                                              |
|----------------------------------------------------------------|--------------------------------------------------------------|
| <code>inv(A)</code>                                            | Compute the inverse of a sparse matrix                       |
| <code>expm(A)</code>                                           | Compute the matrix exponential using Pade approximation.     |
| <code>expm_multiply(A, B[, start, stop, num, endpoint])</code> | Compute the action of the matrix exponential of $A$ on $B$ . |

---

**Matrix Operations**

`scipy.sparse.linalg.inv(A)`

Compute the inverse of a sparse matrix

**Parameters**  $A$  : (M,M) ndarray or sparse matrix

**Returns**  $A_{inv}$  : (M,M) ndarray or sparse matrix  
 square matrix to be inverted  
 inverse of  $A$

**Notes**

This computes the sparse inverse of  $A$ . If the inverse of  $A$  is expected to be non-sparse, it will likely be faster to convert  $A$  to dense and use `scipy.linalg.inv`.

New in version 0.12.0.

`scipy.sparse.linalg.expm(A)`

Compute the matrix exponential using Pade approximation.

**Parameters** **A** : (M,M) array\_like or sparse matrix  
**Returns** **expA** : (M,M) <sup>2D Array or Matrix (sparse or dense) to be exponentiated</sup>  
 ndarray  
 Matrix exponential of A

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[R21]

`scipy.sparse.linalg.expm_multiply(A, B, start=None, stop=None, num=None, endpoint=None)`

Compute the action of the matrix exponential of A on B.

**Parameters** **A** : transposable linear operator  
 The operator whose exponential is of interest.  
**B** : ndarray  
 The matrix or vector to be multiplied by the matrix exponential of A.  
**start** : scalar, optional  
 The starting time point of the sequence.  
**stop** : scalar, optional  
 The end time point of the sequence, unless *endpoint* is set to False. In that case, the sequence consists of all but the last of *num* + 1 evenly spaced time points, so that *stop* is excluded. Note that the step size changes when *endpoint* is False.  
**num** : int, optional  
 Number of time points to use.  
**endpoint** : bool, optional  
 If True, *stop* is the last time point. Otherwise, it is not included.  
**Returns** **expm\_A\_B** : ndarray  
 The result of the action  $e^{t_k A} B$ .

**Notes**

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of `numpy.linspace`.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, `expm_A_B[0]` will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

---

**Matrix norms**

`scipy.sparse.linalg.norm(x, ord=None, axis=None)`

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the `ord` parameter.

**Parameters**

- x** : a sparse matrix  
Input sparse matrix.
- ord** : {non-zero int, inf, -inf, 'fro'}, optional  
Order of the norm (see table under `Notes`). `inf` means numpy's `inf` object.
- axis** : {int, 2-tuple of ints, None}, optional  
If `axis` is an integer, it specifies the axis of `x` along which to compute the vector norms. If `axis` is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If `axis` is `None` then either a vector norm (when `x` is 1-D) or a matrix norm (when `x` is 2-D) is returned.

**Returns**

- n** : float or ndarray

**Notes**

Some of the `ord` are not implemented because some associated functions like, `_multi_svd_norm`, are not yet available for sparse matrix.

This docstring is modified based on `numpy.linalg.norm`. <https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py>

The following norms can be calculated:

| ord   | norm for sparse matrices              |
|-------|---------------------------------------|
| None  | Frobenius norm                        |
| 'fro' | Frobenius norm                        |
| inf   | <code>max(sum(abs(x), axis=1))</code> |
| -inf  | <code>min(sum(abs(x), axis=1))</code> |
| 0     | <code>abs(x).sum(axis=axis)</code>    |
| 1     | <code>max(sum(abs(x), axis=0))</code> |
| -1    | <code>min(sum(abs(x), axis=0))</code> |
| 2     | Not implemented                       |
| -2    | Not implemented                       |
| other | Not implemented                       |

The Frobenius norm is given by [R34]:

$$\|A\|_F = [\sum_{i,j} \text{abs}(a_{i,j})^2]^{1/2}$$

**References**

[R34]

**Examples**

```
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[ -4,  -3,  -2],
       [ -1,   0,   1],
       [  2,   3,   4]])
```

```
>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```

`scipy.sparse.linalg.onenormest` (*A*, *t*=2, *itmax*=5, *compute\_v*=False, *compute\_w*=False)

Compute a lower bound of the 1-norm of a sparse matrix.

**Parameters**

- A** : ndarray or other linear operator  
A linear operator that can be transposed and that can produce matrix products.
- t** : int, optional  
A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.
- itmax** : int, optional  
Use at most this many iterations.
- compute\_v** : bool, optional  
Request a norm-maximizing linear operator input vector if True.
- compute\_w** : bool, optional  
Request a norm-maximizing linear operator output vector if True.

**Returns**

- est** : float  
An underestimate of the 1-norm of the sparse matrix.
- v** : ndarray, optional  
The vector such that  $\|Av\|_1 == est*\|v\|_1$ . It can be thought of as an input to the linear operator that gives an output with particularly large norm.
- w** : ndarray, optional  
The vector  $Av$  which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

**Notes**

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about 4t matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

| <code>factorized(A)</code>                          | Return a function for solving a sparse linear system, with $A$ pre-factorized. |
| <code>MatrixRankWarning</code>                      |                                                                                |
| <code>use_solver(**kwargs)</code>                   | Select default sparse direct solver to be used.                                |

`scipy.sparse.linalg.spsolve(A, b, permc_spec=None, use_umfpack=True)`

Solve the sparse linear system  $Ax=b$ , where  $b$  may be a vector or a matrix.

**Parameters**

- A** : ndarray or sparse matrix  
The square matrix  $A$  will be converted into CSC or CSR form
- b** : ndarray or sparse matrix  
The matrix or vector representing the right hand side of the equation. If a vector, `b.shape` must be  $(n,)$  or  $(n, 1)$ .
- permc\_spec** : str, optional  
How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
  - NATURAL: natural ordering.
  - MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
  - MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T+A$ .
  - COLAMD: approximate minimum degree column ordering
- use\_umfpack** : bool, optional  
if True (default) then use umfpack for the solution. This is only referenced if  $b$  is a vector and `scikit-umfpack` is installed.

**Returns**

- x** : ndarray or sparse matrix  
the solution of the sparse linear equation. If  $b$  is a vector, then  $x$  is a vector of size `A.shape[1]` If  $b$  is a matrix, then  $x$  is a matrix of size  $(A.shape[1], b.shape[1])$

**Notes**

For solving the matrix expression  $AX = B$ , this solver assumes the resulting matrix  $X$  is sparse, as is often the case for very sparse inputs. If the resulting  $X$  is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting  $A$  to a dense matrix and using `scipy.linalg.solve` or its variants.

`scipy.sparse.linalg.spsolve_triangular(A, b, lower=True, overwrite_A=False, overwrite_b=False)`

Solve the equation  $Ax = b$  for  $x$ , assuming  $A$  is a triangular matrix.

**Parameters**

- A** : (M, M) sparse matrix  
A sparse square triangular matrix. Should be in CSR format.
- b** : (M,) or (M, N) array\_like  
Right-hand side matrix in  $Ax = b$
- lower** : bool, optional  
Whether  $A$  is a lower or upper triangular matrix. Default is lower triangular matrix.
- overwrite\_A** : bool, optional  
Allow changing  $A$ . The indices of  $A$  are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.
- overwrite\_b** : bool, optional  
Allow overwriting data in  $b$ . Enabling gives a performance gain. Default is False.

**Returns**

- x** : (M,) or (M, N) ndarray  
Solution to the system  $Ax = b$ . Shape of return matches shape of  $b$ .

**Raises**

- LinAlgError**  
If  $A$  is singular or not triangular.

**ValueError**

If shape of  $A$  or shape of  $b$  do not match the requirements.

*Notes*

New in version 0.19.0.

`scipy.sparse.linalg.factorized(A)`

Return a function for solving a sparse linear system, with  $A$  pre-factorized.

**Parameters**  $A$  : (N, N) array\_like

**Returns** `solve` : callable <sup>Input.</sup>

To solve the linear system of equations given in  $A$ , the `solve` callable should be passed an ndarray of shape (N,).

*Examples*

```
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[ 3. ,  2. , -1. ],
...              [ 2. , -2. ,  4. ],
...              [-1. ,  0.5, -1. ]])
>>> solve = factorized(A) # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1) # Uses the LU factors.
array([ 1., -2., -2.])
```

**exception** `scipy.sparse.linalg.MatrixRankWarning`

`scipy.sparse.linalg.use_solver(**kwargs)`

Select default sparse direct solver to be used.

**Parameters** `useUmfpack` : bool, optional

Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True

*Notes*

The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing `useUmfpack = False`, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass `assumeSortedIndices=True` to gain some speed.

| <code>qmr(A, b[, x0, tol, maxiter, xtype, M1, M2, ...])</code> | Use Quasi-Minimal Residual iteration to solve $Ax = b$ .          |

---

`scipy.sparse.linalg.bicg(A, b, x0=None, tol=1e-05, maxiter=None, xtype=None, M=None, callback=None)`

Use BIConjugate Gradient iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}  
 The real or complex N-by-N matrix of the linear system. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).  
 The converged solution.

**info** : integer  
**Provides convergence information:**  
 0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}  
 Starting guess for the solution.

**tol** : float  
 Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer  
 Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}  
 Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function  
 User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**xtype** : {'f','d','F','D'}  
 This parameter is deprecated – avoid using it.  
 The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If A does not have a `typecode` method then it will compute `A.matvec(x0)` to get a typecode. To save the extra computation when A does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

`scipy.sparse.linalg.bicgstab(A, b, x0=None, tol=1e-05, maxiter=None, xtype=None, M=None, callback=None)`

Use BIConjugate Gradient STABILized iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}  
 The real or complex N-by-N matrix of the linear system.

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).  
 The converged solution.

**info** : integer  
**Provides convergence information:**  
 0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}  
 Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**xtype** : {'f','d','F','D'}

This parameter is deprecated – avoid using it.

The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If A does not have a `typecode` method then it will compute `A.matvec(x0)` to get a `typecode`. To save the extra computation when A does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

`scipy.sparse.linalg.cg(A, b, x0=None, tol=1e-05, maxiter=None, xtype=None, M=None, callback=None)`

Use Conjugate Gradient iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system. A must represent a hermitian, positive definite matrix.

**b** : {array, matrix}

Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

**x** : {array, matrix}

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**xtype** : {'f','d','F','D'}

This parameter is deprecated – avoid using it.

The type of the result. If `None`, then it will be determined from `A.dtype.char` and `b`. If `A` does not have a `typecode` method then it will compute `A.matvec(x0)` to get a `typecode`. To save the extra computation when `A` does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

`scipy.sparse.linalg.cg`s (`A`, `b`, `x0=None`, `tol=1e-05`, `maxiter=None`, `xtype=None`, `M=None`, `callback=None`)

Use Conjugate Gradient Squared iteration to solve  $Ax = b$ .

**Parameters** `A` : {sparse matrix, dense matrix, LinearOperator}

The real-valued N-by-N matrix of the linear system.

`b` : {array, matrix}

**Returns** `x` : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

`info` : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

`x0` : {array, matrix}

Starting guess for the solution.

`tol` : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below `tol`.

`maxiter` : integer

Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.

`M` : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for `A`. The preconditioner should approximate the inverse of `A`. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

`callback` : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

`xtype` : {'f','d','F','D'}

This parameter is deprecated – avoid using it.

The type of the result. If `None`, then it will be determined from `A.dtype.char` and `b`. If `A` does not have a `typecode` method then it will compute `A.matvec(x0)` to get a `typecode`. To save the extra computation when `A` does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

`scipy.sparse.linalg.gmres` (`A`, `b`, `x0=None`, `tol=1e-05`, `restart=None`, `maxiter=None`, `xtype=None`, `M=None`, `callback=None`, `restrt=None`)

Use Generalized Minimal RESidual iteration to solve  $Ax = b$ .

**Parameters** `A` : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system.

`b` : {array, matrix}

**Returns** `x` : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

**info** : int

The converged solution.

*Provides convergence information:*

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

*Other Parameters*

**x0** : {array, matrix}

Starting guess for the solution (a vector of zeros by default).

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**restart** : int, optional

Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

**maxiter** : int, optional

Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**xtype** : {'f','d','F','D'}

This parameter is DEPRECATED — avoid using it.  
The type of the result. If None, then it will be determined from A.dtype.char and b. If A does not have a typecode method then it will compute A.matvec(x0) to get a typecode. To save the extra computation when A does not have a typecode attribute use xtype=0 for the same type as b or use xtype='f','d','F',or 'D'. This parameter has been superseded by LinearOperator.

**M** : {sparse matrix, dense matrix, LinearOperator}

Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

**callback** : function

User-supplied function to call after each iteration. It is called as callback(rk), where rk is the current residual vector.

**restrt** : int, optional

DEPRECATED - use *restart* instead.

**See also:**

[LinearOperator](#)

*Notes*

A preconditioner, P, is chosen such that P is close to A but easy to solve for. The preconditioner parameter required by this routine is  $M = P^{-1}$ . The inverse should preferably not be calculated explicitly. Rather, use the following template to produce M:

```
# Construct a linear operator that computes P^-1 * x.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

`scipy.sparse.linalg.lgmres` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=1000*, *M=None*, *callback=None*,  
*inner\_m=30*, *outer\_k=3*, *outer\_v=None*, *store\_outer\_Av=True*)  
 Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm [R24] [R25] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}  
 The real or complex N-by-N matrix of the linear system.
- b** : {array, matrix}  
 Right hand side of the linear system. Has shape (N,) or (N,1).
- x0** : {array, matrix}  
 Starting guess for the solution.
- tol** : float, optional  
 Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : int, optional  
 Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}, optional  
 Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** : function, optional  
 User-supplied function to call after each iteration. It is called as `callback(xk)`, where *xk* is the current solution vector.
- inner\_m** : int, optional  
 Number of inner GMRES iterations per each outer iteration.
- outer\_k** : int, optional  
 Number of vectors to carry between inner GMRES iterations. According to [R24], good values are in the range of 1...3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.
- outer\_v** : list of tuples, optional  
 List containing tuples (*v*, *Av*) of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element *Av* can be *None* if the matrix-vector product should be re-evaluated. This parameter is modified in-place by `lgmres`, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.
- store\_outer\_Av** : bool, optional  
 Whether LGMRES should store also  $A*v$  in addition to vectors *v* in the *outer\_v* list. Default is True.

**Returns**

- x** : array or matrix  
 The converged solution.
- info** : int  
 Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown

### Notes

The LGMRES algorithm [R24] [R25] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements

by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the *outer\_v* argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

[R24], [R25]

`scipy.sparse.linalg.minres` (*A*, *b*, *x0=None*, *shift=0.0*, *tol=1e-05*, *maxiter=None*, *xtype=None*, *M=None*, *callback=None*, *show=False*, *check=False*)

Use MINimum RESidual iteration to solve  $Ax=b$

MINRES minimizes  $\text{norm}(A*x - b)$  for a real symmetric matrix *A*. Unlike the Conjugate Gradient method, *A* can be indefinite or singular.

If *shift* != 0 then the method solves  $(A - \text{shift}*I)x = b$

**Parameters** *A* : {sparse matrix, dense matrix, LinearOperator}  
 The real symmetric N-by-N matrix of the linear system

*b* : {array, matrix}

**Returns** *x* : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}  
 Starting guess for the solution.

**tol** : float  
 Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer  
 Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}  
 Preconditioner for *A*. The preconditioner should approximate the inverse of *A*. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function  
 User-supplied function to call after each iteration. It is called as `callback(xk)`, where *xk* is the current solution vector.

**xtype** : {'f','d','F','D'}  
 This parameter is deprecated – avoid using it.  
 The type of the result. If *None*, then it will be determined from *A.dtype.char* and *b*. If *A* does not have a `dtype` method then it will compute `A.matvec(x0)` to get a `dtype`. To save the extra computation when *A* does not have a `dtype` attribute use `xtype=0` for the same type as *b* or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

*Notes*

THIS FUNCTION IS EXPERIMENTAL AND SUBJECT TO CHANGE!

`scipy.sparse.linalg.qmr(A, b, x0=None, tol=1e-05, maxiter=None, xtype=None, M1=None, M2=None, callback=None)`

Use Quasi-Minimal Residual iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}  
 The real-valued N-by-N matrix of the linear system. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).  
 The converged solution.

**info** : integer

*Provides convergence information:*

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

*Other Parameters*

**x0** : {array, matrix}  
 Starting guess for the solution.

**tol** : float  
 Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer  
 Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M1** : {sparse matrix, dense matrix, LinearOperator}  
 Left preconditioner for A.

**M2** : {sparse matrix, dense matrix, LinearOperator}  
 Right preconditioner for A. Used together with the left preconditioner M1. The matrix  $M1 * A * M2$  should have better conditioned than A alone.

**callback** : function  
 User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**xtype** : {'f','d','F','D'}  
 This parameter is DEPRECATED – avoid using it.  
 The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If A does not have a `typecode` method then it will compute `A.matvec(x0)` to get a `typecode`. To save the extra computation when A does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

---

`scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=100000000.0, iter_lim=None, show=False, calc_var=False)`  
 Find the least-squares solution to a large, sparse, linear system of equations.

The function solves  $Ax = b$  or  $\min ||b - Ax||^2$  or  $\min ||Ax - b||^2 + d^2 ||x||^2$ .

The matrix A may be square or rectangular (over-determined or under-determined), and may have any rank.

1. Unsymmetric equations -- solve  $A*x = b$
2. Linear least squares -- solve  $A*x = b$   
in the least-squares sense
3. Damped least squares -- solve  $\begin{pmatrix} A \\ \text{damp}*I \end{pmatrix} *x = \begin{pmatrix} b \\ 0 \end{pmatrix}$   
in the least-squares sense

**Parameters**

**A** : {sparse matrix, ndarray, LinearOperator}  
Representation of an m-by-n matrix. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : array\_like, shape (m,)   
Right-hand side vector b.

**damp** : float   
Damping coefficient.

**atol, btol** : float, optional   
Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final x will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of damp.)

**conlim** : float, optional   
Another stopping tolerance. `lsqr` terminates if an estimate of  $\text{cond}(A)$  exceeds *conlim*. For compatible systems  $Ax = b$ , *conlim* could be as large as 1.0e+12 (say). For least-squares problems, *conlim* should be less than 1.0e+8. Maximum precision can be obtained by setting `atol = btol = conlim = zero`, but the number of iterations may then be excessive.

**iter\_lim** : int, optional   
Explicit limitation on number of iterations (for safety).

**show** : bool, optional   
Display an iteration log.

**calc\_var** : bool, optional   
Whether to estimate diagonals of  $(A^T A + \text{damp}^2 * I)^{-1}$ .

**Returns**

**x** : ndarray of float   
The final solution.

**istop** : int   
Gives the reason for termination. 1 means x is an approximate solution to  $Ax = b$ . 2 means x approximately solves the least-squares problem.

**itn** : int   
Iteration number upon termination.

**r1norm** : float   
 $\text{norm}(r)$ , where  $r = b - Ax$ .

**r2norm** : float

```

        sqrt( norm(r)^2 + damp^2 * norm(x)^2 ). Equal to rInorm
        if damp == 0.
anorm : float
        Estimate of Frobenius norm of  $Abar = \begin{bmatrix} A \\ damp * I \end{bmatrix}$ .
acond : float
        Estimate of cond(Abar).
arnorm : float
        Estimate of norm(A' * r - damp^2 * x).
xnorm : float
        norm(x)
var : ndarray of float
        If calc_var is True, estimates all diagonals of  $(A' A)^{-1}$  (if damp == 0) or more generally  $(A' A + damp^2 * I)^{-1}$ . This is well defined if A has full column rank or damp > 0. (Not sure what var means if rank(A) < n and damp = 0.)
    
```

### Notes

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of A should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of A is very small or large compared to the other rows of A, the corresponding row of (A b) should be scaled up or down.

In problems 1 and 2, the solution x is easily recovered following column-scaling. Unless better information is known, the nonzero columns of A should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if damp is nonzero. However, the value of damp should be assigned only after attention has been paid to the scaling of A.

The parameter damp is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter acond, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate  $x_0$  is known and if `damp == 0`, one could proceed as follows:

1. Compute a residual vector  $r_0 = b - A * x_0$ .
2. Use LSQR to solve the system  $A * dx = r_0$ .
3. Add the correction dx to obtain a final solution  $x = x_0 + dx$ .

This requires that  $x_0$  be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes  $k_1$  iterations to solve  $A * x = b$  and  $k_2$  iterations to solve  $A * dx = r_0$ . If  $x_0$  is “good”, `norm(r0)` will be smaller than `norm(b)`. If the same stopping tolerances `atol` and `btol` are used for each system,  $k_1$  and  $k_2$  will be similar, but the final solution  $x_0 + dx$  should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value `btol` is suitable for  $A * x = b$ , the larger value `btol * norm(b) / norm(r0)` should be suitable for  $A * dx = r_0$ .

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system  $M * x = b$  efficiently, where M approximates A in some helpful way (e.g. M - A has low rank or its elements are small relative to those of A), LSQR may converge more rapidly on the system  $A * M(\text{inverse}) * z = b$ , after which x can be recovered by solving  $M * x = z$ .

If A is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (cg) and/or SYMMLQ. SYMMLQ is an implementation of symmetric cg that applies to any symmetric A and will converge more rapidly than LSQR. If A is positive definite, there are other implementations of symmetric cg that require slightly less work per iteration than SYMMLQ (but will take the same number of iterations).

**References**

[R31], [R32], [R33]

`scipy.sparse.linalg.lsmr(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False)`

Iterative solver for least-squares problems.

`lsmr` solves the system of linear equations  $Ax = b$ . If the system is inconsistent, it solves the least-squares problem  $\min \|b - Ax\|_2$ .  $A$  is a rectangular matrix of dimension  $m$ -by- $n$ , where all cases are allowed:  $m = n$ ,  $m > n$ , or  $m < n$ .  $B$  is a vector of length  $m$ . The matrix  $A$  may be dense or sparse (usually sparse).

**Parameters** **A** : {matrix, sparse matrix, ndarray, LinearOperator}

Matrix  $A$  in the linear system.

**b** : array\_like, shape (m,)

Vector  $b$  in the linear system.

**damp** : float

Damping factor for regularized least-squares. `lsmr` solves the regularized least-squares problem:

$$\min \| (b - (A) x) \|_2 + \text{damp} \| (0) \quad (\text{damp} * I) \|_2$$

where `damp` is a scalar. If `damp` is `None` or `0`, the system is solved without regularization.

**atol, btol** : float, optional

Stopping tolerances. `lsmr` continues iterations until a certain backward error estimate is smaller than some quantity depending on `atol` and `btol`. Let  $r = b - Ax$  be the residual vector for the current approximate solution  $x$ . If  $Ax = b$  seems to be consistent, `lsmr` terminates when  $\text{norm}(r) \leq \text{atol} * \text{norm}(A) * \text{norm}(x) + \text{btol} * \text{norm}(b)$ . Otherwise, `lsmr` terminates when  $\text{norm}(A^T r) \leq \text{atol} * \text{norm}(A) * \text{norm}(r)$ . If both tolerances are  $1.0e-6$  (say), the final  $\text{norm}(r)$  should be accurate to about 6 digits. (The final  $x$  will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of `LAMBDA`.) If `atol` or `btol` is `None`, a default value of  $1.0e-6$  will be used. Ideally, they should be estimates of the relative error in the entries of  $A$  and  $B$  respectively. For example, if the entries of  $A$  have 7 correct digits, set `atol` =  $1e-7$ . This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

**conlim** : float, optional

`lsmr` terminates if an estimate of  $\text{cond}(A)$  exceeds `conlim`. For compatible systems  $Ax = b$ , `conlim` could be as large as  $1.0e+12$  (say). For least-squares problems, `conlim` should be less than  $1.0e+8$ . If `conlim` is `None`, the default value is  $1e+8$ . Maximum precision can be obtained by setting `atol` = `btol` = `conlim` = `0`, but the number of iterations may then be excessive.

**maxiter** : int, optional

`lsmr` terminates if the number of iterations reaches `maxiter`. The default is `maxiter` =  $\min(m, n)$ . For ill-conditioned systems, a larger value of `maxiter` may be needed.

**show** : bool, optional

Print iterations logs if `show=True`.

**Returns**

**x** : ndarray of float

Least-square solution returned.

**istop** : int

`istop` gives the reason for stopping:

`istop` = 0 means  $x=0$  is a solution.  
 = 1 means  $x$  is an approximate solution to  $A*x = B$ , according to `atol` and `btol`.  
 = 2 means  $x$  approximately solves the least-squares problem according to `atol`.  
 = 3 means  $\text{COND}(A)$  seems to be greater than `CONLIM`.  
 = 4 is the same as 1 with `atol = btol = eps` (machine precision)  
 = 5 is the same as 2 with `atol = eps`.  
 = 6 is the same as 3 with `CONLIM = 1/eps`.  
 = 7 means ITN reached `maxiter` before the other stopping conditions were satisfied.

**itn** : int  
 Number of iterations used.  
**normr** : float  
 $\text{norm}(b-Ax)$   
**normar** : float  
 $\text{norm}(A^T (b - Ax))$   
**norma** : float  
 $\text{norm}(A)$   
**conda** : float  
 Condition number of A.  
**normx** : float  
 $\text{norm}(x)$

**Notes**

New in version 0.11.0.

|                                                           |                                                                                                                    |
|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>eigs(A[, k, M, sigma, which, v0, ncv, ...])</code>  | Find $k$ eigenvalues and eigenvectors of the square matrix $A$ .                                                   |
| <code>eigsh(A[, k, M, sigma, which, v0, ncv, ...])</code> | Find $k$ eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian square matrix $A$ . |
| <code>lobpcg(A, X[, B, M, Y, tol, maxiter, ...])</code>   | Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)                                            |

`scipy.sparse.linalg.eigs(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, OPpart=None)`

Find  $k$  eigenvalues and eigenvectors of the square matrix  $A$ .

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

If  $M$  is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$

**Parameters** **A** : ndarray, sparse matrix or LinearOperator  
 An array, sparse matrix, or LinearOperator representing the operation  $A * x$ , where  $A$  is a real or complex square matrix.  
**k** : int, optional  
 The number of eigenvalues and eigenvectors desired.  $k$  must be smaller than  $N-1$ . It is not possible to compute all eigenvectors of a matrix.

**M** : ndarray, sparse matrix or LinearOperator, optional

An array, sparse matrix, or LinearOperator representing the operation  $M \cdot x$  for the generalized eigenvalue problem

$$A \cdot x = w \cdot M \cdot x.$$

$M$  must represent a real, symmetric matrix if  $A$  is real, and must represent a complex, hermitian matrix if  $A$  is complex. For best results, the data type of  $M$  should be the same as that of  $A$ . Additionally:

If  $\sigma$  is None,  $M$  is positive definite

If  $\sigma$  is specified,  $M$  is positive semi-definite

If  $\sigma$  is None, `eigs` requires an operator to compute the solution of the linear equation  $M \cdot x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix  $M$ , or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator `Minv`, which gives  $x = \text{Minv} \cdot b = M^{-1} \cdot b$ .

**sigma** : real or complex, optional

Find eigenvalues near  $\sigma$  using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - \sigma \cdot M] \cdot x = b$ , where  $M$  is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices  $A$  &  $M$ , or via an iterative solver if either  $A$  or  $M$  is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives  $x = \text{OPinv} \cdot b = [A - \sigma \cdot M]^{-1} \cdot b$ . For a real matrix  $A$ , shift-invert can either be done in imaginary mode or real mode, specified by the parameter `OPpart` ('r' or 'i'). Note that when  $\sigma$  is specified, the keyword 'which' (below) refers to the shifted eigenvalues  $w'[i]$  where:

*If  $A$  is real and `OPpart` == 'r' (default),*

$$w'[i] = 1/2 \cdot [1/(w[i]-\sigma) + 1/(w[i]-\text{conj}(\sigma))].$$

*If  $A$  is real and `OPpart` == 'i',*

$$w'[i] = 1/2i \cdot [1/(w[i]-\sigma) - 1/(w[i]-\text{conj}(\sigma))].$$

*If  $A$  is complex,  $w'[i] = 1/(w[i]-\sigma)$ .*

**v0** : ndarray, optional

Starting vector for iteration. Default: random

**ncv** : int, optional

The number of Lanczos vectors generated  $ncv$  must be greater than  $k$ ; it is recommended that  $ncv > 2 \cdot k$ . Default:  $\min(n, \max(2 \cdot k + 1, 20))$

**which** : str, ['LM' | 'SM' | 'LR' | 'SR' | 'LI' | 'SI'], optional

Which  $k$  eigenvectors and eigenvalues to find:

'LM' : largest magnitude

'SM' : smallest magnitude

'LR' : largest real part

'SR' : smallest real part

'LI' : largest imaginary part

'SI' : smallest imaginary part

When  $\sigma \neq \text{None}$ , 'which' refers to the shifted eigenvalues  $w'[i]$  (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional

Maximum number of Arnoldi update iterations allowed Default:  $n \cdot 10$

**tol** : float, optional

|                |                                                                   |                                                                                                                                                                                                                 |

**Examples**

Find 6 eigenvectors of the identity matrix:

```
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigs(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
>>> vecs.shape
(13, 6)
```

`scipy.sparse.linalg.eigsh`(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return\_eigenvectors=True, Minv=None, OPinv=None, mode='normal')

Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix A.

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

If M is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$

**Parameters** A : An N x N matrix, array, sparse matrix, or LinearOperator representing the operation  $A * x$ , where A is a real symmetric matrix For buckling mode (see below) A must additionally be positive-definite

**k** : int, optional  
 The number of eigenvalues and eigenvectors desired.  $k$  must be smaller than  $N$ . It is not possible to compute all eigenvectors of a matrix.

**Returns**

**w** : array  
 Array of  $k$  eigenvalues

**v** : array  
 An array representing the  $k$  eigenvectors. The column  $v[:, i]$  is the eigenvector corresponding to the eigenvalue  $w[i]$ .

**Other Parameters**

**M** : An  $N \times N$  matrix, array, sparse matrix, or linear operator representing the operation  $M * x$  for the generalized eigenvalue problem  

$$A * x = w * M * x.$$
 $M$  must represent a real, symmetric matrix if  $A$  is real, and must represent a complex, hermitian matrix if  $A$  is complex. For best results, the data type of  $M$  should be the same as that of  $A$ . Additionally:  
 If  $\sigma$  is None,  $M$  is symmetric positive definite  
 If  $\sigma$  is specified,  $M$  is symmetric positive semi-definite  
 In buckling mode,  $M$  is symmetric indefinite

If  $\sigma$  is None, `eigsh` requires an operator to compute the solution of the linear equation  $M * x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix  $M$ , or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator `Minv`, which gives  $x = Minv * b = M^{-1} * b$ .

**sigma** : real  
 Find eigenvalues near  $\sigma$  using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - \sigma * M] x = b$ , where  $M$  is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices  $A$  &  $M$ , or via an iterative solver if either  $A$  or  $M$  is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives  $x = OPinv * b = [A - \sigma * M]^{-1} * b$ . Note that when  $\sigma$  is specified, the keyword ‘which’ refers to the shifted eigenvalues  $w' [i]$  where:  
 if `mode == ‘normal’`,  $w' [i] = 1 / (w[i] - \sigma)$ .  
 if `mode == ‘cayley’`,  $w' [i] = (w[i] + \sigma) / (w[i] - \sigma)$ .  
 if `mode == ‘buckling’`,  $w' [i] = w[i] / (w[i] - \sigma)$ .  
 (see further discussion in ‘mode’ below)

**v0** : ndarray, optional  
 Starting vector for iteration. Default: random

**ncv** : int, optional  
 The number of Lanczos vectors generated `ncv` must be greater than  $k$  and smaller than  $n$ ; it is recommended that `ncv > 2*k`. Default: `min(n, max(2*k + 1, 20))`

**which** : str [‘LM’ | ‘SM’ | ‘LA’ | ‘SA’ | ‘BE’]  
 If  $A$  is a complex hermitian matrix, ‘BE’ is invalid. Which  $k$  eigenvectors and eigenvalues to find:  
 ‘LM’ : Largest (in magnitude) eigenvalues  
 ‘SM’ : Smallest (in magnitude) eigenvalues  
 ‘LA’ : Largest (algebraic) eigenvalues  
 ‘SA’ : Smallest (algebraic) eigenvalues  
 ‘BE’ : Half ( $k/2$ ) from each end of the spectrum  
 When  $k$  is odd, return one more ( $k/2+1$ ) from the high end. When  $\sigma !=$  None, ‘which’ refers to the shifted eigenvalues  $w' [i]$  (see discussion in

‘sigma’, above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional

Maximum number of Arnoldi update iterations allowed Default:  $n \times 10$

**tol** : float

Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

**Minv** : N x N matrix, array, sparse matrix, or LinearOperator

See notes in M, above

**OPinv** : N x N matrix, array, sparse matrix, or LinearOperator

See notes in sigma, above.

**return\_eigenvectors** : bool

Return eigenvectors (True) in addition to eigenvalues

**mode** : string [‘normal’ | ‘buckling’ | ‘cayley’]

Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem  $OP * x'[i] = w'[i] * B * x'[i]$  and transforms the resulting Ritz vectors  $x'[i]$  and Ritz values  $w'[i]$  into the desired eigenvectors and eigenvalues of the problem  $A * x[i] = w[i] * M * x[i]$ . The modes are as follows:

**‘normal’** :  $OP = [A - \text{sigma} * M]^{-1} * M, B = M, w'[i] = 1 / (w[i] - \text{sigma})$

**‘buckling’** :  $OP = [A - \text{sigma} * M]^{-1} * A, B = A, w'[i] = w[i] / (w[i] - \text{sigma})$

**‘cayley’** :  $OP = [A - \text{sigma} * M]^{-1} * [A + \text{sigma} * M], B = M, w'[i] = (w[i] + \text{sigma}) / (w[i] - \text{sigma})$

The choice of mode will affect which eigenvalues are selected by the keyword ‘which’, and can also impact the stability of convergence (see [2] for a discussion)

*Raises*

**ArpackNoConvergence**

When the requested convergence is not obtained.

The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

**See also:**

[eigs](#) eigenvalues and eigenvectors for a general (nonsymmetric) matrix A  
[svds](#) singular value decomposition for a matrix A

**Notes**

This function is a wrapper to the ARPACK [R19] SSEUPD and DSEUPD functions which use the Implicitly Restarted Lanczos Method to find the eigenvalues and eigenvectors [R20].

**Examples**

```
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigsh(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
```

```
>>> vecs.shape
(13, 6)
```

```
scipy.sparse.linalg.lobpcg(A, X, B=None, M=None, Y=None, tol=None, maxiter=20,
                           largest=True, verbosityLevel=0, retLambdaHistory=False,
                           retResidualNormsHistory=False)
```

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}
 

The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.
- X** : array\_like
 

Initial approximation to the k eigenvectors. If A has shape=(n,n) then X should have shape shape=(n,k).
- B** : {dense matrix, sparse matrix, LinearOperator}, optional
 

the right hand side operator in a generalized eigenproblem. by default, B = Identity often called the “mass matrix”
- M** : {dense matrix, sparse matrix, LinearOperator}, optional
 

preconditioner to A; by default M = Identity M should approximate the inverse of A
- Y** : array\_like, optional
 

n-by-sizeY matrix of constraints, sizeY < n The iterations will be performed in the B-orthogonal complement of the column-space of Y. Y must be full rank.

**Returns**

- w** : array
 

Array of k eigenvalues
- v** : array
 

An array of k eigenvectors. V has the same shape as X.

**Other Parameters**

- tol** : scalar, optional
 

Solver tolerance (stopping criterion) by default:  $\text{tol} = n * \sqrt{\text{eps}}$
- maxiter** : integer, optional
 

maximum number of iterations by default:  $\text{maxiter} = \min(n, 20)$
- largest** : bool, optional
 

when True, solve for the largest eigenvalues, otherwise the smallest
- verbosityLevel** : integer, optional
 

controls solver output. default:  $\text{verbosityLevel} = 0$ .
- retLambdaHistory** : boolean, optional
 

whether to return eigenvalue history
- retResidualNormsHistory** : boolean, optional
 

whether to return history of residual norms

### Notes

If both `retLambdaHistory` and `retResidualNormsHistory` are True, the return tuple has the following format (lambda, V, lambda history, residual norms history).

In the following  $n$  denotes the matrix size and  $m$  the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size  $3 \cdot m$  on every iteration by calling the “standard” dense eigensolver, so if  $m$  is not small enough compared to  $n$ , it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. `numpy` or `scipy` function in this case. If one calls the LOBPCG algorithm for  $5 \cdot m > n$ , it will most likely break internally, so the code tries to call the standard function instead.

It is not that  $n$  should be large for the LOBPCG to work, but rather the ratio  $n/m$  should be large. If you call the LOBPCG code with  $m=1$  and  $n=10$ , it should work, though  $n$  is small. The method is intended for extremely large  $n/m$ , see e.g., reference [28] in <http://arxiv.org/abs/0705.2626>

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary  $m$  to make this better.
2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large  $n$ , so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for  $A$ , which is easy to code since  $A$  is tridiagonal.

#### Examples

Solve  $Ax = \lambda Bx$  with constraints and preconditioning.

```
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = [np.arange(n, dtype=np.float64) + 1]
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1.,  0.,  0., ...,  0.,  0.,  0.],
       [ 0.,  2.,  0., ...,  0.,  0.,  0.],
       [ 0.,  0.,  3., ...,  0.,  0.,  0.],
       ...,
       [ 0.,  0.,  0., ..., 98.,  0.,  0.],
       [ 0.,  0.,  0., ...,  0., 99.,  0.],
       [ 0.,  0.,  0., ...,  0.,  0., 100.]])
```

Constraints.

```
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```
>>> X = np.random.rand(n, 3)
```

Preconditioner – inverse of  $A$  (as an abstract linear operator).

```
>>> invA = spdiags([1./vals[0]], 0, n, n)
>>> def precondition( x ):
...     return invA * x
>>> M = LinearOperator(matvec=precond, shape=(n, n), dtype=float)
```

Here, `invA` could of course have been used directly as a preconditioner. Let us then solve the problem:

```
>>> eigs, vecs = lobpcg(A, X, Y=Y, M=M, tol=1e-4, maxiter=40, largest=False)
>>> eigs
array([ 4.,  5.,  6.]
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

---

`svds(A[, k, ncv, tol, which, v0, maxiter, ...])` Compute the largest k singular values/vectors for a sparse matrix.

---

`scipy.sparse.linalg.svds(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True)`

Compute the largest k singular values/vectors for a sparse matrix.

**Parameters**

**A** : {sparse matrix, LinearOperator}  
Array to compute the SVD on, of shape (M, N)

**k** : int, optional  
Number of singular values and vectors to compute. Must be  $1 \leq k < \min(A.shape)$ .

**ncv** : int, optional  
The number of Lanczos vectors generated ncv must be greater than k+1 and smaller than n; it is recommended that  $ncv > 2*k$  Default:  $\min(n, \max(2*k + 1, 20))$

**tol** : float, optional  
Tolerance for singular values. Zero (default) means machine precision.

**which** : str, ['LM' | 'SM'], optional  
Which k singular values to find:

- 'LM' : largest singular values
- 'SM' : smallest singular values

New in version 0.12.0.

**v0** : ndarray, optional  
Starting vector for iteration, of length  $\min(A.shape)$ . Should be an (approximate) left singular vector if  $N > M$  and a right singular vector otherwise.  
Default: random  
New in version 0.12.0.

**maxiter** : int, optional  
Maximum number of iterations.  
New in version 0.12.0.

**return\_singular\_vectors** : bool or str, optional

- True: return singular vectors (True) in addition to singular values.

New in version 0.12.0.

- "u": only return the u matrix, without computing vh (if  $N > M$ ).
- "vh": only return the vh matrix, without computing u (if  $N \leq M$ ).

New in version 0.16.0.

**Returns**

**u** : ndarray, shape=(M, k)  
Unitary matrix having left singular vectors as columns. If `return_singular_vectors` is "vh", this variable is not computed, and None is returned instead.

**s** : ndarray, shape=(k,)  
The singular values.

**vt** : ndarray, shape=(k, N)

Unitary matrix having right singular vectors as rows. If *return\_singular\_vectors* is “u”, this variable is not computed, and None is returned instead.

**Notes**

This is a naive implementation using ARPACK as an eigensolver on  $A.H * A$  or  $A * A.H$ , depending on which one is more efficient.

Complete or incomplete LU factorizations

|----------------------------------------------------------------|---------------------------------------------------------------------|
| <code>splu(A[, permc_spec, diag_pivot_thresh, ...])</code>     | Compute the LU decomposition of a sparse, square matrix.            |
| <code>spilu(A[, drop_tol, fill_factor, drop_rule, ...])</code> | Compute an incomplete LU decomposition for a sparse, square matrix. |
| <code>SuperLU</code>                                           | LU factorization of a sparse matrix.                                |

---

`scipy.sparse.linalg.splu(A, permc_spec=None, diag_pivot_thresh=None, drop_tol=None, relax=None, panel_size=None, options={})`  
 Compute the LU decomposition of a sparse, square matrix.

**Parameters**

- A** : sparse matrix  
 Sparse matrix to factorize. Should be in CSR or CSC format.
- permc\_spec** : str, optional  
 How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)
  - NATURAL: natural ordering.
  - MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
  - MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T A + A$ .
  - COLAMD: approximate minimum degree column ordering
- diag\_pivot\_thresh** : float, optional  
 Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user’s guide for details [R39]
- drop\_tol** : float, optional  
 (deprecated) No effect.
- relax** : int, optional  
 Expert option for customizing the degree of relaxing supernodes. See SuperLU user’s guide for details [R39]
- panel\_size** : int, optional  
 Expert option for customizing the panel size. See SuperLU user’s guide for details [R39]
- options** : dict, optional  
 Dictionary containing additional expert options to SuperLU. See SuperLU user guide [R39] (section 2.4 on the ‘Options’ argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE')` to turn equilibration off and perform a single iterative refinement.

**Returns**

- invA** : `scipy.sparse.linalg.SuperLU`  
 Object, which has a `solve` method.

**See also:**

`spilu` incomplete LU decomposition

**Notes**

This function uses the SuperLU library.

## References

[R39]

`scipy.sparse.linalg.spilu` (*A*, *drop\_tol=None*, *fill\_factor=None*, *drop\_rule=None*,  
*perm\_spec=None*, *diag\_pivot\_thresh=None*, *relax=None*,  
*panel\_size=None*, *options=None*)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of *A*.

**Parameters**

- A** : (N, N) array\_like  
Sparse matrix to factorize
- drop\_tol** : float, optional  
Drop tolerance ( $0 \leq \text{tol} \leq 1$ ) for an incomplete LU decomposition. (default: 1e-4)
- fill\_factor** : float, optional  
Specifies the fill ratio upper bound ( $\geq 1.0$ ) for ILU. (default: 10)
- drop\_rule** : str, optional  
Comma-separated string of drop rules to use. Available rules: `basic`, `provs`, `column`, `area`, `secondary`, `dynamic`, `interp`. (Default: `basic, area`)  
See SuperLU documentation for details.

**Remaining other options**

**Returns**

- invA\_approx** : `scipy.sparse.linalg.SuperLU`  
Object, which has a `solve` method.

See also:

[`splu`](#) complete LU decomposition

## Notes

To improve the better approximation to the inverse, you may need to increase *fill\_factor* AND decrease *drop\_tol*.

This function uses the SuperLU library.

**class** `scipy.sparse.linalg.SuperLU`  
LU factorization of a sparse matrix.

Factorization is represented as:

$$P_r * A * P_c = L * U$$

To construct these `SuperLU` objects, call the `splu` and `spilu` functions.

## Notes

New in version 0.14.0.

## Examples

The LU decomposition can be used to solve matrix equations. Consider:

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1, 2, 0, 4], [1, 0, 0, 1], [1, 0, 2, 1], [2, 2, 1, 0.]])
```

This can be solved for a given right-hand side:

```
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1.,  2.,  3.,  4.]
```

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The L and U factors are sparse matrices in CSC format:

```
>>> lu.L.A
array([[ 1. ,  0. ,  0. ,  0. ],
       [ 0. ,  1. ,  0. ,  0. ],
       [ 0. ,  0. ,  1. ,  0. ],
       [ 1. ,  0.5,  0.5,  1. ]])
>>> lu.U.A
array([[ 2.,  0.,  1.,  4.],
       [ 0.,  2.,  1.,  1.],
       [ 0.,  0.,  1.,  1.],
       [ 0.,  0.,  0., -5.]])
```

The permutation matrices can be constructed:

```
>>> Pr = csc_matrix((4, 4))
>>> Pr[lu.perm_r, np.arange(4)] = 1
>>> Pc = csc_matrix((4, 4))
>>> Pc[np.arange(4), lu.perm_c] = 1
```

We can reassemble the original matrix:

```
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1.,  2.,  0.,  4.],
       [ 1.,  0.,  0.,  1.],
       [ 1.,  0.,  2.,  1.],
       [ 2.,  2.,  1.,  0.]])
```

### Attributes

| <code>L</code>      | Lower triangular factor with unit diagonal as a <code>scipy.sparse.csc_matrix</code> . |
| <code>U</code>      | Upper triangular factor as a <code>scipy.sparse.csc_matrix</code> .                    |

---

#### SuperLU.`shape`

Shape of the original matrix as a tuple of ints.

#### SuperLU.`nnz`

Number of nonzero elements in the matrix.

SuperLU.**perm\_c**

Permutation Pc represented as an array of indices.

The column permutation matrix can be reconstructed via:

```
>>> Pc = np.zeros((n, n))
>>> Pc[np.arange(n), perm_c] = 1
```

SuperLU.**perm\_r**

Permutation Pr represented as an array of indices.

The row permutation matrix can be reconstructed via:

```
>>> Pr = np.zeros((n, n))
>>> Pr[perm_r, np.arange(n)] = 1
```

SuperLU.**L**

Lower triangular factor with unit diagonal as a `scipy.sparse.csc_matrix`.

New in version 0.14.0.

SuperLU.**U**

Upper triangular factor as a `scipy.sparse.csc_matrix`.

New in version 0.14.0.

### Methods

---

`solve(rhs[, trans])` Solves linear system of equations with one or several right-hand sides.

---

SuperLU.**solve** (*rhs* [, *trans* ])

Solves linear system of equations with one or several right-hand sides.

**Parameters**

- rhs** : ndarray, shape (n,) or (n, k)  
Right hand side(s) of equation
- trans** : {'N', 'T', 'H'}, optional  
Type of system to solve:
  - 'N':  $A * x == rhs$  (default)
  - 'T':  $A^T * x == rhs$
  - 'H':  $A^H * x == rhs$

**Returns**

- x** : ndarray, shape *rhs*.shape  
i.e., normal, transposed, and hermitian conjugate.  
Solution vector(s)

---

`ArpackNoConvergence(msg, eigenvalues, ...)` ARPACK iteration did not converge  
`ArpackError(info[, infodict])` ARPACK error

---

### Exceptions

**exception** `scipy.sparse.linalg.ArpackNoConvergence` (*msg, eigenvalues, eigenvectors*)  
 ARPACK iteration did not converge

**Functions**

|                                                                |                                                                                 |
|----------------------------------------------------------------|---------------------------------------------------------------------------------|
| <code>aslinearoperator(A)</code>                               | Return A as a LinearOperator.                                                   |
| <code>bicg(A, b[, x0, tol, maxiter, xtype, M, ...])</code>     | Use BIConjugate Gradient iteration to solve $Ax = b$ .                          |
| <code>bicgstab(A, b[, x0, tol, maxiter, xtype, M, ...])</code> | Use BIConjugate Gradient STABILized iteration to solve $Ax = b$ .               |
| <code>cg(A, b[, x0, tol, maxiter, xtype, M, callback])</code>  | Use Conjugate Gradient iteration to solve $Ax = b$ .                            |
| <code>cgs(A, b[, x0, tol, maxiter, xtype, M, callback])</code> | Use Conjugate Gradient Squared iteration to solve $Ax = b$ .                    |
| <code>eigs(A[, k, M, sigma, which, v0, ncv, ...])</code>       | Find k eigenvalues and eigenvectors of the square matrix A.                     |
| <code>eigsh(A[, k, M, sigma, which, v0, ncv, ...])</code>      | Find k eigenvalues and eigenvectors of the real symmetric square matrix or c    |
| <code>expm(A)</code>                                           | Compute the matrix exponential using Pade approximation.                        |
| <code>expm_multiply(A, B[, start, stop, num, endpoint])</code> | Compute the action of the matrix exponential of A on B.                         |
| <code>factorized(A)</code>                                     | Return a function for solving a sparse linear system, with A pre-factorized.    |
| <code>gmres(A, b[, x0, tol, restart, maxiter, ...])</code>     | Use Generalized Minimal RESidual iteration to solve $Ax = b$ .                  |
| <code>inv(A)</code>                                            | Compute the inverse of a sparse matrix                                          |
| <code>lgmres(A, b[, x0, tol, maxiter, M, ...])</code>          | Solve a matrix equation using the LGMRES algorithm.                             |
| <code>lobpcg(A, X[, B, M, Y, tol, maxiter, ...])</code>        | Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPC           |
| <code>lsmr(A, b[, damp, atol, btol, conlim, ...])</code>       | Iterative solver for least-squares problems.                                    |
| <code>lsqr(A, b[, damp, atol, btol, conlim, ...])</code>       | Find the least-squares solution to a large, sparse, linear system of equations. |
| <code>minres(A, b[, x0, shift, tol, maxiter, ...])</code>      | Use MINimum RESidual iteration to solve $Ax=b$                                  |
| <code>norm(x[, ord, axis])</code>                              | Norm of a sparse matrix                                                         |
| <code>onenormest(A[, t, itmax, compute_v, compute_w])</code>   | Compute a lower bound of the 1-norm of a sparse matrix.                         |
| <code>qmr(A, b[, x0, tol, maxiter, xtype, M1, M2, ...])</code> | Use Quasi-Minimal Residual iteration to solve $Ax = b$ .                        |
| <code>spilu(A[, drop_tol, fill_factor, drop_rule, ...])</code> | Compute an incomplete LU decomposition for a sparse, square matrix.             |
| <code>splu(A[, permc_spec, diag_pivot_thresh, ...])</code>     | Compute the LU decomposition of a sparse, square matrix.                        |
| <code>spsolve(A, b[, permc_spec, use_umfpack])</code>          | Solve the sparse linear system $Ax=b$ , where b may be a vector or a matrix.    |
| <code>spsolve_triangular(A, b[, lower, ...])</code>            | Solve the equation $Ax = b$ for x, assuming A is a triangular matrix.           |
| <code>svds(A[, k, ncv, tol, which, v0, maxiter, ...])</code>   | Compute the largest k singular values/vectors for a sparse matrix.              |
| <code>use_solver(**kwargs)</code>                              | Select default sparse direct solver to be used.                                 |

## 5.21.2 Usage information

There are seven available sparse matrix types:

1. `csc_matrix`: Compressed Sparse Column format
2. `csr_matrix`: Compressed Sparse Row format
3. `bsr_matrix`: Block Sparse Row format
4. `lil_matrix`: List of Lists format
5. `dok_matrix`: Dictionary of Keys format
6. `coo_matrix`: COOrdinate format (aka IJV, triplet format)
7. `dia_matrix`: DIAgonal format

To construct a matrix efficiently, use either `dok_matrix` or `lil_matrix`. The `lil_matrix` class supports basic slicing and fancy indexing with a similar syntax to NumPy arrays. As illustrated below, the COO format may also be used to efficiently construct matrices. Despite their similarity to NumPy arrays, it is **strongly discouraged** to use NumPy functions directly on these matrices because NumPy may not properly convert them for computations, leading to unexpected (and incorrect) results. If you do want to apply a NumPy function to these matrices, first check if SciPy has its own implementation for the given sparse matrix class, or **convert the sparse matrix to a NumPy array** (e.g. using the `toarray()` method of the class) first before applying the method.

To perform manipulations such as multiplication or inversion, first convert the matrix to either CSC or CSR format. The `lil_matrix` format is row-based, so conversion to CSR is efficient, whereas conversion to CSC is less so.

All conversions among the CSR, CSC, and COO formats are efficient, linear-time operations.

### Matrix vector product

To do a vector product between a sparse matrix and a vector simply use the matrix `dot` method, as described in its docstring:

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

**Warning:** As of NumPy 1.7, `np.dot` is not aware of sparse matrices, therefore using it will result on unexpected results or errors. The corresponding dense array should be obtained first instead:

```
>>> np.dot(A.toarray(), v)
array([ 1, -3, -1], dtype=int64)
```

but then all the performance advantages would be lost.

The CSR format is specially suitable for fast matrix vector products.

## Example 1

Construct a 1000x1000 `lil_matrix` and add some values to it:

```
>>> from scipy.sparse import lil_matrix
>>> from scipy.sparse.linalg import spsolve
>>> from numpy.linalg import solve, norm
>>> from numpy.random import rand

>>> A = lil_matrix((1000, 1000))
>>> A[0, :100] = rand(100)
>>> A[1, 100:200] = A[0, :100]
>>> A.setdiag(rand(1000))
```

Now convert it to CSR format and solve  $Ax = b$  for  $x$ :

```
>>> A = A.tocsr()
>>> b = rand(1000)
>>> x = spsolve(A, b)
```

Convert it to a dense matrix and solve, and check that the result is the same:

```
>>> x_ = solve(A.toarray(), b)
```

Now we can compute norm of the error with:

```
>>> err = norm(x-x_)
>>> err < 1e-10
True
```

It should be small :)

## Example 2

Construct a matrix in COO format:

```
>>> from scipy import sparse
>>> from numpy import array
>>> I = array([0, 3, 1, 0])
>>> J = array([0, 3, 1, 2])
>>> V = array([4, 5, 7, 9])
>>> A = sparse.coo_matrix((V, (I, J)), shape=(4, 4))
```

Notice that the indices do not need to be sorted.

Duplicate  $(i,j)$  entries are summed when converting to CSR or CSC.

```
>>> I = array([0, 0, 1, 3, 1, 0, 0])
>>> J = array([0, 2, 1, 3, 1, 0, 0])
>>> V = array([1, 1, 1, 1, 1, 1, 1])
>>> B = sparse.coo_matrix((V, (I, J)), shape=(4, 4)).tocsr()
```

This is useful for constructing finite-element stiffness and mass matrices.

## Further Details

CSR column indices are not necessarily sorted. Likewise for CSC row indices. Use the `.sorted_indices()` and `.sort_indices()` methods when sorted indices are required (e.g. when passing data to other libraries).

## 5.22 Sparse linear algebra (`scipy.sparse.linalg`)

### 5.22.1 Abstract linear operators

|                                           |                                                        |
|-------------------------------------------|--------------------------------------------------------|
| <code>LinearOperator(dtype, shape)</code> | Common interface for performing matrix vector products |
| <code>aslinearoperator(A)</code>          | Return A as a LinearOperator.                          |

**class** `scipy.sparse.linalg.LinearOperator` (*dtype, shape*)

Common interface for performing matrix vector products

Many iterative methods (e.g. `cg`, `gmres`) do not need to know the individual entries of a matrix to solve a linear system  $A*x=b$ . Such solvers only require the computation of matrix vector products,  $A*v$  where  $v$  is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete `LinearOperator`, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods `_matvec` and `_matmat`, and the attributes/properties `shape` (pair of integers) and `dtype` (may be `None`). It may call the `__init__` on this class to have these attributes validated. Implementing `_matvec` automatically implements `_matmat` (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement `_rmatvec` or `_adjoint` to implement the Hermitian adjoint (conjugate transpose). As with `_matvec` and `_matmat`, implementing either `_rmatvec` or `_adjoint` implements the other automatically. Implementing `_adjoint` is preferable; `_rmatvec` is mostly there for backwards compatibility.

**Parameters**

- shape** : tuple  
Matrix dimensions (M,N).
- matvec** : callable  $f(v)$   
Returns  $A * v$ .
- rmatvec** : callable  $f(v)$   
Returns  $A^H * v$ , where  $A^H$  is the conjugate transpose of  $A$ .
- matmat** : callable  $f(V)$   
Returns  $A * V$ , where  $V$  is a dense matrix with dimensions (N,K).
- dtype** : dtype  
Data type of the matrix.

**See also:**

[`aslinearoperator`](#)

Construct `LinearOperator`s

**Notes**

The user-defined `matvec()` function must properly handle the case where  $v$  has shape  $(N,)$  as well as the  $(N,1)$  case. The shape of the return type is handled internally by `LinearOperator`.

LinearOperator instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite LinearOperator, that defers linear operations to the original operators and combines the results.

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([ 2.,  3.])
>>> A * np.ones(2)
array([ 2.,  3.]
```

**Attributes**

|      |                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------|
| args | (tuple) For linear operators describing products etc. of other linear operators, the operands of the binary operation. |
|------|------------------------------------------------------------------------------------------------------------------------|

**Methods**

|                          |                                                |
|--------------------------|------------------------------------------------|
| <code>__call__(x)</code> |                                                |
| <code>adjoint()</code>   | Hermitian adjoint.                             |
| <code>dot(x)</code>      | Matrix-matrix or matrix-vector multiplication. |
| <code>matmat(X)</code>   | Matrix-matrix multiplication.                  |
| <code>matvec(x)</code>   | Matrix-vector multiplication.                  |
| <code>rmatvec(x)</code>  | Adjoint matrix-vector multiplication.          |
| <code>transpose()</code> | Transpose this linear operator.                |

LinearOperator.**\_\_call\_\_**(x)

LinearOperator.**adjoint**()

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

**Returns** **A\_H**: LinearOperator  
Hermitian adjoint of self.

LinearOperator.**dot**(x)

Matrix-matrix or matrix-vector multiplication.

**Parameters** **x**: array\_like  
1-d or 2-d array, representing a vector or matrix.

**Returns** **Ax**: array  
1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

`LinearOperator.matmat(X)`

Matrix-matrix multiplication.

Performs the operation  $y=A*X$  where  $A$  is an  $M \times N$  linear operator and  $X$  dense  $N \times K$  matrix or ndarray.

**Parameters**  $X$  : {matrix, ndarray}

**Returns**  $Y$  : {matrix, ndarray} An array with shape  $(N,K)$ .

A matrix or ndarray with shape  $(M,K)$  depending on the type of the  $X$  argument.

#### Notes

This `matmat` wraps any user-specified `matmat` routine or overridden `_matmat` method to ensure that  $y$  has the correct type.

`LinearOperator.matvec(x)`

Matrix-vector multiplication.

Performs the operation  $y=A*x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array.

**Parameters**  $x$  : {matrix, ndarray}

**Returns**  $y$  : {matrix, ndarray} An array with shape  $(N,)$  or  $(N,1)$ .

A matrix or ndarray with shape  $(M,)$  or  $(M,1)$  depending on the type and shape of the  $x$  argument.

#### Notes

This `matvec` wraps the user-specified `matvec` routine or overridden `_matvec` method to ensure that  $y$  has the correct shape and type.

`LinearOperator.rmatvec(x)`

Adjoint matrix-vector multiplication.

Performs the operation  $y = A^H * x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array.

**Parameters**  $x$  : {matrix, ndarray}

**Returns**  $y$  : {matrix, ndarray} An array with shape  $(M,)$  or  $(M,1)$ .

A matrix or ndarray with shape  $(N,)$  or  $(N,1)$  depending on the type and shape of the  $x$  argument.

#### Notes

This `rmatvec` wraps the user-specified `rmatvec` routine or overridden `_rmatvec` method to ensure that  $y$  has the correct shape and type.

`LinearOperator.transpose()`

Transpose this linear operator.

Returns a `LinearOperator` that represents the transpose of this one. Can be abbreviated `self.T` instead of `self.transpose()`.

`scipy.sparse.linalg.aslinearoperator(A)`

Return  $A$  as a `LinearOperator`.

*'A' may be any of the following types:*

- ndarray
- matrix
- sparse matrix (e.g. `csr_matrix`, `lil_matrix`, etc.)
- `LinearOperator`

- An object with `.shape` and `.matvec` attributes

See the `LinearOperator` documentation for additional information.

**Examples**

```
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1,2,3],[4,5,6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

## 5.22.2 Matrix Operations

---

|                                                                |                                                          |
|----------------------------------------------------------------|----------------------------------------------------------|
| <code>inv(A)</code>                                            | Compute the inverse of a sparse matrix                   |
| <code>expm(A)</code>                                           | Compute the matrix exponential using Pade approximation. |
| <code>expm_multiply(A, B[, start, stop, num, endpoint])</code> | Compute the action of the matrix exponential of A on B.  |

---

`scipy.sparse.linalg.inv(A)`  
 Compute the inverse of a sparse matrix

**Parameters** `A` : (M,M) ndarray or sparse matrix  
**Returns** `Ainv` : (M,M) ndarray or sparse matrix  
 square matrix to be inverted  
 inverse of `A`

**Notes**

This computes the sparse inverse of `A`. If the inverse of `A` is expected to be non-sparse, it will likely be faster to convert `A` to dense and use `scipy.linalg.inv`.

New in version 0.12.0.

`scipy.sparse.linalg.expm(A)`  
 Compute the matrix exponential using Pade approximation.

**Parameters** `A` : (M,M) array\_like or sparse matrix  
**Returns** `expA` : (M,M) ndarray  
 2D Array or Matrix (sparse or dense) to be exponentiated  
 Matrix exponential of `A`

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[R331]

`scipy.sparse.linalg.expm_multiply(A, B, start=None, stop=None, num=None, endpoint=None)`  
 Compute the action of the matrix exponential of A on B.

**Parameters** `A` : transposable linear operator  
 The operator whose exponential is of interest.  
`B` : ndarray  
 The matrix or vector to be multiplied by the matrix exponential of `A`.  
`start` : scalar, optional  
 The starting time point of the sequence.

**stop** : scalar, optional  
The end time point of the sequence, unless *endpoint* is set to False. In that case, the sequence consists of all but the last of `num + 1` evenly spaced time points, so that *stop* is excluded. Note that the step size changes when *endpoint* is False.

**num** : int, optional  
Number of time points to use.

**endpoint** : bool, optional  
If True, *stop* is the last time point. Otherwise, it is not included.

**Returns** **expm\_A\_B** : ndarray  
The result of the action  $e^{t_k A} B$ .

### Notes

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of `numpy.linspace`.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, `expm_A_B[0]` will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

### References

## 5.22.3 Matrix norms

---

|                                                              |                                                         |
|--------------------------------------------------------------|---------------------------------------------------------|
| <code>norm(x[, ord, axis])</code>                            | Norm of a sparse matrix                                 |
| <code>onenormest(A[, t, itmax, compute_v, compute_w])</code> | Compute a lower bound of the 1-norm of a sparse matrix. |

---

`scipy.sparse.linalg.norm(x, ord=None, axis=None)`

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the `ord` parameter.

**Parameters**

- x** : a sparse matrix  
Input sparse matrix.
- ord** : {non-zero int, inf, -inf, 'fro'}, optional  
Order of the norm (see table under *Notes*). `inf` means numpy's *inf* object.
- axis** : {int, 2-tuple of ints, None}, optional  
If *axis* is an integer, it specifies the axis of *x* along which to compute the vector norms. If *axis* is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If *axis* is None then either a vector norm (when *x* is 1-D) or a matrix norm (when *x* is 2-D) is returned.

**Returns** **n** : float or ndarray

### Notes

Some of the `ord` are not implemented because some associated functions like, `_multi_svd_norm`, are not yet available for sparse matrix.

This docstring is modified based on `numpy.linalg.norm`. <https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py>

The following norms can be calculated:

| ord   | norm for sparse matrices |
|-------|--------------------------|
| None  | Frobenius norm           |
| 'fro' | Frobenius norm           |
| inf   | max(sum(abs(x), axis=1)) |
| -inf  | min(sum(abs(x), axis=1)) |
| 0     | abs(x).sum(axis=axis)    |
| 1     | max(sum(abs(x), axis=0)) |
| -1    | min(sum(abs(x), axis=0)) |
| 2     | Not implemented          |
| -2    | Not implemented          |
| other | Not implemented          |

The Frobenius norm is given by [R344]:

$$\|A\|_F = [\sum_{i,j} \text{abs}(a_{i,j})^2]^{1/2}$$

### Examples

```
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[ -4,  -3,  -2],
       [ -1,   0,   1],
       [  2,   3,   4]])

>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```

`scipy.sparse.linalg.onenormest` (*A*, *t*=2, *itmax*=5, *compute\_v*=False, *compute\_w*=False)

Compute a lower bound of the 1-norm of a sparse matrix.

**Parameters**

- A** : ndarray or other linear operator  
A linear operator that can be transposed and that can produce matrix products.
- t** : int, optional

A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.

**itmax** : int, optional  
Use at most this many iterations.

**compute\_v** : bool, optional  
Request a norm-maximizing linear operator input vector if True.

**compute\_w** : bool, optional  
Request a norm-maximizing linear operator output vector if True.

**Returns** **est** : float  
An underestimate of the 1-norm of the sparse matrix.

**v** : ndarray, optional  
The vector such that  $\|Av\|_1 == est * \|v\|_1$ . It can be thought of as an input to the linear operator that gives an output with particularly large norm.

**w** : ndarray, optional  
The vector  $Av$  which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

**Notes**

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about  $4t$  matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

### 5.22.4 Solving linear problems

Direct methods for linear equation systems:

---

|                                                       |                                                                                |
|-------------------------------------------------------|--------------------------------------------------------------------------------|
| <code>spsolve(A, b[, permc_spec, use_umfpack])</code> | Solve the sparse linear system $Ax=b$ , where $b$ may be a vector or a matrix. |
| <code>spsolve_triangular(A, b[, lower, ...])</code>   | Solve the equation $Ax = b$ for $x$ , assuming $A$ is a triangular matrix.     |
| <code>factorized(A)</code>                            | Return a function for solving a sparse linear system, with $A$ pre-factorized. |
| <code>MatrixRankWarning</code>                        |                                                                                |
| <code>use_solver(**kwargs)</code>                     | Select default sparse direct solver to be used.                                |

---

`scipy.sparse.linalg.spsolve(A, b, permc_spec=None, use_umfpack=True)`

Solve the sparse linear system  $Ax=b$ , where  $b$  may be a vector or a matrix.

**Parameters**

- A** : ndarray or sparse matrix  
The square matrix  $A$  will be converted into CSC or CSR form
- b** : ndarray or sparse matrix  
The matrix or vector representing the right hand side of the equation. If a vector,  $b.shape$  must be  $(n,)$  or  $(n, 1)$ .
- permc\_spec** : str, optional  
How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)
  - NATURAL: natural ordering.

- MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
- MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T + A$ .
- COLAMD: approximate minimum degree column ordering

**use\_umfpack** : bool, optional  
 if True (default) then use umfpack for the solution. This is only referenced if *b* is a vector and `scikit-umfpack` is installed.

**Returns** **x** : ndarray or sparse matrix  
 the solution of the sparse linear equation. If *b* is a vector, then *x* is a vector of size `A.shape[1]`. If *b* is a matrix, then *x* is a matrix of size `(A.shape[1], b.shape[1])`.

**Notes**

For solving the matrix expression  $AX = B$ , this solver assumes the resulting matrix *X* is sparse, as is often the case for very sparse inputs. If the resulting *X* is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting *A* to a dense matrix and using `scipy.linalg.solve` or its variants.

`scipy.sparse.linalg.spsolve_triangular` (*A*, *b*, *lower=True*, *overwrite\_A=False*, *overwrite\_b=False*)

Solve the equation  $Ax = b$  for *x*, assuming *A* is a triangular matrix.

**Parameters** **A** : (M, M) sparse matrix  
 A sparse square triangular matrix. Should be in CSR format.

**b** : (M,) or (M, N) array\_like  
 Right-hand side matrix in  $Ax = b$

**lower** : bool, optional  
 Whether *A* is a lower or upper triangular matrix. Default is lower triangular matrix.

**overwrite\_A** : bool, optional  
 Allow changing *A*. The indices of *A* are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.

**overwrite\_b** : bool, optional  
 Allow overwriting data in *b*. Enabling gives a performance gain. Default is False.

**Returns** **x** : (M,) or (M, N) ndarray  
 Solution to the system  $Ax = b$ . Shape of return matches shape of *b*.

**Raises** **LinAlgError**  
 If *A* is singular or not triangular.

**ValueError**  
 If shape of *A* or shape of *b* do not match the requirements.

**Notes**

New in version 0.19.0.

`scipy.sparse.linalg.factorized` (*A*)

Return a function for solving a sparse linear system, with *A* pre-factorized.

**Parameters** **A** : (N, N) array\_like  
 Input.

**Returns** **solve** : callable  
 To solve the linear system of equations given in *A*, the *solve* callable should be passed an ndarray of shape (N,).

**Examples**

```
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[ 3. ,  2. , -1. ],
...              [ 2. , -2. ,  4. ],
...              [-1. ,  0.5, -1. ]])
>>> solve = factorized(A) # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1) # Uses the LU factors.
array([ 1., -2., -2.]
```

**exception** `scipy.sparse.linalg.MatrixRankWarning`

`scipy.sparse.linalg.use_solver` (\*\*kwargs)

Select default sparse direct solver to be used.

**Parameters** `useUmfpack` : bool, optional  
Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True

**Notes**

The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing `useUmfpack = False`, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass `assumeSortedIndices=True` to gain some speed.

Iterative methods for linear equation systems:

|                                                                |                                                                   |
|----------------------------------------------------------------|-------------------------------------------------------------------|
| <code>bicg(A, b[, x0, tol, maxiter, xtype, M, ...])</code>     | Use BIConjugate Gradient iteration to solve $Ax = b$ .            |
| <code>bicgstab(A, b[, x0, tol, maxiter, xtype, M, ...])</code> | Use BIConjugate Gradient STABILized iteration to solve $Ax = b$ . |
| <code>cg(A, b[, x0, tol, maxiter, xtype, M, callback])</code>  | Use Conjugate Gradient iteration to solve $Ax = b$ .              |
| <code>cgs(A, b[, x0, tol, maxiter, xtype, M, callback])</code> | Use Conjugate Gradient Squared iteration to solve $Ax = b$ .      |
| <code>gmres(A, b[, x0, tol, restart, maxiter, ...])</code>     | Use Generalized Minimal RESidual iteration to solve $Ax = b$ .    |
| <code>lgmres(A, b[, x0, tol, maxiter, M, ...])</code>          | Solve a matrix equation using the LGMRES algorithm.               |
| <code>minres(A, b[, x0, shift, tol, maxiter, ...])</code>      | Use MINimum RESidual iteration to solve $Ax=b$                    |
| <code>qmr(A, b[, x0, tol, maxiter, xtype, M1, M2, ...])</code> | Use Quasi-Minimal Residual iteration to solve $Ax = b$ .          |

`scipy.sparse.linalg.bicg` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *xtype=None*, *M=None*, *callback=None*)

Use BIConjugate Gradient iteration to solve  $Ax = b$ .

**Parameters** `A` : {sparse matrix, dense matrix, LinearOperator}  
The real or complex N-by-N matrix of the linear system. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

`b` : {array, matrix}

**Returns** `x` : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

`info` : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

`x0` : {array, matrix}

Starting guess for the solution.

**tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer  
Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}  
Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function  
User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**xtype** : {'f','d','F','D'}  
This parameter is deprecated – avoid using it.  
The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If A does not have a `typecode` method then it will compute `A.matvec(x0)` to get a typecode. To save the extra computation when A does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',`or `'D'`. This parameter has been superseded by `LinearOperator`.

`scipy.sparse.linalg.bicgstab` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *xtype=None*, *M=None*, *callback=None*)

Use BIConjugate Gradient STABILized iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}  
The real or complex N-by-N matrix of the linear system.

**b** : {array, matrix}

**Returns** **x** : {array, matrix}  
Right hand side of the linear system. Has shape (N,) or (N,1).  
The converged solution.

**info** : integer  
**Provides convergence information:**  
0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}  
Starting guess for the solution.

**tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer  
Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}  
Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function  
User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**xtype** : {'f','d','F','D'}

This parameter is deprecated – avoid using it.

The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If `A` does not have a `typecode` method then it will compute `A.matvec(x0)` to get a `typecode`. To save the extra computation when `A` does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

`scipy.sparse.linalg.cg`(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *xtype=None*, *M=None*, *callback=None*)

Use Conjugate Gradient iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system. `A` must represent a hermitian, positive definite matrix.

**b** : {array, matrix}

**Returns** **x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).

The converged solution.

**info** : integer

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer

Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for `A`. The preconditioner should approximate the inverse of `A`. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**xtype** : {'f','d','F','D'}

This parameter is deprecated – avoid using it.

The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If `A` does not have a `typecode` method then it will compute `A.matvec(x0)` to get a `typecode`. To save the extra computation when `A` does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

`scipy.sparse.linalg.cgs`(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *xtype=None*, *M=None*, *callback=None*)

Use Conjugate Gradient Squared iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real-valued N-by-N matrix of the linear system.

**Returns**

- b** : {array, matrix}
- x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).  
The converged solution.
- info** : integer  
*Provides convergence information:*  
0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- x0** : {array, matrix}  
Starting guess for the solution.
- tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : integer  
Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}  
Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** : function  
User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.
- xtype** : {'f','d','F','D'}  
This parameter is deprecated – avoid using it.  
The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If A does not have a `typecode` method then it will compute `A.matvec(x0)` to get a typecode. To save the extra computation when A does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

`scipy.sparse.linalg.gmres(A, b, x0=None, tol=1e-05, restart=None, maxiter=None, xtype=None, M=None, callback=None, restrt=None)`

Use Generalized Minimal RESidual iteration to solve  $Ax = b$ .

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}  
The real or complex N-by-N matrix of the linear system.
- b** : {array, matrix}

**Returns**

- x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).  
The converged solution.
- info** : int  
*Provides convergence information:*  
•0 : successful exit  
•>0 : convergence to tolerance not achieved, number of iterations  
•<0 : illegal input or breakdown

**Other Parameters**

- x0** : {array, matrix}  
Starting guess for the solution (a vector of zeros by default).
- tol** : float

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**restart** : int, optional

Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

**maxiter** : int, optional

Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**xtype** : {'f','d','F','D'}

This parameter is DEPRECATED — avoid using it.

The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If `A` does not have a `typecode` method then it will compute `A.matvec(x0)` to get a typecode. To save the extra computation when `A` does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

**M** : {sparse matrix, dense matrix, LinearOperator}

Inverse of the preconditioner of `A`. `M` should approximate the inverse of `A` and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(rk)`, where `rk` is the current residual vector.

**restrt** : int, optional

DEPRECATED - use *restart* instead.

See also:

[LinearOperator](#)

### Notes

A preconditioner, `P`, is chosen such that `P` is close to `A` but easy to solve for. The preconditioner parameter required by this routine is  $M = P^{-1}$ . The inverse should preferably not be calculated explicitly. Rather, use the following template to produce `M`:

```
# Construct a linear operator that computes P^-1 * x.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

```
scipy.sparse.linalg.lgmres(A, b, x0=None, tol=1e-05, maxiter=1000, M=None, callback=None,
                           inner_m=30, outer_k=3, outer_v=None, store_outer_Av=True)
```

Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm [R334] [R335] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}

The real or complex N-by-N matrix of the linear system.

**b** : {array, matrix}

Right hand side of the linear system. Has shape (N,) or (N,1).

**x0** : {array, matrix}

Starting guess for the solution.

**tol** : float, optional

Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : int, optional  
 Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}, optional  
 Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function, optional  
 User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

**inner\_m** : int, optional  
 Number of inner GMRES iterations per each outer iteration.

**outer\_k** : int, optional  
 Number of vectors to carry between inner GMRES iterations. According to [R334], good values are in the range of 1...3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.

**outer\_v** : list of tuples, optional  
 List containing tuples (v, Av) of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element Av can be None if the matrix-vector product should be re-evaluated. This parameter is modified in-place by lgmres, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.

**store\_outer\_Av** : bool, optional  
 Whether LGMRES should store also A\*v in addition to vectors v in the outer\_v list. Default is True.

**Returns**

**x** : array or matrix  
 The converged solution.

**info** : int  
 Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

**Notes**

The LGMRES algorithm [R334] [R335] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the *outer\_v* argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

**References**

[R334], [R335]

scipy.sparse.linalg.minres (A, b, x0=None, shift=0.0, tol=1e-05, maxiter=None, xtype=None, M=None, callback=None, show=False, check=False)  
 Use MINimum RESidual iteration to solve Ax=b

MINRES minimizes  $\text{norm}(A*x - b)$  for a real symmetric matrix  $A$ . Unlike the Conjugate Gradient method,  $A$  can be indefinite or singular.

If  $\text{shift} \neq 0$  then the method solves  $(A - \text{shift}*I)x = b$

**Parameters**

- A** : {sparse matrix, dense matrix, LinearOperator}  
The real symmetric N-by-N matrix of the linear system
- b** : {array, matrix}

**Returns**

- x** : {array, matrix} Right hand side of the linear system. Has shape (N,) or (N,1).  
The converged solution.
- info** : integer

**Provides convergence information:**

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

**Other Parameters**

- x0** : {array, matrix}  
Starting guess for the solution.
- tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.
- maxiter** : integer  
Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- M** : {sparse matrix, dense matrix, LinearOperator}  
Preconditioner for  $A$ . The preconditioner should approximate the inverse of  $A$ . Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** : function  
User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.
- xtype** : {'f','d','F','D'}  
This parameter is deprecated – avoid using it.  
The type of the result. If `None`, then it will be determined from `A.dtype.char` and `b`. If  $A$  does not have a `typecode` method then it will compute `A.matvec(x0)` to get a `typecode`. To save the extra computation when  $A$  does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',` or `'D'`. This parameter has been superseded by `LinearOperator`.

### Notes

THIS FUNCTION IS EXPERIMENTAL AND SUBJECT TO CHANGE!

#### *This file is a translation of the following MATLAB implementation:*

<http://www.stanford.edu/group/SOL/software/minres/matlab/>

`scipy.sparse.linalg.qmr(A, b, x0=None, tol=1e-05, maxiter=None, xtype=None, M1=None, M2=None, callback=None)`

Use Quasi-Minimal Residual iteration to solve  $Ax = b$ .

**Parameters** **A** : {sparse matrix, dense matrix, LinearOperator}  
 The real-valued N-by-N matrix of the linear system. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : {array, matrix}  
 Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns** **x** : {array, matrix}  
 The converged solution.

**info** : integer  
**Provides convergence information:**  
 0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** : {array, matrix}  
 Starting guess for the solution.

**tol** : float  
 Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below *tol*.

**maxiter** : integer  
 Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M1** : {sparse matrix, dense matrix, LinearOperator}  
 Left preconditioner for A.

**M2** : {sparse matrix, dense matrix, LinearOperator}  
 Right preconditioner for A. Used together with the left preconditioner M1. The matrix  $M1 * A * M2$  should have better conditioned than A alone.

**callback** : function  
 User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**xtype** : {'f','d','F','D'}  
 This parameter is DEPRECATED – avoid using it.  
 The type of the result. If None, then it will be determined from `A.dtype.char` and `b`. If A does not have a `typecode` method then it will compute `A.matvec(x0)` to get a typecode. To save the extra computation when A does not have a `typecode` attribute use `xtype=0` for the same type as `b` or use `xtype='f','d','F',`or `'D'`. This parameter has been superseded by `LinearOperator`.

|----------------------------------------------------------|---------------------------------------------------------------------------------|
| <code>lsqr(A, b[, damp, atol, btol, conlim, ...])</code> | Find the least-squares solution to a large, sparse, linear system of equations. |
| <code>lsmr(A, b[, damp, atol, btol, conlim, ...])</code> | Iterative solver for least-squares problems.                                    |

---

`scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=10000000.0, iter_lim=None, show=False, calc_var=False)`

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves  $Ax = b$  or  $\min ||b - Ax||^2$  or  $\min ||Ax - b||^2 + d^2 ||x||^2$ .

The matrix A may be square or rectangular (over-determined or under-determined), and may have any rank.

1. Unsymmetric equations -- solve  $A * x = b$

2. Linear least squares -- solve  $Ax = b$   
in the least-squares sense
3. Damped least squares -- solve  $\begin{pmatrix} A \\ \text{damp} \cdot I \end{pmatrix} x = \begin{pmatrix} b \\ 0 \end{pmatrix}$   
in the least-squares sense

**Parameters**

**A** : {sparse matrix, ndarray, LinearOperator}  
Representation of an m-by-n matrix. It is required that the linear operator can produce  $Ax$  and  $A^T x$ .

**b** : array\_like, shape (m,)  
Right-hand side vector b.

**damp** : float  
Damping coefficient.

**atol, btol** : float, optional  
Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final x will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of damp.)

**conlim** : float, optional  
Another stopping tolerance. lsqr terminates if an estimate of  $\text{cond}(A)$  exceeds *conlim*. For compatible systems  $Ax = b$ , *conlim* could be as large as 1.0e+12 (say). For least-squares problems, *conlim* should be less than 1.0e+8. Maximum precision can be obtained by setting *atol* = *btol* = *conlim* = zero, but the number of iterations may then be excessive.

**iter\_lim** : int, optional  
Explicit limitation on number of iterations (for safety).

**show** : bool, optional  
Display an iteration log.

**calc\_var** : bool, optional  
Whether to estimate diagonals of  $(A^T A + \text{damp}^2 \cdot I)^{-1}$ .

**Returns**

**x** : ndarray of float  
The final solution.

**istop** : int  
Gives the reason for termination. 1 means x is an approximate solution to  $Ax = b$ . 2 means x approximately solves the least-squares problem.

**itn** : int  
Iteration number upon termination.

**r1norm** : float  
 $\text{norm}(r)$ , where  $r = b - Ax$ .

**r2norm** : float  
 $\sqrt{\text{norm}(r)^2 + \text{damp}^2 * \text{norm}(x)^2}$ . Equal to *r1norm* if *damp* == 0.

**anorm** : float  
Estimate of Frobenius norm of  $A_{\text{bar}} = \begin{bmatrix} A \\ \text{damp} \cdot I \end{bmatrix}$ .

**acond** : float  
Estimate of  $\text{cond}(A_{\text{bar}})$ .

**arnorm** : float  
Estimate of  $\text{norm}(A^T * r - \text{damp}^2 * x)$ .

**xnorm** : float  
 $\text{norm}(x)$

**var** : ndarray of float

If `calc_var` is `True`, estimates all diagonals of  $(A'A)^{-1}$  (if `damp == 0`) or more generally  $(A'A + \text{damp}^2 * I)^{-1}$ . This is well defined if  $A$  has full column rank or `damp > 0`. (Not sure what `var` means if  $\text{rank}(A) < n$  and `damp = 0`.)

**Notes**

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of  $A$  should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of  $A$  is very small or large compared to the other rows of  $A$ , the corresponding row of  $(A b)$  should be scaled up or down.

In problems 1 and 2, the solution  $x$  is easily recovered following column-scaling. Unless better information is known, the nonzero columns of  $A$  should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if `damp` is nonzero. However, the value of `damp` should be assigned only after attention has been paid to the scaling of  $A$ .

The parameter `damp` is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter `acond`, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate  $x_0$  is known and if `damp == 0`, one could proceed as follows:

1. Compute a residual vector  $r_0 = b - A * x_0$ .
2. Use LSQR to solve the system  $A * dx = r_0$ .
3. Add the correction  $dx$  to obtain a final solution  $x = x_0 + dx$ .

This requires that  $x_0$  be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes  $k_1$  iterations to solve  $A * x = b$  and  $k_2$  iterations to solve  $A * dx = r_0$ . If  $x_0$  is “good”,  $\text{norm}(r_0)$  will be smaller than  $\text{norm}(b)$ . If the same stopping tolerances `atol` and `btol` are used for each system,  $k_1$  and  $k_2$  will be similar, but the final solution  $x_0 + dx$  should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value `btol` is suitable for  $A * x = b$ , the larger value  $\text{btol} * \text{norm}(b) / \text{norm}(r_0)$  should be suitable for  $A * dx = r_0$ .

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system  $M * x = b$  efficiently, where  $M$  approximates  $A$  in some helpful way (e.g.  $M - A$  has low rank or its elements are small relative to those of  $A$ ), LSQR may converge more rapidly on the system  $A * M(\text{inverse}) * z = b$ , after which  $x$  can be recovered by solving  $M * x = z$ .

If  $A$  is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (`cg`) and/or `SYMMLQ`. `SYMMLQ` is an implementation of symmetric `cg` that applies to any symmetric  $A$  and will converge more rapidly than LSQR. If  $A$  is positive definite, there are other implementations of symmetric `cg` that require slightly less work per iteration than `SYMMLQ` (but will take the same number of iterations).

`scipy.sparse.linalg.lsmr(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False)`

Iterative solver for least-squares problems.

`lsmr` solves the system of linear equations  $Ax = b$ . If the system is inconsistent, it solves the least-squares problem  $\min ||b - Ax||_2$ .  $A$  is a rectangular matrix of dimension  $m$ -by- $n$ , where all cases are allowed:  $m = n$ ,  $m > n$ , or  $m < n$ .  $B$  is a vector of length  $m$ . The matrix  $A$  may be dense or sparse (usually sparse).

**Parameters**  $A$  : {matrix, sparse matrix, ndarray, LinearOperator}  
 Matrix  $A$  in the linear system.

**b** : array\_like, shape (m,)

Vector b in the linear system.

**damp** : float

Damping factor for regularized least-squares. `lsqr` solves the regularized least-squares problem:

$$\min \| (b - (A + \text{damp} \cdot I)x) \|_2$$

where damp is a scalar. If damp is None or 0, the system is solved without regularization.

**atol, btol** : float, optional

Stopping tolerances. `lsqr` continues iterations until a certain backward error estimate is smaller than some quantity depending on atol and btol. Let  $r = b - Ax$  be the residual vector for the current approximate solution  $x$ . If  $Ax = b$  seems to be consistent, `lsqr` terminates when  $\text{norm}(r) \leq \text{atol} * \text{norm}(A) * \text{norm}(x) + \text{btol} * \text{norm}(b)$ . Otherwise, `lsqr` terminates when  $\text{norm}(A^T r) \leq \text{atol} * \text{norm}(A) * \text{norm}(r)$ . If both tolerances are  $1.0e-6$  (say), the final  $\text{norm}(r)$  should be accurate to about 6 digits. (The final  $x$  will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of LAMBDA.) If *atol* or *btol* is None, a default value of  $1.0e-6$  will be used. Ideally, they should be estimates of the relative error in the entries of A and B respectively. For example, if the entries of A have 7 correct digits, set  $\text{atol} = 1e-7$ . This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

**conlim** : float, optional

`lsqr` terminates if an estimate of  $\text{cond}(A)$  exceeds *conlim*. For compatible systems  $Ax = b$ , *conlim* could be as large as  $1.0e+12$  (say). For least-squares problems, *conlim* should be less than  $1.0e+8$ . If *conlim* is None, the default value is  $1e+8$ . Maximum precision can be obtained by setting  $\text{atol} = \text{btol} = \text{conlim} = 0$ , but the number of iterations may then be excessive.

**maxiter** : int, optional

`lsqr` terminates if the number of iterations reaches *maxiter*. The default is  $\text{maxiter} = \min(m, n)$ . For ill-conditioned systems, a larger value of *maxiter* may be needed.

**show** : bool, optional

Print iterations logs if *show*=True.

### Returns

**x** : ndarray of float

Least-square solution returned.

**istop** : int

istop gives the reason for stopping:

```
istop = 0 means x=0 is a solution.
       = 1 means x is an approximate solution to A*x = B,
           according to atol and btol.
       = 2 means x approximately solves the least-squares problem
           according to atol.
       = 3 means COND(A) seems to be greater than CONLIM.
       = 4 is the same as 1 with atol = btol = eps (machine
           precision)
       = 5 is the same as 2 with atol = eps.
       = 6 is the same as 3 with CONLIM = 1/eps.
       = 7 means ITN reached maxiter before the other stopping
           conditions were satisfied.
```

**itn** : int  
 Number of iterations used.

**normr** : float  
 $\text{norm}(b - Ax)$

**normar** : float  
 $\text{norm}(A^T (b - Ax))$

**norma** : float  
 $\text{norm}(A)$

**conda** : float  
 Condition number of A.

**normx** : float  
 $\text{norm}(x)$

**Notes**

New in version 0.11.0.

### 5.22.5 Matrix factorizations

Eigenvalue problems:

|                                                           |                                                                                                      |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>eigs(A[, k, M, sigma, which, v0, ncv, ...])</code>  | Find k eigenvalues and eigenvectors of the square matrix A.                                          |
| <code>eigsh(A[, k, M, sigma, which, v0, ncv, ...])</code> | Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix. |
| <code>lobpcg(A, X[, B, M, Y, tol, maxiter, ...])</code>   | Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)                              |

`scipy.sparse.linalg.eigs(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, OPpart=None)`

Find k eigenvalues and eigenvectors of the square matrix A.

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for w[i] eigenvalues with corresponding eigenvectors x[i].

If M is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for w[i] eigenvalues with corresponding eigenvectors x[i]

- Parameters**
- A** : ndarray, sparse matrix or LinearOperator  
 An array, sparse matrix, or LinearOperator representing the operation  $A * x$ , where A is a real or complex square matrix.
  - k** : int, optional  
 The number of eigenvalues and eigenvectors desired. *k* must be smaller than N-1. It is not possible to compute all eigenvectors of a matrix.
  - M** : ndarray, sparse matrix or LinearOperator, optional  
 An array, sparse matrix, or LinearOperator representing the operation  $M*x$  for the generalized eigenvalue problem  
 $A * x = w * M * x$ .  
 M must represent a real, symmetric matrix if A is real, and must represent a complex, hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:
    - If *sigma* is None, M is positive definite
    - If *sigma* is specified, M is positive semi-definite

If `sigma` is `None`, `eigs` requires an operator to compute the solution of the linear equation  $M * x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix `M`, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator `Minv`, which gives  $x = Minv * b = M^{-1} * b$ .

**sigma** : real or complex, optional

Find eigenvalues near `sigma` using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - sigma * M] * x = b$ , where `M` is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices `A` & `M`, or via an iterative solver if either `A` or `M` is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives  $x = OPinv * b = [A - sigma * M]^{-1} * b$ . For a real matrix `A`, shift-invert can either be done in imaginary mode or real mode, specified by the parameter `OPpart` ('r' or 'i'). Note that when `sigma` is specified, the keyword 'which' (below) refers to the shifted eigenvalues  $w' [i]$  where:

*If A is real and OPpart == 'r' (default),*

$$w' [i] = 1/2 * [1/(w[i]-sigma) + 1/(w[i]-conj(sigma))].$$

*If A is real and OPpart == 'i',*

$$w' [i] = 1/2i * [1/(w[i]-sigma) - 1/(w[i]-conj(sigma))].$$

*If A is complex,  $w' [i] = 1/(w[i]-sigma)$ .*

**v0** : ndarray, optional

Starting vector for iteration. Default: random

**ncv** : int, optional

The number of Lanczos vectors generated `ncv` must be greater than `k`; it is recommended that `ncv > 2*k`. Default: `min(n, max(2*k + 1, 20))`

**which** : str, ['LM' | 'SM' | 'LR' | 'SR' | 'LI' | 'SI'], optional

Which `k` eigenvectors and eigenvalues to find:

- 'LM' : largest magnitude
- 'SM' : smallest magnitude
- 'LR' : largest real part
- 'SR' : smallest real part
- 'LI' : largest imaginary part
- 'SI' : smallest imaginary part

When `sigma != None`, 'which' refers to the shifted eigenvalues  $w'[i]$  (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional

Maximum number of Arnoldi update iterations allowed Default: `n*10`

**tol** : float, optional

Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.

**return\_eigenvectors** : bool, optional

Return eigenvectors (True) in addition to eigenvalues

**Minv** : ndarray, sparse matrix or LinearOperator, optional

See notes in `M`, above.

**OPinv** : ndarray, sparse matrix or LinearOperator, optional

See notes in `sigma`, above.

**OPpart** : {'r' or 'i'}, optional

**Returns** `w` : ndarray See notes in `sigma`, above  
 Array of  $k$  eigenvalues.  
`v` : ndarray  
 An array of  $k$  eigenvectors. `v[:, i]` is the eigenvector corresponding to the eigenvalue `w[i]`.

**Raises** **ArpackNoConvergence**  
 When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

**See also:**

`eigsh` eigenvalues and eigenvectors for symmetric matrix `A`  
`svds` singular value decomposition for a matrix `A`

**Notes**

This function is a wrapper to the ARPACK [R327] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [R328].

**References**

[R327], [R328]

**Examples**

Find 6 eigenvectors of the identity matrix:

```
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigs(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
>>> vecs.shape
(13, 6)
```

`scipy.sparse.linalg.eigsh`(`A`, `k=6`, `M=None`, `sigma=None`, `which='LM'`, `v0=None`, `ncv=None`, `maxiter=None`, `tol=0`, `return_eigenvectors=True`, `Minv=None`, `OPinv=None`, `mode='normal'`)

Find  $k$  eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix `A`.

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for `w[i]` eigenvalues with corresponding eigenvectors `x[i]`.

If `M` is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for `w[i]` eigenvalues with corresponding eigenvectors `x[i]`

**Parameters** `A` : An  $N \times N$  matrix, array, sparse matrix, or `LinearOperator` representing the operation  $A * x$ , where `A` is a real symmetric matrix For buckling mode (see below) `A` must additionally be positive-definite

`k` : int, optional  
 The number of eigenvalues and eigenvectors desired.  $k$  must be smaller than  $N$ . It is not possible to compute all eigenvectors of a matrix.

**Returns** `w` : array  
 Array of  $k$  eigenvalues

`v` : array  
 An array representing the  $k$  eigenvectors. The column `v[:, i]` is the eigenvector corresponding to the eigenvalue `w[i]`.

**Other Parameters**

`M` : An  $N \times N$  matrix, array, sparse matrix, or linear operator representing

the operation  $M * x$  for the generalized eigenvalue problem

$$A * x = w * M * x.$$

$M$  must represent a real, symmetric matrix if  $A$  is real, and must represent a complex, hermitian matrix if  $A$  is complex. For best results, the data type of  $M$  should be the same as that of  $A$ . Additionally:

If  $\sigma$  is `None`,  $M$  is symmetric positive definite

If  $\sigma$  is specified,  $M$  is symmetric positive semi-definite

In buckling mode,  $M$  is symmetric indefinite.

If  $\sigma$  is `None`, `eigsh` requires an operator to compute the solution of the linear equation  $M * x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix  $M$ , or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator `Minv`, which gives  $x = \text{Minv} * b = M^{-1} * b$ .

**sigma** : real

Find eigenvalues near  $\sigma$  using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - \sigma * M] x = b$ , where  $M$  is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices  $A$  &  $M$ , or via an iterative solver if either  $A$  or  $M$  is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives  $x = \text{OPinv} * b = [A - \sigma * M]^{-1} * b$ . Note that when  $\sigma$  is specified, the keyword ‘which’ refers to the shifted eigenvalues  $w' [i]$  where:

if `mode == 'normal'`,  $w' [i] = 1 / (w[i] - \sigma)$ .

if `mode == 'cayley'`,  $w' [i] = (w[i] + \sigma) / (w[i] - \sigma)$ .

if `mode == 'buckling'`,  $w' [i] = w[i] / (w[i] - \sigma)$ .

(see further discussion in ‘mode’ below)

**v0** : ndarray, optional

Starting vector for iteration. Default: random

**ncv** : int, optional

The number of Lanczos vectors generated `ncv` must be greater than  $k$  and smaller than  $n$ ; it is recommended that  $\text{ncv} > 2 * k$ . Default:  $\min(n, \max(2 * k + 1, 20))$

**which** : str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']

If  $A$  is a complex hermitian matrix, ‘BE’ is invalid. Which  $k$  eigenvectors and eigenvalues to find:

‘LM’ : Largest (in magnitude) eigenvalues

‘SM’ : Smallest (in magnitude) eigenvalues

‘LA’ : Largest (algebraic) eigenvalues

‘SA’ : Smallest (algebraic) eigenvalues

‘BE’ : Half ( $k/2$ ) from each end of the spectrum

When  $k$  is odd, return one more ( $k/2+1$ ) from the high end. When  $\sigma \neq \text{None}$ , ‘which’ refers to the shifted eigenvalues  $w' [i]$  (see discussion in ‘sigma’, above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional

Maximum number of Arnoldi update iterations allowed Default:  $n * 10$

**tol** : float

Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

**Minv** :  $N \times N$  matrix, array, sparse matrix, or LinearOperator

See notes in `M`, above

**OPinv** :  $N \times N$  matrix, array, sparse matrix, or `LinearOperator`

See notes in `sigma`, above.

**return\_eigenvectors** : bool

Return eigenvectors (True) in addition to eigenvalues

**mode** : string ['normal' | 'buckling' | 'cayley']

Specify strategy to use for shift-invert mode. This argument applies only for real-valued `A` and `sigma` != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem  $OP * x'[i] = w'[i] * B * x'[i]$  and transforms the resulting Ritz vectors  $x'[i]$  and Ritz values  $w'[i]$  into the desired eigenvectors and eigenvalues of the problem  $A * x[i] = w[i] * M * x[i]$ . The modes are as follows:

**'normal'** :  $OP = [A - \text{sigma} * M]^{-1} * M$ ,  $B = M$ ,  $w'[i] = 1 / (w[i] - \text{sigma})$

**'buckling'** :  $OP = [A - \text{sigma} * M]^{-1} * A$ ,  $B = A$ ,  $w'[i] = w[i] / (w[i] - \text{sigma})$

**'cayley'** :  $OP = [A - \text{sigma} * M]^{-1} * [A + \text{sigma} * M]$ ,  $B = M$ ,  $w'[i] = (w[i] + \text{sigma}) / (w[i] - \text{sigma})$

The choice of mode will affect which eigenvalues are selected by the keyword 'which', and can also impact the stability of convergence (see [2] for a discussion)

**Raises**

**ArpackNoConvergence**

When the requested convergence is not obtained.

The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

**See also:**

`eigs` eigenvalues and eigenvectors for a general (nonsymmetric) matrix `A`  
`svds` singular value decomposition for a matrix `A`

**Notes**

This function is a wrapper to the ARPACK [R329] SSEUPD and DSEUPD functions which use the Implicitly Restarted Lanczos Method to find the eigenvalues and eigenvectors [R330].

**Examples**

```
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigsh(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
>>> vecs.shape
(13, 6)
```

`scipy.sparse.linalg.lobpcg(A, X, B=None, M=None, Y=None, tol=None, maxiter=20, largest=True, verbosityLevel=0, retLambdaHistory=False, retResidualNormsHistory=False)`

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

**Parameters** `A` : {sparse matrix, dense matrix, `LinearOperator`}

The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.

**X** : array\_like  
Initial approximation to the  $k$  eigenvectors. If  $A$  has shape  $(n,n)$  then  $X$  should have shape  $(n,k)$ .

**B** : {dense matrix, sparse matrix, LinearOperator}, optional  
the right hand side operator in a generalized eigenproblem. by default,  $B = \text{Identity}$  often called the “mass matrix”

**M** : {dense matrix, sparse matrix, LinearOperator}, optional  
preconditioner to  $A$ ; by default  $M = \text{Identity}$   $M$  should approximate the inverse of  $A$

**Y** : array\_like, optional  
 $n$ -by- $\text{size}Y$  matrix of constraints,  $\text{size}Y < n$  The iterations will be performed in the  $B$ -orthogonal complement of the column-space of  $Y$ .  $Y$  must be full rank.

**Returns**

**w** : array  
Array of  $k$  eigenvalues

**v** : array  
An array of  $k$  eigenvectors.  $V$  has the same shape as  $X$ .

**Other Parameters**

**tol** : scalar, optional  
Solver tolerance (stopping criterion) by default:  $\text{tol} = n * \sqrt{\text{eps}}$

**maxiter** : integer, optional  
maximum number of iterations by default:  $\text{maxiter} = \min(n, 20)$

**largest** : bool, optional  
when True, solve for the largest eigenvalues, otherwise the smallest

**verbosityLevel** : integer, optional  
controls solver output. default:  $\text{verbosityLevel} = 0$ .

**retLambdaHistory** : boolean, optional  
whether to return eigenvalue history

**retResidualNormsHistory** : boolean, optional  
whether to return history of residual norms

### Notes

If both `retLambdaHistory` and `retResidualNormsHistory` are True, the return tuple has the following format (lambda, V, lambda history, residual norms history).

In the following  $n$  denotes the matrix size and  $m$  the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size  $3 * m$  on every iteration by calling the “standard” dense eigensolver, so if  $m$  is not small enough compared to  $n$ , it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. numpy or scipy function in this case. If one calls the LOBPCG algorithm for  $5 * m > n$ , it will most likely break internally, so the code tries to call the standard function instead.

It is not that  $n$  should be large for the LOBPCG to work, but rather the ratio  $n/m$  should be large. If you call the LOBPCG code with  $m = 1$  and  $n = 10$ , it should work, though  $n$  is small. The method is intended for extremely large  $n/m$ , see e.g., reference [28] in <http://arxiv.org/abs/0705.2626>

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary  $m$  to make this better.
2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large  $n$ , so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for  $A$ , which is easy to code since  $A$  is tridiagonal.

### Acknowledgements

lobpcg.py code was written by Robert Cimrman. Many thanks belong to Andrew Knyazev, the author of the algorithm, for lots of advice and support.

### Examples

Solve  $Ax = \lambda Bx$  with constraints and preconditioning.

```
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = [np.arange(n, dtype=np.float64) + 1]
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1.,  0.,  0., ...,  0.,  0.,  0.],
       [ 0.,  2.,  0., ...,  0.,  0.,  0.],
       [ 0.,  0.,  3., ...,  0.,  0.,  0.],
       ...,
       [ 0.,  0.,  0., ..., 98.,  0.,  0.],
       [ 0.,  0.,  0., ...,  0., 99.,  0.],
       [ 0.,  0.,  0., ...,  0.,  0., 100.]])
```

Constraints.

```
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```
>>> X = np.random.rand(n, 3)
```

Preconditioner – inverse of A (as an abstract linear operator).

```
>>> invA = spdiags([1./vals[0]], 0, n, n)
>>> def precondition(x):
...     return invA * x
>>> M = LinearOperator(matvec=precond, shape=(n, n), dtype=float)
```

Here, invA could of course have been used directly as a preconditioner. Let us then solve the problem:

```
>>> eigs, vecs = lobpcg(A, X, Y=Y, M=M, tol=1e-4, maxiter=40, largest=False)
>>> eigs
array([ 4.,  5.,  6.])
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

---

`svds(A[, k, ncv, tol, which, v0, maxiter, ...])` Compute the largest k singular values/vectors for a sparse matrix.

---

`scipy.sparse.linalg.svds` (*A*, *k*=6, *ncv*=None, *tol*=0, *which*='LM', *v0*=None, *maxiter*=None, *return\_singular\_vectors*=True)

Compute the largest *k* singular values/vectors for a sparse matrix.

**Parameters**

**A** : {sparse matrix, LinearOperator}  
Array to compute the SVD on, of shape (M, N)

**k** : int, optional  
Number of singular values and vectors to compute. Must be  $1 \leq k < \min(A.shape)$ .

**ncv** : int, optional  
The number of Lanczos vectors generated *ncv* must be greater than *k*+1 and smaller than *n*; it is recommended that  $ncv > 2*k$  Default:  $\min(n, \max(2*k + 1, 20))$

**tol** : float, optional  
Tolerance for singular values. Zero (default) means machine precision.

**which** : str, ['LM' | 'SM'], optional  
Which *k* singular values to find:

- 'LM' : largest singular values
- 'SM' : smallest singular values

New in version 0.12.0.

**v0** : ndarray, optional  
Starting vector for iteration, of length  $\min(A.shape)$ . Should be an (approximate) left singular vector if  $N > M$  and a right singular vector otherwise.  
Default: random  
New in version 0.12.0.

**maxiter** : int, optional  
Maximum number of iterations.  
New in version 0.12.0.

**return\_singular\_vectors** : bool or str, optional

- True: return singular vectors (True) in addition to singular values.  
New in version 0.12.0.
- "u": only return the u matrix, without computing *vh* (if  $N > M$ ).
- "vh": only return the *vh* matrix, without computing *u* (if  $N \leq M$ ).  
New in version 0.16.0.

**Returns**

**u** : ndarray, shape=(M, k)  
Unitary matrix having left singular vectors as columns. If *return\_singular\_vectors* is "vh", this variable is not computed, and None is returned instead.

**s** : ndarray, shape=(k,)  
The singular values.

**vt** : ndarray, shape=(k, N)  
Unitary matrix having right singular vectors as rows. If *return\_singular\_vectors* is "u", this variable is not computed, and None is returned instead.

### Notes

This is a naive implementation using ARPACK as an eigensolver on  $A.H * A$  or  $A * A.H$ , depending on which one is more efficient.

Complete or incomplete LU factorizations

---

`splu(A[, permc_spec, diag_pivot_thresh, ...])` Compute the LU decomposition of a sparse, square matrix.

Continued on next page

Table 5.208 – continued from previous page

|                                                                |                                                                     |
|----------------------------------------------------------------|---------------------------------------------------------------------|
| <code>spilu(A[, drop_tol, fill_factor, drop_rule, ...])</code> | Compute an incomplete LU decomposition for a sparse, square matrix. |
| <code>SuperLU</code>                                           | LU factorization of a sparse matrix.                                |

`scipy.sparse.linalg.spilu(A, permc_spec=None, diag_pivot_thresh=None, drop_tol=None, relax=None, panel_size=None, options={})`  
 Compute the LU decomposition of a sparse, square matrix.

**Parameters**

- A** : sparse matrix  
 Sparse matrix to factorize. Should be in CSR or CSC format.
- permc\_spec** : str, optional  
 How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
  - **NATURAL**: natural ordering.
  - **MMD\_ATA**: minimum degree ordering on the structure of  $A^T A$ .
  - **MMD\_AT\_PLUS\_A**: minimum degree ordering on the structure of  $A^T A + A$ .
  - **COLAMD**: approximate minimum degree column ordering
- diag\_pivot\_thresh** : float, optional  
 Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user's guide for details [R349]
- drop\_tol** : float, optional  
 (deprecated) No effect.
- relax** : int, optional  
 Expert option for customizing the degree of relaxing supernodes. See SuperLU user's guide for details [R349]
- panel\_size** : int, optional  
 Expert option for customizing the panel size. See SuperLU user's guide for details [R349]
- options** : dict, optional  
 Dictionary containing additional expert options to SuperLU. See SuperLU user guide [R349] (section 2.4 on the 'Options' argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE')` to turn equilibration off and perform a single iterative refinement.

**Returns**

- invA** : `scipy.sparse.linalg.SuperLU`  
 Object, which has a `solve` method.

**See also:**

`spilu` incomplete LU decomposition

**Notes**

This function uses the SuperLU library.

**References**

[R349]

`scipy.sparse.linalg.spilu(A, drop_tol=None, fill_factor=None, drop_rule=None, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options=None)`  
 Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of A.

**Parameters**

- A** : (N, N) array\_like  
 Sparse matrix to factorize

**drop\_tol** : float, optional  
Drop tolerance ( $0 \leq \text{tol} \leq 1$ ) for an incomplete LU decomposition. (default:  $1e-4$ )

**fill\_factor** : float, optional  
Specifies the fill ratio upper bound ( $\geq 1.0$ ) for ILU. (default: 10)

**drop\_rule** : str, optional  
Comma-separated string of drop rules to use. Available rules: `basic`, `prows`, `column`, `area`, `secondary`, `dynamic`, `interp`. (Default: `basic, area`)  
See SuperLU documentation for details.

**Remaining other options**  
Same as for `splu`.

**Returns** **invA\_approx** : `scipy.sparse.linalg.SuperLU`  
Object, which has a `solve` method.

**See also:**

`splu` complete LU decomposition

**Notes**

To improve the better approximation to the inverse, you may need to increase `fill_factor` AND decrease `drop_tol`.

This function uses the SuperLU library.

**class** `scipy.sparse.linalg.SuperLU`  
LU factorization of a sparse matrix.

Factorization is represented as:

$$P_r * A * P_c = L * U$$

To construct these `SuperLU` objects, call the `splu` and `spilu` functions.

**Notes**

New in version 0.14.0.

**Examples**

The LU decomposition can be used to solve matrix equations. Consider:

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1, 2, 0, 4], [1, 0, 0, 1], [1, 0, 2, 1], [2, 2, 1, 0]])
```

This can be solved for a given right-hand side:

```
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1.,  2.,  3.,  4.])
```

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The L and U factors are sparse matrices in CSC format:

```
>>> lu.L.A
array([[ 1. ,  0. ,  0. ,  0. ],
       [ 0. ,  1. ,  0. ,  0. ],
       [ 0. ,  0. ,  1. ,  0. ],
       [ 1. ,  0.5,  0.5,  1. ]])
>>> lu.U.A
array([[ 2.,  0.,  1.,  4.],
       [ 0.,  2.,  1.,  1.],
       [ 0.,  0.,  1.,  1.],
       [ 0.,  0.,  0., -5.]])
```

The permutation matrices can be constructed:

```
>>> Pr = csc_matrix((4, 4))
>>> Pr[lu.perm_r, np.arange(4)] = 1
>>> Pc = csc_matrix((4, 4))
>>> Pc[np.arange(4), lu.perm_c] = 1
```

We can reassemble the original matrix:

```
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1.,  2.,  0.,  4.],
       [ 1.,  0.,  0.,  1.],
       [ 1.,  0.,  2.,  1.],
       [ 2.,  2.,  1.,  0.]])
```

### Attributes

|---------------------|----------------------------------------------------------------------------------------|
| <code>shape</code>  | Shape of the original matrix as a tuple of ints.                                       |
| <code>nnz</code>    | Number of nonzero elements in the matrix.                                              |
| <code>perm_c</code> | Permutation Pc represented as an array of indices.                                     |
| <code>perm_r</code> | Permutation Pr represented as an array of indices.                                     |
| <code>L</code>      | Lower triangular factor with unit diagonal as a <code>scipy.sparse.csc_matrix</code> . |
| <code>U</code>      | Upper triangular factor as a <code>scipy.sparse.csc_matrix</code> .                    |

---

#### SuperLU.`shape`

Shape of the original matrix as a tuple of ints.

#### SuperLU.`nnz`

Number of nonzero elements in the matrix.

#### SuperLU.`perm_c`

Permutation Pc represented as an array of indices.

The column permutation matrix can be reconstructed via:

```
>>> Pc = np.zeros((n, n))
>>> Pc[np.arange(n), perm_c] = 1
```

SuperLU.**perm\_r**

Permutation Pr represented as an array of indices.

The row permutation matrix can be reconstructed via:

```
>>> Pr = np.zeros((n, n))
>>> Pr[perm_r, np.arange(n)] = 1
```

SuperLU.**L**

Lower triangular factor with unit diagonal as a `scipy.sparse.csc_matrix`.

New in version 0.14.0.

SuperLU.**U**

Upper triangular factor as a `scipy.sparse.csc_matrix`.

New in version 0.14.0.

**Methods**

---

`solve(rhs[, trans])` Solves linear system of equations with one or several right-hand sides.

---

SuperLU.**solve** (*rhs* [, *trans* ])

Solves linear system of equations with one or several right-hand sides.

**Parameters**

- rhs** : ndarray, shape (n,) or (n, k)  
Right hand side(s) of equation
- trans** : { 'N', 'T', 'H' }, optional  
Type of system to solve:
  - 'N':  $A * x == rhs$  (default)
  - 'T':  $A^T * x == rhs$
  - 'H':  $A^H * x == rhs$

**Returns**

- x** : ndarray, shape  $rhs.shape$   
i.e., normal, transposed, and hermitian conjugate.  
Solution vector(s)

## 5.22.6 Exceptions

| <code>breadth_first_order(csgraph, i_start[, ...])</code>     | Return a breadth-first ordering starting with specified node.                    |
| <code>depth_first_order(csgraph, i_start[, ...])</code>       | Return a depth-first ordering starting with specified node.                      |
| <code>breadth_first_tree(csgraph, i_start[, directed])</code> | Return the tree generated by a breadth-first search                              |
| <code>depth_first_tree(csgraph, i_start[, directed])</code>   | Return a tree generated by a depth-first search.                                 |
| <code>minimum_spanning_tree(csgraph[, overwrite])</code>      | Return a minimum spanning tree of an undirected graph                            |
| <code>reverse_cuthill_mckee(graph[, symmetric_mode])</code>   | Returns the permutation array that orders a sparse CSR or CSC matrix             |
| <code>maximum_bipartite_matching(graph[, perm_type])</code>   | Returns an array of row or column permutations that makes the diagonal           |
| <code>structural_rank(graph)</code>                           | Compute the structural rank of a graph (matrix) with a given sparsity pattern    |
| <code>NegativeCycleError</code>                               |                                                                                  |

`scipy.sparse.csgraph.connected_components` (*csgraph*, *directed=True*, *connection='weak'*, *return\_labels=True*)

Analyze the connected components of a sparse graph

New in version 0.11.0.

**Parameters** `csgraph` : array\_like or sparse matrix

The N x N matrix representing the compressed sparse graph. The input `csgraph` will be converted to `csr` format for the calculation.

**directed** : bool, optional

If `True` (default), then operate on a directed graph: only move from point `i` to point `j` along paths `csgraph[i, j]`. If `False`, then find the shortest path on an undirected graph: the algorithm can progress from point `i` to `j` along `csgraph[i, j]` or `csgraph[j, i]`.

**connection** : str, optional

['weak'|'strong']. For directed graphs, the type of connection to use. Nodes `i` and `j` are strongly connected if a path exists both from `i` to `j` and from `j` to `i`. Nodes `i` and `j` are weakly connected if only one of these paths exists. If `directed == False`, this keyword is not referenced.

**return\_labels** : bool, optional

If `True` (default), then return the labels for each of the connected components.

**Returns**

`n_components`: int

The number of connected components.

`labels`: ndarray

The length-N array of labels of the connected components.

**References**

[R278]

`scipy.sparse.csgraph.laplacian` (*csgraph*, *normed=False*, *return\_diag=False*, *use\_out\_degree=False*)

Return the Laplacian matrix of a directed graph.

**Parameters**

- csgraph** : array\_like or sparse matrix, 2 dimensions  
compressed-sparse graph, with shape (N, N).
- normed** : bool, optional  
If True, then compute normalized Laplacian.
- return\_diag** : bool, optional  
If True, then also return an array related to vertex degrees.
- use\_out\_degree** : bool, optional  
If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns**

- lap** : ndarray or sparse matrix  
The N x N laplacian matrix of *csgraph*. It will be a numpy array (dense) if the input was dense, or a sparse matrix otherwise.
- diag** : ndarray, optional  
The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

**Notes**

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

**Examples**

```
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```

`scipy.sparse.csgraph.shortest_path` (*csgraph*, *method='auto'*, *directed=True*, *return\_predecessors=False*, *unweighted=False*, *overwrite=False*, *indices=None*)

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters**

- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
- method** : string ['auto'|'FW'|'D'], optional  
Algorithm to use for shortest paths. Options are:

*‘auto’* – (default) select the best among *‘FW’*, *‘D’*, *‘BF’*, or *‘J’*

based on the input data.

*‘FW’* – *Floyd-Warshall algorithm*. Computational cost is approximately  $O[N^3]$ . The input csgraph will be converted to a dense representation.

*‘D’* – *Dijkstra’s algorithm with Fibonacci heaps*. Computational

cost is approximately  $O[N(N*k + N*\log(N))]$ , where  $k$  is the average number of connected edges per node. The input csgraph will be converted to a csr representation.

*‘BF’* – *Bellman-Ford algorithm*. This algorithm can be used when

weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately  $O[N(N^2*k)]$ , where  $k$  is the average number of connected edges per node. The input csgraph will be converted to a csr representation.

*‘J’* – *Johnson’s algorithm*. Like the *Bellman-Ford algorithm*,

Johnson’s algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra’s algorithm for faster computation.

**directed** : bool, optional

If True (default), then find the shortest path on a directed graph: only move from point  $i$  to point  $j$  along paths  $\text{csgraph}[i, j]$ . If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along  $\text{csgraph}[i, j]$  or  $\text{csgraph}[j, i]$

**return\_predecessors** : bool, optional

If True, return the size  $(N, N)$  predecessor matrix

**unweighted** : bool, optional

If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**overwrite** : bool, optional

If True, overwrite csgraph with the result. This applies only if method == ‘FW’ and csgraph is a dense, c-ordered array with dtype=float64.

**indices** : array\_like or int, optional

If specified, only compute the paths for the points at the given indices. Incompatible with method == ‘FW’.

**Returns**

**dist\_matrix** : ndarray

The  $N \times N$  matrix of distances between graph nodes.  $\text{dist\_matrix}[i,j]$  gives the shortest distance from point  $i$  to point  $j$  along the graph.

**predecessors** : ndarray

Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry  $\text{predecessors}[i, j]$  gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then

**Raises** **NegativeCycleError**:  $\text{predecessors}[i, j] = -9999$

if there are negative cycles in the graph

*Notes*

As currently implemented, Dijkstra’s algorithm and Johnson’s algorithm do not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are non-equal edges, `method='D'` may yield an incorrect result.

```
scipy.sparse.csgraph.dijkstra(csgraph, directed=True, indices=None,
                             return_predecessors=False, unweighted=False, limit=np.inf)
```

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

- Parameters**
- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of non-negative distances representing the input graph.
  - directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`
  - indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.
  - return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
  - unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
  - limit** : float, optional  
The maximum distance to calculate, must be  $\geq 0$ . Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance  $> \text{limit}$ . For such pairs, the distance will be equal to `np.inf` (i.e., not connected).
- Returns**
- dist\_matrix** : ndarray  
New in version 0.14.0.  
The matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.
  - predecessors** : ndarray  
Returned only if `return_predecessors == True`. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

*Notes*

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are not equal and both are nonzero, setting `directed=False` will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford’s algorithm or Johnson’s algorithm.

```
scipy.sparse.csgraph.floyd_warshall(csgraph, directed=True, return_predecessors=False,
                                    unweighted=False, overwrite=False)
```

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

- Parameters**
- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
  - directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
  - return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
  - unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
  - overwrite** : bool, optional  
If True, overwrite csgraph with the result. This applies only if csgraph is a dense, c-ordered array with dtype=float64.
- Returns**
- dist\_matrix** : ndarray  
The N x N matrix of distances between graph nodes. dist\_matrix[i,j] gives the shortest distance from point i to point j along the graph.
  - predecessors** : ndarray  
Returned only if return\_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999
- Raises**
- NegativeCycleError**:  
if there are negative cycles in the graph

```
scipy.sparse.csgraph.bellman_ford(csgraph, directed=True, indices=None,
                                return_predecessors=False, unweighted=False)
```

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra's algorithm may be faster.

New in version 0.11.0.

- Parameters**
- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
The N x N array of distances representing the input graph.
  - directed** : bool, optional  
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
  - indices** : array\_like or int, optional  
if specified, only compute the paths for the points at the given indices.
  - return\_predecessors** : bool, optional  
If True, return the size (N, N) predecessor matrix
  - unweighted** : bool, optional  
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- Returns**
- dist\_matrix** : ndarray  
The N x N matrix of distances between graph nodes. dist\_matrix[i,j] gives the shortest distance from point i to point j along the graph.

**predecessors** : ndarray  
 Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`.

**Raises** **NegativeCycleError**:  
 if there are negative cycles in the graph

*Notes*

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

`scipy.sparse.csgraph.johnson` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using Johnson's algorithm.

Johnson's algorithm combines the Bellman-Ford algorithm and Dijkstra's algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, `dijkstra()` may be faster.

New in version 0.11.0.

**Parameters**

- csgraph** : array, matrix, or sparse matrix, 2 dimensions  
 The  $N \times N$  array of distances representing the input graph.
- directed** : bool, optional  
 If True (default), then find the shortest path on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`
- indices** : array\_like or int, optional  
 if specified, only compute the paths for the points at the given indices.
- return\_predecessors** : bool, optional  
 If True, return the size  $(N, N)$  predecessor matrix
- unweighted** : bool, optional  
 If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns**

- dist\_matrix** : ndarray  
 The  $N \times N$  matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point  $i$  to point  $j$  along the graph.
- predecessors** : ndarray  
 Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`.

**Raises** **NegativeCycleError**:  
 if there are negative cycles in the graph

*Notes*

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

`scipy.sparse.csgraph.breadth_first_order` (*csgraph*, *i\_start*, *directed=True*, *return\_predecessors=True*)

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

**Parameters**

- csgraph** : array\_like or sparse matrix  
The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** : int  
The index of starting node.
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- return\_predecessors** : bool, optional  
If True (default), then return the predecessor array (see below).

**Returns**

- node\_array** : ndarray, one dimension  
The breadth-first list of nodes, starting with specified node. The length of node\_array is the number of nodes reachable from the specified node.
- predecessors** : ndarray, one dimension  
Returned only if return\_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

`scipy.sparse.csgraph.depth_first_order` (*csgraph*, *i\_start*, *directed=True*, *return\_predecessors=True*)

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters**

- csgraph** : array\_like or sparse matrix  
The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** : int  
The index of starting node.
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- return\_predecessors** : bool, optional  
If True (default), then return the predecessor array (see below).

**Returns**

- node\_array** : ndarray, one dimension  
The breadth-first list of nodes, starting with specified node. The length of node\_array is the number of nodes reachable from the specified node.
- predecessors** : ndarray, one dimension  
Returned only if return\_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

`scipy.sparse.csgraph.breadth_first_tree` (*csgraph*, *i\_start*, *directed=True*)

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

**Parameters**

- csgraph** : array\_like or sparse matrix  
The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** : int  
The index of starting node.
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.

**Returns**

- cstree** : csr matrix  
The N x N directed compressed-sparse representation of the breadth-first tree drawn from `csgraph`, starting at the specified node.

### Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
  
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.

`scipy.sparse.csgraph.depth_first_tree` (*csgraph*, *i\_start*, *directed=True*)

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

**Parameters**

- csgraph** : array\_like or sparse matrix  
The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** : int  
The index of starting node.
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**Returns**

- csmtree** : csr matrix  
The N x N directed compressed-sparse representation of the depth- first tree drawn from csgraph, starting at the specified node.

### Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])

```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

`scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)`  
Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

**Parameters**

- csgraph** : array\_like or sparse matrix, 2 dimensions  
The N x N matrix representing an undirected graph over N nodes (see notes below).
- overwrite** : bool, optional  
if true, then parts of the input graph will be overwritten for efficiency.

**Returns**

- span\_tree** : csr matrix  
The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

**Notes**

This routine uses undirected graphs as input and output. That is, if graph[i, j] and graph[j, i] are both zero, then nodes i and j do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

**Examples**

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
    
```

`scipy.sparse.csgraph.reverse_cuthill_mckee` (*graph*, *symmetric\_mode=False*)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix  $A+A.T$ . If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

**Parameters** **graph** : sparse matrix  
Input sparse in CSC or CSR sparse matrix format.  
**symmetric\_mode** : bool, optional  
Is input matrix guaranteed to be symmetric.

**Returns** **perm** : ndarray  
Array of permuted row and column indices.

**Notes**

New in version 0.15.0.

**References**

E. Cuthill and J. McKee, “Reducing the Bandwidth of Sparse Symmetric Matrices”, ACM ‘69 Proceedings of the 1969 24th national conference, (1969).

`scipy.sparse.csgraph.maximum_bipartite_matching` (*graph*, *perm\_type*=‘row’)

Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.

Such a permutation is always possible provided that the matrix is nonsingular. This function looks at the structure of the matrix only. The input matrix will be converted to CSC matrix format if necessary.

**Parameters** **graph** : sparse matrix  
Input sparse in CSC format  
**perm\_type** : str, {‘row’, ‘column’}  
Type of permutation to generate.

**Returns** **perm** : ndarray  
Array of row or column permutations.

**Notes**

This function relies on a maximum cardinality bipartite matching algorithm based on a breadth-first search (BFS) of the underlying graph.

New in version 0.15.0.

`scipy.sparse.csgraph.structural_rank` (*graph*)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

**Parameters** **graph** : sparse matrix  
Input sparse matrix.

**Returns** **rank** : int  
The structural rank of the sparse graph.  
New in version 0.19.0.

`scipy.sparse.csgraph.construct_dist_matrix` (*graph*, *predecessors*, *directed=True*, *null\_value=np.inf*)

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

**Parameters**

- graph** : array\_like or sparse  
The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.
- predecessors** : array\_like  
The N x N matrix of predecessors of each node (see Notes below).
- directed** : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- null\_value** : bool, optional  
value to use for distances between unconnected nodes. Default is `np.inf`

**Returns**

- dist\_matrix** : ndarray  
The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

**Notes**

The predecessor matrix is of the form returned by `graph_shortest_path`. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

`scipy.sparse.csgraph.csgraph_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*)

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

**Parameters**

- graph** : array\_like  
Input graph. Shape should be (n\_nodes, n\_nodes).
- null\_value** : float or None (optional)  
Value that denotes non-edges in the graph. Default is zero.
- infinity\_null** : bool  
If True (default), then infinite entries (both positive and negative) are treated as null edges.
- nan\_null** : bool  
If True (default), then NaN entries are treated as non-edges

**Returns**

- csgraph** : csr\_matrix  
Compressed sparse representation of graph,

`scipy.sparse.csgraph.csgraph_from_masked` (*graph*)

Construct a CSR-format graph from a masked array.

New in version 0.11.0.

**Parameters** **graph** : MaskedArray  
 Input graph. Shape should be (n\_nodes, n\_nodes).  
**Returns** **csgraph** : csr\_matrix  
 Compressed sparse representation of graph,

`scipy.sparse.csgraph.csgraph_masked_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*,  
*infinity\_null=True*, *copy=True*)  
 Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

**Parameters** **graph** : array\_like  
 Input graph. Shape should be (n\_nodes, n\_nodes).  
**null\_value** : float or None (optional)  
 Value that denotes non-edges in the graph. Default is zero.  
**infinity\_null** : bool  
 If True (default), then infinite entries (both positive and negative) are treated as null edges.  
**nan\_null** : bool  
 If True (default), then NaN entries are treated as non-edges  
**Returns** **csgraph** : MaskedArray  
 masked array representation of graph

`scipy.sparse.csgraph.csgraph_to_dense` (*csgraph*, *null\_value=0*)  
 Convert a sparse graph representation to a dense representation

New in version 0.11.0.

**Parameters** **csgraph** : csr\_matrix, csc\_matrix, or lil\_matrix  
 Sparse representation of a graph.  
**null\_value** : float, optional  
 The value used to indicate null edges in the dense representation. Default is 0.  
**Returns** **graph** : ndarray  
 The dense representation of the sparse graph.

### Notes

For normal sparse graph representations, calling `csgraph_to_dense` with `null_value=0` produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in `scipy.sparse` will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default `scipy.sparse` behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[ inf,  0.],
       [ inf,  inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

`scipy.sparse.csgraph.csgraph_to_masked(csgraph)`

Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

**Parameters** **csgraph** : `csr_matrix`, `csc_matrix`, or `lil_matrix`  
 Sparse representation of a graph.  
**Returns** **graph** : `MaskedArray`  
 The masked dense representation of the sparse graph.

`scipy.sparse.csgraph.reconstruct_path(csgraph, predecessors, directed=True)`

Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

**Parameters** **csgraph** : `array_like` or sparse matrix  
 The  $N \times N$  matrix representing the directed or undirected graph from which the predecessors are drawn.  
**predecessors** : `array_like`, one dimension  
 The length- $N$  array of indices of predecessors for the tree. The index of the parent of node  $i$  is given by `predecessors[i]`.  
**directed** : `bool`, optional  
 If `True` (default), then operate on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If `False`, then operate on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`.  
**Returns** **cstree** : `csr matrix`  
 The  $N \times N$  directed compressed-sparse representation of the tree drawn from `csgraph` which is encoded by the predecessor list.

## 5.23.2 Graph Representations

This module uses graphs which are stored in a matrix format. A graph with  $N$  nodes can be represented by an  $(N \times N)$  adjacency matrix  $G$ . If there is a connection from node  $i$  to node  $j$ , then  $G[i, j] = w$ , where  $w$  is the weight of the connection. For nodes  $i$  and  $j$  which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by  $G[i, j] = 0$ , infinity, or `NaN`.

- for dense masked representations (of type `np.ma.MaskedArray`), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```

>>> G_dense = np.array([[0, 2, 1],
...                    [2, 0, 0],
...                    [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)

```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```

>>> G2_data = np.array([[np.inf, 2,      0      ],
...                    [2,      np.inf, np.inf],
...                    [0,      np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2.,  0.,  2.,  0.])

```

Here we have used a utility routine from the `csgraph` submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

## Directed vs. Undirected

Matrices may represent either directed or undirected graphs. This is specified throughout the `csgraph` module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node `i` to node `j` can be accomplished over the edge `G[i, j]`, but not the edge `G[j, i]`. In a non-directed graph, traversal from node `i` to node `j` can be accomplished over either `G[i, j]` or `G[j, i]`. If both edges are not null, and the two have unequal weights, then the smaller of the two is used. Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to `True` or `False`. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either `scipy.sparse` representations (`csr`, `csc`, or `lil` format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and `NaN` entries.

## 5.24 Spatial algorithms and data structures (`scipy.spatial`)

### 5.24.1 Nearest-neighbor Queries

|                                       |                                           |
|---------------------------------------|-------------------------------------------|
| <code>KDTree(data[, leafsize])</code> | kd-tree for quick nearest-neighbor lookup |
| <code>cKDTree</code>                  | kd-tree for quick nearest-neighbor lookup |
| <code>distance</code>                 |                                           |
| <code>Rectangle(maxes, mins)</code>   | Hyperrectangle class.                     |

**class** `scipy.spatial.KDTree` (*data*, *leafsize=10*)  
kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of `k`-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

**Parameters**    **data** : (N,K) array\_like

The data points to be indexed. This array is not copied, and so modifying this data will result in bogus results.

**leafsize** : int, optional

The number of points at which the algorithm switches over to brute-force. Has to be positive.

**Raises**

**RuntimeError**

The maximum recursion limit can be exceeded for large data sets. If this happens, either increase the value for the *leafsize* parameter or increase the recursion limit by:

```
>>> import sys
>>> sys.setrecursionlimit(10000)
```

**See also:**

`cKDTree`    Implementation of `KDTree` in Cython

**Notes**

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the  $r$  closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the  $r$  approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

The tree also supports all-neighbors queries, both with arrays of points and with other kd-trees. These do use a reasonably efficient algorithm, but the kd-tree is not necessarily the best data structure for this sort of calculation.

### Methods

|                                                          |                                                        |
|----------------------------------------------------------|--------------------------------------------------------|
| <code>count_neighbors(other, r[, p])</code>              | Count how many nearby pairs can be formed.             |
| <code>innernode(split_dim, split, less, greater)</code>  |                                                        |
| <code>leafnode(idx)</code>                               |                                                        |
| <code>node</code>                                        |                                                        |
| <code>query(x[, k, eps, p, distance_upper_bound])</code> | Query the kd-tree for nearest neighbors                |
| <code>query_ball_point(x, r[, p, eps])</code>            | Find all points within distance $r$ of point(s) $x$ .  |
| <code>query_ball_tree(other, r[, p, eps])</code>         | Find all pairs of points whose distance is at most $r$ |
| <code>query_pairs(r[, p, eps])</code>                    | Find all pairs of points within a distance.            |
| <code>sparse_distance_matrix(other, max_distance)</code> | Compute a sparse distance matrix                       |

`KDTree.count_neighbors` (*other*,  $r$ ,  $p=2.0$ )

Count how many nearby pairs can be formed.

Count the number of pairs ( $x_1, x_2$ ) can be formed, with  $x_1$  drawn from self and  $x_2$  drawn from *other*, and where  $\text{distance}(x_1, x_2, p) \leq r$ . This is the “two-point correlation” described in Gray and Moore 2000, “N-body problems in statistical learning”, and the code here is based on their algorithm.

**Parameters** **other** : KDTree instance

The other tree to draw points from.

**r** : float or one-dimensional array of floats

The radius to produce a count for. Multiple radii are searched with a single tree traversal.

**p** : float,  $1 \leq p \leq \text{infinity}$ , optional

Which Minkowski  $p$ -norm to use

**Returns** **result** : int or 1-D array of ints

The number of pairs. Note that this is internally stored in a numpy int, and so may overflow if very large ( $2e9$ ).

`KDTree.query` ( $x$ ,  $k=1$ ,  $eps=0$ ,  $p=2$ ,  $distance\_upper\_bound=inf$ )

Query the kd-tree for nearest neighbors

**Parameters** **x** : array\_like, last dimension self.m

An array of points to query.

**k** : int, optional

The number of nearest neighbors to return.

**eps** : nonnegative float, optional

Return approximate nearest neighbors; the  $k$ th returned value is guaranteed to be no further than  $(1+eps)$  times the distance to the real  $k$ th nearest neighbor.

**p** : float,  $1 \leq p \leq \text{infinity}$ , optional

Which Minkowski  $p$ -norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance

**distance\_upper\_bound** : nonnegative float, optional

Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

**Returns** **d** : float or array of floats  
 The distances to the nearest neighbors. If x has shape tuple+(self.m,), then d has shape tuple if k is one, or tuple+(k,) if k is larger than one. Missing neighbors (e.g. when k > n or distance\_upper\_bound is given) are indicated with infinite distances. If k is None, then d is an object array of shape tuple, containing lists of distances. In either case the hits are sorted by distance (nearest first).

**i** : integer or array of integers  
 The locations of the neighbors in self.data. i is the same shape as d.

**Examples**

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = spatial.KDTree(list(zip(x.ravel(), y.ravel())))
>>> tree.data
array([[0, 2],
       [0, 3],
       [0, 4],
       [0, 5],
       [0, 6],
       [0, 7],
       [1, 2],
       [1, 3],
       [1, 4],
       [1, 5],
       [1, 6],
       [1, 7],
       [2, 2],
       [2, 3],
       [2, 4],
       [2, 5],
       [2, 6],
       [2, 7],
       [3, 2],
       [3, 3],
       [3, 4],
       [3, 5],
       [3, 6],
       [3, 7],
       [4, 2],
       [4, 3],
       [4, 4],
       [4, 5],
       [4, 6],
       [4, 7]])
>>> pts = np.array([[0, 0], [2.1, 2.9]])
>>> tree.query(pts)
(array([ 2.0, 2.9],      0.14142136)), array([ 0, 13]))
>>> tree.query(pts[0])
(2.0, 0)
```

`KDTree.query_ball_point(x, r, p=2.0, eps=0)`  
 Find all points within distance r of point(s) x.

**Parameters**

- x** : array\_like, shape tuple + (self.m.)  
The point or points to search for neighbors of.
- r** : positive float  
The radius of points to return.
- p** : float, optional  
Which Minkowski p-norm to use. Should be in the range [1, inf].
- eps** : nonnegative float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .

**Returns**

**results** : list or array of lists  
If *x* is a single point, returns a list of the indices of the neighbors of *x*. If *x* is an array of points, returns an object array of shape tuple containing lists of neighbors.

### Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a KDTree and using `query_ball_tree`.

### Examples

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
>>> points = zip(x.ravel(), y.ravel())
>>> tree = spatial.KDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[5, 10, 11, 15]
```

Query multiple points and plot the results:

```
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point([2, 0], [3, 3], 1):
...     nearby_points = points[results]
...     plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```

`KDTree.query_ball_tree` (*other*, *r*, *p*=2.0, *eps*=0)

Find all pairs of points whose distance is at most *r*

**Parameters**

- other** : KDTree instance  
The tree containing points to search against.
- r** : float  
The maximum distance, has to be positive.
- p** : float, optional  
Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \infty$ .
- eps** : float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**Returns**

- results** : list of lists  
For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

`KDTree.query_pairs` (*r*, *p*=2.0, *eps*=0)

Find all pairs of points within a distance.

**Parameters**

- r** : positive float  
The maximum distance.
- p** : float, optional  
Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \infty$ .
- eps** : float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**Returns**

- results** : set  
Set of pairs  $(i, j)$ , with  $i < j$ , for which the corresponding positions are close.

`KDTree.sparse_distance_matrix` (*other*, *max\_distance*, *p*=2.0)

Compute a sparse distance matrix

Computes a distance matrix between two KDTrees, leaving as zero any distance greater than `max_distance`.

**Parameters** **other** : KDTree  
**max\_distance** : positive float  
**Returns** **p** : float, optional  
**result** : dok\_matrix  
 Sparse matrix representing the results in “dictionary of keys” format.

**class** `scipy.spatial.cKDTree`  
 kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary trie, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the `r` closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the `r` approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

**Parameters** **data** : array\_like, shape (n,m)  
 The `n` data points of dimension `m` to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with `copy_data=True`.

**leafsize** : positive int, optional  
 The number of points at which the algorithm switches over to brute-force. Default: 16.

**compact\_nodes** : bool, optional  
 If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.

**copy\_data** : bool, optional  
 If True the data is always copied to protect the kd-tree against data corruption. Default: False.

**balanced\_tree** : bool, optional  
 If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

**boxsize** : array\_like or scalar, optional  
 Apply a m-d toroidal topology to the KDTree.. The topology is generated by  $x_i + n_i L_i$  where  $n_i$  are integers and  $L_i$  is the boxsize along i-th dimension. The input data shall be wrapped into  $[0, L_i)$ . A `ValueError` is raised if any of the data is outside of this bound.

| <code>query_pairs(self, r[, p, eps])</code>                    | Find all pairs of points whose distance is at most r. |
| <code>sparse_distance_matrix(self, other, max_distance)</code> | Compute a sparse distance matrix                      |

`cKDTree.count_neighbors` (*self, other, r, p=2., weights=None, cumulative=True*)

Count how many nearby pairs can be formed. (pair-counting)

Count the number of pairs (x1,x2) can be formed, with x1 drawn from *self* and x2 drawn from *other*, and where `distance(x1, x2, p) <= r`.

Data points on *self* and *other* are optionally weighted by the `weights` argument. (See below)

The algorithm we implement here is based on [R356]. See notes for further discussion.

**Parameters** `other` : `cKDTree` instance

The other tree to draw points from, can be the same tree as *self*.

`r` : float or one-dimensional array of floats

The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative(`cumulative=False`), `r` defines the edges of the bins, and must be non-decreasing.

`p` : float, optional

$1 \leq p \leq \text{infinity}$ . Which Minkowski p-norm to use. Default 2.0.

`weights` : tuple, array\_like, or None, optional

If None, the pair-counting is unweighted. If given as a tuple, `weights[0]` is the weights of points in *self*, and `weights[1]` is the weights of points in *other*; either can be None to indicate the points are unweighted. If given as an array\_like, `weights` is the weights of points in *self* and *other*. For this to make sense, *self* and *other* must be the same tree. If *self* and *other* are two different trees, a `ValueError` is raised. Default: None

`cumulative` : bool, optional

Whether the returned counts are cumulative. When `cumulative` is set to `False` the algorithm is optimized to work with a large number of bins (>10) specified by `r`. When `cumulative` is set to `True`, the

algorithm is optimized to work with a small number of  $r$ . Default: `True`

**Returns** **result** : scalar or 1-D array

The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If `cumulative` is `False`, `result[i]` contains the counts with  $(-\infty \text{ if } i == 0 \text{ else } r[i-1]) < R \leq r[i]$

### Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of  $D$  measures the clustering signal in  $D$ . [R357]

For example, given the position of two sets of objects,

- objects  $D$  (data) contains the clustering signal, and
- objects  $R$  (random) that contains no signal,

$$\xi(r) = \frac{\langle D, D \rangle - 2f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},$$

where the brackets represents counting pairs between two data sets in a finite bin around  $r$  (distance), corresponding to setting `cumulative=False`, and  $f = \text{float}(\text{len}(D)) / \text{float}(\text{len}(R))$  is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [R356]. We switch between two different pair-cumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [R360].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([R358], section 2.2), or to properly calculate the average of data per distance bin (e.g. [R359], section 2.1 on redshift).

`cKDTree`.**query** (*self*, *x*, *k=1*, *eps=0*, *p=2*, *distance\_upper\_bound=np.inf*, *n\_jobs=1*)

Query the kd-tree for nearest neighbors

**Parameters** **x** : array\_like, last dimension self.m

An array of points to query.

**k** : list of integer or integer

The list of k-th nearest neighbors to return. If *k* is an integer it is treated as a list of [1, ... *k*] (`range(1, k+1)`). Note that the counting starts from 1.

**eps** : non-negative float

Return approximate nearest neighbors; the k-th returned value is guaranteed to be no further than  $(1+\text{eps})$  times the distance to the real k-th nearest neighbor.

**p** : float,  $1 \leq p \leq \text{infinity}$

Which Minkowski *p*-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance

**distance\_upper\_bound** : nonnegative float  
 Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

**n\_jobs** : int, optional  
 Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.

**Returns**

**d** : array of floats  
 The distances to the nearest neighbors. If `x` has shape `tuple+(self.m,)`, then `d` has shape `tuple+(k,)`. When `k == 1`, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.

**i** : ndarray of ints  
 The locations of the neighbors in `self.data`. If `x` has shape `tuple+(self.m,)`, then `i` has shape `tuple+(k,)`. When `k == 1`, the last dimension of the output is squeezed. Missing neighbors are indicated with `self.n`.

**Notes**

If the KD-Tree is periodic, the position `x` is wrapped into the box.

When the input `k` is a list, a query for `arange(max(k))` is performed, but only columns that store the requested values of `k` are preserved. This is implemented in a manner that reduces memory usage.

**Examples**

```
>>> tree = cKDTree(data)
```

To query the nearest neighbours and return squeezed result, use

```
>>> dd, ii = tree.query(x, k=1)
```

To query the nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query(x, k=[1])
```

To query the second nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query(x, k=[2])
```

To query the first and second nearest neighbours, use

```
>>> dd, ii = tree.query(x, k=2)
```

or, be more specific

```
>>> dd, ii = tree.query(x, k=[1, 2])
```

`cKDTree.query_ball_point` (*self*, *x*, *r*, *p=2.*, *eps=0*)

Find all points within distance *r* of point(s) *x*.

**Parameters**

- x** : array\_like, shape tuple + (self.m,)  
 The point or points to search for neighbors of.
- r** : positive float  
 The radius of points to return.

**p** : float, optional  
Which Minkowski p-norm to use. Should be in the range [1, inf].

**eps** : nonnegative float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .

**n\_jobs** : int, optional  
Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.

**Returns** **results** : list or array of lists  
If  $x$  is a single point, returns a list of the indices of the neighbors of  $x$ . If  $x$  is an array of points, returns an object array of shape tuple containing lists of neighbors.

### Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a cKDTree and using `query_ball_tree`.

### Examples

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = zip(x.ravel(), y.ravel())
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[4, 8, 9, 12]
```

`cKDTree.query_ball_tree` (*self*, *other*, *r*, *p=2.*, *eps=0*)

Find all pairs of points whose distance is at most *r*

**Parameters** **other** : cKDTree instance  
The tree containing points to search against.

**r** : float  
The maximum distance, has to be positive.

**p** : float, optional  
Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ .

**eps** : float, optional  
Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**Returns** **results** : list of lists  
For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

`cKDTree.query_pairs` (*self*, *r*, *p=2.*, *eps=0*)

Find all pairs of points whose distance is at most *r*.

**Parameters** **r** : positive float  
The maximum distance.

**p** : float, optional  
Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ .

**eps** : float, optional

Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1+eps)$ , and branches are added in bulk if their furthest points are nearer than  $r * (1+eps)$ . *eps* has to be non-negative.

**output\_type** : string, optional  
 Choose the output container, 'set' or 'ndarray'. Default: 'set'

**Returns** **results** : set or ndarray  
 Set of pairs  $(i, j)$ , with  $i < j$ , for which the corresponding positions are close. If *output\_type* is 'ndarray', an ndarray is returned instead of a set.

`cKDTree.sparse_distance_matrix` (*self, other, max\_distance, p=2.*)

Compute a sparse distance matrix

Computes a distance matrix between two cKDTrees, leaving as zero any distance greater than *max\_distance*.

**Parameters** **other** : cKDTree  
**max\_distance** : positive float  
**p** : float,  $1 \leq p \leq \infty$   
 Which Minkowski p-norm to use.  
**output\_type** : string, optional  
 Which container to use for output data. Options: 'dok\_matrix', 'coo\_matrix', 'dict' or 'ndarray'. Default: 'dok\_matrix'.

**Returns** **result** : dok\_matrix, coo\_matrix, dict or ndarray  
 Sparse matrix representing the results in "dictionary of keys" format. If a dict is returned the keys are (i,j) tuples of indices. If *output\_type* is 'ndarray' a record array with fields 'i', 'j', and 'k' is returned,

*Distance computations (scipy.spatial.distance)*

**Function Reference** Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

---

`scipy.spatial.distance.pdist` (*X, metric='euclidean', p=None, w=None, V=None, VI=None*)

Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

**Parameters** **X** : ndarray  
 An m by n array of m original observations in an n-dimensional space.  
**metric** : str or function, optional  
 The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.  
**p** : double, optional  
 The p-norm to apply Only for Minkowski, weighted and unweighted. Default: 2.  
**w** : ndarray, optional  
 The weight vector. Only for weighted Minkowski. Mandatory

**V** : ndarray, optional  
The variance vector Only for standardized Euclidean. Default: `var(X, axis=0, ddof=1)`

**VI** : ndarray, optional  
The inverse of the covariance matrix Only for Mahalanobis. Default: `inv(cov(X.T)).T`

**Returns** **Y** : ndarray  
Returns a condensed distance matrix Y. For each  $i$  and  $j$  (where  $i < j < m$ ), where  $m$  is the number of original observations. The metric `dist(u=X[i], v=X[j])` is computed and stored in entry  $ij$ .

**See also:**

[\*squareform\*](#) converts between condensed distance matrices and square distance matrices.

**Notes**

See [\*squareform\*](#) for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. `Y = pdist(X, 'euclidean')`

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix  $X$ .

2. `Y = pdist(X, 'minkowski', p)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  ( $p$ -norm) where  $p \geq 1$ .

3. `Y = pdist(X, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = pdist(X, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}$$

$V$  is the variance vector;  $V[i]$  is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5. `Y = pdist(X, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6. `Y = pdist(X, 'cosine')`

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|*\|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7. `Y = pdist(X, 'correlation')`

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8. `Y = pdist(X, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9.Y = pdist(X, 'jaccard')

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree.

10.Y = pdist(X, 'chebyshev')

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|$$

11.Y = pdist(X, 'canberra')

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

12.Y = pdist(X, 'braycurtis')

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}$$

13.Y = pdist(X, 'mahalanobis', VI=None)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the VI variable) is the inverse covariance. If VI is not None, VI will be used as the inverse covariance matrix.

14.Y = pdist(X, 'yule')

Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

15.Y = pdist(X, 'matching')

Synonym for 'hamming'.

16.Y = pdist(X, 'dice')

Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)

17.Y = pdist(X, 'kulsinski')

Computes the Kulsinski distance between each pair of boolean vectors. (see kulsinski function documentation)

18.Y = pdist(X, 'rogerstanimoto')

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)

19.Y = pdist(X, 'russellrao')

Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

```
20.Y = pdist(X, 'sokalmichener')
```

Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

```
21.Y = pdist(X, 'sokalsneath')
```

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

```
22.Y = pdist(X, 'wminkowski')
```

Computes the weighted Minkowski distance between each pair of vectors. (see wminkowski function documentation)

```
23.Y = pdist(X, f)
```

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = pdist(X, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = pdist(X, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function sokalsneath. This would result in sokalsneath being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

```
dm = pdist(X, 'sokalsneath')
```

```
scipy.spatial.distance.cdist(XA, XB, metric='euclidean', p=None, V=None, VI=None,
                             w=None)
```

Computes distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

**Parameters** **XA** : ndarray

An  $m_A$  by  $n$  array of  $m_A$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.

**XB** : ndarray

An  $m_B$  by  $n$  array of  $m_B$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.

**metric** : str or callable, optional

The distance metric to use. If a string, the distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'wminkowski', 'yule'.

**p** : double, optional

The p-norm to apply Only for Minkowski, weighted and unweighted. Default: 2.

**w** : ndarray, optional

The weight vector. Only for weighted Minkowski. Mandatory

**V** : ndarray, optional

The variance vector Only for standardized Euclidean. Default: `var(vstack([XA, XB]), axis=0, ddof=1)`

|                |                               |                                                                                                                                                                  |
|----------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <b>VI</b> : ndarray, optional | The inverse of the covariance matrix Only for Mahalanobis. Default: <code>inv(cov(vstack([XA, XB]).T)).T</code>                                                  |
| <b>Returns</b> | <b>Y</b> : ndarray            | A $m_A$ by $m_B$ distance matrix is returned. For each $i$ and $j$ , the metric <code>dist(u=XA[i], v=XB[j])</code> is computed and stored in the $ij$ th entry. |
| <b>Raises</b>  | <b>ValueError</b>             | An exception is thrown if $XA$ and $XB$ do not have the same number of columns.                                                                                  |

**Notes**

The following are common calling conventions:

1. `Y = cdist(XA, XB, 'euclidean')`

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix  $X$ .

2. `Y = cdist(XA, XB, 'minkowski', p)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  ( $p$ -norm) where  $p \geq 1$ .

3. `Y = cdist(XA, XB, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = cdist(XA, XB, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}.$$

$V$  is the variance vector;  $V[i]$  is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5. `Y = cdist(XA, XB, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6. `Y = cdist(XA, XB, 'cosine')`

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|* \|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7. `Y = cdist(XA, XB, 'correlation')`

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8. `Y = cdist(XA, XB, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9. `Y = cdist(XA, XB, 'jaccard')`

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree where at least one of them is non-zero.

10. `Y = cdist(XA, XB, 'chebyshev')`

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|.$$

11.Y = `cdist(XA, XB, 'canberra')`

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

12.Y = `cdist(XA, XB, 'braycurtis')`

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}$$

13.Y = `cdist(XA, XB, 'mahalanobis', VI=None)`

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the `VI` variable) is the inverse covariance. If `VI` is not `None`, `VI` will be used as the inverse covariance matrix.

14.Y = `cdist(XA, XB, 'yule')`

Computes the Yule distance between the boolean vectors. (see [yule](#) function documentation)

15.Y = `cdist(XA, XB, 'matching')`

Synonym for 'hamming'.

16.Y = `cdist(XA, XB, 'dice')`

Computes the Dice distance between the boolean vectors. (see [dice](#) function documentation)

17.Y = `cdist(XA, XB, 'kulsinski')`

Computes the Kulsinski distance between the boolean vectors. (see [kulsinski](#) function documentation)

18.Y = `cdist(XA, XB, 'rogerstanimoto')`

Computes the Rogers-Tanimoto distance between the boolean vectors. (see [rogerstanimoto](#) function documentation)

19.Y = `cdist(XA, XB, 'russellrao')`

Computes the Russell-Rao distance between the boolean vectors. (see [russellrao](#) function documentation)

20.Y = `cdist(XA, XB, 'sokalmichener')`

Computes the Sokal-Michener distance between the boolean vectors. (see [sokalmichener](#) function documentation)

```
21.Y = cdist(XA, XB, 'sokalsneath')
```

Computes the Sokal-Sneath distance between the vectors. (see [sokalsneath](#) function documentation)

```
22.Y = cdist(XA, XB, 'wminkowski')
```

Computes the weighted Minkowski distance between the vectors. (see [wminkowski](#) function documentation)

```
23.Y = cdist(XA, XB, f)
```

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = cdist(XA, XB, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = cdist(XA, XB, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function [sokalsneath](#). This would result in [sokalsneath](#) being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

```
dm = cdist(XA, XB, 'sokalsneath')
```

### Examples

Find the Euclidean distances between four 2-D coordinates:

```
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
...          (35.1174, -89.9711),
...          (35.9728, -83.9422),
...          (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0.         ,  4.7044,  1.6172,  1.8856],
       [ 4.7044,  0.         ,  6.0893,  3.3561],
       [ 1.6172,  6.0893,  0.         ,  2.8477],
       [ 1.8856,  3.3561,  2.8477,  0.         ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```
>>> a = np.array([[0, 0, 0],
...              [0, 0, 1],
...              [0, 1, 0],
...              [0, 1, 1],
...              [1, 0, 0],
...              [1, 0, 1],
...              [1, 1, 0],
...              [1, 1, 1]])
>>> b = np.array([0.1, 0.2, 0.4])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
       [ 0.9],
       [ 1.3],
       [ 1.5],
       [ 1.5],
       [ 1.5],
       [ 1.7],
       [ 1.7]])
```

```
[ 2.1],
 [ 2.3]])
```

`scipy.spatial.distance.squareform(X, force='no', checks=True)`

Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters**

- X** : ndarray  
Either a condensed or redundant distance matrix.
- force** : str, optional  
As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.
- checks** : bool, optional  
If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that  $X - X.T$  is small and  $\text{diag}(X)$  is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

**Returns**

- Y** : ndarray  
If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

### Notes

1.  $v = \text{squareform}(X)$

Given a square  $d$ -by- $d$  symmetric distance matrix  $X$ ,  $v = \text{squareform}(X)$  returns a  $d * (d-1) / 2$  (or  $\binom{n}{2}$ ) sized vector  $v$ .

$v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  is the distance between points  $i$  and  $j$ . If  $X$  is non-square or asymmetric, an error is returned.

2.  $X = \text{squareform}(v)$

Given a  $d*(d-1)/2$  sized  $v$  for some integer  $d \geq 2$  encoding distances as described,  $X = \text{squareform}(v)$  returns a  $d$  by  $d$  distance matrix  $X$ . The  $X[i, j]$  and  $X[j, i]$  values are set to  $v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  and all diagonal elements are zero.

In Scipy 0.19.0, `squareform` stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

`scipy.spatial.distance.directed_hausdorff(u, v, seed=0)`

Computes the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

**Parameters**

- u** : (M,N) ndarray  
Input array.
- v** : (O,N) ndarray  
Input array.
- seed** : int or None  
Local `np.random.RandomState` seed. Default is 0, a random shuffling of  $u$  and  $v$  that guarantees reproducibility.

**Returns**

- d** : double  
The directed Hausdorff distance between arrays  $u$  and  $v$ ,
- index\_1** : int  
index of point contributing to Hausdorff pair in  $u$
- index\_2** : int  
index of point contributing to Hausdorff pair in  $v$

**See also:**

`scipy.spatial.procrustes`

Another similarity test for two data sets

**Notes**

Uses the early break technique and the random sampling approach described by [R40]. Although worst-case performance is  $O(m * o)$  (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is  $O(m)$ , which is satisfied by selecting an inner loop distance that is less than `cmax` and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to  $O(m)$ .

New in version 0.19.0.

**References**

[R40]

**Examples**

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
...              (0.0, 1.0),
...              (-1.0, 0.0),
...              (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
...              (0.0, 2.0),
...              (-2.0, 0.0),
...              (0.0, -4.0)])

>>> directed_hausdorff(u, v)[0]
2.23606797749979
>>> directed_hausdorff(v, u)[0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

---

|                                                          |                                                                                     |
|----------------------------------------------------------|-------------------------------------------------------------------------------------|
| <code>is_valid_dm(D[, tol, throw, name, warning])</code> | Returns True if input array is a valid distance matrix.                             |
| <code>is_valid_y(y[, warning, throw, name])</code>       | Returns True if the input array is a valid condensed distance matrix.               |
| <code>num_obs_dm(d)</code>                               | Returns the number of original observations that correspond to a square, redundant  |
| <code>num_obs_y(Y)</code>                                | Returns the number of original observations that correspond to a condensed distance |

---

`scipy.spatial.distance.is_valid_dm(D, tol=0.0, throw=False, name='D', warning=False)`

Returns True if input array is a valid distance matrix.

Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

**Parameters**

- D** : ndarray  
The candidate object to test for validity.
- tol** : float, optional  
The distance matrix should be symmetric. *tol* is the maximum difference between entries  $i_j$  and  $j_i$  for the distance metric to be considered symmetric.
- throw** : bool, optional  
An exception is thrown if the distance matrix passed is not valid.
- name** : str, optional  
The name of the variable to checked. This is useful if *throw* is set to True so the offending variable can be identified in the exception message when an exception is thrown.
- warning** : bool, optional  
Instead of throwing an exception, a warning message is raised.

**Returns**

- valid** : bool  
True if the variable *D* passed is a valid distance matrix.

#### Notes

Small numerical differences in *D* and *D.T* and non-zerosness of the diagonal are ignored if they are within the tolerance specified by *tol*.

`scipy.spatial.distance.is_valid_y(y, warning=False, throw=False, name=None)`

Returns True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient  $\binom{n}{2}$  for some positive integer *n*.

**Parameters**

- y** : ndarray  
The condensed distance matrix.
- warning** : bool, optional  
Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. *name* is used when referencing the offending variable.
- throw** : bool, optional  
Throws an exception if the variable passed is not a valid condensed distance matrix.
- name** : bool, optional  
Used when referencing the offending variable in the warning or exception message.

`scipy.spatial.distance.num_obs_dm(d)`

Returns the number of original observations that correspond to a square, redundant distance matrix.

**Parameters**

- d** : ndarray  
The target distance matrix.

**Returns**

- num\_obs\_dm** : int  
The number of observations in the redundant distance matrix.

`scipy.spatial.distance.num_obs_y(Y)`

Returns the number of original observations that correspond to a condensed distance matrix.

**Parameters**

- Y** : ndarray  
Condensed distance matrix.

**Returns** `n` : int

The number of observations in the condensed distance matrix  $Y$ .

Distance functions between two numeric vectors  $u$  and  $v$ . Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

|                                     |                                                                     |
|-------------------------------------|---------------------------------------------------------------------|

| <code>correlation(u, v)</code>      | Computes the correlation distance between two 1-D arrays.           |
| <code>cosine(u, v)</code>           | Computes the Cosine distance between 1-D arrays.                    |
| <code>euclidean(u, v)</code>        | Computes the Euclidean distance between two 1-D arrays.             |
| <code>mahalanobis(u, v, VI)</code>  | Computes the Mahalanobis distance between two 1-D arrays.           |
| <code>minkowski(u, v, p)</code>     | Computes the Minkowski distance between two 1-D arrays.             |
| <code>seuclidean(u, v, V)</code>    | Returns the standardized Euclidean distance between two 1-D arrays. |
| <code>squeuclidean(u, v)</code>     | Computes the squared Euclidean distance between two 1-D arrays.     |
| <code>wminkowski(u, v, p, w)</code> | Computes the weighted Minkowski distance between two 1-D arrays.    |

`scipy.spatial.distance.braycurtis(u, v)`

Computes the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

$$\sum |u_i - v_i| / \sum |u_i + v_i|$$

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

**Parameters** `u` : (N,) array\_like  
 Input array.  
`v` : (N,) array\_like  
 Input array.

**Returns** `braycurtis` : double  
 The Bray-Curtis distance between 1-D arrays  $u$  and  $v$ .

`scipy.spatial.distance.canberra(u, v)`

Computes the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

**Parameters** `u` : (N,) array\_like  
 Input array.  
`v` : (N,) array\_like  
 Input array.

**Returns** `canberra` : double  
 The Canberra distance between vectors  $u$  and  $v$ .

**Notes**

When  $u[i]$  and  $v[i]$  are 0 for given  $i$ , then the fraction  $0/0 = 0$  is used in the calculation.

`scipy.spatial.distance.chebyshev(u, v)`

Computes the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays  $u$  and  $v$ , which is defined as

$$\max_i |u_i - v_i|.$$

**Parameters** **u** : (N,) array\_like  
Input vector.

**v** : (N,) array\_like

**Returns** **chebyshev** : double  
Input vector.  
The Chebyshev distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.cityblock` ( $u$ ,  $v$ )

Computes the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays  $u$  and  $v$ , which is defined as

$$\sum_i |u_i - v_i|.$$

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like

**Returns** **cityblock** : double  
Input array.  
The City Block (Manhattan) distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.correlation` ( $u$ ,  $v$ )

Computes the correlation distance between two 1-D arrays.

The correlation distance between  $u$  and  $v$ , is defined as

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\| (u - \bar{u}) \|_2 \| (v - \bar{v}) \|_2}$$

where  $\bar{u}$  is the mean of the elements of  $u$  and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like

**Returns** **correlation** : double  
Input array.  
The correlation distance between 1-D array  $u$  and  $v$ .

`scipy.spatial.distance.cosine` ( $u$ ,  $v$ )

Computes the Cosine distance between 1-D arrays.

The Cosine distance between  $u$  and  $v$ , is defined as

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}.$$

where  $u \cdot v$  is the dot product of  $u$  and  $v$ .

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like

**Returns** **cosine** : double  
Input array.  
The Cosine distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.euclidean` ( $u$ ,  $v$ )

Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\|u - v\|_2$$

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**Returns** **euclidean** : double  
The Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.mahalanobis` ( $u, v, VI$ )  
Computes the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\sqrt{(u - v)V^{-1}(u - v)^T}$$

where  $V$  is the covariance matrix. Note that the argument  $VI$  is the inverse of  $V$ .

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**VI** : ndarray  
The inverse of the covariance matrix.  
**Returns** **mahalanobis** : double  
The Mahalanobis distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.minkowski` ( $u, v, p$ )  
Computes the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\|u - v\|_p = \left(\sum |u_i - v_i|^p\right)^{1/p}.$$

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**p** : int  
The order of the norm of the difference  $\|u - v\|_p$ .  
**Returns** **d** : double  
The Minkowski distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.seuclidean` ( $u, v, V$ )  
Returns the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between  $u$  and  $v$ .

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**V** : (N,) array\_like  
 $V$  is an 1-D array of component variances. It is usually computed among a larger collection vectors.  
**Returns** **seuclidean** : double  
The standardized Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sqeuclidean` ( $u, v$ )  
Computes the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between  $u$  and  $v$  is defined as

$$\|u - v\|_2^2.$$

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.

**Returns** **squeclidean** : double  
The squared Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.wminkowski(u, v, p, w)`  
Computes the weighted Minkowski distance between two 1-D arrays.

The weighted Minkowski distance between  $u$  and  $v$ , defined as

$$\left( \sum (|w_i(u_i - v_i)|^p) \right)^{1/p}.$$

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**p** : int  
The order of the norm of the difference  $\|u - v\|_p$ .  
**w** : (N,) array\_like  
The weight vector.

**Returns** **wminkowski** : double  
The weighted Minkowski distance between vectors  $u$  and  $v$ .

Distance functions between two boolean vectors (representing sets)  $u$  and  $v$ . As in the case of numerical vectors, `pdist` is more efficient for computing the distances between all pairs.

---

---

`scipy.spatial.distance.dice(u, v)`  
Computes the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between  $u$  and  $v$ , is

$$\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) ndarray, bool  
Input 1-D array.  
**v** : (N,) ndarray, bool  
Input 1-D array.

**Returns** **dice** : double  
The Dice dissimilarity between 1-D arrays  $u$  and  $v$ .

`scipy.spatial.distance.hamming(u, v)`  
Computes the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays  $u$  and  $v$ , is simply the proportion of disagreeing components in  $u$  and  $v$ . If  $u$  and  $v$  are boolean vectors, the Hamming distance is

$$\frac{c_{01} + c_{10}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**Returns** **hamming** : double  
 The Hamming distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.jaccard` ( $u, v$ )

Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
 Input array.  
**Returns** **jaccard** : double  
 The Jaccard distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.kulsinski` ( $u, v$ )

Computes the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
 Input array.  
**Returns** **kulsinski** : double  
 The Kulsinski distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.matching` ( $u, v$ )

Computes the Hamming distance between two boolean 1-D arrays.

This is a deprecated synonym for `hamming`.

`scipy.spatial.distance.rogerstanimoto` ( $u, v$ )

Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{R}{c_{TT} + c_{FF} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters** **u** : (N,) array\_like, bool

**Returns** **rogerstanimoto** : double  
 Input array.  
**v** : (N,) array\_like, bool  
 Input array.  
 The Rogers-Tanimoto dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.russellrao` ( $u, v$ )

Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays,  $u$  and  $v$ , is defined as

$$\frac{n - c_{TT}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
**Returns** **russellrao** : double  
 Input array.  
 The Russell-Rao dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sokalmichener` ( $u, v$ )

Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{R}{S + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ ,  $R = 2 * (c_{TF} + c_{FT})$  and  $S = c_{FF} + c_{TT}$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
**Returns** **sokalmichener** : double  
 Input array.  
 The Sokal-Michener dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sokalsneath` ( $u, v$ )

Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between  $u$  and  $v$ ,

$$\frac{R}{c_{TT} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
**Returns** **sokalsneath** : double  
 Input array.  
 The Sokal-Sneath dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.yule` ( $u, v$ )

Computes the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

$$\frac{R}{c_{TT} * c_{FF} + \frac{R}{2}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2.0 * c_{TF} * c_{FT}$ .

**Parameters** **u** : (N,) array\_like, bool  
                   Input array.  
**v** : (N,) array\_like, bool  
                   Input array.  
**Returns** **yule** : double  
                   The Yule dissimilarity between vectors  $u$  and  $v$ .

`hamming` also operates over discrete numerical vectors.

### Functions

| <code>braycurtis(u, v)</code>                            | Computes the Bray-Curtis distance between two 1-D arrays.                           |
| <code>callable(object) -&gt; bool</code>                 | Return whether the object is callable (i.e., some kind of function).                |
| <code>canberra(u, v)</code>                              | Computes the Canberra distance between two 1-D arrays.                              |
| <code>cdist(XA, XB[, metric, p, V, VI, w])</code>        | Computes distance between each pair of the two collections of inputs.               |
| <code>cdist_fn</code>                                    |                                                                                     |
| <code>chebyshev(u, v)</code>                             | Computes the Chebyshev distance.                                                    |
| <code>cityblock(u, v)</code>                             | Computes the City Block (Manhattan) distance.                                       |
| <code>converter(X)</code>                                |                                                                                     |
| <code>correlation(u, v)</code>                           | Computes the correlation distance between two 1-D arrays.                           |
| <code>cosine(u, v)</code>                                | Computes the Cosine distance between 1-D arrays.                                    |
| <code>dice(u, v)</code>                                  | Computes the Dice dissimilarity between two boolean 1-D arrays.                     |
| <code>directed_hausdorff(u, v[, seed])</code>            | Computes the directed Hausdorff distance between two N-D arrays.                    |
| <code>euclidean(u, v)</code>                             | Computes the Euclidean distance between two 1-D arrays.                             |
| <code>hamming(u, v)</code>                               | Computes the Hamming distance between two 1-D arrays.                               |
| <code>is_valid_dm(D[, tol, throw, name, warning])</code> | Returns True if input array is a valid distance matrix.                             |
| <code>is_valid_y(y[, warning, throw, name])</code>       | Returns True if the input array is a valid condensed distance matrix.               |
| <code>jaccard(u, v)</code>                               | Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.          |
| <code>kulsinski(u, v)</code>                             | Computes the Kulsinski dissimilarity between two boolean 1-D arrays.                |
| <code>mahalanobis(u, v, VI)</code>                       | Computes the Mahalanobis distance between two 1-D arrays.                           |
| <code>matching(u, v)</code>                              | Computes the Hamming distance between two boolean 1-D arrays.                       |
| <code>minkowski(u, v, p)</code>                          | Computes the Minkowski distance between two 1-D arrays.                             |
| <code>norm(a[, ord, axis, keepdims])</code>              | Matrix or vector norm.                                                              |
| <code>num_obs_dm(d)</code>                               | Returns the number of original observations that correspond to a square, redundant  |
| <code>num_obs_y(Y)</code>                                | Returns the number of original observations that correspond to a condensed distance |
| <code>pdist(X[, metric, p, w, V, VI])</code>             | Pairwise distances between observations in n-dimensional space.                     |
| <code>pdist_fn</code>                                    |                                                                                     |
| <code>rogerstanimoto(u, v)</code>                        | Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.          |
| <code>russellrao(u, v)</code>                            | Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.              |
| <code>seuclidean(u, v, V)</code>                         | Returns the standardized Euclidean distance between two 1-D arrays.                 |
| <code>sokalmichener(u, v)</code>                         | Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.           |
| <code>sokalsneath(u, v)</code>                           | Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.             |
| <code>squeuclidean(u, v)</code>                          | Computes the squared Euclidean distance between two 1-D arrays.                     |
| <code>squareform(X[, force, checks])</code>              | Converts a vector-form distance vector to a square-form distance matrix, and vice-  |
| <code>wminkowski(u, v, p, w)</code>                      | Computes the weighted Minkowski distance between two 1-D arrays.                    |
| <code>yule(u, v)</code>                                  | Computes the Yule dissimilarity between two boolean 1-D arrays.                     |

---

**class** `scipy.spatial.Rectangle` (*maxes, mins*)  
Hyperrectangle class.

Represents a Cartesian product of intervals.

### Methods

---

|                                                 |                                                                             |
|-------------------------------------------------|-----------------------------------------------------------------------------|
| <code>max_distance_point(x[, p])</code>         | Return the maximum distance between input and points in the hyperrectangle. |
| <code>max_distance_rectangle(other[, p])</code> | Compute the maximum distance between points in the two hyperrectangles.     |
| <code>min_distance_point(x[, p])</code>         | Return the minimum distance between input and points in the hyperrectangle. |
| <code>min_distance_rectangle(other[, p])</code> | Compute the minimum distance between points in the two hyperrectangles.     |
| <code>split(d, split)</code>                    | Produce two hyperrectangles by splitting.                                   |
| <code>volume()</code>                           | Total volume.                                                               |

---

`Rectangle.max_distance_point` (*x, p=2.0*)

Return the maximum distance between input and points in the hyperrectangle.

**Parameters** **x** : array\_like  
Input array.  
**p** : float, optional  
Input.

`Rectangle.max_distance_rectangle` (*other, p=2.0*)

Compute the maximum distance between points in the two hyperrectangles.

**Parameters** **other** : hyperrectangle  
Input.  
**p** : float, optional  
Input.

`Rectangle.min_distance_point` (*x, p=2.0*)

Return the minimum distance between input and points in the hyperrectangle.

**Parameters** **x** : array\_like  
Input.  
**p** : float, optional  
Input.

`Rectangle.min_distance_rectangle` (*other, p=2.0*)

Compute the minimum distance between points in the two hyperrectangles.

**Parameters** **other** : hyperrectangle  
Input.  
**p** : float  
Input.

`Rectangle.split` (*d, split*)

Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

**Parameters** **d** : int  
Axis to split hyperrectangle along.  
**split** : float  
Position along axis *d* to split at.

`Rectangle.volume` ()

Total volume.

## 5.24.2 Delaunay Triangulation, Convex Hulls and Voronoi Diagrams

---

|                                                                |                                              |
|----------------------------------------------------------------|----------------------------------------------|
| <code>Delaunay(points[, furthest_site, ...])</code>            | Delaunay tessellation in N dimensions.       |
| <code>ConvexHull(points[, incremental, qhull_options])</code>  | Convex hulls in N dimensions.                |
| <code>Voronoi(points[, furthest_site, ...])</code>             | Voronoi diagrams in N dimensions.            |
| <code>SphericalVoronoi(points[, radius, center])</code>        | Voronoi diagrams on the surface of a sphere. |
| <code>HalfspaceIntersection(halfspaces, interior_point)</code> | Halfspace intersections in N dimensions.     |

---

**class** `scipy.spatial.Delaunay` (*points*, *furthest\_site=False*, *incremental=False*, *qhull\_options=None*)  
 Delaunay tessellation in N dimensions.

New in version 0.9.

|                   |                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>points</b> : ndarray of floats, shape (npoints, ndim)<br>Coordinates of points to triangulate                                                                                                                                               |

|                   | <b>ValueError</b><br>Raised if an incompatible array is given as input.                                                                                                                                                                        |

### Notes

The tessellation is computed using the Qhull library [Qhull library](#).

---

**Note:** Unless you pass in the Qhull option “QJ”, Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the *coplanar* attribute.

---

### Examples

Triangulation of a set of points:

```
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices.copy())
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```

Point indices and coordinates for the two triangles forming the triangulation:

```
>>> tri.simplices
array([[2, 3, 0],
       [3, 1, 0]], dtype=int32) # may vary
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```
>>> points[tri.simplices]
array([[ 1. ,  0. ],
       [ 1. ,  1. ],
       [ 0. ,  0. ]],
       [[ 1. ,  1. ],
        [ 0. ,  1.1],
        [ 0. ,  0. ]]) # may vary
```

Triangle 0 is the only neighbor of triangle 1, and it's opposite to vertex 1 of triangle 1:

```
>>> tri.neighbors[1]
array([-1,  0, -1], dtype=int32)
>>> points[tri.simplices[1,1]]
array([ 0. ,  1.1])
```

We can find out which triangle points are in:

```
>>> p = np.array([(0.1, 0.2), (1.5, 0.5), (0.5, 1.05)])
>>> tri.find_simplex(p)
array([ 1, -1,  1], dtype=int32)
```

We can also compute barycentric coordinates in triangle 1 for these points:

```
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[ 0.1      ,  0.09090909,  0.80909091],
       [ 1.5      , -0.90909091,  0.40909091],
       [ 0.5      ,  0.5      ,  0.          ]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

*Attributes*

---

|                                       |                                                                     |
|---------------------------------------|---------------------------------------------------------------------|
| <code>transform</code>                | Affine transform from $x$ to the barycentric coordinates $c$ .      |
| <code>vertex_to_simplex</code>        | Lookup array, from a vertex, to some simplex which it is a part of. |
| <code>convex_hull</code>              | Vertices of facets forming the convex hull of the point set.        |
| <code>vertex_neighbor_vertices</code> | Neighboring vertices of vertices.                                   |

---

Delaunay.**transform**

Affine transform from  $x$  to the barycentric coordinates  $c$ .

*Type* ndarray of double, shape (nsimplex, ndim+1, ndim)

This is defined by:

$$T c = x - r$$

At vertex  $j$ ,  $c_j = 1$  and the other coordinates zero.

For simplex  $i$ , `transform[i, :ndim, :ndim]` contains inverse of the matrix  $T$ , and `transform[i, ndim, :]` contains the vector  $r$ .

Delaunay.**vertex\_to\_simplex**

Lookup array, from a vertex, to some simplex which it is a part of.

*Type* ndarray of int, shape (npoints,)

Delaunay.**convex\_hull**

Vertices of facets forming the convex hull of the point set.

*Type* ndarray of int, shape (nfaces, ndim)

The array contains the indices of the points belonging to the (N-1)-dimensional facets that form the convex hull of the triangulation.

---

**Note:** Computing convex hulls via the Delaunay triangulation is inefficient and subject to increased numerical instability. Use `ConvexHull` instead.

---

Delaunay.**vertex\_neighbor\_vertices**

Neighboring vertices of vertices.

Tuple of two ndarrays of int: (indices, indptr). The indices of neighboring vertices of vertex  $k$  are `indptr[indices[k]:indices[k+1]]`.

|                                       |                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| points                                | (ndarray of double, shape (npoints, ndim)) Coordinates of input points.                                                                                                                                                                                                                                                                                   |
| simplices                             | (ndarray of ints, shape (nsimplex, ndim+1)) Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.                                                                                                                                                                                          |
| neighbors                             | (ndarray of ints, shape (nsimplex, ndim+1)) Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.                                                                                                                                                        |
| equations                             | (ndarray of double, shape (nsimplex, ndim+2)) [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see <a href="#">Qhull documentation</a> for more).                                                                                                                                                                         |
| paraboloid_scale,<br>paraboloid_shift | (float) Scale and shift for the extra paraboloid dimension (see <a href="#">Qhull documentation</a> for more).                                                                                                                                                                                                                                            |
| coplanar                              | (ndarray of int, shape (ncoplanar, 3)) Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were <i>not</i> included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed. .. versionadded:: 0.12.0 |
| vertices                              | Same as <i>simplices</i> , but deprecated.                                                                                                                                                                                                                                                                                                                |

**Methods**

|                                                        |                                                                         |
|--------------------------------------------------------|-------------------------------------------------------------------------|
| <code>add_points(points[, restart])</code>             | Process a set of additional new points.                                 |
| <code>close()</code>                                   | Finish incremental processing.                                          |
| <code>find_simplex(self, xi[, bruteforce, tol])</code> | Find the simplices containing the given points.                         |
| <code>lift_points(self, x)</code>                      | Lift points to the Qhull paraboloid.                                    |
| <code>plane_distance(self, xi)</code>                  | Compute hyperplane distances to the point <i>xi</i> from all simplices. |

---

`Delaunay.add_points` (*points*, *restart=False*)

Process a set of additional new points.

**Parameters**    **points** : ndarray

New points to add. The dimensionality should match that of the initial points.

**restart** : bool, optional

Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**        **QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

`close`

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

`Delaunay.close` ()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

`Delaunay.find_simplex` (*self*, *xi*, *bruteforce=False*, *tol=None*)

Find the simplices containing the given points.

**Parameters**    **tri** : DelaunayInfo

Delaunay triangulation

**xi** : ndarray of double, shape (... , ndim)

**bruteforce** : bool, optional  
 Whether to only perform a brute-force search  
**tol** : float, optional  
 Tolerance allowed in the inside-triangle check. Default is  $100 * \text{eps}$ .  
**Returns** **i** : ndarray of int, same shape as *xi*  
 Indices of simplices containing each point. Points outside the triangulation get the value -1.

**Notes**

This uses an algorithm adapted from Qhull's `qh_findbestfacet`, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in  $N+1$  dimensions, the algorithm falls back to directed search in  $N$  dimensions.

`Delaunay.lift_points` (*self*, *x*)  
 Lift points to the Qhull paraboloid.

`Delaunay.plane_distance` (*self*, *xi*)  
 Compute hyperplane distances to the point *xi* from all simplices.

**class** `scipy.spatial.ConvexHull` (*points*, *incremental=False*, *qhull\_options=None*)  
 Convex hulls in  $N$  dimensions.

New in version 0.12.0.

**Parameters** **points** : ndarray of floats, shape (npoints, ndim)  
 Coordinates of points to construct a convex hull from  
**incremental** : bool, optional  
 Allow adding new points incrementally. This takes up some additional resources.  
**qhull\_options** : str, optional  
 Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qx" for  $\text{ndim} > 4$  and "" otherwise) Option "Qt" is always enabled.  
**Raises** **QhullError**  
 Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.  
**ValueError**  
 Raised if an incompatible array is given as input.

**Notes**

The convex hull is computed using the [Qhull library](#).

**References**

[\[Qhull\]](#)

**Examples**

Convex hull of a random set of points:

```

>>> from scipy.spatial import ConvexHull
>>> points = np.random.rand(30, 2) # 30 random points in 2-D
>>> hull = ConvexHull(points)
  
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> for simplex in hull.simplices:
...     plt.plot(points[simplex, 0], points[simplex, 1], 'k-')
```

We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:

```
>>> plt.plot(points[hull.vertices,0], points[hull.vertices,1], 'r--', lw=2)
>>> plt.plot(points[hull.vertices[0],0], points[hull.vertices[0],1], 'ro')
>>> plt.show()
```

|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| points    | (ndarray of double, shape (npoints, ndim)) Coordinates of input points.                                                                                                                                                                                                                                                               |
| vertices  | (ndarray of ints, shape (nvertices,)) Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.                                                                                                                     |
| simplices | (ndarray of ints, shape (nfacet, ndim)) Indices of points forming the simplicial facets of the convex hull.                                                                                                                                                                                                                           |
| neighbors | (ndarray of ints, shape (nfacet, ndim)) Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.                                                                                                                                                                            |
| equations | (ndarray of double, shape (nfacet, ndim+1)) [normal, offset] forming the hyperplane equation of the facet (see <a href="#">Qhull documentation</a> for more).                                                                                                                                                                         |
| coplanar  | (ndarray of int, shape (ncoplanar, 3)) Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were <i>not</i> included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed. |
| area      | (float) Area of the convex hull                                                                                                                                                                                                                                                                                                       |
| volume    | (float) Volume of the convex hull                                                                                                                                                                                                                                                                                                     |

### Methods

`close`

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

`ConvexHull.close` ()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**class** `scipy.spatial.Voronoi` (*points*, *furthest\_site=False*, *incremental=False*, *qhull\_options=None*)

Voronoi diagrams in N dimensions.

New in version 0.12.0.

|                   |                                                          |                                                                                                                                                                   |
|-------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>points</b> : ndarray of floats, shape (npoints, ndim) | Coordinates of points to construct a convex hull from                                                                                                             |
|                   | <b>furthest_site</b> : bool, optional                    | Whether to compute a furthest-site Voronoi diagram. Default: False                                                                                                |
|                   | <b>incremental</b> : bool, optional                      | Allow adding new points incrementally. This takes up some additional resources.                                                                                   |
|                   | <b>qhull_options</b> : str, optional                     | Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qbb Qc Qz Qx” for ndim > 4 and “Qbb Qc Qz” otherwise. Incremental mode omits “Qz”.) |
| <b>Raises</b>     | <b>QhullError</b>                                        | Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.                                          |
|                   | <b>ValueError</b>                                        | Raised if an incompatible array is given as input.                                                                                                                |

**Notes**

The Voronoi diagram is computed using the [Qhull library](#).

### Examples

Voronoi diagram for a set of point:

```
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2],
...                    [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:

```
>>> vor.vertices
array([[ 0.5,  0.5],
       [ 1.5,  0.5],
       [ 0.5,  1.5],
       [ 1.5,  1.5]])
```

There is a single finite Voronoi region, and four finite Voronoi ridges:

```
>>> vor.regions
[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [3, 2, 0, 1], [2, -1, 0], [3, -
>>> vor.ridge_vertices
[[-1, 0], [-1, 0], [-1, 1], [-1, 1], [0, 1], [-1, 3], [-1, 2], [2, 3], [-1, 3], [-1, 2], [0, 2],
```

The ridges are perpendicular between lines drawn between the following input points:

```
>>> vor.ridge_points
array([[0, 1],
       [0, 3],
       [6, 3],
       [6, 7],
```

```
[3, 4],
[5, 8],
[5, 2],
[5, 4],
[8, 7],
[2, 1],
[4, 1],
[4, 7]], dtype=int32)
```

**Attributes**

|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>points</code>         | (ndarray of double, shape (npoints, ndim)) Coordinates of input points.                                                                                                                                      |
| <code>vertices</code>       | (ndarray of double, shape (nvertices, ndim)) Coordinates of the Voronoi vertices.                                                                                                                            |
| <code>ridge_points</code>   | (ndarray of ints, shape (nridges, 2)) Indices of the points between which each Voronoi ridge lies.                                                                                                           |
| <code>ridge_vertices</code> | (list of list of ints, shape (nridges, *)) Indices of the Voronoi vertices forming each Voronoi ridge.                                                                                                       |
| <code>regions</code>        | (list of list of ints, shape (nregions, *)) Indices of the Voronoi vertices forming each Voronoi region. -1 indicates vertex outside the Voronoi diagram.                                                    |
| <code>point_region</code>   | (list of ints, shape (npoints)) Index of the Voronoi region for each input point. If qhull option “Qc” was not specified, the list will contain -1 for points that are not associated with a Voronoi region. |

**Methods**

|                                            |                                         |
|--------------------------------------------|-----------------------------------------|
| <code>add_points(points[, restart])</code> | Process a set of additional new points. |
| <code>close()</code>                       | Finish incremental processing.          |

`Voronoi.add_points` (*points*, *restart=False*)

Process a set of additional new points.

**Parameters**    **points** : ndarray

New points to add. The dimensionality should match that of the initial points.

**restart** : bool, optional

Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**        **QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

`close`

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

`Voronoi.close` ()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**class** `scipy.spatial.SphericalVoronoi` (*points*, *radius=None*, *center=None*)

Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

**Parameters**

- points** : ndarray of floats, shape (npoints, 3)  
Coordinates of points to construct a spherical Voronoi diagram from
- radius** : float, optional  
Radius of the sphere (Default: 1)
- center** : ndarray of floats, shape (3,)  
Center of sphere (Default: origin)

**See also:**

**Voronoi** Conventional Voronoi diagrams in N dimensions.

**Notes**

The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [Caroli]. A 3D Delaunay tetrahedralization is obtained by including the origin of the coordinate system as the fourth vertex of each simplex of the Convex Hull. The circumcenters of all tetrahedra in the system are calculated and projected to the surface of the sphere, producing the Voronoi vertices. The Delaunay tetrahedralization neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

The surface area of spherical polygons is calculated by decomposing them into triangles and using L'Huilier's Theorem to calculate the spherical excess of each triangle [Weisstein]. The sum of the spherical excesses is multiplied by the square of the sphere radius to obtain the surface area of the spherical polygon. For nearly-degenerate spherical polygons an area of approximately 0 is returned by default, rather than attempting the unstable calculation.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement). The reconstitution of the surface area of the sphere, measured as the sum of the surface areas of all Voronoi regions, is closest to 100 % for larger (>> 10) numbers of generators.

**Examples**

```
>>> from matplotlib import colors
>>> from mpl_toolkits.mplot3d.art3d import Poly3DCollection
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import SphericalVoronoi
>>> from mpl_toolkits.mplot3d import proj3d
>>> # set input data
>>> points = np.array([[0, 0, 1], [0, 0, -1], [1, 0, 0],
...                  [0, 1, 0], [0, -1, 0], [-1, 0, 0], ])
>>> center = np.array([0, 0, 0])
>>> radius = 1
>>> # calculate spherical Voronoi diagram
>>> sv = SphericalVoronoi(points, radius, center)
>>> # sort vertices (optional, helpful for plotting)
>>> sv.sort_vertices_of_regions()
>>> # generate plot
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> # plot the unit sphere for reference (optional)
>>> u = np.linspace(0, 2 * np.pi, 100)
```

```

>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
>>> # plot generator points
>>> ax.scatter(points[:, 0], points[:, 1], points[:, 2], c='b')
>>> # plot Voronoi vertices
>>> ax.scatter(sv.vertices[:, 0], sv.vertices[:, 1], sv.vertices[:, 2],
...           c='g')
>>> # indicate Voronoi regions (as Euclidean polygons)
>>> for region in sv.regions:
...     random_color = colors.rgb2hex(np.random.rand(3))
...     polygon = Poly3DCollection([sv.vertices[region]], alpha=1.0)
...     polygon.set_color(random_color)
...     ax.add_collection3d(polygon)
>>> plt.show()
    
```

### Attributes

|          |                                                                                                                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| points   | (double array of shape (npoints, 3)) the points in 3D to generate the Voronoi diagram from                                                                |
| radius   | (double) radius of the sphere Default: None (forces estimation, which is less precise)                                                                    |
| center   | (double array of shape (3,)) center of the sphere Default: None (assumes sphere is centered at origin)                                                    |
| vertices | (double array of shape (nvertices, 3)) Voronoi vertices corresponding to points                                                                           |
| regions  | (list of list of integers of shape (npoints, _)) the n-th entry is a list consisting of the indices of the vertices belonging to the n-th point in points |

### Methods

---

`sort_vertices_of_regions()` For each region in regions, it sorts the indices of the Voronoi vertices such that the resulting p

---

`SphericalVoronoi.sort_vertices_of_regions()`

For each region in regions, it sorts the indices of the Voronoi vertices such that the resulting points are in

a clockwise or counterclockwise order around the generator point.

This is done as follows: Recall that the  $n$ -th region in regions surrounds the  $n$ -th generator in points and that the  $k$ -th Voronoi vertex in vertices is the projected circumcenter of the tetrahedron obtained by the  $k$ -th triangle in `_tri.simplices` (and the origin). For each region  $n$ , we choose the first triangle (=Voronoi vertex) in `_tri.simplices` and a vertex of that triangle not equal to the center  $n$ . These determine a unique neighbor of that triangle, which is then chosen as the second triangle. The second triangle will have a unique vertex not equal to the current vertex or the center. This determines a unique neighbor of the second triangle, which is then chosen as the third triangle and so forth. We proceed through all the triangles (=Voronoi vertices) belonging to the generator in points and obtain a sorted version of the vertices of its surrounding region.

```
class scipy.spatial.HalfspaceIntersection (halfspaces, interior_point, incremental=False,
   qhull_options=None)
```

Halfspace intersections in  $N$  dimensions.

New in version 0.19.0.

**Parameters**

- halfspaces** : ndarray of floats, shape (nineq, ndim+1)  
Stacked Inequalities of the form  $Ax + b \leq 0$  in format  $[A; b]$
- interior\_point** : ndarray of floats, shape (ndim,)  
Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming.
- incremental** : bool, optional  
Allow adding new halfspaces incrementally. This takes up some additional resources.
- qhull\_options** : str, optional  
Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qx" for  $\text{ndim} > 4$  and "" otherwise) Option "H" is always enabled.

**Raises**

- QhullError**  
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- ValueError**  
Raised if an incompatible array is given as input.

#### Notes

The intersections are computed using the [Qhull library](#). This reproduces the "qhull" functionality of Qhull.

#### References

[Qhull], [R350]

#### Examples

Halfspace intersection of planes forming some polygon

```
>>> from scipy.spatial import HalfspaceIntersection
>>> import numpy as np
>>> halfspaces = np.array([[ -1,  0.,  0.],
...                       [ 0., -1.,  0.],
...                       [ 2.,  1., -4.],
...                       [-0.5,  1., -2.]])
>>> feasible_point = np.array([0.5, 0.5])
>>> hs = HalfspaceIntersection(halfspaces, feasible_point)
```

Plot halfspaces as filled regions and intersection points:

```

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot('111', aspect='equal')
>>> xlim, ylim = (-1, 3), (-1, 3)
>>> ax.set_xlim(xlim)
>>> ax.set_ylim(ylim)
>>> x = np.linspace(-1, 3, 100)
>>> symbols = ['-', '+', 'x', '*']
>>> signs = [0, 0, -1, -1]
>>> fmt = {"color": None, "edgecolor": "b", "alpha": 0.5}
>>> for h, sym, sign in zip(halfspaces, symbols, signs):
...     hlist = h.tolist()
...     fmt["hatch"] = sym
...     if h[1]== 0:
...         ax.axvline(-h[2]/h[0], label='{}x+{}y+{}=0'.format(*hlist))
...         xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
...         ax.fill_between(xi, ylim[0], ylim[1], **fmt)
...     else:
...         ax.plot(x, (-h[2]-h[0]*x)/h[1], label='{}x+{}y+{}=0'.format(*hlist))
...         ax.fill_between(x, (-h[2]-h[0]*x)/h[1], ylim[sign], **fmt)
>>> x, y = zip(*hs.intersections)
>>> ax.plot(x, y, 'o', markersize=8)
    
```

By default, qhull does not provide with a way to compute an interior point. This can easily be computed using linear programming. Considering halfspaces of the form  $Ax + b \leq 0$ , solving the linear program:

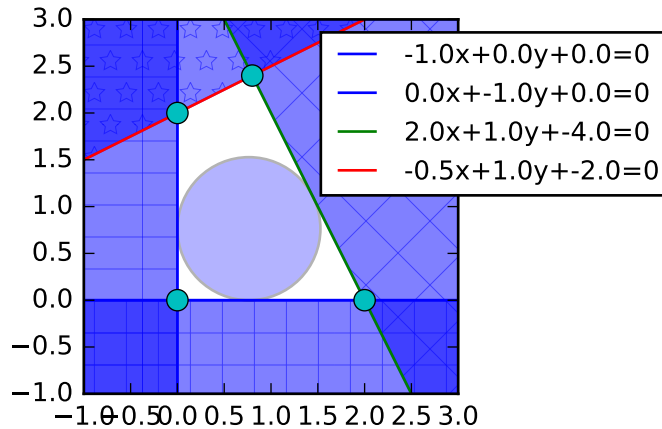

$$\begin{aligned} & \max y \\ & \text{s.t. } Ax + y\|A_i\| \leq -b \end{aligned}$$

With  $A_i$  being the rows of A, i.e. the normals to each plane.

Will yield a point x that is furthest inside the convex polyhedron. To be precise, it is the center of the largest hypersphere of radius y inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron (see [R350] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

```

>>> from scipy.optimize import linprog
>>> from matplotlib.patches import Circle
>>> norm_vector = np.reshape(np.linalg.norm(halfspaces[:, :-1], axis=1),
...     (halfspaces.shape[0], 1))
>>> c = np.zeros((halfspaces.shape[1],))
>>> c[-1] = -1
>>> A = np.hstack((halfspaces[:, :-1], norm_vector))
>>> b = - halfspaces[:, -1:]
>>> res = linprog(c, A_ub=A, b_ub=b)
>>> x = res.x[:-1]
>>> y = res.x[-1]
>>> circle = Circle(x, radius=y, alpha=0.3)
>>> ax.add_patch(circle)
>>> plt.legend(bbox_to_anchor=(1.6, 1.0))
>>> plt.show()
    
```

### Attributes

|                                      |                                                                                                                                                                                                                            |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| halfspaces                           | (ndarray of double, shape (nineq, ndim+1)) Input halfspaces.                                                                                                                                                               |
| interior_point                       | Input interior point.                                                                                                                                                                                                      |
| :ndarray of floats,<br>shape (ndim,) |                                                                                                                                                                                                                            |
| intersections                        | (ndarray of double, shape (ninter, ndim)) Intersections of all halfspaces.                                                                                                                                                 |
| dual_points                          | (ndarray of double, shape (nineq, ndim)) Dual points of the input halfspaces.                                                                                                                                              |
| dual_facets                          | (list of lists of ints) Indices of points forming the (non necessarily simplicial) facets of the dual convex hull.                                                                                                         |
| dual_vertices                        | (ndarray of ints, shape (nvertices,)) Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order. |
| dual_equations                       | (ndarray of double, shape (nfacet, ndim+1)) [normal, offset] forming the hyperplane equation of the dual facet (see <a href="#">Qhull documentation</a> for more).                                                         |
| dual_area                            | (float) Area of the dual convex hull                                                                                                                                                                                       |
| dual_volume                          | (float) Volume of the dual convex hull                                                                                                                                                                                     |

### Methods

|                                                    |                                             |
|----------------------------------------------------|---------------------------------------------|
| <code>add_halfspaces(halfspaces[, restart])</code> | Process a set of additional new halfspaces. |
| <code>close()</code>                               | Finish incremental processing.              |

`HalfspaceIntersection.add_halfspaces(halfspaces, restart=False)`

Process a set of additional new halfspaces.

|                   |                                                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>halfspaces</b> : ndarray<br>New halfspaces to add. The dimensionality should match that of the initial halfspaces.                         |
|                   | <b>restart</b> : bool, optional<br>Whether to restart processing from scratch, rather than adding halfspaces incrementally.                   |
| <b>Raises</b>     | <b>QhullError</b><br>Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled. |

**See also:**

`close`

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after `close` has been called.

`HalfspaceIntersection.close()`  
 Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

### 5.24.3 Plotting Helpers

|                                              |                                              |
|----------------------------------------------|----------------------------------------------|
| <code>del aunay_plot_2d(tri[, ax])</code>    | Plot the given Delaunay triangulation in 2-D |
| <code>convex_hull_plot_2d(hull[, ax])</code> | Plot the given convex hull diagram in 2-D    |
| <code>voronoi_plot_2d(vor[, ax])</code>      | Plot the given Voronoi diagram in 2-D        |

`scipy.spatial.delaunay_plot_2d(tri, ax=None)`  
 Plot the given Delaunay triangulation in 2-D

**Parameters** **tri** : `scipy.spatial.Delaunay` instance  
 Triangulation to plot  
**ax** : `matplotlib.axes.Axes` instance, optional  
 Axes to plot on  
**Returns** **fig** : `matplotlib.figure.Figure` instance  
 Figure for the plot

**See also:**

`Delaunay`, `matplotlib.pyplot.triplot`

**Notes**

Requires Matplotlib.

`scipy.spatial.convex_hull_plot_2d(hull, ax=None)`  
 Plot the given convex hull diagram in 2-D

**Parameters** **hull** : `scipy.spatial.ConvexHull` instance  
 Convex hull to plot  
**ax** : `matplotlib.axes.Axes` instance, optional  
 Axes to plot on  
**Returns** **fig** : `matplotlib.figure.Figure` instance  
 Figure for the plot

**See also:**

`ConvexHull`

**Notes**

Requires Matplotlib.

`scipy.spatial.voronoi_plot_2d(vor, ax=None, **kw)`  
 Plot the given Voronoi diagram in 2-D

**Parameters**

- vor** : `scipy.spatial.Voronoi` instance  
Diagram to plot
- ax** : `matplotlib.axes.Axes` instance, optional  
Axes to plot on
- show\_points**: **bool, optional**  
Add the Voronoi points to the plot.
- show\_vertices** : bool, optional  
Add the Voronoi vertices to the plot.
- line\_colors** : string, optional  
Specifies the line color for polygon boundaries
- line\_width** : float, optional  
Specifies the line width for polygon boundaries
- line\_alpha**: **float, optional**  
Specifies the line alpha for polygon boundaries

**Returns**

- fig** : `matplotlib.figure.Figure` instance  
Figure for the plot

**See also:**[Voronoi](#)**Notes**

Requires Matplotlib.

**See also:**[Tutorial](#)

## 5.24.4 Simplex representation

The simplices (triangles, tetrahedra, ...) appearing in the Delaunay tessellation (N-dim simplices), convex hull facets, and Voronoi ridges (N-1 dim simplices) are represented in the following scheme:

```
tess = Delaunay(points)
hull = ConvexHull(points)
voro = Voronoi(points)

# coordinates of the j-th vertex of the i-th simplex
tess.points[tess.simplices[i, j], :]      # tessellation element
hull.points[hull.simplices[i, j], :]     # convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :] # ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition:

`tess.neighbors[i, j]` is the neighboring simplex of the i-th simplex, opposite to the j-vertex. It is -1 in case of no neighbor.

Convex hull facets also define a hyperplane equation:

```
(hull.equations[i, :-1] * coord).sum() + hull.equations[i, -1] == 0
```

Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding N+1 dimensional paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.

## Functions

|                                                    |                                                                     |
|----------------------------------------------------|---------------------------------------------------------------------|
| <code>tsearch(tri, xi)</code>                      | Find simplices containing the given points.                         |
| <code>distance_matrix(x, y[, p, threshold])</code> | Compute the distance matrix.                                        |
| <code>minkowski_distance(x, y[, p])</code>         | Compute the $L^p$ distance between two arrays.                      |
| <code>minkowski_distance_p(x, y[, p])</code>       | Compute the $p$ -th power of the $L^p$ distance between two arrays. |
| <code>procrustes(data1, data2)</code>              | Procrustes analysis, a similarity test for two data sets.           |

`scipy.spatial.tsearch` (*tri, xi*)

Find simplices containing the given points. This function does the same thing as `Delaunay.find_simplex`.

New in version 0.9.

**See also:**

`Delaunay.find_simplex`

`scipy.spatial.distance_matrix` (*x, y, p=2, threshold=1000000*)

Compute the distance matrix.

Returns the matrix of all pair-wise distances.

**Parameters**

- x** : (M, K) array\_like  
Matrix of M vectors in K dimensions.
- y** : (N, K) array\_like  
Matrix of N vectors in K dimensions.
- p** : float, 1 <= p <= infinity  
Which Minkowski p-norm to use.
- threshold** : positive int  
If  $M * N * K > threshold$ , algorithm uses a Python loop instead of large temporary arrays.

**Returns**

- result** : (M, N) ndarray  
Matrix containing the distance from every vector in *x* to every vector in *y*.

### Examples

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0,0],[0,1]], [[1,0],[1,1]])
array([[ 1.         ,  1.41421356],
       [ 1.41421356,  1.         ]])
```

`scipy.spatial.minkowski_distance` (*x, y, p=2*)

Compute the  $L^p$  distance between two arrays.

**Parameters**

- x** : (M, K) array\_like  
Input array.
- y** : (N, K) array\_like  
Input array.
- p** : float, 1 <= p <= infinity  
Which Minkowski p-norm to use.

### Examples

```
>>> from scipy.spatial import minkowski_distance
>>> minkowski_distance([[0,0],[0,0]], [[1,1],[0,1]])
array([ 1.41421356,  1.         ])
```

`scipy.spatial.minkowski_distance_p(x, y, p=2)`

Compute the p-th power of the L\*\*p distance between two arrays.

For efficiency, this function computes the L\*\*p distance but does not extract the pth root. If  $p$  is 1 or infinity, this is equal to the actual L\*\*p distance.

**Parameters**

- x** : (M, K) array\_like  
Input array.
- y** : (N, K) array\_like  
Input array.
- p** : float,  $1 \leq p \leq \text{infinity}$   
Which Minkowski p-norm to use.

### Examples

```
>>> from scipy.spatial import minkowski_distance_p
>>> minkowski_distance_p([[0,0],[0,0]], [[1,1],[0,1]])
array([2, 1])
```

`scipy.spatial.procrustes(data1, data2)`

Procrustes analysis, a similarity test for two data sets.

Each input matrix is a set of points or vectors (the rows of the matrix). The dimension of the space is the number of columns of each matrix. Given two identically sized matrices, procrustes standardizes both such that:

- $\text{tr}(AA^T) = 1$ .
- Both sets of points are centered around the origin.

Procrustes ([R365], [R366]) then applies the optimal transform to the second matrix (including scaling/dilation, rotations, and reflections) to minimize  $M^2 = \sum(\text{data1} - \text{data2})^2$ , or the sum of the squares of the pointwise differences between the two input datasets.

This function was not designed to handle datasets with different numbers of datapoints (rows). If two data sets have different dimensionality (different number of columns), simply add columns of zeros to the smaller of the two.

**Parameters**

- data1** : array\_like  
Matrix, n rows represent points in k (columns) space *data1* is the reference data, after it is standardised, the data from *data2* will be transformed to fit the pattern in *data1* (must have >1 unique points).
- data2** : array\_like  
n rows of data in k space to be fit to *data1*. Must be the same shape (numrows, numcols) as *data1* (must have >1 unique points).

**Returns**

- mtx1** : array\_like  
A standardized version of *data1*.
- mtx2** : array\_like  
The orientation of *data2* that best fits *data1*. Centered, but not necessarily  $\text{tr}(AA^T) = 1$ .
- disparity** : float  
 $M^2$  as defined above.

**Raises**

- ValueError**  
If the input arrays are not two-dimensional. If the shape of the input arrays is different. If the input arrays have zero columns or zero rows.

See also:

`scipy.linalg.orthogonal_procrustes`  
`scipy.spatial.distance.directed_hausdorff`  
 Another similarity test for two data sets

*Notes*

- The disparity should not depend on the order of the input matrices, but the output matrices will, as only the first output matrix is guaranteed to be scaled such that  $tr(AA^T) = 1$ .
- Duplicate data points are generally ok, duplicating a data point will increase its effect on the procrustes fit.
- The disparity scales as the number of points per input matrix.

*References*

[R365], [R366]

*Examples*

```
>>> from scipy.spatial import procrustes
```

The matrix b is a rotated, shifted, scaled and mirrored version of a here:

```
>>> a = np.array([[1, 3], [1, 2], [1, 1], [2, 1]], 'd')
>>> b = np.array([[4, -2], [4, -4], [4, -6], [2, -6]], 'd')
>>> mtx1, mtx2, disparity = procrustes(a, b)
>>> round(disparity)
0.0
```

## 5.25 Distance computations (`scipy.spatial.distance`)

### 5.25.1 Function Reference

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

|                                                   |                                                                                          |
|---------------------------------------------------|------------------------------------------------------------------------------------------|
| <code>pdist(X[, metric, p, w, V, VI])</code>      | Pairwise distances between observations in n-dimensional space.                          |
| <code>cdist(XA, XB[, metric, p, V, VI, w])</code> | Computes distance between each pair of the two collections of inputs.                    |
| <code>squareform(X[, force, checks])</code>       | Converts a vector-form distance vector to a square-form distance matrix, and vice-versa. |
| <code>directed_hausdorff(u, v[, seed])</code>     | Computes the directed Hausdorff distance between two N-D arrays.                         |

`scipy.spatial.distance.pdist` (*X*, *metric*='euclidean', *p*=None, *w*=None, *V*=None, *VI*=None)

Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

- Parameters**
- X** : ndarray  
An m by n array of m original observations in an n-dimensional space.
  - metric** : str or function, optional  
The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'squeuclidean', 'yule'.
  - p** : double, optional  
The p-norm to apply Only for Minkowski, weighted and unweighted. Default: 2.
  - w** : ndarray, optional  
The weight vector. Only for weighted Minkowski. Mandatory

**V** : ndarray, optional  
The variance vector Only for standardized Euclidean. Default: `var(X, axis=0, ddof=1)`

**VI** : ndarray, optional  
The inverse of the covariance matrix Only for Mahalanobis. Default: `inv(cov(X.T)).T`

**Returns** **Y** : ndarray  
Returns a condensed distance matrix Y. For each  $i$  and  $j$  (where  $i < j < m$ ), where  $m$  is the number of original observations. The metric `dist(u=X[i], v=X[j])` is computed and stored in entry  $ij$ .

**See also:**

[`squareform`](#) converts between condensed distance matrices and square distance matrices.

**Notes**

See `squareform` for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. `Y = pdist(X, 'euclidean')`

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix  $X$ .

2. `Y = pdist(X, 'minkowski', p)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  (p-norm) where  $p \geq 1$ .

3. `Y = pdist(X, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = pdist(X, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}$$

$V$  is the variance vector;  $V[i]$  is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5. `Y = pdist(X, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6. `Y = pdist(X, 'cosine')`

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|*\|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7. `Y = pdist(X, 'correlation')`

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8. `Y = pdist(X, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9.Y = pdist(X, 'jaccard')

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree.

10.Y = pdist(X, 'chebyshev')

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|$$

11.Y = pdist(X, 'canberra')

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

12.Y = pdist(X, 'braycurtis')

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}$$

13.Y = pdist(X, 'mahalanobis', VI=None)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the VI variable) is the inverse covariance. If VI is not None, VI will be used as the inverse covariance matrix.

14.Y = pdist(X, 'yule')

Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

15.Y = pdist(X, 'matching')

Synonym for 'hamming'.

16.Y = pdist(X, 'dice')

Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)

17.Y = pdist(X, 'kulsinski')

Computes the Kulsinski distance between each pair of boolean vectors. (see kulsinski function documentation)

18.Y = pdist(X, 'rogerstanimoto')

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)

19.Y = pdist(X, 'russellrao')

Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

```
20.Y = pdist(X, 'sokalmichener')
```

Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

```
21.Y = pdist(X, 'sokalsneath')
```

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

```
22.Y = pdist(X, 'wminkowski')
```

Computes the weighted Minkowski distance between each pair of vectors. (see wminkowski function documentation)

```
23.Y = pdist(X, f)
```

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = pdist(X, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = pdist(X, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function sokalsneath. This would result in sokalsneath being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

```
dm = pdist(X, 'sokalsneath')
```

```
scipy.spatial.distance.cdist(XA, XB, metric='euclidean', p=None, V=None, VI=None,
                             w=None)
```

Computes distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

**Parameters** **XA** : ndarray

An  $m_A$  by  $n$  array of  $m_A$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.

**XB** : ndarray

An  $m_B$  by  $n$  array of  $m_B$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.

**metric** : str or callable, optional

The distance metric to use. If a string, the distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'wminkowski', 'yule'.

**p** : double, optional

The p-norm to apply Only for Minkowski, weighted and unweighted. Default: 2.

**w** : ndarray, optional

The weight vector. Only for weighted Minkowski. Mandatory

**V** : ndarray, optional

The variance vector Only for standardized Euclidean. Default: `var(vstack([XA, XB]), axis=0, ddof=1)`

|                |                               |                                                                                                                                                                  |
|----------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <b>VI</b> : ndarray, optional | The inverse of the covariance matrix Only for Mahalanobis. Default: <code>inv(cov(vstack([XA, XB]).T)).T</code>                                                  |
| <b>Returns</b> | <b>Y</b> : ndarray            | A $m_A$ by $m_B$ distance matrix is returned. For each $i$ and $j$ , the metric <code>dist(u=XA[i], v=XB[j])</code> is computed and stored in the $ij$ th entry. |
| <b>Raises</b>  | <b>ValueError</b>             | An exception is thrown if $XA$ and $XB$ do not have the same number of columns.                                                                                  |

**Notes**

The following are common calling conventions:

1. `Y = cdist(XA, XB, 'euclidean')`

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix  $X$ .

2. `Y = cdist(XA, XB, 'minkowski', p)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  ( $p$ -norm) where  $p \geq 1$ .

3. `Y = cdist(XA, XB, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = cdist(XA, XB, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}$$

$V$  is the variance vector;  $V[i]$  is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5. `Y = cdist(XA, XB, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6. `Y = cdist(XA, XB, 'cosine')`

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|* \|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7. `Y = cdist(XA, XB, 'correlation')`

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8. `Y = cdist(XA, XB, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9. `Y = cdist(XA, XB, 'jaccard')`

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree where at least one of them is non-zero.

10. `Y = cdist(XA, XB, 'chebyshev')`

Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|.$$

11.Y = `cdist(XA, XB, 'canberra')`

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

12.Y = `cdist(XA, XB, 'braycurtis')`

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}$$

13.Y = `cdist(XA, XB, 'mahalanobis', VI=None)`

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the VI variable) is the inverse covariance. If VI is not None, VI will be used as the inverse covariance matrix.

14.Y = `cdist(XA, XB, 'yule')`

Computes the Yule distance between the boolean vectors. (see [yule](#) function documentation)

15.Y = `cdist(XA, XB, 'matching')`

Synonym for 'hamming'.

16.Y = `cdist(XA, XB, 'dice')`

Computes the Dice distance between the boolean vectors. (see [dice](#) function documentation)

17.Y = `cdist(XA, XB, 'kulsinski')`

Computes the Kulsinski distance between the boolean vectors. (see [kulsinski](#) function documentation)

18.Y = `cdist(XA, XB, 'rogerstanimoto')`

Computes the Rogers-Tanimoto distance between the boolean vectors. (see [rogerstanimoto](#) function documentation)

19.Y = `cdist(XA, XB, 'russellrao')`

Computes the Russell-Rao distance between the boolean vectors. (see [russellrao](#) function documentation)

20.Y = `cdist(XA, XB, 'sokalmichener')`

Computes the Sokal-Michener distance between the boolean vectors. (see [sokalmichener](#) function documentation)

```
21.Y = cdist(XA, XB, 'sokalsneath')
```

Computes the Sokal-Sneath distance between the vectors. (see `sokalsneath` function documentation)

```
22.Y = cdist(XA, XB, 'wminkowski')
```

Computes the weighted Minkowski distance between the vectors. (see `wminkowski` function documentation)

```
23.Y = cdist(XA, XB, f)
```

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = cdist(XA, XB, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = cdist(XA, XB, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function `sokalsneath`. This would result in `sokalsneath` being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

```
dm = cdist(XA, XB, 'sokalsneath')
```

### Examples

Find the Euclidean distances between four 2-D coordinates:

```
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
...          (35.1174, -89.9711),
...          (35.9728, -83.9422),
...          (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0.        ,  4.7044,  1.6172,  1.8856],
       [ 4.7044,  0.        ,  6.0893,  3.3561],
       [ 1.6172,  6.0893,  0.        ,  2.8477],
       [ 1.8856,  3.3561,  2.8477,  0.        ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```
>>> a = np.array([[0, 0, 0],
...              [0, 0, 1],
...              [0, 1, 0],
...              [0, 1, 1],
...              [1, 0, 0],
...              [1, 0, 1],
...              [1, 1, 0],
...              [1, 1, 1]])
>>> b = np.array([0.1, 0.2, 0.4])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
       [ 0.9],
       [ 1.3],
       [ 1.5],
       [ 1.5],
       [ 1.5],
       [ 1.7],
       [ 1.7]])
```

```
[ 2.1],
 [ 2.3]])
```

`scipy.spatial.distance.squareform(X, force='no', checks=True)`

Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters**

- X** : ndarray  
Either a condensed or redundant distance matrix.
- force** : str, optional  
As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.
- checks** : bool, optional  
If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that  $X - X.T$  is small and  $\text{diag}(X)$  is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

**Returns**

- Y** : ndarray  
If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

### Notes

1.  $v = \text{squareform}(X)$

Given a square  $d$ -by- $d$  symmetric distance matrix  $X$ ,  $v = \text{squareform}(X)$  returns a  $d * (d-1) / 2$  (or  $\binom{d}{2}$ ) sized vector  $v$ .

$v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  is the distance between points  $i$  and  $j$ . If  $X$  is non-square or asymmetric, an error is returned.

2.  $X = \text{squareform}(v)$

Given a  $d*(d-1)/2$  sized  $v$  for some integer  $d \geq 2$  encoding distances as described,  $X = \text{squareform}(v)$  returns a  $d$  by  $d$  distance matrix  $X$ . The  $X[i, j]$  and  $X[j, i]$  values are set to  $v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  and all diagonal elements are zero.

In Scipy 0.19.0, `squareform` stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

`scipy.spatial.distance.directed_hausdorff(u, v, seed=0)`

Computes the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

**Parameters**

- u** : (M,N) ndarray  
Input array.
- v** : (O,N) ndarray  
Input array.
- seed** : int or None  
Local `np.random.RandomState` seed. Default is 0, a random shuffling of  $u$  and  $v$  that guarantees reproducibility.

**Returns**

- d** : double  
The directed Hausdorff distance between arrays  $u$  and  $v$ ,
- index\_1** : int  
index of point contributing to Hausdorff pair in  $u$
- index\_2** : int  
index of point contributing to Hausdorff pair in  $v$

**See also:**

`scipy.spatial.procrustes`

Another similarity test for two data sets

**Notes**

Uses the early break technique and the random sampling approach described by [R364]. Although worst-case performance is  $O(m * o)$  (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is  $O(m)$ , which is satisfied by selecting an inner loop distance that is less than `cmax` and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to  $O(m)$ .

New in version 0.19.0.

**References**

[R364]

**Examples**

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
...              (0.0, 1.0),
...              (-1.0, 0.0),
...              (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
...              (0.0, 2.0),
...              (-2.0, 0.0),
...              (0.0, -4.0)])

>>> directed_hausdorff(u, v) [0]
2.23606797749979
>>> directed_hausdorff(v, u) [0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```
>>> max(directed_hausdorff(u, v) [0], directed_hausdorff(v, u) [0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```
>>> directed_hausdorff(v, u) [1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

---

|                                                          |                                                                                     |
|----------------------------------------------------------|-------------------------------------------------------------------------------------|
| <code>is_valid_dm(D[, tol, throw, name, warning])</code> | Returns True if input array is a valid distance matrix.                             |
| <code>is_valid_y(y[, warning, throw, name])</code>       | Returns True if the input array is a valid condensed distance matrix.               |
| <code>num_obs_dm(d)</code>                               | Returns the number of original observations that correspond to a square, redundant  |
| <code>num_obs_y(Y)</code>                                | Returns the number of original observations that correspond to a condensed distance |

---

`scipy.spatial.distance.is_valid_dm(D, tol=0.0, throw=False, name='D', warning=False)`

Returns True if input array is a valid distance matrix.

Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

**Parameters**

- D** : ndarray  
The candidate object to test for validity.
- tol** : float, optional  
The distance matrix should be symmetric. *tol* is the maximum difference between entries  $i,j$  and  $j,i$  for the distance metric to be considered symmetric.
- throw** : bool, optional  
An exception is thrown if the distance matrix passed is not valid.
- name** : str, optional  
The name of the variable to checked. This is useful if *throw* is set to True so the offending variable can be identified in the exception message when an exception is thrown.
- warning** : bool, optional  
Instead of throwing an exception, a warning message is raised.

**Returns**

- valid** : bool  
True if the variable *D* passed is a valid distance matrix.

#### Notes

Small numerical differences in *D* and *D.T* and non-zerosness of the diagonal are ignored if they are within the tolerance specified by *tol*.

`scipy.spatial.distance.is_valid_y(y, warning=False, throw=False, name=None)`

Returns True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient  $\binom{n}{2}$  for some positive integer *n*.

**Parameters**

- y** : ndarray  
The condensed distance matrix.
- warning** : bool, optional  
Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. *name* is used when referencing the offending variable.
- throw** : bool, optional  
Throws an exception if the variable passed is not a valid condensed distance matrix.
- name** : bool, optional  
Used when referencing the offending variable in the warning or exception message.

`scipy.spatial.distance.num_obs_dm(d)`

Returns the number of original observations that correspond to a square, redundant distance matrix.

**Parameters**

- d** : ndarray  
The target distance matrix.

**Returns**

- num\_obs\_dm** : int  
The number of observations in the redundant distance matrix.

`scipy.spatial.distance.num_obs_y(Y)`

Returns the number of original observations that correspond to a condensed distance matrix.

**Parameters**

- Y** : ndarray  
Condensed distance matrix.

**Returns** `n` : int

The number of observations in the condensed distance matrix  $Y$ .

Distance functions between two numeric vectors  $u$  and  $v$ . Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

| <code>euclidean(u, v)</code>        | Computes the Euclidean distance between two 1-D arrays.             |
| <code>mahalanobis(u, v, VI)</code>  | Computes the Mahalanobis distance between two 1-D arrays.           |
| <code>minkowski(u, v, p)</code>     | Computes the Minkowski distance between two 1-D arrays.             |
| <code>seuclidean(u, v, V)</code>    | Returns the standardized Euclidean distance between two 1-D arrays. |
| <code>squeuclidean(u, v)</code>     | Computes the squared Euclidean distance between two 1-D arrays.     |
| <code>wminkowski(u, v, p, w)</code> | Computes the weighted Minkowski distance between two 1-D arrays.    |

`scipy.spatial.distance.braycurtis(u, v)`

Computes the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

$$\sum |u_i - v_i| / \sum |u_i + v_i|$$

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

**Parameters** `u` : (N,) array\_like

Input array.

`v` : (N,) array\_like

Input array.

**Returns** `braycurtis` : double

The Bray-Curtis distance between 1-D arrays  $u$  and  $v$ .

`scipy.spatial.distance.canberra(u, v)`

Computes the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

**Parameters** `u` : (N,) array\_like

Input array.

`v` : (N,) array\_like

Input array.

**Returns** `canberra` : double

The Canberra distance between vectors  $u$  and  $v$ .

**Notes**

When  $u[i]$  and  $v[i]$  are 0 for given  $i$ , then the fraction  $0/0 = 0$  is used in the calculation.

`scipy.spatial.distance.chebyshev(u, v)`

Computes the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays  $u$  and  $v$ , which is defined as

$$\max_i |u_i - v_i|.$$

**Parameters** **u** : (N,) array\_like  
Input vector.

**v** : (N,) array\_like

**Returns** **chebyshev** : double  
Input vector.  
The Chebyshev distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.cityblock` ( $u$ ,  $v$ )

Computes the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays  $u$  and  $v$ , which is defined as

$$\sum_i |u_i - v_i|.$$

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like

**Returns** **cityblock** : double  
Input array.  
The City Block (Manhattan) distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.correlation` ( $u$ ,  $v$ )

Computes the correlation distance between two 1-D arrays.

The correlation distance between  $u$  and  $v$ , is defined as

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\| (u - \bar{u}) \|_2 \| (v - \bar{v}) \|_2}$$

where  $\bar{u}$  is the mean of the elements of  $u$  and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like

**Returns** **correlation** : double  
Input array.  
The correlation distance between 1-D array  $u$  and  $v$ .

`scipy.spatial.distance.cosine` ( $u$ ,  $v$ )

Computes the Cosine distance between 1-D arrays.

The Cosine distance between  $u$  and  $v$ , is defined as

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}.$$

where  $u \cdot v$  is the dot product of  $u$  and  $v$ .

**Parameters** **u** : (N,) array\_like  
Input array.

**v** : (N,) array\_like

**Returns** **cosine** : double  
Input array.  
The Cosine distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.euclidean` ( $u$ ,  $v$ )

Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\|u - v\|_2$$

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**Returns** **euclidean** : double  
 The Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.mahalanobis` ( $u, v, VI$ )  
 Computes the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\sqrt{(u - v)V^{-1}(u - v)^T}$$

where  $V$  is the covariance matrix. Note that the argument  $VI$  is the inverse of  $V$ .

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**VI** : ndarray  
 The inverse of the covariance matrix.  
**Returns** **mahalanobis** : double  
 The Mahalanobis distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.minkowski` ( $u, v, p$ )  
 Computes the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\|u - v\|_p = \left(\sum |u_i - v_i|^p\right)^{1/p}.$$

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**p** : int  
 The order of the norm of the difference  $\|u - v\|_p$ .  
**Returns** **d** : double  
 The Minkowski distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.seuclidean` ( $u, v, V$ )  
 Returns the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between  $u$  and  $v$ .

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**V** : (N,) array\_like  
 $V$  is an 1-D array of component variances. It is usually computed among a larger collection vectors.  
**Returns** **seuclidean** : double  
 The standardized Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sqeuclidean` ( $u, v$ )  
 Computes the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between  $u$  and  $v$  is defined as

$$\|u - v\|_2^2.$$

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.

**Returns** **squeclidean** : double  
The squared Euclidean distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.wminkowski(u, v, p, w)`  
Computes the weighted Minkowski distance between two 1-D arrays.

The weighted Minkowski distance between  $u$  and  $v$ , defined as

$$\left( \sum (|w_i(u_i - v_i)|^p) \right)^{1/p}.$$

**Parameters** **u** : (N,) array\_like  
Input array.  
**v** : (N,) array\_like  
Input array.  
**p** : int  
The order of the norm of the difference  $\|u - v\|_p$ .  
**w** : (N,) array\_like  
The weight vector.

**Returns** **wminkowski** : double  
The weighted Minkowski distance between vectors  $u$  and  $v$ .

Distance functions between two boolean vectors (representing sets)  $u$  and  $v$ . As in the case of numerical vectors, `pdist` is more efficient for computing the distances between all pairs.

---

---

`scipy.spatial.distance.dice(u, v)`  
Computes the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between  $u$  and  $v$ , is

$$\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) ndarray, bool  
Input 1-D array.  
**v** : (N,) ndarray, bool  
Input 1-D array.

**Returns** **dice** : double  
The Dice dissimilarity between 1-D arrays  $u$  and  $v$ .

`scipy.spatial.distance.hamming(u, v)`  
Computes the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays  $u$  and  $v$ , is simply the proportion of disagreeing components in  $u$  and  $v$ . If  $u$  and  $v$  are boolean vectors, the Hamming distance is

$$\frac{c_{01} + c_{10}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like  
 Input array.  
**v** : (N,) array\_like  
 Input array.  
**Returns** **hamming** : double  
 The Hamming distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.jaccard(u, v)`

Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
 Input array.  
**Returns** **jaccard** : double  
 The Jaccard distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.kulsinski(u, v)`

Computes the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u** : (N,) array\_like, bool  
 Input array.  
**v** : (N,) array\_like, bool  
 Input array.  
**Returns** **kulsinski** : double  
 The Kulsinski distance between vectors  $u$  and  $v$ .

`scipy.spatial.distance.matching(u, v)`

Computes the Hamming distance between two boolean 1-D arrays.

This is a deprecated synonym for `hamming`.

`scipy.spatial.distance.rogerstanimoto(u, v)`

Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{R}{c_{TT} + c_{FF} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters** **u** : (N,) array\_like, bool

**Returns** **rogerstanimoto**: double  
 Input array.  
**v**: (N,) array\_like, bool  
 Input array.  
 The Rogers-Tanimoto dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.russellrao` ( $u, v$ )

Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays,  $u$  and  $v$ , is defined as

$$\frac{n - c_{TT}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters** **u**: (N,) array\_like, bool  
 Input array.  
**v**: (N,) array\_like, bool  
**Returns** **russellrao**: double  
 Input array.  
 The Russell-Rao dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sokalmichener` ( $u, v$ )

Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays  $u$  and  $v$ , is defined as

$$\frac{R}{S + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ ,  $R = 2 * (c_{TF} + c_{FT})$  and  $S = c_{FF} + c_{TT}$ .

**Parameters** **u**: (N,) array\_like, bool  
 Input array.  
**v**: (N,) array\_like, bool  
**Returns** **sokalmichener**: double  
 Input array.  
 The Sokal-Michener dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.sokalsneath` ( $u, v$ )

Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between  $u$  and  $v$ ,

$$\frac{R}{c_{TT} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters** **u**: (N,) array\_like, bool  
 Input array.  
**v**: (N,) array\_like, bool  
**Returns** **sokalsneath**: double  
 Input array.  
 The Sokal-Sneath dissimilarity between vectors  $u$  and  $v$ .

`scipy.spatial.distance.yule` ( $u, v$ )

Computes the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

$$\frac{R}{c_{TT} * c_{FF} + \frac{R}{2}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2.0 * c_{TF} * c_{FT}$ .

**Parameters**

**u** : (N,) array\_like, bool  
Input array.

**v** : (N,) array\_like, bool  
Input array.

**Returns**

**yule** : double  
The Yule dissimilarity between vectors  $u$  and  $v$ .

`hamming` also operates over discrete numerical vectors.

## 5.26 Special functions (`scipy.special`)

Nearly all of the functions below are universal functions and follow broadcasting and automatic array-looping rules. Exceptions are noted.

### See also:

`scipy.special.cython_special` – Typed Cython versions of special functions

### 5.26.1 Error handling

Errors are handled by returning NaNs or other appropriate values. Some of the special function routines can emit warnings or raise exceptions when an error occurs. By default this is disabled; to query and control the current error handling state the following functions are provided.

|                                     |                                                          |
|-------------------------------------|----------------------------------------------------------|
| <code>geterr</code>                 | Get the current way of handling special-function errors. |
| <code>seterr</code>                 | Set how special-function errors are handled.             |
| <code>errstate</code>               | Context manager for special-function error handling.     |
| <code>SpecialFunctionWarning</code> | Warning that can be emitted by special functions.        |
| <code>SpecialFunctionError</code>   | Exception that can be raised by special functions.       |

`scipy.special.geterr()`

Get the current way of handling special-function errors.

**Returns**

**err** : dict

A dictionary with keys “singular”, “underflow”, “overflow”, “slow”, “loss”, “no\_result”, “domain”, “arg”, and “other”, whose values are from the strings “ignore”, “warn”, and “raise”. The keys represent possible special-function errors, and the values define how these errors are handled.

### See also:

`seterr` set how special-function errors are handled  
`errstate` context manager for special-function error handling  
`numpy.geterr` similar numpy function for floating-point errors

### Notes

For complete documentation of the types of special-function errors and treatment options, see `seterr`.

### Examples

By default all errors are ignored.

```

>>> import scipy.special as sc
>>> for key, value in sorted(sc.geterr().items()):
...     print("{}: {}".format(key, value))
...
arg: ignore
domain: ignore
loss: ignore
no_result: ignore
other: ignore
overflow: ignore
singular: ignore
slow: ignore
underflow: ignore

```

`scipy.special.seterr()`

Set how special-function errors are handled.

**Parameters** **all**: {'ignore', 'warn', 'raise'}, optional

Set treatment for all type of special-function errors at once. The options are:

- 'ignore' Take no action when the error occurs
- 'warn' Print a `SpecialFunctionWarning` when the error occurs (via the Python `warnings` module).
- 'raise' Raise a `SpecialFunctionError` when the error occurs.

The default is to not change the current behavior. If behaviors for additional categories of special-function errors are specified, then `all` is applied first, followed by the additional categories.

**singular**: {'ignore', 'warn', 'raise'}, optional

Treatment for singularities.

**underflow**: {'ignore', 'warn', 'raise'}, optional

Treatment for underflow.

**overflow**: {'ignore', 'warn', 'raise'}, optional

Treatment for overflow.

**slow**: {'ignore', 'warn', 'raise'}, optional

Treatment for slow convergence.

**loss**: {'ignore', 'warn', 'raise'}, optional

Treatment for loss of accuracy.

**no\_result**: {'ignore', 'warn', 'raise'}, optional

Treatment for failing to find a result.

**domain**: {'ignore', 'warn', 'raise'}, optional

Treatment for an invalid argument to a function.

**arg**: {'ignore', 'warn', 'raise'}, optional

Treatment for an invalid parameter to a function.

**other**: {'ignore', 'warn', 'raise'}, optional

Treatment for an unknown error.

**Returns**

**olderr**: dict

Dictionary containing the old settings.

**See also:**

`geterr` get the current way of handling special-function errors

`errstate` context manager for special-function error handling

`numpy.seterr`

similar numpy function for floating-point errors

### Examples

```
>>> import scipy.special as sc
>>> from numpy.testing import assert_raises
>>> sc.gammaln(0)
inf
>>> olderr = sc.seterr(singular='raise')
>>> with assert_raises(sc.SpecialFunctionError):
...     sc.gammaln(0)
...
>>> _ = sc.seterr(**olderr)
```

We can also raise for every category except one.

```
>>> olderr = sc.seterr(all='raise', singular='ignore')
>>> sc.gammaln(0)
inf
>>> with assert_raises(sc.SpecialFunctionError):
...     sc.spence(-1)
...
>>> _ = sc.seterr(**olderr)
```

**class** `scipy.special.errstate`

Context manager for special-function error handling.

Using an instance of `errstate` as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with `seterr`, and upon exiting it is restored to what it was before.

**Parameters** **kwargs** : {all, singular, underflow, overflow, slow, loss, no\_result, domain, arg, other}  
Keyword arguments. The valid keywords are possible special-function errors. Each keyword should have a string value that defines the treatment for the particular type of error. Values must be 'ignore', 'warn', or 'other'. See `seterr` for details.

### See also:

`geterr` get the current way of handling special-function errors  
`seterr` set how special-function errors are handled  
`numpy.errstate` similar numpy function for floating-point errors

### Examples

```
>>> import scipy.special as sc
>>> from numpy.testing import assert_raises
>>> sc.gammaln(0)
inf
>>> with sc.errstate(singular='raise'):
...     with assert_raises(sc.SpecialFunctionError):
...         sc.gammaln(0)
...
>>> sc.gammaln(0)
inf
```

We can also raise on every category except one.

```
>>> with sc.errstate(all='raise', singular='ignore'):
...     sc.gammaln(0)
...     with assert_raises(sc.SpecialFunctionError):
...         sc.spence(-1)
...
inf
```

**exception** `scipy.special.SpecialFunctionWarning`

Warning that can be emitted by special functions.

**exception** `scipy.special.SpecialFunctionError`

Exception that can be raised by special functions.

## 5.26.2 Available functions

### Airy functions

|                           |                                                                             |
|---------------------------|-----------------------------------------------------------------------------|
| <code>airy(z)</code>      | Airy functions and their derivatives.                                       |
| <code>airye(z)</code>     | Exponentially scaled Airy functions and their derivatives.                  |
| <code>ai_zeros(nt)</code> | Compute $nt$ zeros and values of the Airy function $Ai$ and its derivative. |
| <code>bi_zeros(nt)</code> | Compute $nt$ zeros and values of the Airy function $Bi$ and its derivative. |
| <code>itairy(x)</code>    | Integrals of Airy functions                                                 |

`scipy.special.airy(z) = <ufunc 'airy'>`

Airy functions and their derivatives.

**Parameters** `z`: array\_like

**Returns** `Ai, Aip, Bi, Bip`: ndarrays

Real or complex argument.  
Airy functions  $Ai$  and  $Bi$ , and their derivatives  $Aip$  and  $Bip$ .

**See also:**

`airye` exponentially scaled Airy functions.

**Notes**

The Airy functions  $Ai$  and  $Bi$  are two independent solutions of

$$y''(x) = xy(x).$$

For real  $z$  in  $[-10, 10]$ , the computation is carried out by calling the Cephes [R368] `airy` routine, which uses power series summation for small  $z$  and rational minimax approximations for large  $z$ .

Outside this range, the AMOS [R369] `zairy` and `zbiry` routines are employed. They are computed using power series for  $|z| < 1$  and the following relations to modified Bessel functions for larger  $z$  (where  $t \equiv 2z^{3/2}/3$ ):

$$\begin{aligned} Ai(z) &= \frac{1}{\pi\sqrt{3}} K_{1/3}(t) \\ Ai'(z) &= -\frac{z}{\pi\sqrt{3}} K_{2/3}(t) \\ Bi(z) &= \sqrt{\frac{z}{3}} (I_{-1/3}(t) + I_{1/3}(t)) \\ Bi'(z) &= \frac{z}{\sqrt{3}} (I_{-2/3}(t) + I_{2/3}(t)) \end{aligned}$$

**References**

[R368], [R369]

`scipy.special.airye`(*z*) = <ufunc 'airye'>

Exponentially scaled Airy functions and their derivatives.

Scaling:

```
eAi = Ai * exp(2.0/3.0*z*sqrt(z))
eAip = Aip * exp(2.0/3.0*z*sqrt(z))
eBi = Bi * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
eBip = Bip * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
```

**Parameters** *z* : array\_like

**Returns** **eAi, eAip, eBi, eBip** : array\_like Real or complex argument.

Airy functions Ai and Bi, and their derivatives Aip and Bip

**See also:**

`airy`

**Notes**

Wrapper for the AMOS [R370] routines *zairy* and *zbiry*.

**References**

[R370]

`scipy.special.ai_zeros`(*nt*)

Compute *nt* zeros and values of the Airy function Ai and its derivative.

Computes the first *nt* zeros, *a*, of the Airy function Ai(*x*); first *nt* zeros, *ap*, of the derivative of the Airy function Ai'(*x*); the corresponding values Ai(*a*); and the corresponding values Ai'(*a*).

**Parameters** *nt* : int

**Returns** *a* : ndarray Number of zeros to compute

First *nt* zeros of Ai(*x*)

*ap* : ndarray

First *nt* zeros of Ai'(*x*)

*ai* : ndarray

Values of Ai(*x*) evaluated at first *nt* zeros of Ai'(*x*)

*aip* : ndarray

Values of Ai'(*x*) evaluated at first *nt* zeros of Ai(*x*)

**References**

[R367]

`scipy.special.bi_zeros`(*nt*)

Compute *nt* zeros and values of the Airy function Bi and its derivative.

Computes the first *nt* zeros, *b*, of the Airy function Bi(*x*); first *nt* zeros, *b*', of the derivative of the Airy function Bi'(*x*); the corresponding values Bi(*b*); and the corresponding values Bi'(*b*).

**Parameters** *nt* : int

**Returns** *b* : ndarray Number of zeros to compute

First *nt* zeros of Bi(*x*)

**bp** : ndarray  
First  $nt$  zeros of  $\text{Bi}'(x)$

**bi** : ndarray  
Values of  $\text{Bi}(x)$  evaluated at first  $nt$  zeros of  $\text{Bi}'(x)$

**bip** : ndarray  
Values of  $\text{Bi}'(x)$  evaluated at first  $nt$  zeros of  $\text{Bi}(x)$

`scipy.special.ellipj(u, m) = <ufunc 'ellipj'>`

Jacobian elliptic functions

Calculates the Jacobian elliptic functions of parameter  $m$  between 0 and 1, and real argument  $u$ .

**Parameters** **m** : array\_like  
Parameter.

**u** : array\_like  
Argument.

**Returns** **sn, cn, dn, ph** : ndarrays  
The returned functions:

$\text{sn}(u|m)$ ,  $\text{cn}(u|m)$ ,  $\text{dn}(u|m)$

The value  $ph$  is such that if  $u = \text{ellipk}(ph, m)$ , then  $\text{sn}(u|m) = \sin(ph)$  and  $\text{cn}(u|m) = \cos(ph)$ .

**See also:**

**`ellipk`** Complete elliptic integral of the first kind.

**Notes**

Wrapper for the Cephes [R404] routine `ellpj`.

These functions are periodic, with quarter-period on the real axis equal to the complete elliptic integral `ellipk(m)`.

Relation to incomplete elliptic integral: If  $u = \text{ellipk}(phi, m)$ , then  $\text{sn}(u|m) = \sin(phi)$ , and  $\text{cn}(u|m) = \cos(phi)$ . The  $phi$  is called the amplitude of  $u$ .

Computation is by means of the arithmetic-geometric mean algorithm, except when  $m$  is within  $1e-9$  of 0 or 1. In the latter case with  $m$  close to 1, the approximation applies only for  $phi < pi/2$ .

**References**

[R404]

`scipy.special.ellipk(m)`

Complete elliptic integral of the first kind.

This function is defined as

$$K(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

**Parameters** **m** : array\_like

**Returns** **K** : array\_like The parameter of the elliptic integral.

Value of the elliptic integral.

**See also:**

**`ellipkm1`** Complete elliptic integral of the first kind around  $m = 1$

**`ellipkinc`** Incomplete elliptic integral of the first kind

**`ellipe`** Complete elliptic integral of the second kind

**`ellipeinc`** Incomplete elliptic integral of the second kind

**Notes**

For more precision around point  $m = 1$ , use `ellipkm1`, which this function calls.

`scipy.special.ellipkm1(p) = <ufunc 'ellipkm1'>`

Complete elliptic integral of the first kind around  $m = 1$

This function is defined as

$$K(p) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

where  $m = 1 - p$ .

**Parameters** **p** : array\_like

**Returns** **K** : ndarray Defines the parameter of the elliptic integral as  $m = 1 - p$ .

Value of the elliptic integral.

**See also:**

**`ellipk`** Complete elliptic integral of the first kind  
**`ellipkinc`** Incomplete elliptic integral of the first kind  
**`ellipe`** Complete elliptic integral of the second kind  
**`ellipeinc`** Incomplete elliptic integral of the second kind

**Notes**

Wrapper for the Cephes [R406] routine `ellpk`.

For  $p \leq 1$ , computation uses the approximation,

$$K(p) \approx P(p) - \log(p)Q(p),$$

where  $P$  and  $Q$  are tenth-order polynomials. The argument  $p$  is used internally rather than  $m$  so that the logarithmic singularity at  $m = 1$  will be shifted to the origin; this preserves maximum accuracy. For  $p > 1$ , the identity

$$K(p) = K(1/p)/\sqrt{p}$$

is used.

**References**

[R406]

`scipy.special.ellipkinc(phi, m) = <ufunc 'ellipkinc'>`

Incomplete elliptic integral of the first kind

This function is defined as

$$K(\phi, m) = \int_0^\phi [1 - m \sin(t)^2]^{-1/2} dt$$

This function is also called  $F(\phi, m)$ .

|                   |                         |                                    |

**`ellipe`** Complete elliptic integral of the second kind  
**`ellipeinc`** Incomplete elliptic integral of the second kind

**Notes**

Wrapper for the Cephes [R405] routine `ellik`. The computation is carried out using the arithmetic-geometric mean algorithm.

**References**

[R405]

`scipy.special.ellipe(m) = <ufunc 'ellipe'>`

Complete elliptic integral of the second kind

This function is defined as

$$E(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{1/2} dt$$

**Parameters** **m** : array\_like  
 Defines the parameter of the elliptic integral.

**Returns** **E** : ndarray  
 Value of the elliptic integral.

**See also:**

[`ellipkm1`](#) Complete elliptic integral of the first kind, near  $m = 1$   
[`ellipk`](#) Complete elliptic integral of the first kind  
[`ellipkinc`](#) Incomplete elliptic integral of the first kind  
[`ellipeinc`](#) Incomplete elliptic integral of the second kind

**Notes**

Wrapper for the Cephes [R402] routine `ellpe`.

For  $m > 0$  the computation uses the approximation,

$$E(m) \approx P(1 - m) - (1 - m) \log(1 - m)Q(1 - m),$$

where  $P$  and  $Q$  are tenth-order polynomials. For  $m < 0$ , the relation

$$E(m) = E(m/(m - 1))\sqrt{1 - m}$$

is used.

---

`scipy.special.jv(v, z) = <ufunc 'jv'>`

Bessel function of the first kind of real order and complex argument.

**Parameters**

- `v`: array\_like  
Order (float).
- `z`: array\_like  
Argument (float or complex).

**Returns**

- `J`: ndarray  
Value of the Bessel function,  $J_v(z)$ .

**See also:**

`jve`  $J_v$  with leading exponential behavior stripped off.  
`spherical_jn` spherical Bessel functions.

**Notes**

For positive  $v$  values, the computation is carried out using the AMOS [R459] `zbesj` routine, which exploits the connection to the modified Bessel function  $I_v$ ,

$$J_v(z) = \exp(n\pi i/2)I_v(-iz) \quad (\Im z > 0)$$

$$J_v(z) = \exp(-n\pi i/2)I_v(iz) \quad (\Im z < 0)$$

For negative  $v$  values the formula,

$$J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)$$

is used, where  $Y_v(z)$  is the Bessel function of the second kind, computed using the AMOS routine `zbesy`. Note that the second term is exactly zero for integer  $v$ ; to improve accuracy the second term is explicitly omitted for  $v$  values such that  $v = \text{floor}(v)$ .

Not to be confused with the spherical Bessel functions (see `spherical_jn`).

### References

[R459]

`scipy.special.jn(v, z) = <ufunc 'jn'>`

Bessel function of the first kind of real order and complex argument.

**Parameters**

- v** : array\_like  
Order (float).
- z** : array\_like  
Argument (float or complex).

**Returns**

- J** : ndarray  
Value of the Bessel function,  $J_v(z)$ .

**See also:**

[jve](#)  $J_v$  with leading exponential behavior stripped off.

[spherical\\_jn](#)  
spherical Bessel functions.

### Notes

For positive  $v$  values, the computation is carried out using the AMOS [R454] `zbesj` routine, which exploits the connection to the modified Bessel function  $I_v$ ,

$$\begin{aligned} J_v(z) &= \exp(n\pi i/2)I_v(-iz) & (\Im z > 0) \\ J_v(z) &= \exp(-n\pi i/2)I_v(iz) & (\Im z < 0) \end{aligned}$$

For negative  $v$  values the formula,

$$J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)$$

is used, where  $Y_v(z)$  is the Bessel function of the second kind, computed using the AMOS routine `zbesy`. Note that the second term is exactly zero for integer  $v$ ; to improve accuracy the second term is explicitly omitted for  $v$  values such that  $v = \text{floor}(v)$ .

Not to be confused with the spherical Bessel functions (see [spherical\\_jn](#)).

### References

[R454]

`scipy.special.jve(v, z) = <ufunc 'jve'>`

Exponentially scaled Bessel function of order  $v$ .

Defined as:

```
jve(v, z) = jv(v, z) * exp(-abs(z.imag))
```

**Parameters**

- v** : array\_like  
Order (float).
- z** : array\_like  
Argument (float or complex).

**Returns**

- J** : ndarray  
Value of the exponentially scaled Bessel function.

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [R460] *zbesj* routine, which exploits the connection to the modified Bessel function  $I_\nu$ ,

$$\begin{aligned} J_\nu(z) &= \exp(n\pi i/2) I_\nu(-iz) & (\Im z > 0) \\ J_\nu(z) &= \exp(-n\pi i/2) I_\nu(iz) & (\Im z < 0) \end{aligned}$$

For negative  $\nu$  values the formula,

$$J_{-\nu}(z) = J_\nu(z) \cos(\pi\nu) - Y_\nu(z) \sin(\pi\nu)$$

is used, where  $Y_\nu(z)$  is the Bessel function of the second kind, computed using the AMOS routine *zbesy*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

**References**

[R460]

`scipy.special.yn(n, x) = <ufunc 'yn'>`

Bessel function of the second kind of integer order and real argument.

**Parameters** **n** : array\_like  
Order (integer).  
**z** : array\_like  
Argument (float).  
**Returns** **Y** : ndarray  
Value of the Bessel function,  $Y_n(x)$ .

**See also:**

[yv](#) For real order and real or complex argument.

**Notes**

Wrapper for the Cephes [R540] routine *yn*.

The function is evaluated by forward recurrence on  $n$ , starting with values computed by the Cephes routines *y0* and *y1*. If  $n = 0$  or  $1$ , the routine for *y0* or *y1* is called directly.

**References**

[R540]

`scipy.special.yv(v, z) = <ufunc 'yv'>`

Bessel function of the second kind of real order and complex argument.

**Parameters** **v** : array\_like  
Order (float).  
**z** : array\_like  
Argument (float or complex).  
**Returns** **Y** : ndarray  
Value of the Bessel function of the second kind,  $Y_\nu(x)$ .

**See also:**

[yve](#)  $Y_\nu$  with leading exponential behavior stripped off.

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [R543] *zbesy* routine, which exploits the connection to the Hankel Bessel functions  $H_\nu^{(1)}$  and  $H_\nu^{(2)}$ ,

$$Y_\nu(z) = \frac{1}{2i}(H_\nu^{(1)} - H_\nu^{(2)}).$$

For negative  $\nu$  values the formula,

$$Y_{-\nu}(z) = Y_\nu(z) \cos(\pi\nu) + J_\nu(z) \sin(\pi\nu)$$

is used, where  $J_\nu(z)$  is the Bessel function of the first kind, computed using the AMOS routine *zbesj*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

**References**

[R543]

`scipy.special.yve` ( $\nu, z$ ) = <ufunc 'yve'>

Exponentially scaled Bessel function of the second kind of real order.

Returns the exponentially scaled Bessel function of the second kind of real order  $\nu$  at complex  $z$ :

```
yve( $\nu, z$ ) = yv( $\nu, z$ ) * exp(-abs( $z$ .imag))
```

|                   |                                      |                                                    |
|-------------------|--------------------------------------|----------------------------------------------------|
| <b>Parameters</b> | <b><math>\nu</math></b> : array_like | Order (float).                                     |
|                   | <b><math>z</math></b> : array_like   | Argument (float or complex).                       |
| <b>Returns</b>    | <b><math>Y</math></b> : ndarray      | Value of the exponentially scaled Bessel function. |

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [R544] *zbesy* routine, which exploits the connection to the Hankel Bessel functions  $H_\nu^{(1)}$  and  $H_\nu^{(2)}$ ,

$$Y_\nu(z) = \frac{1}{2i}(H_\nu^{(1)} - H_\nu^{(2)}).$$

For negative  $\nu$  values the formula,

$$Y_{-\nu}(z) = Y_\nu(z) \cos(\pi\nu) + J_\nu(z) \sin(\pi\nu)$$

is used, where  $J_\nu(z)$  is the Bessel function of the first kind, computed using the AMOS routine *zbesj*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

**References**

[R544]

`scipy.special.kn` ( $n, x$ ) = <ufunc 'kn'>

Modified Bessel function of the second kind of integer order  $n$

Returns the modified Bessel function of the second kind for integer order  $n$  at real  $z$ .

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions.

**Parameters**  **$n$**  : array\_like of int

**Returns**

|                                      |                                                                 |
|--------------------------------------|-----------------------------------------------------------------|
| <code>z</code> : array_like of float | Order of Bessel functions (floats will truncate with a warning) |
| <code>out</code> : ndarray           | Argument at which to evaluate the Bessel functions              |
|                                      | The results                                                     |

**See also:**

`kv` Same function, but accepts real order and complex argument  
`kvp` Derivative of this function

**Notes**

Wrapper for AMOS [R471] routine `zbesk`. For a discussion of the algorithm used, see [R472] and the references therein.

**References**

[R471], [R472]

**Examples**

Plot the function of several orders for real input:

```
>>> from scipy.special import kn
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in range(6):
...     plt.plot(x, kn(N, x), label='$K_{%d}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_n(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:

```
>>> kn([4, 5, 6], 1)
array([ 44.23241585, 360.9605896 , 3653.83831186])
```

`scipy.special.kv`( $\nu, z$ ) = <ufunc 'kv'>

Modified Bessel function of the second kind of real order  $\nu$

Returns the modified Bessel function of the second kind for real order  $\nu$  at complex  $z$ .

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions. They are defined as those solutions of the modified Bessel equation for which,

$$K_\nu(x) \sim \sqrt{\pi/(2x)} \exp(-x)$$

as  $x \rightarrow \infty$  [R475].

**Parameters**

- v** : array\_like of float  
Order of Bessel functions
- z** : array\_like of complex  
Argument at which to evaluate the Bessel functions

**Returns**

- out** : ndarray  
The results. Note that input must be of complex type to get complex output, e.g. `kv(3, -2+0j)` instead of `kv(3, -2)`.

**See also:**

***kve*** This function with leading exponential behavior stripped off.  
***kvp*** Derivative of this function

**Notes**

Wrapper for AMOS [R473] routine *zbesk*. For a discussion of the algorithm used, see [R474] and the references therein.

**References**

[R473], [R474], [R475]

**Examples**

Plot the function of several orders for real input:

```
>>> from scipy.special import kv
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in np.linspace(0, 6, 5):
...     plt.plot(x, kv(N, x), label='$K_{%d}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_{\nu}(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:

```
>>> kv([4, 4.5, 5], 1+2j)
array([ 0.1992+2.3892j,  2.3493+3.6j      ,  7.2827+3.8104j])
```

`scipy.special.kve` ( $\nu, z$ ) = <ufunc 'kve'>

Exponentially scaled modified Bessel function of the second kind.

Returns the exponentially scaled, modified Bessel function of the second kind (sometimes called the third kind) for real order  $\nu$  at complex  $z$ :

$$\text{kve}(\nu, z) = \text{kv}(\nu, z) * \exp(z)$$

|                   |                                  |                                                                       |
|-------------------|----------------------------------|-----------------------------------------------------------------------|
| <b>Parameters</b> | <b>v</b> : array_like of float   | Order of Bessel functions                                             |
|                   | <b>z</b> : array_like of complex | Argument at which to evaluate the Bessel functions                    |

`kve` This function with leading exponential behavior stripped off.

**Notes**

For real  $z$  and  $v \in [-50, 50]$ , the evaluation is carried out using Temme’s method [R447]. For larger orders, uniform asymptotic expansions are applied.

For complex  $z$  and positive  $v$ , the AMOS [R448] `zbesi` routine is called. It uses a power series for small  $z$ , the asymptotic expansion for large  $abs(z)$ , the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for  $I_v(z)$  and  $J_v(z)$  for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of  $z$  is positive). For negative  $v$ , the formula

$$I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z)$$

is used, where  $K_v(z)$  is the modified Bessel function of the second kind, evaluated using the AMOS routine `zbesk`.

`scipy.special.ive(v, z) = <ufunc ‘ive’>`

Exponentially scaled modified Bessel function of the first kind

Defined as:

```
ive(v, z) = iv(v, z) * exp(-abs(z.real))
```

**Parameters** **v** : array\_like of float  
Order.

**z** : array\_like of float or complex

**Returns** **out** : ndarray  
Argument.

Values of the exponentially scaled modified Bessel function.

**Notes**

For positive  $v$ , the AMOS [R449] `zbesi` routine is called. It uses a power series for small  $z$ , the asymptotic expansion for large  $abs(z)$ , the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for  $I_v(z)$  and  $J_v(z)$  for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of  $z$  is positive). For negative  $v$ , the formula

$$I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z)$$

is used, where  $K_v(z)$  is the modified Bessel function of the second kind, evaluated using the AMOS routine `zbesk`.

Order of Bessel function

**nt** : int  
Number of zeros to return

### References

[R542]

`scipy.special.y0_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel function  $Y_0(z)$ , and derivative at each zero.

The derivatives are given by  $Y_0'(z_0) = -Y_1(z_0)$  at each zero  $z_0$ .

**Parameters**

**nt** : int  
Number of zeros to return

**complex** : bool, default False  
Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

**z0n** : ndarray  
Location of *n*th zero of  $Y_0(z)$

**y0pz0n** : ndarray  
Value of derivative  $Y_0'(z_0)$  for *n*th zero

### References

[R536]

`scipy.special.y1_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel function  $Y_1(z)$ , and derivative at each zero.

The derivatives are given by  $Y_1'(z_1) = Y_0(z_1)$  at each zero  $z_1$ .

**Parameters**

**nt** : int  
Number of zeros to return

**complex** : bool, default False  
Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

**z1n** : ndarray  
Location of *n*th zero of  $Y_1(z)$

**y1pz1n** : ndarray  
Value of derivative  $Y_1'(z_1)$  for *n*th zero

### References

[R538]

`scipy.special.y1p_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel derivative  $Y_1'(z)$ , and value at each zero.

The values are given by  $Y_1(z_1)$  at each  $z_1$  where  $Y_1'(z_1)=0$ .

**Parameters**

**nt** : int  
Number of zeros to return

**complex** : bool, default False  
Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

**Returns**

**z1pn** : ndarray

Location of nth zero of  $Y_1'(z)$   
**y1z1pn** : ndarray  
 Value of derivative  $Y_1(z_1)$  for nth zero

`scipy.special.j0(x)` = <ufunc 'j0'>  
 Bessel function of the first kind of order 0.

**Parameters**    **x** : array\_like  
 Argument (float).

**Returns**        **J** : ndarray  
 Value of the Bessel function of the first kind of order 0 at *x*.

### See also:

`jv`            Bessel function of real order and complex argument.

`spherical_jn`  
 spherical Bessel functions.

### Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval the following rational approximation is used:

$$J_0(x) \approx (w - r_1^2)(w - r_2^2) \frac{P_3(w)}{Q_8(w)},$$

where  $w = x^2$  and  $r_1, r_2$  are the zeros of  $J_0$ , and  $P_3$  and  $Q_8$  are polynomials of degrees 3 and 8, respectively.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [R452] routine `j0`. It should not to be confused with the spherical Bessel functions (see `spherical_jn`).

### References

[R452]

`scipy.special.j1(x)` = <ufunc 'j1'>  
 Bessel function of the first kind of order 1.

**Parameters** `x` : array\_like  
**Returns** `J` : ndarray     Argument (float).  
Value of the Bessel function of the first kind of order 1 at `x`.

**See also:**

`jv`  
[spherical\\_jn](#)  
spherical Bessel functions.

**Notes**

The domain is divided into the intervals  $[0, 8]$  and  $(8, \text{infinity})$ . In the first interval a 24 term Chebyshev expansion is used. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephys [R453] routine `j1`. It should not to be confused with the spherical Bessel functions (see [spherical\\_jn](#)).

**References**

[R453]

`scipy.special.y0(x) = <ufunc 'y0'>`  
Bessel function of the second kind of order 0.

**Parameters** `x` : array\_like  
**Returns** `Y` : ndarray     Argument (float).  
Value of the Bessel function of the second kind of order 0 at `x`.

**See also:**

`j0`, `yv`

**Notes**

The domain is divided into the intervals  $[0, 5]$  and  $(5, \text{infinity})$ . In the first interval a rational approximation  $R(x)$  is employed to compute,

$$Y_0(x) = R(x) + \frac{2 \log(x) J_0(x)}{\pi},$$

where  $J_0$  is the Bessel function of the first kind of order 0.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephys [R535] routine `y0`.

**References**

[R535]

`scipy.special.y1(x) = <ufunc 'y1'>`  
Bessel function of the second kind of order 1.

**Parameters** `x` : array\_like  
**Returns** `Y` : ndarray     Argument (float).  
Value of the Bessel function of the second kind of order 1 at `x`.

**See also:**

`j1`, `yn`, `yv`

**Notes**

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 25 term Chebyshev expansion is used, and computing  $J_1$  (the Bessel function of the first kind) is required. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephys [R537] routine `y1`.

**References**

[R537]

`scipy.special.i0(x) = <ufunc 'i0'>`

Modified Bessel function of order 0.

Defined as,

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(ix),$$

where  $J_0$  is the Bessel function of the first kind of order 0.

**Parameters** `x`: array\_like

**Returns** `I`: ndarray Argument (float)

Value of the modified Bessel function of order 0 at  $x$ .

**See also:**

`iv`, `i0e`

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [R439] routine `i0`.

[R439]

`scipy.special.i0e(x) = <ufunc 'i0e'>`

Exponentially scaled modified Bessel function of order 0.

Defined as:

$$i0e(x) = \exp(-\text{abs}(x)) * i0(x).$$

**Parameters** `x`: array\_like

**Returns** `I`: ndarray Argument (float)

Value of the exponentially scaled modified Bessel function of order 0 at  $x$ .

**See also:**

`iv`, `i0`

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in `i0`, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephys [R440] routine `i0e`.

**References**

[R440]

`scipy.special.i1(x) = <ufunc 'i1'>`

Modified Bessel function of order 1.

Defined as,

$$I_1(x) = \frac{1}{2}x \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k+1)!} = -iJ_1(ix),$$

where  $J_1$  is the Bessel function of the first kind of order 1.

**Parameters** `x`: array\_like

**Returns** `I`: ndarray Argument (float)

Value of the modified Bessel function of order 1 at  $x$ .

**See also:**

`iv`, `ile`

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [R441] routine `i1`.

**References**

[R441]

`scipy.special.ile(x) = <ufunc 'ile'>`

Exponentially scaled modified Bessel function of order 1.

Defined as:

$$\text{ile}(x) = \exp(-\text{abs}(x)) * \text{i1}(x)$$

**Parameters** `x`: array\_like

**Returns** `I`: ndarray Argument (float)

Value of the exponentially scaled modified Bessel function of order 1 at  $x$ .

**See also:**

`iv`, `il`

*Notes*

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in `i1`, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephys [R442] routine `i1e`.

*References*

[R442]

`scipy.special.k0(x) = <ufunc 'k0'>`

Modified Bessel function of the second kind of order 0,  $K_0$ .

This function is also sometimes referred to as the modified Bessel function of the third kind of order 0.

**Parameters** `x` : array\_like

**Returns** `K` : ndarray Argument (float).

Value of the modified Bessel function  $K_0$  at  $x$ .

**See also:**

`kv`, `k0e`

*Notes*

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [R463] routine `k0`.

*References*

[R463]

`scipy.special.k0e(x) = <ufunc 'k0e'>`

Exponentially scaled modified Bessel function K of order 0

Defined as:

$$k0e(x) = \exp(x) * k0(x).$$

**Parameters** `x` : array\_like

**Returns** `K` : ndarray Argument (float)

Value of the exponentially scaled modified Bessel function K of order 0 at  $x$ .

**See also:**

`kv`, `k0`

*Notes*

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [R464] routine `k0e`.

**References**[\[R464\]](#)`scipy.special.k1(x) = <ufunc 'k1'>`Modified Bessel function of the second kind of order 1,  $K_1(x)$ .

**Parameters** `x` : array\_like  
Argument (float)

**Returns** `K` : ndarray  
Value of the modified Bessel function K of order 1 at  $x$ .

**See also:**`kv, k1e`**Notes**

The range is partitioned into the two intervals  $[0, 2]$  and  $(2, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [\[R465\]](#) routine `k1`.

**References**[\[R465\]](#)`scipy.special.k1e(x) = <ufunc 'k1e'>`

Exponentially scaled modified Bessel function K of order 1

Defined as:

$$k1e(x) = \exp(x) * k1(x)$$

**Parameters** `x` : array\_like  
Argument (float)

**Returns** `K` : ndarray  
Value of the exponentially scaled modified Bessel function K of order 1 at  $x$ .

**See also:**`kv, k1`**Notes**

The range is partitioned into the two intervals  $[0, 2]$  and  $(2, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [\[R466\]](#) routine `k1e`.

Table 5.244 – continued from previous page

`besselpoly(a, lmb, nu)` Weighted integral of a Bessel function.

`scipy.special.itj0y0(x) = <ufunc 'itj0y0'>`

Integrals of Bessel functions of order 0

Returns simple integrals from 0 to  $x$  of the zeroth order Bessel functions  $j_0$  and  $y_0$ .

**Returns**  $ij_0, iy_0$

`scipy.special.it2j0y0(x) = <ufunc 'it2j0y0'>`

Integrals related to Bessel functions of order 0

**Returns**  $ij_0$   $\text{integral}((1-j_0(t))/t, t=0..x)$   
 $iy_0$   $\text{integral}(y_0(t)/t, t=x..inf)$

`scipy.special.iti0k0(x) = <ufunc 'iti0k0'>`

Integrals of modified Bessel functions of order 0

Returns simple integrals from 0 to  $x$  of the zeroth order modified Bessel functions  $i_0$  and  $k_0$ .

**Returns**  $ii_0, ik_0$

`scipy.special.it2i0k0(x) = <ufunc 'it2i0k0'>`

Integrals related to modified Bessel functions of order 0

**Returns**  $ii_0$   $\text{integral}((i_0(t)-1)/t, t=0..x)$   
 $ik_0$   $\text{int}(k_0(t)/t, t=x..inf)$

`scipy.special.besselpoly(a, lmb, nu) = <ufunc 'besselpoly'>`

Weighted integral of a Bessel function.

$$\int_0^1 x^\lambda J_\nu(2ax) dx$$

where  $J_\nu$  is a Bessel function and  $\lambda = lmb, \nu = nu$ .

**Derivatives of Bessel Functions**

|                              |                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------|
| <code>jvp(v, z[, n])</code>  | Compute nth derivative of Bessel function $J_\nu(z)$ with respect to $z$ .          |
| <code>yvp(v, z[, n])</code>  | Compute nth derivative of Bessel function $Y_\nu(z)$ with respect to $z$ .          |
| <code>kvp(v, z[, n])</code>  | Compute nth derivative of real-order modified Bessel function $K_\nu(z)$            |
| <code>ivp(v, z[, n])</code>  | Compute nth derivative of modified Bessel function $I_\nu(z)$ with respect to $z$ . |
| <code>h1vp(v, z[, n])</code> | Compute nth derivative of Hankel function $H1_\nu(z)$ with respect to $z$ .         |
| <code>h2vp(v, z[, n])</code> | Compute nth derivative of Hankel function $H2_\nu(z)$ with respect to $z$ .         |

`scipy.special.jvp(v, z, n=1)`

Compute nth derivative of Bessel function  $J_\nu(z)$  with respect to  $z$ .

**Parameters**  $v$  : float Order of Bessel function  
 $z$  : complex Argument at which to evaluate the derivative  
 $n$  : int, default 1 Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [R462].

**References**

[R461], [R462]

`scipy.special.yvp`(*v*, *z*, *n=1*)

Compute *n*th derivative of Bessel function  $Y_v(z)$  with respect to *z*.

**Parameters**

- v** : float  
Order of Bessel function
- z** : complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [R546].

**References**

[R545], [R546]

`scipy.special.kvp`(*v*, *z*, *n=1*)

Compute *n*th derivative of real-order modified Bessel function  $K_v(z)$

$K_v(z)$  is the modified Bessel function of the second kind. Derivative is calculated with respect to *z*.

**Parameters**

- v** : array\_like of float  
Order of Bessel function
- z** : array\_like of complex  
Argument at which to evaluate the derivative
- n** : int  
Order of derivative. Default is first derivative.

**Returns**

- out** : ndarray  
The results

**Notes**

The derivative is computed using the relation DLFM 10.29.5 [R479].

**References**

[R478], [R479]

**Examples**

Calculate multiple values at order 5:

```
>>> from scipy.special import kvp
>>> kvp(5, (1, 2, 3+5j))
array([-1849.0354+0.j      , -25.7735+0.j      , -0.0307+0.0875jj])
```

Calculate for a single value at multiple orders:

```
>>> kvp((4, 4.5, 5), 1)
array([-184.0309, -568.9585, -1849.0354])
```

`scipy.special.ivp` ( $v, z, n=1$ )

Compute  $n$ th derivative of modified Bessel function  $I_v(z)$  with respect to  $z$ .

**Parameters**

- v** : array\_like of float  
Order of Bessel function
- z** : array\_like of complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.29.5 [R451].

**References**

[R450], [R451]

`scipy.special.h1vp` ( $v, z, n=1$ )

Compute  $n$ th derivative of Hankel function  $H_1v(z)$  with respect to  $z$ .

**Parameters**

- v** : float  
Order of Hankel function
- z** : complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [R432].

**References**

[R431], [R432]

`scipy.special.h2vp` ( $v, z, n=1$ )

Compute  $n$ th derivative of Hankel function  $H_2v(z)$  with respect to  $z$ .

**Parameters**

- v** : float  
Order of Hankel function
- z** : complex  
Argument at which to evaluate the derivative
- n** : int, default 1  
Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [R434].

`scipy.special.spherical_jn(n, z, derivative=False)`

Spherical Bessel function of the first kind or its derivative.

Defined as [R524],

$$j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z),$$

where  $J_n$  is the Bessel function of the first kind.

**Parameters**

- n** : int, array\_like  
Order of the Bessel function ( $n \geq 0$ ).
- z** : complex or float, array\_like  
Argument of the Bessel function.
- derivative** : bool, optional  
If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- jn** : ndarray

#### Notes

For real arguments greater than the order, the function is computed using the ascending recurrence [R525]. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations [R526],

$$j'_n = j_{n-1} - \frac{n+1}{2} j_n.$$

$$j'_0 = -j_1$$

New in version 0.18.0.

#### References

[R524], [R525], [R526]

`scipy.special.spherical_yn(n, z, derivative=False)`

Spherical Bessel function of the second kind or its derivative.

Defined as [R529],

$$y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z),$$

where  $Y_n$  is the Bessel function of the second kind.

**Parameters**

- n** : int, array\_like  
Order of the Bessel function ( $n \geq 0$ ).
- z** : complex or float, array\_like  
Argument of the Bessel function.
- derivative** : bool, optional  
If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- yn** : ndarray

**Notes**

For real arguments, the function is computed using the ascending recurrence [R530]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [R531],

$$y'_n = y_{n-1} - \frac{n+1}{2}y_n.$$

$$y'_0 = -y_1$$

New in version 0.18.0.

**References**

[R529], [R530], [R531]

`scipy.special.spherical_in` ( $n, z, derivative=False$ )

Modified spherical Bessel function of the first kind or its derivative.

Defined as [R522],

$$i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z),$$

where  $I_n$  is the modified Bessel function of the first kind.

**Parameters**    **n** : int, array\_like

Order of the Bessel function ( $n \geq 0$ ).

**z** : complex or float, array\_like

Argument of the Bessel function.

**derivative** : bool, optional

If True, the value of the derivative (rather than the function itself) is returned.

**Returns**        **in** : ndarray

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind.

The derivative is computed using the relations [R523],

$$i'_n = i_{n-1} - \frac{n+1}{2}i_n.$$

$$i'_1 = i_0$$

New in version 0.18.0.

**References**

[R522], [R523]

`scipy.special.spherical_kn` ( $n, z, derivative=False$ )

Modified spherical Bessel function of the second kind or its derivative.

Defined as [R527],

$$k_n(z) = \sqrt{\frac{\pi}{2z}} K_{n+1/2}(z),$$

where  $K_n$  is the modified Bessel function of the second kind.

**Parameters**

- n** : int, array\_like  
Order of the Bessel function ( $n \geq 0$ ).
- z** : complex or float, array\_like  
Argument of the Bessel function.
- derivative** : bool, optional  
If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- kn** : ndarray

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations [R528],

$$k'_n = -k_{n-1} - \frac{n+1}{2}k_n.$$

$$k'_0 = -k_1$$

New in version 0.18.0.

**Riccati-Bessel Functions**

These are not universal functions:

|                               |                                                                        |
|-------------------------------|------------------------------------------------------------------------|
| <code>riccati_jn(n, x)</code> | Compute Riccati-Bessel function of the first kind and its derivative.  |
| <code>riccati_yn(n, x)</code> | Compute Riccati-Bessel function of the second kind and its derivative. |

`scipy.special.riccati_jn(n, x)`

Compute Riccati-Bessel function of the first kind and its derivative.

The Riccati-Bessel function of the first kind is defined as  $xj_n(x)$ , where  $j_n$  is the spherical Bessel function of the first kind of order  $n$ .

This function computes the value and first derivative of the Riccati-Bessel function for all orders up to and including  $n$ .

**Parameters**

- n** : int  
Maximum order of function to compute
- x** : float  
Argument at which to evaluate

**Returns**

- jn** : ndarray  
Value of  $j_0(x), \dots, j_n(x)$
- jnp** : ndarray  
First derivative  $j_0'(x), \dots, j_n'(x)$

**Notes**

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [R511].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R510].

**References**

[R510], [R511]

`scipy.special.riccati_yn` ( $n, x$ )

Compute Riccati-Bessel function of the second kind and its derivative.

The Riccati-Bessel function of the second kind is defined as  $xy_n(x)$ , where  $y_n$  is the spherical Bessel function of the second kind of order  $n$ .

This function computes the value and first derivative of the function for all orders up to and including  $n$ .

|                   |                      |                                            |
|-------------------|----------------------|--------------------------------------------|
| <b>Parameters</b> | <b>n</b> : int       | Maximum order of function to compute       |

**Struve Functions**

---

|                                   |                                                      |
|-----------------------------------|------------------------------------------------------|
| <code>struve</code> ( $v, x$ )    | Struve function.                                     |
| <code>modstruve</code> ( $v, x$ ) | Modified Struve function.                            |
| <code>itstruve0</code> ( $x$ )    | Integral of the Struve function of order 0.          |
| <code>it2struve0</code> ( $x$ )   | Integral related to the Struve function of order 0.  |
| <code>itmodstruve0</code> ( $x$ ) | Integral of the modified Struve function of order 0. |

---

`scipy.special.struve` ( $v, x$ ) = <ufunc 'struve'>

Struve function.

Return the value of the Struve function of order  $v$  at  $x$ . The Struve function is defined as,

$$H_v(x) = (z/2)^{v+1} \sum_{n=0}^{\infty} \frac{(-1)^n (z/2)^{2n}}{\Gamma(n + \frac{3}{2})\Gamma(n + v + \frac{3}{2})},$$

where  $\Gamma$  is the gamma function.

|                   |                       |                                                                                     |
|-------------------|-----------------------|-------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>v</b> : array_like | Order of the Struve function (float).                                               |
|                   | <b>x</b> : array_like | Argument of the Struve function (float; must be positive unless $v$ is an integer). |
| <b>Returns</b>    | <b>H</b> : ndarray    | Value of the Struve function of order $v$ at $x$ .                                  |

**See also:**

`modstruve`

**Notes**

Three methods discussed in [R532] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if  $|z| < |v| + 20$ )
- asymptotic large- $z$  expansion (if  $z \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

**References**

[R532]

`scipy.special.modstruve` ( $v, x$ ) = <ufunc 'modstruve'>  
Modified Struve function.

Return the value of the modified Struve function of order  $v$  at  $x$ . The modified Struve function is defined as,

$$L_v(x) = -i \exp(-\pi v/2) H_v(x),$$

where  $H_v$  is the Struve function.

|                   |                       |                                                                                     |
|-------------------|-----------------------|-------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>v</b> : array_like | Order of the modified Struve function (float).                                      |
|                   | <b>x</b> : array_like | Argument of the Struve function (float; must be positive unless $v$ is an integer). |
| <b>Returns</b>    | <b>L</b> : ndarray    | Value of the modified Struve function of order $v$ at $x$ .                         |

**See also:**

`struve`

**Notes**

Three methods discussed in [R493] are used to evaluate the function:

- power series
- expansion in Bessel functions (if  $|z| < |v| + 20$ )
- asymptotic large- $z$  expansion (if  $z \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

`scipy.special.it2struve0(x)` = <ufunc 'it2struve0'>

Integral related to the Struve function of order 0.

Returns the integral,

$$\int_x^\infty \frac{H_0(t)}{t} dt$$

where  $H_0$  is the Struve function of order 0.

**Parameters**    **x** : array\_like

**Returns**        **I** : ndarray      Lower limit of integration.

The value of the integral.

**See also:**

`struve`

`scipy.special.bdtr(k, n, p) = <ufunc 'bdtr'>`

Binomial distribution cumulative distribution function.

Sum of the terms 0 through  $k$  of the Binomial probability density.

$$\text{bdtr}(k, n, p) = \sum_{j=0}^k \binom{n}{j} p^j (1-p)^{n-j}$$

|                   |                       |                                                                                                     |
|-------------------|-----------------------|-----------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>k</b> : array_like | Number of successes (int).                                                                          |
|                   | <b>n</b> : array_like | Number of events (int).                                                                             |
|                   | <b>p</b> : array_like | Probability of success in a single event (float).                                                   |
| <b>Returns</b>    | <b>y</b> : ndarray    | Probability of $k$ or fewer successes in $n$ independent events with success probabilities of $p$ . |

**Notes**

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtr}(k, n, p) = I_{1-p}(n - k, k + 1).$$

Wrapper for the Cephes [R371] routine `bdtr`.

**References**

[R371]

`scipy.special.bdtrc(k, n, p) = <ufunc 'bdtrc'>`

Binomial distribution survival function.

Sum of the terms  $k + 1$  through  $n$  of the binomial probability density,

$$\text{bdtrc}(k, n, p) = \sum_{j=k+1}^n \binom{n}{j} p^j (1-p)^{n-j}$$

|                   |                       |                                           |
|-------------------|-----------------------|-------------------------------------------|
| <b>Parameters</b> | <b>k</b> : array_like | Number of successes (int).                |
|                   | <b>n</b> : array_like | Number of events (int)                    |
|                   | <b>p</b> : array_like | Probability of success in a single event. |
| <b>Returns</b>    | <b>y</b> : ndarray    |                                           |

Probability of  $k + 1$  or more successes in  $n$  independent events with success probabilities of  $p$ .

**See also:**

`bdtr`, `betainc`

**Notes**

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtrc}(k, n, p) = I_p(k + 1, n - k).$$

Wrapper for the Cephes [R372] routine `bdtrc`.

**References**

[R372]

`scipy.special.bdtri(k, n, y) = <ufunc 'bdtri'>`

Inverse function to `bdtr` with respect to  $p$ .

Finds the event probability  $p$  such that the sum of the terms 0 through  $k$  of the binomial probability density is equal to the given cumulative probability  $y$ .

**Parameters**

- k** : array\_like  
Number of successes (float).
- n** : array\_like  
Number of events (float)
- y** : array\_like  
Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).

**Returns**

- p** : ndarray  
The event probability such that  $\text{bdtr}(k, n, p) = y$ .

**See also:**

`bdtr`, `betaincinv`

**Notes**

The computation is carried out using the inverse beta integral function and the relation,:

$$1 - p = \text{betaincinv}(n - k, k + 1, y).$$

Wrapper for the Cephes [R373] routine `bdtri`.

**References**

[R373]

`scipy.special.bdtrik(y, n, p) = <ufunc 'bdtrik'>`

Inverse function to `bdtr` with respect to  $k$ .

Finds the number of successes  $k$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for  $n$  events with probability  $p$  is equal to the given cumulative probability  $y$ .

**Parameters**

- y** : array\_like  
Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).
- n** : array\_like  
Number of events (float).
- p** : array\_like

**Returns** **k** : ndarray      Success probability (float).  
The number of successes  $k$  such that  $bdtr(k, n, p) = y$ .

**See also:**`bdtr`**Notes**

Formula 26.5.24 of [R374] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

Wrapper for the CDFLIB [R375] Fortran routine `cdfbin`.

**References**`[R374]`, `[R375]`

`scipy.special.bdtrin(k, y, p) = <ufunc 'bdtrin'>`

Inverse function to `bdtr` with respect to  $n$ .

Finds the number of events  $n$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for events with probability  $p$  is equal to the given cumulative probability  $y$ .

**Parameters** **k** : array\_like      Number of successes (float).  
**y** : array\_like      Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).  
**p** : array\_like      Success probability (float).

**Returns** **n** : ndarray      The number of events  $n$  such that  $bdtr(k, n, p) = y$ .

**See also:**`bdtr`**Notes**

Formula 26.5.24 of [R376] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

Wrapper for the CDFLIB [R377] Fortran routine `cdfbin`.

**References**`[R376]`, `[R377]`

`scipy.special.btdtr(a, b, x) = <ufunc 'btdtr'>`

Cumulative density function of the beta distribution.

Returns the integral from zero to  $x$  of the beta probability density function,

$$I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1} dt$$

where  $\Gamma$  is the gamma function.

**Parameters**

- a** : array\_like  
Shape parameter ( $a > 0$ ).
- b** : array\_like  
Shape parameter ( $b > 0$ ).
- x** : array\_like  
Upper limit of integration, in  $[0, 1]$ .

**Returns**

- I** : ndarray  
Cumulative density function of the beta distribution with parameters  $a$  and  $b$  at  $x$ .

**See also:**`betainc`**Notes**

This function is identical to the incomplete beta integral function `betainc`.

Wrapper for the Cephes [R384] routine `btdtr`.

**References**

[R384]

`scipy.special.btdtri(a, b, p) = <ufunc 'btdtri'>`

The  $p$ -th quantile of the beta distribution.

This function is the inverse of the beta cumulative distribution function, `btdtr`, returning the value of  $x$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**

- a** : array\_like  
Shape parameter ( $a > 0$ ).
- b** : array\_like  
Shape parameter ( $b > 0$ ).
- p** : array\_like  
Cumulative probability, in  $[0, 1]$ .

**Returns**

- x** : ndarray  
The quantile corresponding to  $p$ .

**See also:**`betaincinv, btdtr`**Notes**

The value of  $x$  is found by interval halving or Newton iterations.

Wrapper for the Cephes [R385] routine `incbi`, which solves the equivalent problem of finding the inverse of the incomplete beta integral.

**References**

[R385]

`scipy.special.btdtria(p, b, x) = <ufunc 'btdtria'>`

Inverse of `btdtr` with respect to  $a$ .

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of  $a$ , returning the value of  $a$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**

- p** : array\_like  
Cumulative probability, in [0, 1].
- b** : array\_like  
Shape parameter ( $b > 0$ ).
- x** : array\_like  
The quantile, in [0, 1].

**Returns**

- a** : ndarray  
The value of the shape parameter  $a$  such that  $btdtr(a, b, x) = p$ .

**See also:**

`btdtr` Cumulative density function of the beta distribution.  
`btdtri` Inverse with respect to  $x$ .  
`btdtrib` Inverse with respect to  $b$ .

**Notes**

Wrapper for the CDFLIB [R386] Fortran routine `cdfbet`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [R387]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

**References**

[R386], [R387]

`scipy.special.btdtrib(a, p, x) = <ufunc 'btdtrib'>`  
 Inverse of `btdtr` with respect to  $b$ .

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of  $b$ , returning the value of  $b$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**

- a** : array\_like  
Shape parameter ( $a > 0$ ).
- p** : array\_like  
Cumulative probability, in [0, 1].
- x** : array\_like  
The quantile, in [0, 1].

**Returns**

- b** : ndarray  
The value of the shape parameter  $b$  such that  $btdtr(a, b, x) = p$ .

**See also:**

`btdtr` Cumulative density function of the beta distribution.  
`btdtri` Inverse with respect to  $x$ .  
`btdtria` Inverse with respect to  $a$ .

**Notes**

Wrapper for the CDFLIB [R388] Fortran routine `cdfbet`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [R389]. Computation of  $b$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $b$ .

**References**

[R388], [R389]

`scipy.special.fdtf` ( $dfn, dfd, x$ ) = <ufunc 'fdtr'>

F cumulative distribution function.

Returns the value of the cumulative density function of the F-distribution, also known as Snedecor's F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters  $d_n$  and  $d_d$  is the distribution of the random variable,

$$X = \frac{U_n/d_n}{U_d/d_d},$$

where  $U_n$  and  $U_d$  are random variables distributed  $\chi^2$ , with  $d_n$  and  $d_d$  degrees of freedom, respectively.

**Parameters**

- dfn** : array\_like  
First parameter (positive float).
- dfd** : array\_like  
Second parameter (positive float).
- x** : array\_like  
Argument (nonnegative float).

**Returns**

- y** : ndarray  
The CDF of the F-distribution with parameters  $dfn$  and  $dfd$  at  $x$ .

**Notes**

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{x d_n / (d_d + x d_n)}(d_n/2, d_d/2).$$

Wrapper for the Cephes [R415] routine `fdtr`.

**References**

[R415]

`scipy.special.fdtfc` ( $dfn, dfd, x$ ) = <ufunc 'fdtrc'>

F survival function.

Returns the complemented F-distribution function (the integral of the density from  $x$  to infinity).

**Parameters**

- dfn** : array\_like  
First parameter (positive float).
- dfd** : array\_like  
Second parameter (positive float).
- x** : array\_like  
Argument (nonnegative float).

**Returns**

- y** : ndarray  
The complemented F-distribution function with parameters  $dfn$  and  $dfd$  at  $x$ .

**See also:**

`fdtr`

**Notes**

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{d_d/(d_d+x d_n)}(d_d/2, d_n/2).$$

Wrapper for the Cephes [R416] routine `fdtrc`.

**References**

[R416]

`scipy.special.fdttri(dfn, dfd, p) = <ufunc 'fdtri'>`

The  $p$ -th quantile of the F-distribution.

This function is the inverse of the F-distribution CDF, `fdtr`, returning the  $x$  such that `fdtr(dfn, dfd, x) = p`.

|                   |                                                               |
|-------------------|---------------------------------------------------------------|
| <b>Parameters</b> | <b>dfn</b> : array_like<br>First parameter (positive float).  |
|                   | <b>dfd</b> : array_like<br>Second parameter (positive float). |
|                   | <b>p</b> : array_like<br>Cumulative probability, in [0, 1].   |
| <b>Returns</b>    | <b>x</b> : ndarray<br>The quantile corresponding to $p$ .     |

**Notes**

The computation is carried out using the relation to the inverse regularized beta function,  $I_x^{-1}(a, b)$ . Let  $z = I_p^{-1}(d_d/2, d_n/2)$ . Then,

$$x = \frac{d_d(1-z)}{d_n z}.$$

If  $p$  is such that  $x < 0.5$ , the following relation is used instead for improved stability: let  $z' = I_{1-p}^{-1}(d_n/2, d_d/2)$ . Then,

$$x = \frac{d_d z'}{d_n(1-z')}.$$

Wrapper for the Cephes [R417] routine `fdtri`.

**References**

[R417]

`scipy.special.fdttridfd(dfn, p, x) = <ufunc 'fdtridfd'>`

Inverse to `fdtr` vs `dfd`

Finds the F density argument `dfd` such that `fdtr(dfn, dfd, x) == p`.

`scipy.special.gdtr(a, b, x) = <ufunc 'gdtr'>`

Gamma distribution cumulative density function.

Returns the integral from zero to  $x$  of the gamma probability density function,

$$F = \int_0^x \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

**Parameters** **a** : array\_like

The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .

**b** : array\_like  
The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).

**x** : array\_like  
The quantile (upper limit of integration; float).

**Returns** **F** : ndarray  
The CDF of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

**See also:**

`gdtrc` 1 - CDF of the gamma distribution.

**Notes**

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function). Wrapper for the Cephes [R423] routine `gdt r`.

**References**

[R423]

`scipy.special.gdtrc` ( $a, b, x$ ) = <ufunc 'gdtrc'>  
Gamma distribution survival function.

Integral from  $x$  to infinity of the gamma probability density function,

$$F = \int_x^\infty \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

**Parameters** **a** : array\_like  
The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .

**b** : array\_like  
The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).

**x** : array\_like  
The quantile (lower limit of integration; float).

**Returns** **F** : ndarray  
The survival function of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

**See also:**

`gdt r`, `gdtri`

**Notes**

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function). Wrapper for the Cephes [R424] routine `gdt rc`.

**References**

[R424]

`scipy.special.gdttria` ( $p, b, x, out=None$ ) = <ufunc 'gdttria'>  
Inverse of `gdt r` vs  $a$ .

Returns the inverse with respect to the parameter  $a$  of  $p = \text{gdtr}(a, b, x)$ , the cumulative distribution function of the gamma distribution.

**Parameters**

- p** : array\_like  
Probability values.
- b** : array\_like  
 $b$  parameter values of  $\text{gdtr}(a, b, x)$ .  $b$  is the “shape” parameter of the gamma distribution.
- x** : array\_like  
Nonnegative real values, from the domain of the gamma distribution.
- out** : ndarray, optional  
If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of  $a$ ,  $b$  and  $x$ . *out* is then the array returned by the function.

**Returns**

- a** : ndarray  
Values of the  $a$  parameter such that  $p = \text{gdtr}(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.

**See also:**

`gdtr` CDF of the gamma distribution.  
`gdtrib` Inverse with respect to  $b$  of  $\text{gdtr}(a, b, x)$ .  
`gdtrix` Inverse with respect to  $x$  of  $\text{gdtr}(a, b, x)$ .

**Notes**

Wrapper for the CDFLIB [R425] Fortran routine `cdfgam`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [R426]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

**References**

[R425], [R426]

**Examples**

First evaluate `gdtr`.

```
>>> from scipy.special import gdtr, gdtria
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtria(p, 3.4, 5.6)
1.2
```

`scipy.special.gdtrib(a, p, x, out=None) = <ufunc 'gdtrib'>`

Inverse of `gdtr` vs  $b$ .

Returns the inverse with respect to the parameter  $b$  of  $p = \text{gdtr}(a, b, x)$ , the cumulative distribution function of the gamma distribution.

**Parameters**

- a** : array\_like  
 $a$  parameter values of  $\text{gdtr}(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.
- p** : array\_like

**x** : array\_like  
 Probability values.

**out** : ndarray, optional  
 Nonnegative real values, from the domain of the gamma distribution.

**Returns** **b** : ndarray  
 If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of `a`, `b` and `x`. `out` is then the array returned by the function.

Values of the `b` parameter such that  $p = \text{gdftr}(a, b, x)$ . `b` is the “shape” parameter of the gamma distribution.

**See also:**

**`gdftr`** CDF of the gamma distribution.  
**`gdftria`** Inverse with respect to `a` of `gdftr(a, b, x)`.  
**`gdftrix`** Inverse with respect to `x` of `gdftr(a, b, x)`.

**Notes**

Wrapper for the CDFLIB [R427] Fortran routine `cdfgam`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [R428]. Computation of  $b$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $b$ .

**References**

[R427], [R428]

**Examples**

First evaluate `gdftr`.

```
>>> from scipy.special import gdftr, gdftrib
>>> p = gdftr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdftrib(1.2, p, 5.6)
3.3999999999723882
```

`scipy.special.gdftrix(a, b, p, out=None) = <ufunc 'gdftrix'>`

Inverse of `gdftr` vs `x`.

Returns the inverse with respect to the parameter `x` of  $p = \text{gdftr}(a, b, x)$ , the cumulative distribution function of the gamma distribution. This is also known as the  $p$ 'th quantile of the distribution.

**Parameters** **a** : array\_like  
`a` parameter values of `gdftr(a, b, x)`.  $1/a$  is the “scale” parameter of the gamma distribution.

**b** : array\_like  
`b` parameter values of `gdftr(a, b, x)`. `b` is the “shape” parameter of the gamma distribution.

**p** : array\_like  
 Probability values.

**out** : ndarray, optional

**Returns** `x` : ndarray  
 If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of `a`, `b` and `x`. `out` is then the array returned by the function.  
 Values of the `x` parameter such that  $p = \text{gdftr}(a, b, x)$ .

**See also:**

`gdftr` CDF of the gamma distribution.  
`gdftria` Inverse with respect to `a` of `gdftr(a, b, x)`.  
`gdftrib` Inverse with respect to `b` of `gdftr(a, b, x)`.

**Notes**

Wrapper for the CDFLIB [R429] Fortran routine `cdfgam`.

The cumulative distribution function `p` is computed using a routine by DiDinato and Morris [R430]. Computation of `x` involves a search for a value that produces the desired value of `p`. The search relies on the monotonicity of `p` with `x`.

**References**

[R429], [R430]

**Examples**

First evaluate `gdftr`.

```
>>> from scipy.special import gdftr, gdftria
>>> p = gdftr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdftria(1.2, 3.4, p)
5.5999999999999996
```

`scipy.special.nbdtr(k, n, p) = <ufunc 'nbdtr'>`  
 Negative binomial cumulative distribution function.

Returns the sum of the terms 0 through `k` of the negative binomial distribution probability mass function,

$$F = \sum_{j=0}^k \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities `p`, this is the probability that `k` or fewer failures precede the `n`th success.

**Parameters** `k` : array\_like  
 The maximum number of allowed failures (nonnegative int).  
`n` : array\_like  
 The target number of successes (positive int).  
`p` : array\_like  
 Probability of success in a single event (float).  
**Returns** `F` : ndarray  
 The probability of `k` or fewer failures before `n` successes in a sequence of events with individual success probability `p`.

**See also:**

`nbdtrc`

**Notes**

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdt r}(k, n, p) = I_p(n, k + 1).$$

Wrapper for the Cephes [R494] routine `nbdt r`.

**References**

[R494]

`scipy.special.nbdtrc(k, n, p) = <ufunc 'nbdtrc'>`

Negative binomial survival function.

Returns the sum of the terms  $k + 1$  to infinity of the negative binomial distribution probability mass function,

$$F = \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that more than  $k$  failures precede the  $n$ th success.

**Parameters** **k** : array\_like

The maximum number of allowed failures (nonnegative int).

**n** : array\_like

The target number of successes (positive int).

**p** : array\_like

Probability of success in a single event (float).

**Returns** **F** : ndarray

The probability of  $k + 1$  or more failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

**Notes**

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdtrc}(k, n, p) = I_{1-p}(k + 1, n).$$

Wrapper for the Cephes [R495] routine `nbdt rc`.

**References**

[R495]

`scipy.special.nbdtri(k, n, y) = <ufunc 'nbdtri'>`

Inverse of `nbdt r` vs  $p$ .

Returns the inverse with respect to the parameter  $p$  of  $y = \text{nbdt r}(k, n, p)$ , the negative binomial cumulative distribution function.

**Parameters** **k** : array\_like

The maximum number of allowed failures (nonnegative int).

**n** : array\_like

The target number of successes (positive int).

**y** : array\_like

**Returns** `p` : ndarray The probability of  $k$  or fewer failures before  $n$  successes (float).  
 Probability of success in a single event (float) such that  $nbdr(k, n, p) = y$ .

**See also:**

`nbdr` Cumulative distribution function of the negative binomial.  
`nbdr_ik` Inverse with respect to  $k$  of  $nbdr(k, n, p)$ .  
`nbdr_in` Inverse with respect to  $n$  of  $nbdr(k, n, p)$ .

**Notes**

Wrapper for the Cephes [R496] routine `nbdr_i`.

**References**

[R496]

`scipy.special.nbdr_ik`( $y, n, p$ ) = `<ufunc 'nbdr_ik'>`  
 Inverse of `nbdr` vs  $k$ .

Returns the inverse with respect to the parameter  $k$  of  $y = nbdr(k, n, p)$ , the negative binomial cumulative distribution function.

**Parameters** `y` : array\_like The probability of  $k$  or fewer failures before  $n$  successes (float).  
`n` : array\_like The target number of successes (positive int).  
`p` : array\_like Probability of success in a single event (float).

**Returns** `k` : ndarray The maximum number of allowed failures such that  $nbdr(k, n, p) = y$ .

**See also:**

`nbdr` Cumulative distribution function of the negative binomial.  
`nbdr_i` Inverse with respect to  $p$  of  $nbdr(k, n, p)$ .  
`nbdr_in` Inverse with respect to  $n$  of  $nbdr(k, n, p)$ .

**Notes**

Wrapper for the CDFLIB [R497] Fortran routine `cdfnbn`.

Formula 26.5.26 of [R498],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

**References**

[R497], [R498]

`scipy.special.nbdr_in`( $k, y, p$ ) = `<ufunc 'nbdr_in'>`  
 Inverse of `nbdr` vs  $n$ .

Returns the inverse with respect to the parameter  $n$  of  $y = nbdr(k, n, p)$ , the negative binomial cumulative distribution function.

**Parameters** `k` : array\_like

|                |                       |                                                                        |

| <b>ncdfdtridfn</b> | Calculate dfn, given CDF and iCDF values.             |

**`ncfdtrinc`** Calculate noncentrality parameter, given CDF, iCDF, dfn, dfd.

#### Notes

Wrapper for the CDFLIB [R501] Fortran routine `cdffnc`.

The cumulative distribution function is computed using Formula 26.6.20 of [R502]:

$$F(d_n, d_d, n_c, f) = \sum_{j=0}^{\infty} e^{-n_c/2} \frac{(n_c/2)^j}{j!} I_x\left(\frac{d_n}{2} + j, \frac{d_d}{2}\right),$$

where  $I$  is the regularized incomplete beta function, and  $x = fd_n/(fd_n + d_d)$ .

The computation time required for this routine is proportional to the noncentrality parameter  $nc$ . Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.

#### References

[R501], [R502]

#### Examples

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central F distribution, for  $nc=0$ . Compare with the F-distribution from `scipy.stats`:

```
>>> x = np.linspace(-1, 8, num=500)
>>> dfn = 3
>>> dfd = 2
>>> ncf_stats = stats.f.cdf(x, dfn, dfd)
>>> ncf_special = special.ncfdtr(dfn, dfd, 0, x)

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()
```

`scipy.special.ncfdtridfd(p, f, dfn, nc) = <ufunc 'ncfdtridfd'>`  
 Calculate degrees of freedom (denominator) for the noncentral F-distribution.

See `ncfdtr` for more details.

#### Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

`scipy.special.ncfdtridfn(p, f, dfd, nc) = <ufunc 'ncfdtridfn'>`  
 Calculate degrees of freedom (numerator) for the noncentral F-distribution.

See `ncfdtr` for more details.

#### Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

`scipy.special.ncfdtri(p, dfn, dfd, nc) = <ufunc 'ncfdtri'>`  
 Inverse cumulative distribution function of the non-central F distribution.

See `ncfdtr` for more details.

`scipy.special.ncfdtrinc(p, f, dfn, dfd) = <ufunc 'ncfdtrinc'>`  
 Calculate non-centrality parameter for non-central F distribution.

See `ncfdtr` for more details.

`scipy.special.nctdtr(df, nc, t) = <ufunc 'nctdtr'>`  
 Cumulative distribution function of the non-central  $t$  distribution.

**Parameters**

- df**: array\_like  
 Degrees of freedom of the distribution. Should be in range (0, inf).
- nc**: array\_like  
 Noncentrality parameter. Should be in range (-1e6, 1e6).
- t**: array\_like  
 Quantiles, i.e. the upper limit of integration.

**Returns** `cdf` : float or ndarray  
 The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

**See also:**

`nctdtrit` Inverse CDF (iCDF) of the non-central t distribution.  
`nctdtridf` Calculate degrees of freedom, given CDF and iCDF values.  
`nctdtrinc` Calculate non-centrality parameter, given CDF iCDF values.

**Examples**

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central t distribution, for `nc=0`. Compare with the t-distribution from `scipy.stats`:

```
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.nctdtr(df, 0, x)

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-')
>>> plt.show()
```

`scipy.special.nctdtridf` ( $p, nc, t$ ) = <ufunc 'nctdtridf'>  
 Calculate degrees of freedom for non-central t distribution.

See `nctdtr` for more details.

**Parameters** `p` : array\_like  
 CDF values, in range (0, 1].  
`nc` : array\_like  
 Noncentrality parameter. Should be in range (-1e6, 1e6).

**t** : array\_like  
Quantiles, i.e. the upper limit of integration.

`scipy.special.nctdtrit` (*df, nc, p*) = <ufunc 'nctdtrit'>  
Inverse cumulative distribution function of the non-central t distribution.  
See `nctdtr` for more details.

**Parameters**

- df** : array\_like  
Degrees of freedom of the distribution. Should be in range (0, inf).
- nc** : array\_like  
Noncentrality parameter. Should be in range (-1e6, 1e6).
- p** : array\_like  
CDF values, in range (0, 1].

`scipy.special.nctdtrinc` (*df, p, t*) = <ufunc 'nctdtrinc'>  
Calculate non-centrality parameter for non-central t distribution.  
See `nctdtr` for more details.

**Parameters**

- df** : array\_like  
Degrees of freedom of the distribution. Should be in range (0, inf).
- p** : array\_like  
CDF values, in range (0, 1].
- t** : array\_like  
Quantiles, i.e. the upper limit of integration.

`scipy.special.nrdtrimn` (*p, x, std*) = <ufunc 'nrdtrimn'>  
Calculate mean of normal distribution given other params.

**Parameters**

- p** : array\_like  
CDF values, in range (0, 1].
- x** : array\_like  
Quantiles, i.e. the upper limit of integration.
- std** : array\_like  
Standard deviation.

**Returns**

- mn** : float or ndarray  
The mean of the normal distribution.

**See also:**

`nrdtrimn`, `ndtr`

`scipy.special.nrdtrisd` (*p, x, mn*) = <ufunc 'nrdtrisd'>  
Calculate standard deviation of normal distribution given other params.

**Parameters**

- p** : array\_like  
CDF values, in range (0, 1].
- x** : array\_like  
Quantiles, i.e. the upper limit of integration.
- mn** : float or ndarray  
The mean of the normal distribution.

**Returns**

- std** : array\_like  
Standard deviation.

**See also:**

`nrdtrisd`, `ndtr`

`scipy.special.pdtr` (*k, m*) = <ufunc 'pdtr'>  
Poisson cumulative distribution function

Returns the sum of the first  $k$  terms of the Poisson distribution:  $\sum(\exp(-m) * m^{**j} / j!, j=0..k) = \text{gammaincc}(k+1, m)$ . Arguments must both be positive and  $k$  an integer.

`scipy.special.pdtrc(k, m) = <ufunc 'pdtrc'>`

Poisson survival function

Returns the sum of the terms from  $k+1$  to infinity of the Poisson distribution:  $\sum(\exp(-m) * m^{**j} / j!, j=k+1..inf) = \text{gammainc}(k+1, m)$ . Arguments must both be positive and  $k$  an integer.

`scipy.special.pdtri(k, y) = <ufunc 'pdtri'>`

Inverse to `pdtr` vs  $m$

Returns the Poisson variable  $m$  such that the sum from 0 to  $k$  of the Poisson density is equal to the given probability  $y$ : calculated by `gammaincinv(k+1, y)`.  $k$  must be a nonnegative integer and  $y$  between 0 and 1.

`scipy.special.pdtrik(p, m) = <ufunc 'pdtrik'>`

Inverse to `pdtr` vs  $k$

Returns the quantile  $k$  such that `pdtr(k, m) = p`

`scipy.special.stdtr(df, t) = <ufunc 'stdtr'>`

Student t distribution cumulative density function

Returns the integral from minus infinity to  $t$  of the Student t distribution with  $df > 0$  degrees of freedom:

```
gamma((df+1)/2) / (sqrt(df*pi) * gamma(df/2)) *
integral((1+x**2/df)**(-df/2-1/2), x=-inf..t)
```

`scipy.special.stdtridf(p, t) = <ufunc 'stdtridf'>`

Inverse of `stdtr` vs  $df$

Returns the argument  $df$  such that `stdtr(df, t)` is equal to  $p$ .

`scipy.special.stdtrit(df, p) = <ufunc 'stdtrit'>`

Inverse of `stdtr` vs  $t$

Returns the argument  $t$  such that `stdtr(df, t)` is equal to  $p$ .

`scipy.special.chdtr(v, x) = <ufunc 'chdtr'>`

Chi square cumulative distribution function

Returns the area under the left hand tail (from 0 to  $x$ ) of the Chi square probability density function with  $v$  degrees of freedom:

```
1 / (2**(v/2) * gamma(v/2)) * integral(t**(v/2-1) * exp(-t/2), t=0..x)
```

`scipy.special.chdtrc(v, x) = <ufunc 'chdtrc'>`

Chi square survival function

Returns the area under the right hand tail (from  $x$  to infinity) of the Chi square probability density function with  $v$  degrees of freedom:

```
1 / (2**(v/2) * gamma(v/2)) * integral(t**(v/2-1) * exp(-t/2), t=x..inf)
```

`scipy.special.chdtri(v, p) = <ufunc 'chdtri'>`

Inverse to `chdtrc`

Returns the argument  $x$  such that `chdtrc(v, x) == p`.

`scipy.special.chdtriv(p, x) = <ufunc 'chdtriv'>`

Inverse to `chdtr` vs  $v$

Returns the argument  $v$  such that `chdtr(v, x) == p`.

`scipy.special.ndtr(x) = <ufunc 'ndtr'>`

Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to  $x$

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-t^2/2) dt$$

**Parameters** `x`: array\_like, real or complex

**Returns** ndarray  
Argument

The value of the normal CDF evaluated at  $x$

**See also:**

`erf`, `erfc`, `scipy.stats.norm`, `log_ndtr`

`scipy.special.log_ndtr(x) = <ufunc 'log_ndtr'>`

Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to  $x$ :

```
log(1/sqrt(2*pi) * integral(exp(-t**2 / 2), t=-inf..x))
```

**Parameters** `x`: array\_like, real or complex

**Returns** ndarray  
Argument

The value of the log of the normal CDF evaluated at  $x$

**See also:**

`erf`, `erfc`, `scipy.stats.norm`, `ndtr`

`scipy.special.ndtri(y) = <ufunc 'ndtri'>`

Inverse of `ndtr` vs  $x$

Returns the argument  $x$  for which the area under the Gaussian probability density function (integrated from minus infinity to  $x$ ) is equal to  $y$ .

`scipy.special.chndtr(x, df, nc) = <ufunc 'chndtr'>`

Non-central chi square cumulative distribution function

`scipy.special.chndtridf(x, p, nc) = <ufunc 'chndtridf'>`

Inverse to `chndtr` vs  $df$

`scipy.special.chndtrinc(x, df, p) = <ufunc 'chndtrinc'>`

Inverse to `chndtr` vs  $nc$

`scipy.special.chndtrix(p, df, nc) = <ufunc 'chndtrix'>`

Inverse to `chndtr` vs  $x$

`scipy.special.smirnov(n, e) = <ufunc 'smirnov'>`

Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function (Dn+ or Dn-) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on  $n$  samples is greater than  $e$ .

`scipy.special.smirnovi(n, y) = <ufunc 'smirnovi'>`

Inverse to `smirnov`

Returns  $e$  such that `smirnov(n, e) = y`.

`scipy.special.kolmogorov` (*y*) = <ufunc 'kolmogorov'>

Complementary cumulative distribution function of Kolmogorov distribution

Returns the complementary cumulative distribution function of Kolmogorov's limiting distribution ( $K_n^*$  for large  $n$ ) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as  $n \rightarrow \infty$  of the) probability that  $\sqrt{n} * \max \text{absolute deviation} > y$ .

`scipy.special.kolmogi` (*p*) = <ufunc 'kolmogi'>

Inverse function to kolmogorov

Returns *y* such that `kolmogorov(y) == p`.

`scipy.special.tklmbda` (*x*, *lmbda*) = <ufunc 'tklmbda'>

Tukey-Lambda cumulative distribution function

`scipy.special.logit` (*x*) = <ufunc 'logit'>

Logit ufunc for ndarrays.

The logit function is defined as  $\text{logit}(p) = \log(p/(1-p))$ . Note that  $\text{logit}(0) = -\text{inf}$ ,  $\text{logit}(1) = \text{inf}$ , and  $\text{logit}(p)$  for  $p < 0$  or  $p > 1$  yields nan.

**Parameters**    **x** : ndarray

The ndarray to apply logit to element-wise.

**Returns**        **out** : ndarray

An ndarray of the same shape as *x*. Its entries are logit of the corresponding entry of *x*.

**Notes**

As a ufunc logit takes a number of optional keyword arguments. For more information see [ufuncs](#)

New in version 0.10.0.

`scipy.special.expit` (*x*) = <ufunc 'expit'>

Expit ufunc for ndarrays.

The expit function, also known as the logistic function, is defined as  $\text{expit}(x) = 1/(1+\exp(-x))$ . It is the inverse of the logit function.

**Parameters**    **x** : ndarray

The ndarray to apply expit to element-wise.

**Returns**        **out** : ndarray

An ndarray of the same shape as *x*. Its entries are expit of the corresponding entry of *x*.

**Notes**

As a ufunc expit takes a number of optional keyword arguments. For more information see [ufuncs](#)

New in version 0.10.0.

`scipy.special.boxcox` (*x*, *lmbda*) = <ufunc 'boxcox'>

Compute the Box-Cox transformation.

The Box-Cox transformation is:

$$y = \begin{cases} (x^{**lmbda} - 1) / lmbda & \text{if } lmbda \neq 0 \\ \log(x) & \text{if } lmbda == 0 \end{cases}$$

Returns *nan* if  $x < 0$ . Returns *-inf* if  $x == 0$  and  $lmbda < 0$ .

**Parameters**    **x** : array\_like

Data to be transformed.

**lmbda** : array\_like

**Returns** **y** : array  
Power parameter of the Box-Cox transform.  
Transformed data.

**Notes**

New in version 0.14.0.

**Examples**

```
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([ 0.          , 12.4          , 126.09110641])
>>> boxcox(2, [0, 1, 2])
array([ 0.69314718, 1.          , 1.5          ])
```

`scipy.special.boxcox1p(x, lambda) = <ufunc 'boxcox1p'>`  
Compute the Box-Cox transformation of  $1 + x$ .

The Box-Cox transformation computed by `boxcox1p` is:

$$y = \begin{cases} ((1+x)**\lambda - 1) / \lambda & \text{if } \lambda \neq 0 \\ \log(1+x) & \text{if } \lambda == 0 \end{cases}$$

Returns *nan* if  $x < -1$ . Returns *-inf* if  $x == -1$  and  $\lambda < 0$ .

**Parameters** **x** : array\_like  
Data to be transformed.  
**lambda** : array\_like  
Power parameter of the Box-Cox transform.

**Returns** **y** : array  
Transformed data.

**Notes**

New in version 0.14.0.

**Examples**

```
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([ 9.99950003e-05,  9.99975001e-05,  1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([ 0.00996272,  0.09645476])
```

`scipy.special.inv_boxcox(y, lambda) = <ufunc 'inv_boxcox'>`  
Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

$$y = \begin{cases} (x**\lambda - 1) / \lambda & \text{if } \lambda \neq 0 \\ \log(x) & \text{if } \lambda == 0 \end{cases}$$

**Parameters** **y** : array\_like  
Data to be transformed.  
**lambda** : array\_like  
Power parameter of the Box-Cox transform.

**Returns** **x** : array  
Transformed data.

*Notes*

New in version 0.16.0.

*Examples*

```
>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.]
```

`scipy.special.inv_boxcox1p(y, lambda) = <ufunc 'inv_boxcox1p'>`  
 Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

$$y = \begin{cases} ((1+x)**\lambda - 1) / \lambda & \text{if } \lambda \neq 0 \\ \log(1+x) & \text{if } \lambda == 0 \end{cases}$$

**Parameters** `y`: array\_like  
 Data to be transformed.  
`lambda`: array\_like  
 Power parameter of the Box-Cox transform.  
**Returns** `x`: array  
 Transformed data.

*Notes*

New in version 0.16.0.

*Examples*

```
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.]
```

**Information Theory Functions**

| <code>pseudo_huber(delta, r)</code> | Pseudo-Huber loss function.                                     |

---

`scipy.special.entr(x) = <ufunc 'entr'>`  
 Elementwise function for computing entropy.

$$\text{entr}(x) = \begin{cases} -x \log(x) & x > 0 \\ 0 & x = 0 \\ -\infty & \text{otherwise} \end{cases}$$

**Parameters** `x`: ndarray  
 Input array.

**Returns** `res` : ndarray

The value of the elementwise entropy function at the given points  $x$ .

**See also:**

`kl_div`, `rel_entr`

**Notes**

This function is concave.

New in version 0.15.0.

`scipy.special.rel_entr(x, y) = <ufunc 'rel_entr'>`

Elementwise function for computing relative entropy.

$$\text{rel\_entr}(x, y) = \begin{cases} x \log(x/y) & x > 0, y > 0 \\ 0 & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

**Parameters** `x` : ndarray

First input array.

`y` : ndarray

Second input array.

**Returns** `res` : ndarray

Output array.

**See also:**

`entr`, `kl_div`

**Notes**

This function is jointly convex in  $x$  and  $y$ .

New in version 0.15.0.

`scipy.special.kl_div(x, y) = <ufunc 'kl_div'>`

Elementwise function for computing Kullback-Leibler divergence.

$$\text{kl\_div}(x, y) = \begin{cases} x \log(x/y) - x + y & x > 0, y > 0 \\ y & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

**Parameters** `x` : ndarray

First input array.

`y` : ndarray

Second input array.

**Returns** `res` : ndarray

Output array.

**See also:**

`entr`, `rel_entr`

**Notes**

This function is non-negative and is jointly convex in  $x$  and  $y$ .

New in version 0.15.0.

`scipy.special.huber` (*delta*, *r*) = <ufunc 'huber'>  
 Huber loss function.

$$\text{huber}(\delta, r) = \begin{cases} \infty & \delta < 0 \\ \frac{1}{2}r^2 & 0 \leq \delta, |r| \leq \delta \\ \delta(|r| - \frac{1}{2}\delta) & \text{otherwise} \end{cases}$$

**Parameters**

- delta** : ndarray  
Input array, indicating the quadratic vs. linear loss changepoint.
- r** : ndarray  
Input array, possibly representing residuals.

**Returns**

- res** : ndarray  
The computed Huber loss function values.

**Notes**

This function is convex in *r*.  
 New in version 0.15.0.

`scipy.special.pseudo_huber` (*delta*, *r*) = <ufunc 'pseudo\_huber'>  
 Pseudo-Huber loss function.

$$\text{pseudo\_huber}(\delta, r) = \delta^2 \left( \sqrt{1 + \left(\frac{r}{\delta}\right)^2} - 1 \right)$$

**Parameters**

- delta** : ndarray  
Input array, indicating the soft quadratic vs. linear loss changepoint.
- r** : ndarray  
Input array, possibly representing residuals.

**Returns**

- res** : ndarray  
The computed Pseudo-Huber loss function values.

**Notes**

This function is convex in *r*.  
 New in version 0.15.0.

**Gamma and Related Functions**

Table 5.251 – continued from previous page

|                                 |                                                                                     |
|---------------------------------|-------------------------------------------------------------------------------------|
| <code>multigammaln(a, d)</code> | Returns the log of multivariate gamma, also sometimes called the generalized gamma. |
| <code>digamma(z[, out])</code>  | The digamma function.                                                               |
| <code>poch(z, m)</code>         | Rising factorial $(z)_m$                                                            |

`scipy.special.gamma(z) = <ufunc 'gamma'>`

Gamma function.

The gamma function is often referred to as the generalized factorial since  $z \cdot \text{gamma}(z) = \text{gamma}(z+1)$  and  $\text{gamma}(n+1) = n!$  for natural number  $n$ .

`scipy.special.gammaln(x)`

Logarithm of the absolute value of the Gamma function for real inputs.

**Parameters** `x`: array-like

**Returns** `gammaln`: ndarray  
Values on the real line at which to compute `gammaln`  
Values of `gammaln` at `x`.

**See also:**

`gamma` sign of the gamma function

`loggamma` principal branch of the logarithm of the gamma function

**Notes**

When used in conjunction with `gamma`, this function is useful for working in logspace on the real axis without having to deal with complex numbers, via the relation  $\exp(\text{gammaln}(x)) = \text{gamma}(x)$ .

Note that `gammaln` currently accepts complex-valued inputs, but it is not the same function as for real-valued inputs, and the branch is not well-defined — using `gammaln` with complex is deprecated and will be disallowed in future SciPy versions.

For complex-valued log-gamma, use `loggamma` instead of `gammaln`.

`scipy.special.loggamma(z, out=None) = <ufunc 'loggamma'>`

Principal branch of the logarithm of the Gamma function.

Defined to be  $\log(\Gamma(x))$  for  $x > 0$  and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

**Parameters** `z`: array-like

Values in the complex plain at which to compute `loggamma`

**out**: ndarray, optional

**Returns** `loggamma`: ndarray  
Output array for computed values of `loggamma`  
Values of `loggamma` at `z`.

**See also:**

`gammaln` logarithm of the absolute value of the Gamma function

`gamma` sign of the gamma function

**Notes**

It is not generally true that  $\log \Gamma(z) = \log(\Gamma(z))$ , though the real parts of the functions do agree. The benefit of not defining `loggamma` as  $\log(\Gamma(z))$  is that the latter function has a complicated branch cut structure whereas `loggamma` is analytic except for on the negative real axis.

The identities

$$\begin{aligned}\exp(\log \Gamma(z)) &= \Gamma(z) \\ \log \Gamma(z+1) &= \log(z) + \log \Gamma(z)\end{aligned}$$

make `loggamma` useful for working in complex logspace. However, `loggamma` necessarily returns complex outputs for real inputs, so if you want to work only with real numbers use `gammaaln`. On the real line the two functions are related by  $\exp(\text{loggamma}(x)) = \text{gammaaln}(x) * \exp(\text{gammaaln}(x))$ , though in practice rounding errors will introduce small spurious imaginary components in  $\exp(\text{loggamma}(x))$ .

The implementation here is based on [hare1997].

### References

[hare1997]

`scipy.special.gammasgn(x) = <ufunc 'gammasgn'>`  
Sign of the gamma function.

**See also:**

`gammaaln`, `loggamma`

`scipy.special.gammainc(a, x) = <ufunc 'gammainc'>`  
Regularized lower incomplete gamma function.

Defined as

$$\frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . The function satisfies the relation  $\text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1$  where `gammaincc` is the regularized upper incomplete gamma function.

**See also:**

`gammaincc` regularized upper incomplete gamma function

`gammaincinv`

inverse to `gammainc` versus  $x$

`gammainccinv`

inverse to `gammaincc` versus  $x$

### Notes

The implementation largely follows that of [R421].

### References

[R421]

`scipy.special.gammaincinv(a, y) = <ufunc 'gammaincinv'>`  
Inverse to `gammainc`

Returns  $x$  such that  $\text{gammainc}(a, x) = y$ .

`scipy.special.gammaincc(a, x) = <ufunc 'gammaincc'>`  
Regularized upper incomplete gamma function.

Defined as

$$\frac{1}{\Gamma(a)} \int_x^\infty t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . The function satisfies the relation  $\text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1$  where `gammainc` is the regularized lower incomplete gamma function.

**See also:**

`gammainc` regularized lower incomplete gamma function

`gammaincinv`

inverse to `gammainc` versus  $x$

`gammainccinv`

inverse to `gammaincc` versus  $x$

**Notes**

The implementation largely follows that of [R422].

**References**

[R422]

`scipy.special.gammainccinv(a, y) = <ufunc 'gammainccinv'>`

Inverse to `gammaincc`

Returns  $x$  such that `gammaincc(a, x) == y`.

`scipy.special.beta(a, b) = <ufunc 'beta'>`

Beta function.

`beta(a, b) = gamma(a) * gamma(b) / gamma(a+b)`

`scipy.special.betaln(a, b) = <ufunc 'betaln'>`

Natural logarithm of absolute value of beta function.

Computes  $\ln(\text{abs}(\text{beta}(a, b)))$ .

`scipy.special.betainc(a, b, x) = <ufunc 'betainc'>`

Incomplete beta integral.

Compute the incomplete beta integral of the arguments, evaluated from zero to  $x$ :

`gamma(a+b) / (gamma(a)*gamma(b)) * integral(t**(a-1) (1-t)**(b-1), t=0..x)`.

**Notes**

The incomplete beta is also sometimes defined without the terms in gamma, in which case the above definition is the so-called regularized incomplete beta. Under this definition, you can get the incomplete beta by multiplying the result of the scipy function by `beta(a, b)`.

`scipy.special.betaincinv(a, b, y) = <ufunc 'betaincinv'>`

Inverse function to beta integral.

Compute  $x$  such that `betainc(a, b, x) = y`.

`scipy.special.psi(z, out=None) = <ufunc 'psi'>`

The digamma function.

The logarithmic derivative of the gamma function evaluated at  $z$ .

**Parameters** `z` : array\_like

Real or complex argument.

**out** : ndarray, optional

**Returns** `digamma` : ndarray  
Array for the computed values of `psi`.

Computed values of `psi`.

**Notes**

For large values not close to the negative real axis `psi` is computed using the asymptotic series (5.11.2) from [R508]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [R508] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [R508] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [R509], so the function should maintain full accuracy around the origin.

**References**

[R508], [R509]

`scipy.special.rgamma(z) = <ufunc 'rgamma'>`  
Gamma function inverted

Returns  $1/\text{gamma}(x)$

`scipy.special.polygamma(n, x)`  
Polygamma function  $n$ .

This is the  $n$ th derivative of the digamma (`psi`) function.

**Parameters** `n` : array\_like of int  
The order of the derivative of `psi`.  
`x` : array\_like  
Where to evaluate the polygamma function.  
**Returns** `polygamma` : ndarray  
The result.

**Examples**

```
>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([ 0.64493407,  0.39493407,  0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([ True,  True,  True], dtype=bool)
```

`scipy.special.multigammaln(a, d)`  
Returns the log of multivariate gamma, also sometimes called the generalized gamma.

**Parameters** `a` : ndarray  
The multivariate gamma is computed for each item of  $a$ .  
`d` : int  
The dimension of the space of integration.  
**Returns** `res` : ndarray  
The values of the log multivariate gamma at the given points  $a$ .

**Notes**

The formal definition of the multivariate gamma of dimension  $d$  for a real  $a$  is

$$\Gamma_d(a) = \int_{A>0} e^{-tr(A)} |A|^{a-(d+1)/2} dA$$

with the condition  $a > (d - 1)/2$ , and  $A > 0$  being the set of all the positive definite matrices of dimension  $d$ . Note that  $a$  is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

$$\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^d \Gamma(a - (i - 1)/2).$$

### References

`scipy.special.digamma` ( $z$ ,  $out=None$ ) = <ufunc 'psi'>

The digamma function.

The logarithmic derivative of the gamma function evaluated at  $z$ .

**Parameters**  $z$ : array\_like

Real or complex argument.

**out**: ndarray, optional

**Returns** **digamma**: ndarray  
 Array for the computed values of `psi`.  
 Computed values of `psi`.

### Notes

For large values not close to the negative real axis `psi` is computed using the asymptotic series (5.11.2) from [R396]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [R396] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [R396] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [R397], so the function should maintain full accuracy around the origin.

## Legendre Functions

|                                         |                                                                |
|-----------------------------------------|----------------------------------------------------------------|
| <code>lpmv(m, v, x)</code>              | Associated Legendre function of integer order and real degree. |
| <code>sph_harm(m, n, theta, phi)</code> | Compute spherical harmonics.                                   |

`scipy.special.lpmv(m, v, x) = <ufunc 'lpmv'>`  
 Associated Legendre function of integer order and real degree.

Defined as

$$P_v^m = (-1)^m (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_v(x)$$

where

$$P_v = \sum_{k=0}^{\infty} \frac{(-v)_k (v+1)_k}{(k!)^2} \left( \frac{1-x}{2} \right)^k$$

is the Legendre function of the first kind. Here  $(\cdot)_k$  is the Pochhammer symbol; see [poch](#).

**Parameters**

- m** : array\_like  
Order (int or float). If passed a float not equal to an integer the function returns NaN.
- v** : array\_like  
Degree (float).
- x** : array\_like  
Argument (float). Must have  $|x| \leq 1$ .

**Returns**

- pmv** : ndarray  
Value of the associated Legendre function.

**See also:**

- `lpmn` Compute the associated Legendre function for all orders  $0, \dots, m$  and degrees  $0, \dots, n$ .
- `clpmn` Compute the associated Legendre function at complex arguments.

**Notes**

Note that this implementation includes the Condon-Shortley phase.

**References**

[R486]

`scipy.special.sph_harm(m, n, theta, phi) = <ufunc 'sph_harm'>`

Compute spherical harmonics.

The spherical harmonics are defined as

$$Y_n^m(\theta, \phi) = \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} e^{im\theta} P_n^m(\cos(\phi))$$

where  $P_n^m$  are the associated Legendre functions; see `lpmv`.

- Parameters**
- m** : array\_like  
Order of the harmonic (int); must have  $|m| \leq n$ .
  - n** : array\_like  
Degree of the harmonic (int); must have  $n \geq 0$ . This is often denoted by  $l$  (lower case L) in descriptions of spherical harmonics.
  - theta** : array\_like  
Azimuthal (longitudinal) coordinate; must be in  $[0, 2\pi]$ .
  - phi** : array\_like  
Polar (colatitudinal) coordinate; must be in  $[0, \pi]$ .
- Returns**
- y\_mn** : complex float  
The harmonic  $Y_n^m$  sampled at `theta` and `phi`.

**Notes**

There are different conventions for the meanings of the input arguments `theta` and `phi`. In SciPy `theta` is the azimuthal angle and `phi` is the polar angle. It is common to see the opposite convention, that is, `theta` as the polar angle and `phi` as the azimuthal angle.

Note that SciPy's spherical harmonics include the Condon-Shortley phase [R521] because it is part of `lpmv`.

With SciPy's conventions, the first several spherical harmonics are

$$Y_0^0(\theta, \phi) = \frac{1}{2} \sqrt{\frac{1}{\pi}}$$

$$Y_1^{-1}(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{-i\theta} \sin(\phi)$$

$$Y_1^0(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos(\phi)$$

$$Y_1^1(\theta, \phi) = -\frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{i\theta} \sin(\phi).$$

**References**

[R520], [R521]

These are not universal functions:

|                                     |                                                                       |
|-------------------------------------|-----------------------------------------------------------------------|

| <code>lqmn(m, n, z)</code>          | Sequence of associated Legendre functions of the second kind.         |

`scipy.special.clpmn(m, n, z, type=3)`

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order  $m$  and degree  $n$ ,  $P_{mn}(z) = P_n^m(z)$ , and its derivative,  $P_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $P_{mn}(z)$  and  $P_{mn}'(z)$  for all orders from  $0 \dots m$  and degrees from  $0 \dots n$ .

**Parameters** **m** : int

$|m| \leq n$ ; the order of the Legendre function.

**n** : int

where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function

**z** : float or complex

Input value.

**type** : int, optional

takes values 2 or 3 2: cut on the real axis  $|x| > 1$  3: cut on the real axis

**Returns** **Pmn\_z** :  $(m+1, n+1)$  array

Values for all orders  $0 \dots m$  and degrees  $0 \dots n$

**Pmn\_d\_z** :  $(m+1, n+1)$  array

Derivatives for all orders  $0 \dots m$  and degrees  $0 \dots n$

`lpmn` associated Legendre functions of the first kind for real  $z$

**Notes**

By default, i.e. for `type=3`, phase conventions are chosen according to [R392] such that the function is analytic. The cut lies on the interval  $(-1, 1)$ . Approaching the cut from above or below in general yields a phase factor with respect to Ferrer's function of the first kind (cf. `lpmn`).

For `type=2` a cut at  $|x| > 1$  is chosen. Approaching the real values on the interval  $(-1, 1)$  in the complex plane yields Ferrer's function of the first kind.

**References**

[R392], [R393]

`scipy.special.lpn(n, z)`

Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials),  $P_n(z)$  and derivatives for all degrees from 0 to  $n$  (inclusive).

See also `special.legendre` for polynomial class.

**References**

[R487]

`scipy.special.lqn(n, z)`

Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind,  $Q_n(z)$  and derivatives for all degrees from 0 to  $n$  (inclusive).

**References**

[R489]

`scipy.special.lpmn(m, n, z)`

Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order  $m$  and degree  $n$ ,  $P_{mn}(z) = P_n^m(z)$ , and its derivative,  $P_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $P_{mn}(z)$  and  $P_{mn}'(z)$  for all orders from  $0..m$  and degrees from  $0..n$ .

This function takes a real argument  $z$ . For complex arguments  $z$  use `clpmn` instead.

**Parameters**

- m** : int  
 $|m| \leq n$ ; the order of the Legendre function.
- n** : int  
 where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function
- z** : float

**Returns**

- Pmn\_z** :  $(m+1, n+1)$  array  
 Input value.  
 Values for all orders  $0..m$  and degrees  $0..n$
- Pmn\_d\_z** :  $(m+1, n+1)$  array  
 Derivatives for all orders  $0..m$  and degrees  $0..n$

**See also:**

`clpmn` associated Legendre functions of the first kind for complex  $z$

**Notes**

In the interval  $(-1, 1)$ , Ferrer's function of the first kind is returned. The phase convention used for the intervals  $(1, \infty)$  and  $(-\infty, -1)$  is such that the result is always real.

**References**

[R484], [R485]

`scipy.special.lqmn(m, n, z)`

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order  $m$  and degree  $n$ ,  $Q_{mn}(z) = Q_n^m(z)$ , and its derivative,  $Q_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $Q_{mn}(z)$  and  $Q_{mn}'(z)$  for all orders from  $0..m$  and degrees from  $0..n$ .

**Parameters**

- m** : int  
 $|m| \leq n$ ; the order of the Legendre function.
- n** : int  
 where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function
- z** : complex

**Returns**

- Qmn\_z** :  $(m+1, n+1)$  array  
 Input value.  
 Values for all orders  $0..m$  and degrees  $0..n$
- Qmn\_d\_z** :  $(m+1, n+1)$  array  
 Derivatives for all orders  $0..m$  and degrees  $0..n$

---

`scipy.special.ellip_harm(h2, k2, n, p, s, signm=1, signn=1)`

Ellipsoidal harmonic functions  $E^p_n(l)$

These are also known as Lamé functions of the first kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

|                   |                                  |                                                         |
|-------------------|----------------------------------|---------------------------------------------------------|
| <b>Parameters</b> | <b>h2</b> : float                | $h^{**2}$                                               |
|                   | <b>k2</b> : float                | $k^{**2}$ ; should be larger than $h^{**2}$             |
|                   | <b>n</b> : int                   | Degree                                                  |
|                   | <b>s</b> : float                 | Coordinate                                              |
|                   | <b>p</b> : int                   | Order, can range between $[1, 2n+1]$                    |
|                   | <b>signm</b> : {1, -1}, optional | Sign of prefactor of functions. Can be +/-1. See Notes. |
|                   | <b>signn</b> : {1, -1}, optional | Sign of prefactor of functions. Can be +/-1. See Notes. |
| <b>Returns</b>    | <b>E</b> : float                 | the harmonic $E^p_n(s)$                                 |

**See also:**

`ellip_harm_2`, `ellip_normal`

**Notes**

The geometric interpretation of the ellipsoidal functions is explained in [R399], [R400], [R401]. The *signm* and *signn* arguments control the sign of prefactors for functions according to their type:

K : +1  
 L : signm  
 M : signn  
 N : signm\*signn

New in version 0.15.0.

### Examples

```
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5, 8, 1, 1, 2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lamé equation:

```
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
...     r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 - k**2)*df - n*(n+1)*s**2*f)/f
...     return -r.mean(), r.std()
>>> s = np.linspace(0.1, 10, 200)
>>> k, h, n, p = 8.0, 2.2, 3, 2
>>> E = ellip_harm(h**2, k**2, n, p, s)
>>> E_spl = UnivariateSpline(s, E)
>>> a, a_err = eigenvalue(E_spl(s), E_spl(s,1), E_spl(s,2))
>>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

`scipy.special.ellip_harm_2` (*h2*, *k2*, *n*, *p*, *s*)  
 Ellipsoidal harmonic functions  $F^p_n(l)$

These are also known as Lamé functions of the second kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

|                   |                   |                                             |
|-------------------|-------------------|---------------------------------------------|
| <b>Parameters</b> | <b>h2</b> : float | $h^{**2}$                                   |
|                   | <b>k2</b> : float | $k^{**2}$ ; should be larger than $h^{**2}$ |
|                   | <b>n</b> : int    | Degree.                                     |
|                   | <b>p</b> : int    | Order, can range between $[1, 2n+1]$ .      |
|                   | <b>s</b> : float  | Coordinate                                  |
| <b>Returns</b>    | <b>F</b> : float  | The harmonic $F^p_n(s)$                     |

### See also:

`ellip_harm`, `ellip_normal`

### Notes

Lamé functions of the second kind are related to the functions of the first kind:

$$F^p_n(s) = (2n + 1)E^p_n(s) \int_0^{1/s} \frac{du}{(E^p_n(1/u))^2 \sqrt{(1 - u^2k^2)(1 - u^2h^2)}}$$

New in version 0.15.0.

### Examples

```
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5, 8, 2, 1, 10)
>>> w
0.00108056853382
```

`scipy.special.ellip_normal(h2, k2, n, p)`  
Ellipsoidal harmonic normalization constants  $\gamma_n^p$

The normalization constant is defined as

$$\gamma_n^p = 8 \int_0^h dx \int_h^k dy \frac{(y^2 - x^2)(E_n^p(y)E_n^p(x))^2}{\sqrt{((k^2 - y^2)(y^2 - h^2)(h^2 - x^2)(k^2 - x^2))}}$$

**Parameters**

- h2** : float  
h\*\*2
- k2** : float  
k\*\*2; should be larger than h\*\*2
- n** : int  
Degree.
- p** : int  
Order, can range between [1,2n+1].

**Returns**

- gamma** : float  
The normalization constant  $\gamma_n^p$

**See also:**

`ellip_harm`, `ellip_harm_2`

**Notes**

New in version 0.15.0.

**Examples**

```
>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5, 8, 3, 7)
>>> w
1723.38796997
```

## Orthogonal polynomials

The following functions evaluate values of orthogonal polynomials:

|                                                    |                                                                                   |

`scipy.special.assoc_laguerre(x, n, k=0.0)`

Compute the generalized (associated) Laguerre polynomial of degree  $n$  and order  $k$ .

The polynomial  $L_n^{(k)}(x)$  is orthogonal over  $[0, \infty)$ , with weighting function  $\exp(-x) * x^{**k}$  with  $k > -1$ .

**Notes**

`assoc_laguerre` is a simple wrapper around `eval_genlaguerre`, with reversed argument order  $(x, n, k=0.0) \rightarrow (n, k, x)$ .

`scipy.special.eval_legendre(n, x, out=None) = <ufunc 'eval_legendre'>`

Evaluate Legendre polynomial at a point.

The Legendre polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$P_n(x) = {}_2F_1(-n, n + 1; 1; (1 - x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
 Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**x** : array\_like  
 Points at which to evaluate the Legendre polynomial

**Returns** **P** : ndarray  
 Values of the Legendre polynomial

`scipy.special.eval_chebyt(n, x, out=None) = <ufunc 'eval_chebyt'>`

Evaluate Chebyshev polynomial of the first kind at a point.

The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$T_n(x) = {}_2F_1(n, -n; 1/2; (1 - x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
 Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**x** : array\_like  
 Points at which to evaluate the Chebyshev polynomial

**Returns** **T** : ndarray  
 Values of the Chebyshev polynomial

`scipy.special.eval_hermite` ( $n, x, out=None$ ) = <ufunc 'eval\_hermite'>

Evaluate physicist's Hermite polynomial at a point.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
Degree of the polynomial

**x** : array\_like  
Points at which to evaluate the Hermite polynomial

**Returns** **H** : ndarray  
Values of the Hermite polynomial

evaluate Probabilist's Hermite polynomials

`scipy.special.eval_hermitenorm(n, x, out=None) = <ufunc 'eval_hermitenorm'>`

Evaluate probabilist's (normalized) Hermite polynomial at a point.

Defined by

$$H e_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$H e_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
Degree of the polynomial

**x** : array\_like  
Points at which to evaluate the Hermite polynomial

**Returns** **He** : ndarray  
Values of the Hermite polynomial

`scipy.special.eval_gegenbauer(n, alpha, x, out=None) = <ufunc 'eval_gegenbauer'>`

Evaluate Gegenbauer polynomial at a point.

The Gegenbauer polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$C_n^{(\alpha)} = \frac{(2\alpha)_n}{\Gamma(n+1)} {}_2F_1(-n, 2\alpha+n; \alpha+1/2; (1-z)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters** **n** : array\_like  
Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**alpha** : array\_like  
Parameter

**Returns** **x** : array\_like Points at which to evaluate the Gegenbauer polynomial  
**C** : ndarray Values of the Gegenbauer polynomial

`scipy.special.eval_sh_legendre` (*n*, *x*, *out=None*) = <ufunc 'eval\_sh\_legendre'>  
 Evaluate shifted Legendre polynomial at a point.

These polynomials are defined as

$$P_n^*(x) = P_n(2x - 1)$$

where  $P_n$  is a Legendre polynomial.

**Parameters** **n** : array\_like Degree of the polynomial. If not an integer, the value is determined via the relation to `eval_legendre`.  
**x** : array\_like Points at which to evaluate the shifted Legendre polynomial  
**Returns** **P** : ndarray Values of the shifted Legendre polynomial

`scipy.special.eval_sh_chebyt` (*n*, *x*, *out=None*) = <ufunc 'eval\_sh\_chebyt'>  
 Evaluate shifted Chebyshev polynomial of the first kind at a point.

These polynomials are defined as

$$T_n^*(x) = T_n(2x - 1)$$

where  $T_n$  is a Chebyshev polynomial of the first kind.

**Parameters** **n** : array\_like Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.  
**x** : array\_like Points at which to evaluate the shifted Chebyshev polynomial  
**Returns** **T** : ndarray Values of the shifted Chebyshev polynomial

`numpy.polynomial.chebyshev.Chebyshev`

Chebyshev series

`scipy.special.eval_sh_chebyu(n, x, out=None) = <ufunc 'eval_sh_chebyu'>`

Evaluate shifted Chebyshev polynomial of the second kind at a point.

These polynomials are defined as

$$U_n^*(x) = U_n(2x - 1)$$

where  $U_n$  is a Chebyshev polynomial of the first kind.

**Parameters** `n` : array\_like

Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyu`.

`x` : array\_like

**Returns** `U` : ndarray Points at which to evaluate the shifted Chebyshev polynomial

Values of the shifted Chebyshev polynomial

See also:

`roots_sh_chebyu`

`sh_chebyu` shifted Chebyshev polynomial object

`eval_chebyu`

evaluate Chebyshev polynomials of the second kind

`scipy.special.eval_sh_jacobi(n, p, q, x, out=None) = <ufunc 'eval_sh_jacobi'>`

Evaluate shifted Jacobi polynomial at a point.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the n-th Jacobi polynomial.

**Parameters** `n` : int

Degree of the polynomial. If not an integer, the result is determined via the relation to `binom` and `eval_jacobi`.

`p` : float

Parameter

`q` : float

Parameter

**Returns** `G` : ndarray

Values of the shifted Jacobi polynomial.

`scipy.special.roots_legendre(n, mu=False)`

Gauss-Legendre quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the  $n$ -th degree Legendre polynomial  $P_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = 1.0$ .

**Parameters**

- n** : int  
quadrature order
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`,  
`numpy.polynomial.legendre.leggauss`

`scipy.integrate.fixed_quad`,

`scipy.special.roots_chebyt(n, mu=False)`

Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree Chebyshev polynomial of the first kind,  $T_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = 1/\sqrt{1 - x^2}$ .

**Parameters**

- n** : int  
quadrature order
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`,  
`numpy.polynomial.chebyshev.chebgauss`

`scipy.special.roots_chebyu` ( $n, mu=False$ )

Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree Chebyshev polynomial of the second kind,  $U_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = \sqrt{1 - x^2}$ .

**Parameters** **n** : int  
 quadrature order  
**mu** : bool, optional  
 If True, return the sum of the weights, optional.

**Returns** **x** : ndarray  
 Sample points  
**w** : ndarray  
 Weights  
**mu** : float  
 Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_chebyc` ( $n, mu=False$ )

Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree Chebyshev polynomial of the first kind,  $C_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-2, 2]$  with weight function  $f(x) = 1/\sqrt{1 - (x/2)^2}$ .

**Parameters** **n** : int  
 quadrature order  
**mu** : bool, optional  
 If True, return the sum of the weights, optional.

**Returns** **x** : ndarray  
 Sample points  
**w** : ndarray  
 Weights  
**mu** : float  
 Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_chebys` ( $n, mu=False$ )

Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree Chebyshev polynomial of the second kind,  $S_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-2, 2]$  with weight function  $f(x) = \sqrt{1 - (x/2)^2}$ .

**Parameters** **n** : int  
 quadrature order  
**mu** : bool, optional  
 If True, return the sum of the weights, optional.

**Returns** **x** : ndarray  
 Sample points

**w** : ndarray  
Weights  
**mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_jacobi` (*n*, *alpha*, *beta*, *mu=False*)  
Gauss-Jacobi quadrature.

Computes the sample points and weights for Gauss-Jacobi quadrature. The sample points are the roots of the *n*-th degree Jacobi polynomial,  $P_n^{\alpha,\beta}(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = (1 - x)^\alpha(1 + x)^\beta$ .

**Parameters**

- n** : int  
quadrature order
- alpha** : float  
alpha must be > -1
- beta** : float  
beta must be > 0
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_laguerre` (*n*, *mu=False*)  
Gauss-Laguerre quadrature.

Computes the sample points and weights for Gauss-Laguerre quadrature. The sample points are the roots of the *n*-th degree Laguerre polynomial,  $L_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, \infty]$  with weight function  $f(x) = e^{-x}$ .

**Parameters**

- n** : int  
quadrature order
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`,  
`numpy.polynomial.laguerre.laggauss`

`scipy.special.roots_genlaguerre` (*n*, *alpha*, *mu=False*)  
Gauss-generalized Laguerre quadrature.

Computes the sample points and weights for Gauss-generalized Laguerre quadrature. The sample points are the roots of the  $n$ -th degree generalized Laguerre polynomial,  $L_n^\alpha(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, \infty]$  with weight function  $f(x) = x^\alpha e^{-x}$ .

**Parameters**

- n** : int  
quadrature order
- alpha** : float  
alpha must be  $> -1$
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

`scipy.special.roots_hermite` ( $n, mu=False$ )

Gauss-Hermite (physicist's) quadrature.

Computes the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the  $n$ -th degree Hermite polynomial,  $H_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-\infty, \infty]$  with weight function  $f(x) = e^{-x^2}$ .

**Parameters**

- n** : int  
quadrature order
- mu** : bool, optional  
If True, return the sum of the weights, optional.

**Returns**

- x** : ndarray  
Sample points
- w** : ndarray  
Weights
- mu** : float  
Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`,  
`numpy.polynomial.hermite.hermgauss`, `roots_hermitenorm`

**Notes**

For small  $n$  up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For  $n$  larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large  $n$  (several thousand or more) feasible.

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

The functions below, in turn, return the polynomial coefficients in `orthopoly1d` objects, which function similarly as `numpy.poly1d`. The `orthopoly1d` class also has an attribute `weights` which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an  $n \times 3$  array with roots in the first column, weights in the second column, and total weights in the final column. Note that `orthopoly1d` objects are converted to `poly1d` when doing arithmetic, and lose information of the original orthogonal polynomial.

`scipy.special.legendre(n, monic=False)`

Legendre polynomial.

Defined to be the solution of

$$\frac{d}{dx} \left[ (1 - x^2) \frac{d}{dx} P_n(x) \right] + n(n + 1)P_n(x) = 0;$$

$P_n(x)$  is a polynomial of degree  $n$ .

**Parameters**

- n** : int  
Degree of the polynomial.

**Returns** **monic** : bool, optional  
**P** : orthopoly1d If *True*, scale the leading coefficient to be 1. Default is *False*.  
Legendre polynomial.

**Notes**

The polynomials  $P_n$  are orthogonal over  $[-1, 1]$  with weight function 1.

**Examples**

Generate the 3rd-order Legendre polynomial  $1/2*(5x^3 + 0x^2 - 3x + 0)$ :

```
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([ 2.5,  0. , -1.5,  0. ])
```

`scipy.special.chebyt` (*n*, *monic=False*)  
Chebyshev polynomial of the first kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} T_n - x \frac{d}{dx} T_n + n^2 T_n = 0;$$

$T_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns** **T** : orthopoly1d  
Chebyshev polynomial of the first kind.

**See also:**

[\*chebyu\*](#) Chebyshev polynomial of the second kind.

**Notes**

The polynomials  $T_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{-1/2}$ .

`scipy.special.chebyu` (*n*, *monic=False*)  
Chebyshev polynomial of the second kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} U_n - 3x \frac{d}{dx} U_n + n(n + 2) U_n = 0;$$

$U_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns** **U** : orthopoly1d  
Chebyshev polynomial of the second kind.

**See also:**

[\*chebyt\*](#) Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $U_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{1/2}$ .

`scipy.special.chebyc` ( $n$ , *monic=False*)

Chebyshev polynomial of the first kind on  $[-2, 2]$ .

Defined as  $C_n(x) = 2T_n(x/2)$ , where  $T_n$  is the  $n$ th Chebychev polynomial of the first kind.

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **C** : orthopoly1d  
Chebyshev polynomial of the first kind on  $[-2, 2]$ .

**See also:**

`chebyt` Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $C_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $1/\sqrt{1 - (x/2)^2}$ .

**References**

[R390]

`scipy.special.chebys` ( $n$ , *monic=False*)

Chebyshev polynomial of the second kind on  $[-2, 2]$ .

Defined as  $S_n(x) = U_n(x/2)$  where  $U_n$  is the  $n$ th Chebychev polynomial of the second kind.

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **S** : orthopoly1d  
Chebyshev polynomial of the second kind on  $[-2, 2]$ .

**See also:**

`chebyu` Chebyshev polynomial of the second kind

**Notes**

The polynomials  $S_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $\sqrt{1 - (x/2)^2}$ .

**References**

[R391]

`scipy.special.jacobi` ( $n$ , *alpha*, *beta*, *monic=False*)

Jacobi polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} P_n^{(\alpha, \beta)} + (\beta - \alpha - (\alpha + \beta + 2)x) \frac{d}{dx} P_n^{(\alpha, \beta)} + n(n + \alpha + \beta + 1) P_n^{(\alpha, \beta)} = 0$$

for  $\alpha, \beta > -1$ ;  $P_n^{(\alpha, \beta)}$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.

**alpha** : float  
Parameter, must be greater than -1.

**beta** : float  
Parameter, must be greater than -1.

**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **P** : orthopoly1d  
Jacobi polynomial.

**Notes**

For fixed  $\alpha, \beta$ , the polynomials  $P_n^{(\alpha, \beta)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1-x)^\alpha(1+x)^\beta$ .

`scipy.special.laguerre` (*n*, *monic=False*)

Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n + (1-x) \frac{d}{dx} L_n + n L_n = 0;$$

$L_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.

**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **L** : orthopoly1d  
Laguerre Polynomial.

**Notes**

The polynomials  $L_n$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}$ .

`scipy.special.genlaguerre` (*n*, *alpha*, *monic=False*)

Generalized (associated) Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n^{(\alpha)} + (\alpha + 1 - x) \frac{d}{dx} L_n^{(\alpha)} + n L_n^{(\alpha)} = 0,$$

where  $\alpha > -1$ ;  $L_n^{(\alpha)}$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.

**alpha** : float  
Parameter, must be greater than -1.

**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **L** : orthopoly1d  
Generalized Laguerre polynomial.

**See also:**

[laguerre](#) Laguerre polynomial.

**Notes**

For fixed  $\alpha$ , the polynomials  $L_n^{(\alpha)}$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x} x^\alpha$ .

The Laguerre polynomials are the special case where  $\alpha = 0$ .

`scipy.special.hermite` (*n*, *monic=False*)

Physicist's Hermite polynomial.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **H** : orthopoly1d  
Hermite polynomial.

#### Notes

The polynomials  $H_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2}$ .

`scipy.special.hermite` (*n*, *monic=False*)

Normalized (probabilist's) Hermite polynomial.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **He** : orthopoly1d  
Hermite polynomial.

#### Notes

The polynomials  $He_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2/2}$ .

`scipy.special.gegenbauer` (*n*, *alpha*, *monic=False*)

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} C_n^{(\alpha)} - (2\alpha + 1)x \frac{d}{dx} C_n^{(\alpha)} + n(n + 2\alpha) C_n^{(\alpha)} = 0$$

for  $\alpha > -1/2$ ;  $C_n^{(\alpha)}$  is a polynomial of degree  $n$ .

**Parameters** **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns** **C** : orthopoly1d  
Gegenbauer polynomial.

**Notes**

The polynomials  $C_n^{(\alpha)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{(\alpha-1/2)}$ .

`scipy.special.sh_legendre` (*n*, *monic=False*)  
Shifted Legendre polynomial.

Defined as  $P_n^*(x) = P_n(2x - 1)$  for  $P_n$  the *n*th Legendre polynomial.

**Parameters**    **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns**        **P** : orthopoly1d  
Shifted Legendre polynomial.

**Notes**

The polynomials  $P_n^*$  are orthogonal over  $[0, 1]$  with weight function 1.

`scipy.special.sh_chebyt` (*n*, *monic=False*)  
Shifted Chebyshev polynomial of the first kind.

Defined as  $T_n^*(x) = T_n(2x - 1)$  for  $T_n$  the *n*th Chebyshev polynomial of the first kind.

**Parameters**    **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns**        **T** : orthopoly1d  
Shifted Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $T_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{-1/2}$ .

`scipy.special.sh_chebyu` (*n*, *monic=False*)  
Shifted Chebyshev polynomial of the second kind.

Defined as  $U_n^*(x) = U_n(2x - 1)$  for  $U_n$  the *n*th Chebyshev polynomial of the second kind.

**Parameters**    **n** : int  
Degree of the polynomial.  
**monic** : bool, optional  
If *True*, scale the leading coefficient to be 1. Default is *False*.  
**Returns**        **U** : orthopoly1d  
Shifted Chebyshev polynomial of the second kind.

**Notes**

The polynomials  $U_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{1/2}$ .

`scipy.special.sh_jacobi` (*n*, *p*, *q*, *monic=False*)  
Shifted Jacobi polynomial.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q,q-1)}(2x-1),$$

where  $P_n^{(\cdot,\cdot)}$  is the *n*th Jacobi polynomial.

**Parameters**    **n** : int

|                |                               |                                                                                                                 |
|----------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------|
|                | <b>p</b> : float              | Degree of the polynomial.                                                                                       |
|                | <b>q</b> : float              | Parameter, must have $p > q - 1$ .                                                                              |
|                | <b>monic</b> : bool, optional | Parameter, must be greater than 0.                                                                              |
| <b>Returns</b> | <b>G</b> : orthopoly1d        | If <i>True</i> , scale the leading coefficient to be 1. Default is <i>False</i> .<br>Shifted Jacobi polynomial. |

**Notes**

For fixed  $p, q$ , the polynomials  $G_n^{(p,q)}$  are orthogonal over  $[0, 1]$  with weight function  $(1-x)^{p-q}x^{q-1}$ .

**Warning:** Computing values of high-order polynomials (around `order > 20`) using polynomial coefficients is numerically unstable. To evaluate polynomial values, the `eval_*` functions should be used instead.

**Hypergeometric Functions**

|                                    |                                                                   |
|------------------------------------|-------------------------------------------------------------------|
| <code>hyp2f1(a, b, c, z)</code>    | Gauss hypergeometric function ${}_2F_1(a, b; c; z)$ .             |
| <code>hyp1f1(a, b, x)</code>       | Confluent hypergeometric function ${}_1F_1(a, b; x)$              |
| <code>hyperu(a, b, x)</code>       | Confluent hypergeometric function $U(a, b, x)$ of the second kind |
| <code>hyp0f1(v, x)</code>          | Confluent hypergeometric limit function ${}_0F_1$ .               |
| <code>hyp2f0(a, b, x, type)</code> | Hypergeometric function ${}_2F_0$ in $y$ and an error estimate    |
| <code>hyp1f2(a, b, c, x)</code>    | Hypergeometric function ${}_1F_2$ and error estimate              |
| <code>hyp3f0(a, b, c, x)</code>    | Hypergeometric function ${}_3F_0$ in $y$ and an error estimate    |

`scipy.special.hyp2f1(a, b, c, z) = <ufunc 'hyp2f1'>`

Gauss hypergeometric function  ${}_2F_1(a, b; c; z)$ .

`scipy.special.hyp1f1(a, b, x) = <ufunc 'hyp1f1'>`

Confluent hypergeometric function  ${}_1F_1(a, b; x)$

`scipy.special.hyperu(a, b, x) = <ufunc 'hyperu'>`

Confluent hypergeometric function  $U(a, b, x)$  of the second kind

`scipy.special.hyp0f1(v, x) = <ufunc 'hyp0f1'>`

Confluent hypergeometric limit function  ${}_0F_1$ .

**Parameters** **v, z** : array\_like

**Returns** **hyp0f1** : ndarray

Input values.

The confluent hypergeometric limit function.

**Notes**

This function is defined as:

$${}_0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.$$

It's also the limit as  $q \rightarrow \infty$  of  ${}_1F_1(q; v; z/q)$ , and satisfies the differential equation  $f''(z) + v f'(z) = f(z)$ .

`scipy.special.hyp2f0(a, b, x, type) = <ufunc 'hyp2f0'>`

Hypergeometric function  ${}_2F_0$  in  $y$  and an error estimate

The parameter *type* determines a convergence factor and can be either 1 or 2.

**Returns** y Value of the function  
 err Error estimate

`scipy.special.hyp1f2(a, b, c, x) = <ufunc 'hyp1f2'>`  
 Hypergeometric function 1F2 and error estimate

**Returns** y Value of the function  
 err Error estimate

`scipy.special.hyp3f0(a, b, c, x) = <ufunc 'hyp3f0'>`  
 Hypergeometric function 3F0 in y and an error estimate

**Returns** y Value of the function  
 err Error estimate

### Parabolic Cylinder Functions

|                         |                               |
|-------------------------|-------------------------------|
| <code>pbdv(v, x)</code> | Parabolic cylinder function D |
| <code>pbvv(v, x)</code> | Parabolic cylinder function V |
| <code>pbwa(a, x)</code> | Parabolic cylinder function W |

`scipy.special.pbdv(v, x) = <ufunc 'pbdv'>`  
 Parabolic cylinder function D

Returns (d, dp) the parabolic cylinder function  $Dv(x)$  in d and the derivative,  $Dv'(x)$  in dp.

**Returns** d Value of the function  
 dp Value of the derivative vs x

`scipy.special.pbvv(v, x) = <ufunc 'pbvv'>`  
 Parabolic cylinder function V

Returns the parabolic cylinder function  $Vv(x)$  in v and the derivative,  $Vv'(x)$  in vp.

**Returns** v Value of the function  
 vp Value of the derivative vs x

`scipy.special.pbwa(a, x) = <ufunc 'pbwa'>`  
 Parabolic cylinder function W

Returns the parabolic cylinder function  $W(a, x)$  in w and the derivative,  $W'(a, x)$  in wp.

**Warning:** May not be accurate for large (>5) arguments in a and/or x.

**Returns** w Value of the function  
 wp Value of the derivative vs x

These are not universal functions:

|                             |                                                       |
|-----------------------------|-------------------------------------------------------|
| <code>pbdv_seq(v, x)</code> | Parabolic cylinder functions $Dv(x)$ and derivatives. |
| <code>pbvv_seq(v, x)</code> | Parabolic cylinder functions $Vv(x)$ and derivatives. |
| <code>pbdn_seq(n, z)</code> | Parabolic cylinder functions $Dn(z)$ and derivatives. |

`scipy.special.pbdv_seq(v, x)`  
Parabolic cylinder functions  $Dv(x)$  and derivatives.

**Parameters**

- v** : float  
Order of the parabolic cylinder function
- x** : float  
Value at which to evaluate the function and derivatives

**Returns**

- dv** : ndarray  
Values of  $D_{vi}(x)$ , for  $vi=v-int(v)$ ,  $vi=1+v-int(v)$ , ...,  $vi=v$ .
- dp** : ndarray  
Derivatives  $D_{vi}'(x)$ , for  $vi=v-int(v)$ ,  $vi=1+v-int(v)$ , ...,  $vi=v$ .

**References**

[R505]

`scipy.special.pbvv_seq(v, x)`  
Parabolic cylinder functions  $Vv(x)$  and derivatives.

**Parameters**

- v** : float  
Order of the parabolic cylinder function
- x** : float  
Value at which to evaluate the function and derivatives

**Returns**

- dv** : ndarray  
Values of  $V_{vi}(x)$ , for  $vi=v-int(v)$ ,  $vi=1+v-int(v)$ , ...,  $vi=v$ .
- dp** : ndarray  
Derivatives  $V_{vi}'(x)$ , for  $vi=v-int(v)$ ,  $vi=1+v-int(v)$ , ...,  $vi=v$ .

**References**

[R506]

`scipy.special.pbdn_seq(n, z)`  
Parabolic cylinder functions  $Dn(z)$  and derivatives.

**Parameters**

- n** : int  
Order of the parabolic cylinder function
- z** : complex  
Value at which to evaluate the function and derivatives

**Returns**

- dv** : ndarray  
Values of  $D_i(z)$ , for  $i=0$ , ...,  $i=n$ .
- dp** : ndarray  
Derivatives  $D_i'(z)$ , for  $i=0$ , ...,  $i=n$ .

**Mathieu and Related Functions**

|                              |                                                |
|------------------------------|------------------------------------------------|
| <code>mathieu_a(m, q)</code> | Characteristic value of even Mathieu functions |
|------------------------------|------------------------------------------------|

Continued on next page

Table 5.263 – continued from previous page

---

`mathieu_b(m, q)` Characteristic value of odd Mathieu functions

---

`scipy.special.mathieu_a(m, q) = <ufunc 'mathieu_a'>`

Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution,  $ce_m(z, q)$ , of Mathieu's equation.

`scipy.special.mathieu_b(m, q) = <ufunc 'mathieu_b'>`

Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution,  $se_m(z, q)$ , of Mathieu's equation.

These are not universal functions:

---

`mathieu_even_coef(m, q)` Fourier coefficients for even Mathieu and modified Mathieu functions.  
`mathieu_odd_coef(m, q)` Fourier coefficients for even Mathieu and modified Mathieu functions.

---

`scipy.special.mathieu_even_coef(m, q)`

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

$$ce_{2n}(z, q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz$$

$$ce_{2n+1}(z, q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k+1)z$$

This function returns the coefficients  $A_{(2n)}^{(2k)}$  for even input  $m=2n$ , and the coefficients  $A_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

**Parameters** **m** : int

Order of Mathieu functions. Must be non-negative.

**q** : float ( $\geq 0$ )

Parameter of Mathieu functions. Must be non-negative.

**Returns** **Ak** : ndarray

Even or odd Fourier coefficients, corresponding to even or odd  $m$ .

### References

[R490], [R491]

`scipy.special.mathieu_odd_coef(m, q)`

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

$$se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k+1)z$$

$$se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k+2)z$$

This function returns the coefficients  $B_{(2n+2)}^{(2k+2)}$  for even input  $m=2n+2$ , and the coefficients  $B_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

|                   | <b>q</b>  | Parameter of the function                                        |
|                   | <b>x</b>  | Argument of the function, <i>given in degrees, not radians</i> . |
| <b>Returns</b>    | <b>y</b>  | Value of the function                                            |
|                   | <b>yp</b> | Value of the derivative vs $x$                                   |

`scipy.special.mathieu_modcem1(m, q, x) = <ufunc 'mathieu_modcem1'>`

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind,  $Mc1m(x, q)$ , and its derivative at  $x$  for order  $m$  and parameter  $q$ .

**Returns**     y                             Value of the function  
                   yP                         Value of the derivative vs x

`scipy.special.mathieu_modcem2(m, q, x) = <ufunc 'mathieu_modcem2'>`

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind,  $Mc2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**     y                             Value of the function  
                   yP                         Value of the derivative vs x

`scipy.special.mathieu_modsem1(m, q, x) = <ufunc 'mathieu_modsem1'>`

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind,  $Ms1m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**     y                             Value of the function  
                   yP                         Value of the derivative vs x

`scipy.special.mathieu_modsem2(m, q, x) = <ufunc 'mathieu_modsem2'>`

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind,  $Ms2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**     y                             Value of the function  
                   yP                         Value of the derivative vs x

---

`scipy.special.pro_ang1(m, n, c, x) = <ufunc 'pro_ang1'>`

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**     s

Value of the function  
 sp Value of the derivative vs x

`scipy.special.pro_rad1(m, n, c, x) = <ufunc 'pro_rad1'>`  
 Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns** s Value of the function  
 sp Value of the derivative vs x

`scipy.special.pro_rad2(m, n, c, x) = <ufunc 'pro_rad2'>`  
 Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns** s Value of the function  
 sp Value of the derivative vs x

`scipy.special.obl_ang1(m, n, c, x) = <ufunc 'obl_ang1'>`  
 Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns** s Value of the function  
 sp Value of the derivative vs x

`scipy.special.obl_rad1(m, n, c, x) = <ufunc 'obl_rad1'>`  
 Oblate spheroidal radial function of the first kind and its derivative

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns** s Value of the function  
 sp Value of the derivative vs x

`scipy.special.obl_rad2(m, n, c, x) = <ufunc 'obl_rad2'>`  
 Oblate spheroidal radial function of the second kind and its derivative.

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns** s Value of the function  
 sp Value of the derivative vs x

`scipy.special.pro_cv(m, n, c) = <ufunc 'pro_cv'>`  
 Characteristic value of prolate spheroidal function

Computes the characteristic value of prolate spheroidal wave functions of order  $m$ ,  $n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

`scipy.special.obl_cv(m, n, c) = <ufunc 'obl_cv'>`

Characteristic value of oblate spheroidal function

Computes the characteristic value of oblate spheroidal wave functions of order  $m$ ,  $n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

`scipy.special.pro_cv_seq(m, n, c)`

Characteristic values for prolate spheroidal wave functions.

Compute a sequence of characteristic values for the prolate spheroidal wave functions for mode  $m$  and  $n' = m..n$  and spheroidal parameter  $c$ .

**References**

[R507]

`scipy.special.obl_cv_seq(m, n, c)`

Characteristic values for oblate spheroidal wave functions.

Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode  $m$  and  $n' = m..n$  and spheroidal parameter  $c$ .

**References**

[R503]

`scipy.special.kelvin(x) = <ufunc 'kelvin'>`

Kelvin functions as complex numbers

**Returns** Be, Ke, Bep, Kep

The tuple (Be, Ke, Bep, Kep) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at  $x$ . For example, `kelvin(x)[0].real = ber x` and `kelvin(x)[0].imag = bei x` with similar relationships for `ker` and `kei`.

`scipy.special.kelvin_zeros(nt)`

Compute `nt` zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length `nt`. The tuple contains the arrays of zeros of (`ber`, `bei`, `ker`, `kei`, `ber'`, `bei'`, `ker'`, `kei'`).

## Combinatorics

---

|                                              |                                                                                                      |
|----------------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>comb(N, k[, exact, repetition])</code> | The number of combinations of <i>N</i> things taken <i>k</i> at a time.                              |
| <code>perm(N, k[, exact])</code>             | Permutations of <i>N</i> things taken <i>k</i> at a time, i.e., <i>k</i> -permutations of <i>N</i> . |

---

`scipy.special.comb` (*N, k, exact=False, repetition=False*)  
 The number of combinations of *N* things taken *k* at a time.

This is often expressed as “N choose k”.

**Parameters**

- N** : int, ndarray  
Number of things.
- k** : int, ndarray  
Number of elements taken.
- exact** : bool, optional  
If *exact* is False, then floating point precision is used, otherwise exact long integer is computed.
- repetition** : bool, optional  
If *repetition* is True, then the number of combinations with repetition is computed.

**Returns**

- val** : int, ndarray  
The total number of combinations.

**See also:**

[`binom`](#) Binomial coefficient ufunc

**Notes**

- Array arguments accepted only for `exact=False` case.
- If  $k > N$ ,  $N < 0$ , or  $k < 0$ , then a 0 is returned.

**Examples**

```
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([ 120.,  210.])
>>> comb(10, 3, exact=True)
120L
>>> comb(10, 3, exact=True, repetition=True)
220L
```

`scipy.special.perm(N, k, exact=False)`  
Permutations of N things taken k at a time, i.e., k-permutations of N.

It’s also known as “partial permutations”.

**Parameters**

- N** : int, ndarray  
Number of things.
- k** : int, ndarray  
Number of elements taken.
- exact** : bool, optional  
If *exact* is False, then floating point precision is used, otherwise exact long integer is computed.

**Returns**

- val** : int, ndarray  
The number of k-permutations of N.

**Notes**

- Array arguments accepted only for `exact=False` case.
- If  $k > N$ ,  $N < 0$ , or  $k < 0$ , then a 0 is returned.

**Examples**

```
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([ 720., 5040.])
>>> perm(10, 3, exact=True)
720
```

---

`scipy.special.agm(a, b)`

Arithmetic, Geometric Mean.

Start with  $a_0=a$  and  $b_0=b$  and iteratively compute

$$a_{n+1} = (a_n + b_n) / 2 \quad b_{n+1} = \sqrt{a_n b_n}$$

until  $a_n = b_n$ . The result is `agm(a, b)`

$$\text{agm}(a, b) = \text{agm}(b, a) \quad \text{agm}(a, a) = a \quad \min(a, b) < \text{agm}(a, b) < \max(a, b)$$

`scipy.special.bernoulli(n)`

Bernoulli numbers B<sub>0</sub>..B<sub>n</sub> (inclusive).

### References

[R381]

`scipy.special.binom(n, k) = <ufunc 'binom'>`

Binomial coefficient

See also:

*comb*      The number of combinations of N things taken k at a time.

`scipy.special.diric(x, n)`

Periodic sinc function, also called the Dirichlet function.

The Dirichlet function is defined as:

$$\text{diric}(x) = \frac{\sin(x * n/2)}{(n * \sin(x / 2))},$$

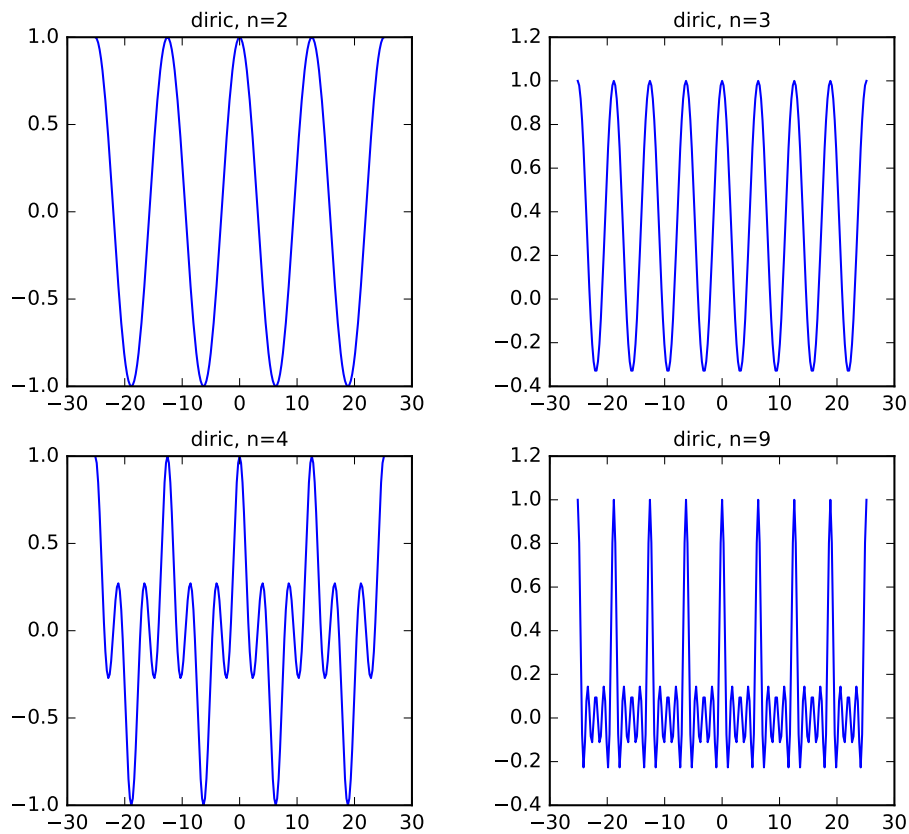

where  $n$  is a positive integer.

**Parameters**    **x** : array\_like      Input data  
                  **n** : int  
**Returns**        **diric** : ndarray      Integer defining the periodicity.

### Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-8*np.pi, 8*np.pi, num=201)
>>> plt.figure(figsize=(8, 8));
>>> for idx, n in enumerate([2, 3, 4, 9]):
...     plt.subplot(2, 2, idx+1)
...     plt.plot(x, special.diric(x, n))
...     plt.title('diric, n={}'.format(n))
>>> plt.show()
```

The following example demonstrates that `diric` gives the magnitudes (modulo the sign and scaling) of the Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```
>>> np.set_printoptions(suppress=True)
```

Create a signal  $x$  of length  $m$  with  $k$  ones:

```
>>> m = 8
>>> k = 3
>>> x = np.zeros(m)
>>> x[:k] = 1
```

Use the FFT to compute the Fourier transform of  $x$ , and inspect the magnitudes of the coefficients:

```
>>> np.abs(np.fft.fft(x))
array([ 3.          ,  2.41421356,  1.          ,  0.41421356,  1.          ,
        0.41421356,  1.          ,  2.41421356])
```

Now find the same values (up to sign) using `diric`. We multiply by  $k$  to account for the different scaling conventions of `numpy.fft.fft` and `diric`:

```
>>> theta = np.linspace(0, 2*np.pi, m, endpoint=False)
>>> k * special.diric(theta, k)
array([ 3.          ,  2.41421356,  1.          , -0.41421356, -1.          ,
       -0.41421356,  1.          ,  2.41421356])
```

`scipy.special.euler` ( $n$ )  
Euler numbers  $E_0..E_n$  (inclusive).

### References

[R414]

`scipy.special.expn` ( $n, x$ ) = <ufunc 'expn'>  
Exponential integral  $E_n$

Returns the exponential integral for integer  $n$  and non-negative  $x$  and  $n$ :

```
integral(exp(-x*t) / t**n, t=1..inf).
```

`scipy.special.exp1` ( $z$ ) = <ufunc 'exp1'>  
Exponential integral  $E_1$  of complex argument  $z$

```
integral(exp(-z*t)/t, t=1..inf).
```

`scipy.special.expi` ( $x$ ) = <ufunc 'expi'>  
Exponential integral  $E_i$

Defined as:

```
integral(exp(t)/t, t=-inf..x)
```

See `expn` for a different exponential integral.

`scipy.special.factorial` ( $n$ , *exact=False*)  
The factorial of a number or array of numbers.

The factorial of non-negative integer  $n$  is the product of all positive integers less than or equal to  $n$ :

```
n! = n * (n - 1) * (n - 2) * ... * 1
```

|                   |                                                                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <p><b>n</b> : int or array_like of ints<br/>Input values. If <math>n &lt; 0</math>, the return value is 0.</p> <p><b>exact</b> : bool, optional<br/>If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the <code>gamma</code> function.</p> |
| <b>Returns</b>    | <p><b>nf</b> : float or int or ndarray<br/>Default is False.<br/>Factorial of <math>n</math>, as integer or float depending on <i>exact</i>.</p>                                                                                                                                                                               |

### Notes

For arrays with `exact=True`, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to `int64` or `object` if necessary.

With `exact=False` the factorial is approximated using the gamma function:

$$n! = \Gamma(n + 1)$$

### Examples

```
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([  6.,  24., 120.])
>>> factorial(arr, exact=True)
array([  6,  24, 120])
>>> factorial(5, exact=True)
120L
```

`scipy.special.factorial2` (*n*, *exact=False*)

Double factorial.

This is the factorial with every second value skipped. E.g.,  $7!! = 7 * 5 * 3 * 1$ . It can be approximated numerically as:

```
n!! = special.gamma(n/2+1)*2**((m+1)/2)/sqrt(pi)  n odd
      = 2**(n/2) * (n/2)!                          n even
```

**Parameters** `n` : int or array\_like

Calculate  $n!!$ . Arrays are only supported with *exact* set to `False`. If  $n < 0$ , the return value is 0.

**exact** : bool, optional

The result can be approximated rapidly using the gamma-formula above (default). If *exact* is set to `True`, calculate the answer exactly using integer arithmetic.

**Returns** `nff` : float or int

Double factorial of *n*, as an int or a float depending on *exact*.

### Examples

```
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105L
```

`scipy.special.factorialk` (*n*, *k*, *exact=True*)

Multifactorial of *n* of order *k*,  $n(!\dots!)$ .

This is the multifactorial of *n* skipping *k* values. For example,

$$\text{factorialk}(17, 4) = 17!!!! = 17 * 13 * 9 * 5 * 1$$

In particular, for any integer *n*, we have

$$\begin{aligned} \text{factorialk}(n, 1) &= \text{factorial}(n) \\ \text{factorialk}(n, 2) &= \text{factorial2}(n) \end{aligned}$$

**Parameters** **n** : int Calculate multifactorial. If  $n < 0$ , the return value is 0.  
**k** : int Order of multifactorial.  
**exact** : bool, optional If exact is set to True, calculate the answer exactly using integer arithmetic.

**Returns** **val** : int Multifactorial of  $n$ .

**Raises** **NotImplementedError** Raises when exact is False

**Examples**

```
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120L
>>> factorialk(5, 3, exact=True)
10L
```

`scipy.special.shichi(x, out=None) = <ufunc 'shichi'>`  
 Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

$$\int_0^x \frac{\sinh t}{t} dt$$

and the hyperbolic cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt$$

where  $\gamma$  is Euler’s constant and  $\log$  is the principle branch of the logarithm.

**Parameters** **x** : array\_like Real or complex points at which to compute the hyperbolic sine and cosine integrals.

**Returns** **si** : ndarray Hyperbolic sine integral at  $x$   
**ci** : ndarray Hyperbolic cosine integral at  $x$

**Notes**

For real arguments with  $x < 0$ , `chi` is the real part of the hyperbolic cosine integral. For such points `chi(x)` and `chi(x + 0j)` differ by a factor of  $1j*\pi$ .

For real arguments the function is computed by calling Cephes’ [R514] `shichi` routine. For complex arguments the algorithm is based on Mpmath’s [R515] `shi` and `chi` routines.

**References**

[R514], [R515]

`scipy.special.sici(x, out=None) = <ufunc 'sici'>`  
 Sine and cosine integrals.

The sine integral is

$$\int_0^x \frac{\sin t}{t} dt$$

and the cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and  $\log$  is the principle branch of the logarithm.

**Parameters** **x** : array\_like  
**Returns** **si** : ndarray Real or complex points at which to compute the sine and cosine integrals.  
**ci** : ndarray Sine integral at x  
Cosine integral at x

#### Notes

For real arguments with  $x < 0$ , **ci** is the real part of the cosine integral. For such points **ci**( $x$ ) and **ci**( $x + 0j$ ) differ by a factor of  $1j\pi$ .

For real arguments the function is computed by calling Cephes' [R516] *sici* routine. For complex arguments the algorithm is based on Mpmath's [R517] *si* and *ci* routines.

#### References

[R516], [R517]

`scipy.special.spence`( $z$ , *out=None*) = <ufunc 'spence'>  
Spence's function, also known as the dilogarithm.

It is defined to be

$$\int_0^z \frac{\log(t)}{1-t} dt$$

for complex  $z$ , where the contour of integration is taken to avoid the branch cut of the logarithm. Spence's function is analytic everywhere except the negative real axis where it has a branch cut.

**Parameters** **z** : array\_like  
**Returns** **s** : ndarray Points at which to evaluate Spence's function  
Computed values of Spence's function

#### Notes

There is a different convention which defines Spence's function by the integral

$$-\int_0^z \frac{\log(1-t)}{t} dt;$$

this is our `spence(1 - z)`.

`scipy.special.zeta`( $x$ , *q=None*, *out=None*)  
Riemann zeta function.

The two-argument version is the Hurwitz zeta function:

$$\zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x},$$

Riemann zeta function corresponds to  $q = 1$ .

**See also:**

`zetac`

`scipy.special.zetac(x) = <ufunc 'zetac'>`  
 Riemann zeta function minus 1.

This function is defined as

$$\zeta(x) = \sum_{k=2}^{\infty} 1/k^x,$$

where  $x > 1$ .

**See also:**

`zeta`

| <code>exprel(x)</code>                                      | Relative error exponential, $(\exp(x)-1)/x$ , for use when $x$ is near zero. |
| <code>sinc(x)</code>                                        | Return the sinc function.                                                    |

---

`scipy.special.cbrt(x) = <ufunc 'cbrt'>`  
 Cube root of  $x$

`scipy.special.exp10(x) = <ufunc 'exp10'>`  
 $10^{**}x$

`scipy.special.exp2(x) = <ufunc 'exp2'>`  
 $2^{**}x$

`scipy.special.radian(d, m, s) = <ufunc 'radian'>`  
 Convert from degrees to radians

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.

`scipy.special.cosdg(x) = <ufunc 'cosdg'>`  
 Cosine of the angle  $x$  given in degrees.

`scipy.special.sindg(x) = <ufunc 'sindg'>`  
 Sine of angle given in degrees

`scipy.special.tandg(x) = <ufunc 'tandg'>`  
 Tangent of angle  $x$  given in degrees.

`scipy.special.cotdgdg(x) = <ufunc 'cotdgdg'>`  
 Cotangent of the angle  $x$  given in degrees.

`scipy.special.log1p(x) = <ufunc 'log1p'>`  
 Calculates  $\log(1+x)$  for use when  $x$  is near zero

`scipy.special.expm1(x) = <ufunc 'expm1'>`  
 $\exp(x) - 1$  for use when  $x$  is near zero.

`scipy.special.cosm1(x) = <ufunc 'cosm1'>`  
 $\cos(x) - 1$  for use when  $x$  is near zero.

`scipy.special.round(x) = <ufunc 'round'>`  
 Round to nearest integer

Returns the nearest integer to  $x$  as a double precision floating point result. If  $x$  ends in 0.5 exactly, the nearest even integer is chosen.

`scipy.special.xlogy(x, y) = <ufunc 'xlogy'>`  
 Compute  $x \cdot \log(y)$  so that the result is 0 if  $x = 0$ .

**Parameters**

- x** : array\_like  
Multiplier
- y** : array\_like  
Argument

**Returns**

- z** : array\_like  
Computed  $x \cdot \log(y)$

#### Notes

New in version 0.13.0.

`scipy.special.xlog1py(x, y) = <ufunc 'xlog1py'>`  
 Compute  $x \cdot \log1p(y)$  so that the result is 0 if  $x = 0$ .

**Parameters**

- x** : array\_like  
Multiplier
- y** : array\_like  
Argument

**Returns**

- z** : array\_like  
Computed  $x \cdot \log1p(y)$

#### Notes

New in version 0.13.0.

`scipy.special.logsumexp(a, axis=None, b=None, keepdims=False, return_sign=False)`  
 Compute the log of the sum of exponentials of input elements.

**Parameters**

- a** : array\_like  
Input array.
- axis** : None or int or tuple of ints, optional  
Axis or axes over which the sum is taken. By default *axis* is None, and all elements are summed.  
New in version 0.11.0.
- keepdims** : bool, optional  
If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.  
New in version 0.15.0.
- b** : array-like, optional

Scaling factor for  $\exp(a)$  must be of the same shape as  $a$  or broadcastable to  $a$ . These values may be negative in order to implement subtraction.

New in version 0.12.0.

**return\_sign** : bool, optional

If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).

New in version 0.16.0.

### Returns

**res** : ndarray

The result, `np.log(np.sum(np.exp(a)))` calculated in a numerically more stable way. If  $b$  is given then `np.log(np.sum(b*np.exp(a)))` is returned.

**sgn** : ndarray

If `return_sign` is True, this will be an array of floating-point numbers matching `res` and +1, 0, or -1 depending on the sign of the result. If False, only one result is returned.

### See also:

`numpy.logaddexp`, `numpy.logaddexp2`

### Notes

Numpy has a `logaddexp` function which is very similar to `logsumexp`, but only handles two arguments. `logaddexp.reduce` is similar to this function, but may be less stable.

### Examples

```
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.4586297444267107
>>> logsumexp(a)
9.4586297444267107
```

### With weights

```
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
9.9170178533034665
>>> np.log(np.sum(b*np.exp(a)))
9.9170178533034647
```

### Returning a sign flag

```
>>> logsumexp([1,2], b=[1,-1], return_sign=True)
(1.5413248546129181, -1.0)
```

Notice that `logsumexp` does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
...                 mask=[False, True, False])
>>> b = (~a.mask).astype(int)
```

```
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005
```

`scipy.special.exprel(x) = <ufunc 'exprel'>`

Relative error exponential,  $(\exp(x)-1)/x$ , for use when  $x$  is near zero.

**Parameters** **x** : ndarray  
Input array.

**Returns** **res** : ndarray  
Output array.

**See also:**

`expm1`,

`scipy.special.sinc(x)`

Return the sinc function.

The sinc function is  $\sin(\pi x)/(\pi x)$ .

**Parameters** **x** : ndarray  
Array (possibly multi-dimensional) of values for which to calculate `sinc(x)`.

**Returns** **out** : ndarray  
`sinc(x)`, which has the same shape as the input.

**Notes**

`sinc(0)` is the limit value 1.

The name `sinc` is short for “sine cardinal” or “sinus cardinalis”.

The sinc function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the sinc function.

[R518], [R519]

**Examples**

```
>>> x = np.linspace(-4, 4, 41)
>>> np.sinc(x)
array([-3.89804309e-17, -4.92362781e-02, -8.40918587e-02,
       -8.90384387e-02, -5.84680802e-02,  3.89804309e-17,
        6.68206631e-02,  1.16434881e-01,  1.26137788e-01,
        8.50444803e-02, -3.89804309e-17, -1.03943254e-01,
       -1.89206682e-01, -2.16236208e-01, -1.55914881e-01,
        3.89804309e-17,  2.33872321e-01,  5.04551152e-01,
        7.56826729e-01,  9.35489284e-01,  1.00000000e+00,
        9.35489284e-01,  7.56826729e-01,  5.04551152e-01,
        2.33872321e-01,  3.89804309e-17, -1.55914881e-01,
       -2.16236208e-01, -1.89206682e-01, -1.03943254e-01,
       -3.89804309e-17,  8.50444803e-02,  1.26137788e-01,
        1.16434881e-01,  6.68206631e-02,  3.89804309e-17,
       -5.84680802e-02, -8.90384387e-02, -8.40918587e-02,
       -4.92362781e-02, -3.89804309e-17])
```

```

>>> plt.plot(x, np.sinc(x))
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.title("Sinc Function")
<matplotlib.text.Text object at 0x...>
>>> plt.ylabel("Amplitude")
<matplotlib.text.Text object at 0x...>
>>> plt.xlabel("X")
<matplotlib.text.Text object at 0x...>
>>> plt.show()
    
```

It works in 2-D as well:

```

>>> x = np.linspace(-4, 4, 401)
>>> xx = np.outer(x, x)
>>> plt.imshow(np.sinc(xx))
<matplotlib.image.AxesImage object at 0x...>
    
```

## 5.27 Statistical functions (`scipy.stats`)

This module contains a large number of probability distributions as well as a growing library of statistical functions.

Each univariate distribution is an instance of a subclass of `rv_continuous` (`rv_discrete` for discrete distributions):

---

|                                                                                          |                                                                   |
|------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| <code>rv_continuous</code> ([ <i>momtype</i> , <i>a</i> , <i>b</i> , <i>xtol</i> , ...]) | A generic continuous random variable class meant for subclassing. |
| <code>rv_discrete</code> ([ <i>a</i> , <i>b</i> , <i>name</i> , <i>badvalue</i> , ...])  | A generic discrete random variable class meant for subclassing.   |
| <code>rv_histogram</code> ( <i>histogram</i> , * <i>args</i> , ** <i>kwargs</i> )        | Generates a distribution given by a histogram.                    |

---

**class** `scipy.stats.rv_continuous` (*momtype*=1, *a*=None, *b*=None, *xtol*=1e-14, *badvalue*=None, *name*=None, *longname*=None, *shapes*=None, *extradoc*=None, *seed*=None)

A generic continuous random variable class meant for subclassing.

`rv_continuous` is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

**Parameters** **momtype** : int, optional

The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.

**a** : float, optional

Lower bound of the support of the distribution, default is minus infinity.

**b** : float, optional

Upper bound of the support of the distribution, default is plus infinity.

**xtol** : float, optional

The tolerance for fixed point calculation for generic ppf.

**badvalue** : float, optional

The value in a result arrays that indicates a value that for which some argument restriction is violated, default is `np.nan`.

**name** : str, optional

The name of the instance. This string is used to construct the default example for distributions.

**longname** : str, optional

This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: *longname* exists for backwards compatibility, do not use for new subclasses.

**shapes** : str, optional

The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, `_pdf` and `_cdf` of the instance.

**extradoc** : str, optional, deprecated

This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: *extradoc* exists for backwards compatibility, do not use for new subclasses.

**seed** : None or int or `numpy.random.RandomState` instance, optional

This parameter defines the `RandomState` object to use for drawing random variates. If None (or `np.random`), the global `np.random` state is used. If integer, it is used to seed the local `RandomState` instance. Default is None.

### Notes

Public methods of an instance of a distribution class (e.g., `pdf`, `cdf`) check their arguments and pass valid arguments to private, computational methods (`_pdf`, `_cdf`). For `pdf(x)`, `x` is valid if it is within the support of a distribution, `self.a <= x <= self.b`. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.)

### Subclassing

New random variables can be defined by subclassing the `rv_continuous` class and re-defining at least the `_pdf` or the `_cdf` method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the `_argcheck` method.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can over-ride:

```
_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf
```

Rarely would you override `_isf`, `_sf` or `_logsf`, but you could.

### Methods that can be overwritten by subclasses

```
_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
```

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.

A note on `shapes`: subclasses need not specify them explicitly. In this case, `shapes` will be automatically deduced from the signatures of the overridden methods (`pdf`, `cdf` etc). If, for some reason, you prefer to avoid relying on introspection, you can specify `shapes` explicitly as an argument to the instance constructor.

### Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters to each call of a method of a distribution.

Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a “frozen” continuous RV object:

```
rv = generic(<shape(s)>, loc=0, scale=1)
```

frozen RV object with the same methods but holding the given shape, location, and scale fixed

### Statistics

Statistics are computed using numerical integration by default. For speed you can redefine this using `_stats`:

- take shape parameters and return mu, mu2, g1, g2
- If you can’t compute one of these, return it as None
- Can also be defined with a keyword argument `moments`, which is a string composed of “m”, “v”, “s”, and/or “k”. Only the components appearing in string should be computed and returned in the order “m”, “v”, “s”, or “k” with missing values returned as None.

Alternatively, you can override `_munp`, which takes `n` and shape parameters and returns the `n`-th non-central moment of the distribution.

### Examples

To create a new Gaussian distribution, we would do the following:

```
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
...     "Gaussian distribution"
...     def _pdf(self, x):
...         return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

`scipy.stats` distributions are *instances*, so here we subclass `rv_continuous` and create an instance. With this, we now have a fully functional distribution with all relevant methods automatically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using `loc` and `scale` parameters: `gaussian.pdf(x, loc, scale)` essentially computes  $y = (x - loc) / scale$  and `gaussian._pdf(y) / scale`.

### Attributes

---

`random_state` Get or set the RandomState object for generating random variates.

---

#### `rv_continuous.random_state`

Get or set the RandomState object for generating random variates.

This can be either None or an existing RandomState object.

If None (or `np.random`), use the RandomState singleton used by `np.random`. If already a RandomState instance, use it. If an int, use a new RandomState instance seeded with `seed`.

### Methods

---

|                                         |                                                                            |
|-----------------------------------------|----------------------------------------------------------------------------|
| <code>rvs(*args, **kwargs)</code>       | Random variates of given type.                                             |
| <code>pdf(x, *args, **kwargs)</code>    | Probability density function at <code>x</code> of the given RV.            |
| <code>logpdf(x, *args, **kwargs)</code> | Log of the probability density function at <code>x</code> of the given RV. |

|                                                            |                                                                                  |
|------------------------------------------------------------|----------------------------------------------------------------------------------|
| <code>cdf(x, *args, **kwargs)</code>                       | Cumulative distribution function of the given RV.                                |
| <code>logcdf(x, *args, **kwargs)</code>                    | Log of the cumulative distribution function at x of the given RV.                |
| <code>sf(x, *args, **kwargs)</code>                        | Survival function (1 - <code>cdf</code> ) at x of the given RV.                  |
| <code>logsf(x, *args, **kwargs)</code>                     | Log of the survival function of the given RV.                                    |
| <code>ppf(q, *args, **kwargs)</code>                       | Percent point function (inverse of <code>cdf</code> ) at q of the given RV.      |
| <code>isf(q, *args, **kwargs)</code>                       | Inverse survival function (inverse of <code>sf</code> ) at q of the given RV.    |
| <code>moment(n, *args, **kwargs)</code>                    | n-th order non-central moment of distribution.                                   |
| <code>stats(*args, **kwargs)</code>                        | Some statistics of the given RV.                                                 |
| <code>entropy(*args, **kwargs)</code>                      | Differential entropy of the RV.                                                  |
| <code>expect([func, args, loc, scale, lb, ub, ...])</code> | Calculate expected value of a function with respect to the distribution.         |
| <code>median(*args, **kwargs)</code>                       | Median of the distribution.                                                      |
| <code>mean(*args, **kwargs)</code>                         | Mean of the distribution.                                                        |
| <code>std(*args, **kwargs)</code>                          | Standard deviation of the distribution.                                          |
| <code>var(*args, **kwargs)</code>                          | Variance of the distribution.                                                    |
| <code>interval(alpha, *args, **kwargs)</code>              | Confidence interval with equal areas around the median.                          |
| <code>__call__(*args, **kwargs)</code>                     | Freeze the distribution for the given arguments.                                 |
| <code>fit(data, *args, **kwargs)</code>                    | Return MLEs for shape (if applicable), location, and scale parameters from data. |
| <code>fit_loc_scale(data, *args)</code>                    | Estimate loc and scale parameters from data using 1st and 2nd moments.           |
| <code>nnlf(theta, x)</code>                                | Return negative loglikelihood function.                                          |

`rv_continuous.rvs(*args, **kwargs)`

Random variates of given type.

**Parameters** `arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional

Location parameter (default=0).

**scale** : array\_like, optional

Scale parameter (default=1).

**size** : int or tuple of ints, optional

Defining number of random variates (default is 1).

**random\_state** : None or int or `np.random.RandomState` instance, optional

If int or `RandomState`, use it for drawing the random variates. If

None, rely on `self.random_state`. Default is None.

**Returns**

**rvs** : ndarray or scalar

Random variates of given *size*.

`rv_continuous.pdf(x, *args, **kwargs)`

Probability density function at x of the given RV.

**Parameters** `x` : array\_like

quantiles

**arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

**Returns**

**pdf** : ndarray

Probability density function evaluated at x

`rv_continuous.logpdf(x, *args, **kwargs)`

Log of the probability density function at x of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters** **x** : array\_like  
 quantiles  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **logpdf** : array\_like  
 Log of the probability density function evaluated at x

`rv_continuous.cdf(x, *args, **kws)`

Cumulative distribution function of the given RV.

**Parameters** **x** : array\_like  
 quantiles  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **cdf** : ndarray  
 Cumulative distribution function evaluated at x

`rv_continuous.logcdf(x, *args, **kws)`

Log of the cumulative distribution function at x of the given RV.

**Parameters** **x** : array\_like  
 quantiles  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **logcdf** : array\_like  
 Log of the cumulative distribution function evaluated at x

`rv_continuous.sf(x, *args, **kws)`

Survival function (1 - cdf) at x of the given RV.

**Parameters** **x** : array\_like  
 quantiles  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)  
**Returns** **sf** : array\_like  
 Survival function evaluated at x

`rv_continuous.logsf(x, *args, **kwargs)`

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as  $(1 - \text{cdf})$ , evaluated at  $x$ .

**Parameters**

- x** : array\_like  
quantiles
- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional  
scale parameter (default=1)

**Returns**

- logsf** : ndarray  
Log of the survival function evaluated at  $x$ .

`rv_continuous.ppf(q, *args, **kwargs)`

Percent point function (inverse of `cdf`) at  $q$  of the given RV.

**Parameters**

- q** : array\_like  
lower tail probability
- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional  
scale parameter (default=1)

**Returns**

- x** : array\_like  
quantile corresponding to the lower tail probability  $q$ .

`rv_continuous.isf(q, *args, **kwargs)`

Inverse survival function (inverse of `sf`) at  $q$  of the given RV.

**Parameters**

- q** : array\_like  
upper tail probability
- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional  
scale parameter (default=1)

**Returns**

- x** : ndarray or scalar  
Quantile corresponding to the upper tail probability  $q$ .

`rv_continuous.moment(n, *args, **kwargs)`

$n$ -th order non-central moment of distribution.

**Parameters**

- n** : int,  $n \geq 1$   
Order of moment.
- arg1, arg2, arg3,...** : float  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional  
scale parameter (default=1)

`rv_continuous.stats` (\*args, \*\*kws)

Some statistics of the given RV.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
 location parameter (default=0)

**scale** : array\_like, optional (continuous RVs only)  
 scale parameter (default=1)

**moments** : str, optional  
 composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns** **stats** : sequence  
 of requested moments.

`rv_continuous.entropy` (\*args, \*\*kws)

Differential entropy of the RV.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional  
 Location parameter (default=0).

**scale** : array\_like, optional (continuous distributions only).  
 Scale parameter (default=1).

**Notes**

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_continuous.expect` (func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, \*\*kws)

Calculate expected value of a function with respect to the distribution.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[x] = \int_{lb}^{ub} f(x) * dist.pdf(x)$$

**Parameters** **func** : callable, optional  
 Function for which integral is calculated. Takes only one argument. The default is the identity mapping  $f(x) = x$ .

**args** : tuple, optional  
 Shape parameters of the distribution.

**loc** : float, optional  
 Location parameter (default=0).

**scale** : float, optional  
 Scale parameter (default=1).

**lb, ub** : scalar, optional  
 Lower and upper bound for integration. Default is set to the support of the distribution.

**conditional** : bool, optional

If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

**Returns** **Additional keyword arguments are passed to the integration routine.**  
**expect** : float

The calculated expected value.

#### Notes

The integration behavior of this function is inherited from *integrate.quad*.

`rv_continuous.median(*args, **kws)`

Median of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

Location parameter, Default is 0.

**scale** : array\_like, optional

Scale parameter, Default is 1.

**Returns** **median** : float

The median of the distribution.

#### See also:

***stats.distributions.rv\_discrete.ppf***

Inverse of the CDF

`rv_continuous.mean(*args, **kws)`

Mean of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

**Returns** **mean** : float

the mean of the distribution

`rv_continuous.std(*args, **kws)`

Standard deviation of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

**Returns** **std** : float

standard deviation of the distribution

`rv_continuous.var(*args, **kws)`

Variance of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **var** : float  
the variance of the distribution

`rv_continuous.interval(alpha, *args, **kwargs)`

Confidence interval with equal areas around the median.

**Parameters** **alpha** : array\_like of float  
Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

**arg1, arg2, ...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional  
location parameter, Default is 0.

**scale** : array\_like, optional  
scale parameter, Default is 1.

**Returns** **a, b** : ndarray of float  
end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

`rv_continuous.__call__(*args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns** **rv\_frozen** : rv\_frozen instance  
The frozen distribution.

`rv_continuous.fit(data, *args, **kwargs)`

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

**Parameters** **data** : array\_like  
Data to use in calculating the MLEs.

**args** : floats, optional  
Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

**kwargs** : floats, optional  
Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fix_a` and `fix_b` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.

- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.
- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

**Returns** `mle_tuple` : tuple of floats  
MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

### Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

### Examples

Generate some data to fit: draw random variates from the `beta` distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter a equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

`rv_continuous.fit_loc_scale` (*data*, \**args*)

Estimate `loc` and `scale` parameters from data using 1st and 2nd moments.

**Parameters** `data` : array\_like  
Data to fit.  
`arg1, arg2, arg3, ...` : array\_like

**Returns**

- Lhat** : float  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- Shat** : float  
Estimated location parameter for the data.
- Sshat** : float  
Estimated scale parameter for the data.

`rv_continuous.nllf(theta, x)`  
Return negative loglikelihood function.

**Notes**

This is  $-\text{sum}(\log \text{pdf}(x, \text{theta}), \text{axis}=0)$  where *theta* are the parameters (including loc and scale).

**class** `scipy.stats.rv_discrete` (*a=0, b=inf, name=None, badvalue=None, moment\_tol=1e-08, values=None, inc=1, longname=None, shapes=None, extradoc=None, seed=None*)

A generic discrete random variable class meant for subclassing.

`rv_discrete` is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

**Parameters**

- a** : float, optional  
Lower bound of the support of the distribution, default: 0
- b** : float, optional  
Upper bound of the support of the distribution, default: plus infinity
- moment\_tol** : float, optional  
The tolerance for the generic calculation of moments.
- values** : tuple of two array\_like, optional  
(*xk, pk*) where *xk* are integers with non-zero probabilities *pk* with  $\text{sum}(pk) = 1$ .
- inc** : integer, optional  
Increment for the support of the distribution. Default is 1. (other values have not been tested)
- badvalue** : float, optional  
The value in a result arrays that indicates a value that for which some argument restriction is violated, default is `np.nan`.
- name** : str, optional  
The name of the instance. This string is used to construct the default example for distributions.
- longname** : str, optional  
This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: *longname* exists for backwards compatibility, do not use for new subclasses.
- shapes** : str, optional  
The shape of the distribution. For example “m, n” for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signatures of the private methods, `_pmf` and `_cdf` of the instance.
- extradoc** : str, optional  
This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: *extradoc* exists for backwards compatibility, do not use for new subclasses.
- seed** : None or int or `numpy.random.RandomState` instance, optional

This parameter defines the RandomState object to use for drawing random variates. If None, the global `np.random` state is used. If integer, it is used to seed the local RandomState instance. Default is None.

### Notes

This class is similar to `rv_continuous`, the main differences being:

- the support of the distribution is a set of integers
- instead of the probability density function, `pdf` (and the corresponding private `_pdf`), this class defines the *probability mass function*, `pmf` (and the corresponding private `_pmf`.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
...     "Poisson distribution"
...     def _pmf(self, k, mu):
...         return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the `loc` parameter to the methods of the instance. For example, `poisson.pmf(x, mu, loc)` delegates the work to `poisson._pmf(x-loc, mu)`.

### Discrete distributions from a list of probabilities

Alternatively, you can construct an arbitrary discrete rv defined on a finite set of values `xk` with  $\text{Prob}\{X=xk\} = pk$  by using the `values` keyword argument to the `rv_discrete` constructor.

### Examples

Custom made discrete distribution:

```
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.1, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
>>>
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
>>> ax.plot(xk, custm.pmf(xk), 'ro', ms=12, mec='r')
>>> ax.vlines(xk, 0, custm.pmf(xk), colors='r', lw=4)
>>> plt.show()
```

Random number generation:

```
>>> R = custm.rvs(size=100)
```

### Attributes

|                              |                                                                   |
|------------------------------|-------------------------------------------------------------------|
| <code>random_state</code>    | Get or set the RandomState object for generating random variates. |
| <code>return_integers</code> | <code>return_integers</code> is deprecated!                       |

### `rv_discrete.random_state`

Get or set the RandomState object for generating random variates.

This can be either None or an existing RandomState object.

If None (or `np.random`), use the RandomState singleton used by `np.random`. If already a RandomState instance, use it. If an int, use a new RandomState instance seeded with `seed`.

### `rv_discrete.return_integers`

`return_integers` is deprecated! `return_integers` attribute is not used anywhere any longer and is deprecated in scipy 0.18.

### Methods

|                                         |                                                                                            |
|-----------------------------------------|--------------------------------------------------------------------------------------------|
| <code>rvs(*args, **kwargs)</code>       | Random variates of given type.                                                             |
| <code>pmf(k, *args, **kwargs)</code>    | Probability mass function at <code>k</code> of the given RV.                               |
| <code>logpmf(k, *args, **kwargs)</code> | Log of the probability mass function at <code>k</code> of the given RV.                    |
| <code>cdf(k, *args, **kwargs)</code>    | Cumulative distribution function of the given RV.                                          |
| <code>logcdf(k, *args, **kwargs)</code> | Log of the cumulative distribution function at <code>k</code> of the given RV.             |
| <code>sf(k, *args, **kwargs)</code>     | Survival function ( $1 - \text{cdf}$ ) at <code>k</code> of the given RV.                  |
| <code>logsf(k, *args, **kwargs)</code>  | Log of the survival function of the given RV.                                              |
| <code>ppf(q, *args, **kwargs)</code>    | Percent point function (inverse of <code>cdf</code> ) at <code>q</code> of the given RV.   |
| <code>isf(q, *args, **kwargs)</code>    | Inverse survival function (inverse of <code>sf</code> ) at <code>q</code> of the given RV. |
| <code>moment(n, *args, **kwargs)</code> | $n$ -th order non-central moment of distribution.                                          |
| <code>stats(*args, **kwargs)</code>     | Some statistics of the given RV.                                                           |
| <code>entropy(*args, **kwargs)</code>   | Differential entropy of the RV.                                                            |

|------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>expect</code> ([func, args, loc, lb, ub, ...]) | Calculate expected value of a function with respect to the distribution for discrete distribution. |
| <code>median</code> (*args, **kwds)                  | Median of the distribution.                                                                        |
| <code>mean</code> (*args, **kwds)                    | Mean of the distribution.                                                                          |
| <code>std</code> (*args, **kwds)                     | Standard deviation of the distribution.                                                            |
| <code>var</code> (*args, **kwds)                     | Variance of the distribution.                                                                      |
| <code>interval</code> (alpha, *args, **kwds)         | Confidence interval with equal areas around the median.                                            |
| <code>__call__</code> (*args, **kwds)                | Freeze the distribution for the given arguments.                                                   |

`rv_discrete.rvs` (\*args, \*\*kwds)

Random variates of given type.

**Parameters** `arg1, arg2, arg3,...` : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

`loc` : array\_like, optional  
Location parameter (default=0).

`size` : int or tuple of ints, optional  
Defining number of random variates (Default is 1). Note that *size* has to be given as keyword, not as positional argument.

**random\_state** : None or int or `np.random.RandomState` instance, optional  
If int or `RandomState`, use it for drawing the random variates. If None, rely on `self.random_state`. Default is None.

**Returns** `rvs` : ndarray or scalar  
Random variates of given *size*.

`rv_discrete.pmf` (k, \*args, \*\*kwds)

Probability mass function at k of the given RV.

**Parameters** `k` : array\_like  
Quantiles.

`arg1, arg2, arg3,...` : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

`loc` : array\_like, optional  
Location parameter (default=0).

**Returns** `pmf` : array\_like  
Probability mass function evaluated at k

`rv_discrete.logpmf` (k, \*args, \*\*kwds)

Log of the probability mass function at k of the given RV.

**Parameters** `k` : array\_like  
Quantiles.

`arg1, arg2, arg3,...` : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

`loc` : array\_like, optional  
Location parameter. Default is 0.

**Returns** `logpmf` : array\_like  
Log of the probability mass function evaluated at k.

`rv_discrete.cdf` (k, \*args, \*\*kwds)

Cumulative distribution function of the given RV.

**Parameters** `k` : array\_like, int  
Quantiles.

`arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional  
Location parameter (default=0).

**Returns** **cdf** : ndarray  
Cumulative distribution function evaluated at *k*.

`rv_discrete.logcdf(k, *args, **kwargs)`  
Log of the cumulative distribution function at *k* of the given RV.

**Parameters** **k** : array\_like, int  
Quantiles.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).

**Returns** **logcdf** : array\_like  
Log of the cumulative distribution function evaluated at *k*.

`rv_discrete.sf(k, *args, **kwargs)`  
Survival function (1 - `cdf`) at *k* of the given RV.

**Parameters** **k** : array\_like  
Quantiles.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).

**Returns** **sf** : array\_like  
Survival function evaluated at *k*.

`rv_discrete.logsf(k, *args, **kwargs)`  
Log of the survival function of the given RV.  
Returns the log of the “survival function,” defined as 1 - `cdf`, evaluated at *k*.

**Parameters** **k** : array\_like  
Quantiles.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).

**Returns** **logsf** : ndarray  
Log of the survival function evaluated at *k*.

`rv_discrete.ppf(q, *args, **kwargs)`  
Percent point function (inverse of `cdf`) at *q* of the given RV.

**Parameters** **q** : array\_like  
Lower tail probability.  
**arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
Location parameter (default=0).

**Returns** **k** : array\_like  
Quantile corresponding to the lower tail probability, *q*.

`rv_discrete.isf(q, *args, **kws)`

Inverse survival function (inverse of `sƒ`) at `q` of the given RV.

**Parameters**

- q** : array\_like  
Upper tail probability.
- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** : array\_like, optional  
Location parameter (default=0).

**Returns**

- k** : ndarray or scalar  
Quantile corresponding to the upper tail probability, `q`.

`rv_discrete.moment(n, *args, **kws)`

`n`-th order non-central moment of distribution.

**Parameters**

- n** : int, `n >= 1`  
Order of moment.
- arg1, arg2, arg3,...** : float  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional  
scale parameter (default=1)

`rv_discrete.stats(*args, **kws)`

Some statistics of the given RV.

**Parameters**

- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** : array\_like, optional  
location parameter (default=0)
- scale** : array\_like, optional (continuous RVs only)  
scale parameter (default=1)
- moments** : str, optional  
composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns**

- stats** : sequence  
of requested moments.

`rv_discrete.entropy(*args, **kws)`

Differential entropy of the RV.

**Parameters**

- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** : array\_like, optional  
Location parameter (default=0).
- scale** : array\_like, optional (continuous distributions only).  
Scale parameter (default=1).

#### Notes

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_discrete.expect` (*func=None, args=(), loc=0, lb=None, ub=None, conditional=False, maxcount=1000, tolerance=1e-10, chunksize=32*)

Calculate expected value of a function with respect to the distribution for discrete distribution.

**Parameters**

- func** : callable, optional  
Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping  $f(k) = k$ .
- args** : tuple, optional  
Shape parameters of the distribution.
- loc** : float, optional  
Location parameter. Default is 0.
- lb, ub** : int, optional  
Lower and upper bound for the summation, default is set to the support of the distribution, inclusive ( $ul \leq k \leq ub$ ).
- conditional** : bool, optional  
If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, *func*, conditional on being in the given interval ( $k$  such that  $ul \leq k \leq ub$ ). Default is False.
- maxcount** : int, optional  
Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.
- tolerance** : float, optional  
Absolute tolerance for the summation. Default is 1e-10.
- chunksize** : int, optional  
Iterate over the support of a distributions in chunks of this size. Default is 32.

**Returns**

- expect** : float  
Expected value.

**Notes**

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, *func*. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only 1e-5. increasing *maxcount* and/or *chunksize* may improve the result, but may also make `zipf` very slow.

The function is not vectorized.

`rv_discrete.median` (*\*args, \*\*kws*)

Median of the distribution.

**Parameters**

- arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** : array\_like, optional  
Location parameter, Default is 0.
- scale** : array\_like, optional  
Scale parameter, Default is 1.

**Returns**

- median** : float  
The median of the distribution.

**See also:**

***stats.distributions.rv\_discrete.ppf***

Inverse of the CDF

`rv_discrete.mean(*args, **kws)`

Mean of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **mean** : float  
the mean of the distribution

`rv_discrete.std(*args, **kws)`

Standard deviation of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **std** : float  
standard deviation of the distribution

`rv_discrete.var(*args, **kws)`

Variance of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
location parameter (default=0)

**scale** : array\_like, optional  
scale parameter (default=1)

**Returns** **var** : float  
the variance of the distribution

`rv_discrete.interval(alpha, *args, **kws)`

Confidence interval with equal areas around the median.

**Parameters** **alpha** : array\_like of float  
Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

**arg1, arg2, ...** : array\_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional  
location parameter, Default is 0.

**scale** : array\_like, optional  
scale parameter, Default is 1.

**Returns** **a, b** : ndarray of float  
end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

`rv_discrete.__call__(*args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters** `arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns** `rv_frozen` : `rv_frozen` instance

The frozen distribution.

**class** `scipy.stats.rv_histogram`(*histogram*, \*args, \*\*kwargs)

Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned datasample.

As a subclass of the `rv_continuous` class, `rv_histogram` inherits from it a collection of generic methods (see `rv_continuous` for the full list), and implements them based on the properties of the provided binned datasample.

**Parameters** `histogram` : tuple of array\_like

Tuple containing two array\_like objects The first containing the content of n bins The second containing the (n+1) bin boundaries In particular the return value `np.histogram` is accepted

### Notes

There are no additional shape parameters except for the `loc` and `scale`. The pdf is defined as a stepwise function from the provided histogram The cdf is a linear interpolation of the pdf.

New in version 0.19.0.

### Examples

Create a `scipy.stats` distribution from a numpy histogram

```
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary `scipy rv_continuous` distribution

```
>>> hist_dist.pdf(1.0)
0.20538577847618705
>>> hist_dist.cdf(2.0)
0.90818568543056499
```

PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the `max` (`min`) of the original dataset

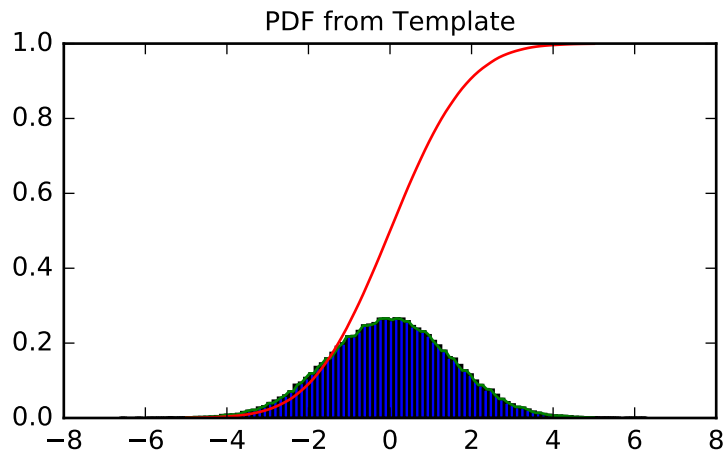

```
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.7591907244498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram

```

>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, normed=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()

```

### Attributes

---

`random_state` Get or set the RandomState object for generating random variates.

---

#### `rv_histogram.random_state`

Get or set the RandomState object for generating random variates.

This can be either None or an existing RandomState object.

If None (or `np.random`), use the RandomState singleton used by `np.random`. If already a RandomState instance, use it. If an int, use a new RandomState instance seeded with `seed`.

### Methods

---

|                                                            |                                                                                            |
|------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| <code>__call__(*args, **kwargs)</code>                     | Freeze the distribution for the given arguments.                                           |
| <code>cdf(x, *args, **kwargs)</code>                       | Cumulative distribution function of the given RV.                                          |
| <code>entropy(*args, **kwargs)</code>                      | Differential entropy of the RV.                                                            |
| <code>expect([func, args, loc, scale, lb, ub, ...])</code> | Calculate expected value of a function with respect to the distribution.                   |
| <code>fit(data, *args, **kwargs)</code>                    | Return MLEs for shape (if applicable), location, and scale parameters from data.           |
| <code>fit_loc_scale(data, *args)</code>                    | Estimate loc and scale parameters from data using 1st and 2nd moments.                     |
| <code>freeze(*args, **kwargs)</code>                       | Freeze the distribution for the given arguments.                                           |
| <code>interval(alpha, *args, **kwargs)</code>              | Confidence interval with equal areas around the median.                                    |
| <code>isf(q, *args, **kwargs)</code>                       | Inverse survival function (inverse of <code>sF</code> ) at <code>q</code> of the given RV. |
| <code>logcdf(x, *args, **kwargs)</code>                    | Log of the cumulative distribution function at <code>x</code> of the given RV.             |
| <code>logpdf(x, *args, **kwargs)</code>                    | Log of the probability density function at <code>x</code> of the given RV.                 |
| <code>logsf(x, *args, **kwargs)</code>                     | Log of the survival function of the given RV.                                              |

| <code>nnlf(theta, x)</code>             | Return negative loglikelihood function.                                     |
| <code>pdf(x, *args, **kwargs)</code>    | Probability density function at x of the given RV.                          |
| <code>ppf(q, *args, **kwargs)</code>    | Percent point function (inverse of <code>cdf</code> ) at q of the given RV. |
| <code>rvs(*args, **kwargs)</code>       | Random variates of given type.                                              |
| <code>sf(x, *args, **kwargs)</code>     | Survival function (1 - <code>cdf</code> ) at x of the given RV.             |
| <code>stats(*args, **kwargs)</code>     | Some statistics of the given RV.                                            |
| <code>std(*args, **kwargs)</code>       | Standard deviation of the distribution.                                     |
| <code>var(*args, **kwargs)</code>       | Variance of the distribution.                                               |

`rv_histogram.__call__(*args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters** `arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns** `rv_frozen` : `rv_frozen` instance

The frozen distribution.

`rv_histogram.cdf(x, *args, **kwargs)`

Cumulative distribution function of the given RV.

**Parameters** `x` : array\_like

quantiles

**arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

**Returns** `cdf` : ndarray

Cumulative distribution function evaluated at `x`

`rv_histogram.entropy(*args, **kwargs)`

Differential entropy of the RV.

**Parameters** `arg1, arg2, arg3,...` : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional

Location parameter (default=0).

**scale** : array\_like, optional (continuous distributions only).

Scale parameter (default=1).

### Notes

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_histogram.expect` (*func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, \*\*kwds*)

Calculate expected value of a function with respect to the distribution.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[x] = \int_{lb}^{ub} f(x) * dist.pdf(x)$$

**Parameters**

- func** : callable, optional  
Function for which integral is calculated. Takes only one argument. The default is the identity mapping  $f(x) = x$ .
- args** : tuple, optional  
Shape parameters of the distribution.
- loc** : float, optional  
Location parameter (default=0).
- scale** : float, optional  
Scale parameter (default=1).
- lb, ub** : scalar, optional  
Lower and upper bound for integration. Default is set to the support of the distribution.
- conditional** : bool, optional  
If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

**Returns**

**expect** : float  
**Additional keyword arguments are passed to the integration routine.**  
The calculated expected value.

#### Notes

The integration behavior of this function is inherited from `integrate.quad`.

`rv_histogram.fit` (*data, \*args, \*\*kwds*)

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `flloc` and `fscale` (for location and scale parameters, respectively).

**Parameters**

- data** : array\_like  
Data to use in calculating the MLEs.
- args** : floats, optional  
Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.
- kwds** : floats, optional  
Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:
  - `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fix_a` and `fix_b` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.

- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.
- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

**Returns** `mle_tuple` : tuple of floats  
MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

**Notes**

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

**Examples**

Generate some data to fit: draw random variates from the `beta` distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter a equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

`rv_histogram.fit_loc_scale` (*data*, \*args)

Estimate `loc` and `scale` parameters from data using 1st and 2nd moments.

**Parameters** `data` : array\_like  
Data to fit.  
`arg1, arg2, arg3,...` : array\_like

**Returns**     **Lhat** : float     The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
                  **Shat** : float     Estimated location parameter for the data.  
                                          Estimated scale parameter for the data.

`rv_histogram.freeze(*args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters**   **arg1, arg2, arg3,...** : array\_like  
                                          The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.  
**Returns**        **rv\_frozen** : rv\_frozen instance  
                                          The frozen distribution.

`rv_histogram.interval(alpha, *args, **kwargs)`

Confidence interval with equal areas around the median.

**Parameters**   **alpha** : array\_like of float  
                                          Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].  
                  **arg1, arg2, ...** : array\_like  
                                          The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
                  **loc** : array\_like, optional  
                                          location parameter, Default is 0.  
                  **scale** : array\_like, optional  
                                          scale parameter, Default is 1.  
**Returns**        **a, b** : ndarray of float  
                                          end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

`rv_histogram.isf(q, *args, **kwargs)`

Inverse survival function (inverse of `sf`) at `q` of the given RV.

**Parameters**   **q** : array\_like  
                                          upper tail probability  
                  **arg1, arg2, arg3,...** : array\_like  
                                          The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
                  **loc** : array\_like, optional  
                                          location parameter (default=0)  
                  **scale** : array\_like, optional  
                                          scale parameter (default=1)  
**Returns**        **x** : ndarray or scalar  
                                          Quantile corresponding to the upper tail probability `q`.

`rv_histogram.logcdf(x, *args, **kwargs)`

Log of the cumulative distribution function at `x` of the given RV.

**Parameters**   **x** : array\_like  
                                          quantiles  
                  **arg1, arg2, arg3,...** : array\_like  
                                          The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
                  **loc** : array\_like, optional  
                                          location parameter (default=0)  
                  **scale** : array\_like, optional  
                                          scale parameter (default=1)

**Returns** **logcdf** : array\_like  
 Log of the cumulative distribution function evaluated at x

`rv_histogram.logpdf(x, *args, **kws)`

Log of the probability density function at x of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters** **x** : array\_like  
 quantiles  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
 location parameter (default=0)

**scale** : array\_like, optional  
 scale parameter (default=1)

**Returns** **logpdf** : array\_like  
 Log of the probability density function evaluated at x

`rv_histogram.logsf(x, *args, **kws)`

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as  $(1 - \text{cdf})$ , evaluated at x.

**Parameters** **x** : array\_like  
 quantiles  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
 location parameter (default=0)

**scale** : array\_like, optional  
 scale parameter (default=1)

**Returns** **logsf** : ndarray  
 Log of the survival function evaluated at x.

`rv_histogram.mean(*args, **kws)`

Mean of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
 location parameter (default=0)

**scale** : array\_like, optional  
 scale parameter (default=1)

**Returns** **mean** : float  
 the mean of the distribution

`rv_histogram.median(*args, **kws)`

Median of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional  
 Location parameter, Default is 0.

**scale** : array\_like, optional  
 Scale parameter, Default is 1.

**Returns** **median** : float

The median of the distribution.

**See also:**

**`stats.distributions.rv_discrete.ppf`**

Inverse of the CDF

`rv_histogram.moment` (*n*, \*args, \*\*kws)

n-th order non-central moment of distribution.

**Parameters** **n** : int, n >= 1

Order of moment.

**arg1, arg2, arg3,...** : float

The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

`rv_histogram.nnlf` (*theta*, *x*)

Return negative loglikelihood function.

**Notes**

This is  $-\text{sum}(\log \text{pdf}(x, \text{theta}), \text{axis}=0)$  where *theta* are the parameters (including loc and scale).

`rv_histogram.pdf` (*x*, \*args, \*\*kws)

Probability density function at x of the given RV.

**Parameters** **x** : array\_like

quantiles

**arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

**Returns** **pdf** : ndarray

Probability density function evaluated at x

`rv_histogram.ppf` (*q*, \*args, \*\*kws)

Percent point function (inverse of `cdf`) at q of the given RV.

**Parameters** **q** : array\_like

lower tail probability

**arg1, arg2, arg3,...** : array\_like

The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array\_like, optional

location parameter (default=0)

**scale** : array\_like, optional

scale parameter (default=1)

**Returns** **x** : array\_like

quantile corresponding to the lower tail probability q.

`rv_histogram.rvs` (\*args, \*\*kws)

Random variates of given type.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** : array\_like, optional  
 Location parameter (default=0).  
**scale** : array\_like, optional  
 Scale parameter (default=1).  
**size** : int or tuple of ints, optional  
 Defining number of random variates (default is 1).  
**random\_state** : None or int or `np.random.RandomState` instance, optional  
 If int or `RandomState`, use it for drawing the random variates. If None, rely on `self.random_state`. Default is None.

**Returns** **rvs** : ndarray or scalar  
 Random variates of given *size*.

`rv_histogram.sf(x, *args, **kws)`  
 Survival function (1 - `cdf`) at `x` of the given RV.

**Parameters** **x** : array\_like  
 quantiles  
**arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)

**Returns** **sf** : array\_like  
 Survival function evaluated at `x`

`rv_histogram.stats(*args, **kws)`  
 Some statistics of the given RV.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional (continuous RVs only)  
 scale parameter (default=1)  
**moments** : str, optional  
 composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns** **stats** : sequence  
 of requested moments.

`rv_histogram.std(*args, **kws)`  
 Standard deviation of the distribution.

**Parameters** **arg1, arg2, arg3,...** : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** : array\_like, optional  
 location parameter (default=0)  
**scale** : array\_like, optional  
 scale parameter (default=1)

**Returns** **std** : float  
 standard deviation of the distribution

`rv_histogram.var` (\*args, \*\*kws)

Variance of the distribution.

**Parameters** `arg1, arg2, arg3,...` : array\_like  
 The shape parameter(s) for the distribution (see docstring of the instance object for more information)

`loc` : array\_like, optional  
 location parameter (default=0)

`scale` : array\_like, optional  
 scale parameter (default=1)

**Returns** `var` : float  
 the variance of the distribution

### 5.27.1 Continuous distributions

|                              |                                                                  |
|------------------------------|------------------------------------------------------------------|
| <code>alpha</code>           | An alpha continuous random variable.                             |
| <code>anglit</code>          | An anglit continuous random variable.                            |
| <code>arcsine</code>         | An arcsine continuous random variable.                           |
| <code>argus</code>           | Argus distribution                                               |
| <code>beta</code>            | A beta continuous random variable.                               |
| <code>betaprime</code>       | A beta prime continuous random variable.                         |
| <code>bradford</code>        | A Bradford continuous random variable.                           |
| <code>burr</code>            | A Burr (Type III) continuous random variable.                    |
| <code>burr12</code>          | A Burr (Type XII) continuous random variable.                    |
| <code>cauchy</code>          | A Cauchy continuous random variable.                             |
| <code>chi</code>             | A chi continuous random variable.                                |
| <code>chi2</code>            | A chi-squared continuous random variable.                        |
| <code>cosine</code>          | A cosine continuous random variable.                             |
| <code>dgamma</code>          | A double gamma continuous random variable.                       |
| <code>dweibull</code>        | A double Weibull continuous random variable.                     |
| <code>erlang</code>          | An Erlang continuous random variable.                            |
| <code>expon</code>           | An exponential continuous random variable.                       |
| <code>exponnorm</code>       | An exponentially modified Normal continuous random variable.     |
| <code>exponweib</code>       | An exponentiated Weibull continuous random variable.             |
| <code>exponpow</code>        | An exponential power continuous random variable.                 |
| <code>f</code>               | An F continuous random variable.                                 |
| <code>fatiguelife</code>     | A fatigue-life (Birnbaum-Saunders) continuous random variable.   |
| <code>fisk</code>            | A Fisk continuous random variable.                               |
| <code>foldcauchy</code>      | A folded Cauchy continuous random variable.                      |
| <code>foldnorm</code>        | A folded normal continuous random variable.                      |
| <code>frechet_r</code>       | A Frechet right (or Weibull minimum) continuous random variable. |
| <code>frechet_l</code>       | A Frechet left (or Weibull maximum) continuous random variable.  |
| <code>genlogistic</code>     | A generalized logistic continuous random variable.               |
| <code>gennorm</code>         | A generalized normal continuous random variable.                 |
| <code>genpareto</code>       | A generalized Pareto continuous random variable.                 |
| <code>genexpon</code>        | A generalized exponential continuous random variable.            |
| <code>genextreme</code>      | A generalized extreme value continuous random variable.          |
| <code>gausshyper</code>      | A Gauss hypergeometric continuous random variable.               |
| <code>gamma</code>           | A gamma continuous random variable.                              |
| <code>gengamma</code>        | A generalized gamma continuous random variable.                  |
| <code>genhalflogistic</code> | A generalized half-logistic continuous random variable.          |
| <code>gilbrat</code>         | A Gilbrat continuous random variable.                            |
| <code>gompertz</code>        | A Gompertz (or truncated Gumbel) continuous random variable.     |

|                            |                                                                    |
|----------------------------|--------------------------------------------------------------------|
| <code>gumbel_r</code>      | A right-skewed Gumbel continuous random variable.                  |
| <code>gumbel_l</code>      | A left-skewed Gumbel continuous random variable.                   |
| <code>halfcauchy</code>    | A Half-Cauchy continuous random variable.                          |
| <code>halflogistic</code>  | A half-logistic continuous random variable.                        |
| <code>halfnorm</code>      | A half-normal continuous random variable.                          |
| <code>halfgennorm</code>   | The upper half of a generalized normal continuous random variable. |
| <code>hypsecant</code>     | A hyperbolic secant continuous random variable.                    |
| <code>invgamma</code>      | An inverted gamma continuous random variable.                      |
| <code>invgauss</code>      | An inverse Gaussian continuous random variable.                    |
| <code>invweibull</code>    | An inverted Weibull continuous random variable.                    |
| <code>johnsonsb</code>     | A Johnson SB continuous random variable.                           |
| <code>johnsonsu</code>     | A Johnson SU continuous random variable.                           |
| <code>kappa4</code>        | Kappa 4 parameter distribution.                                    |
| <code>kappa3</code>        | Kappa 3 parameter distribution.                                    |
| <code>ksone</code>         | General Kolmogorov-Smirnov one-sided test.                         |
| <code>kstwobign</code>     | Kolmogorov-Smirnov two-sided test for large N.                     |
| <code>laplace</code>       | A Laplace continuous random variable.                              |
| <code>levy</code>          | A Levy continuous random variable.                                 |
| <code>levy_l</code>        | A left-skewed Levy continuous random variable.                     |
| <code>levy_stable</code>   | A Levy-stable continuous random variable.                          |
| <code>logistic</code>      | A logistic (or Sech-squared) continuous random variable.           |
| <code>loggamma</code>      | A log gamma continuous random variable.                            |
| <code>loglaplace</code>    | A log-Laplace continuous random variable.                          |
| <code>lognorm</code>       | A lognormal continuous random variable.                            |
| <code>lomax</code>         | A Lomax (Pareto of the second kind) continuous random variable.    |
| <code>maxwell</code>       | A Maxwell continuous random variable.                              |
| <code>mielke</code>        | A Mielke's Beta-Kappa continuous random variable.                  |
| <code>nakagami</code>      | A Nakagami continuous random variable.                             |
| <code>ncx2</code>          | A non-central chi-squared continuous random variable.              |
| <code>ncf</code>           | A non-central F distribution continuous random variable.           |
| <code>nct</code>           | A non-central Student's T continuous random variable.              |
| <code>norm</code>          | A normal continuous random variable.                               |
| <code>pareto</code>        | A Pareto continuous random variable.                               |
| <code>pearson3</code>      | A pearson type III continuous random variable.                     |
| <code>powerlaw</code>      | A power-function continuous random variable.                       |
| <code>powerlognorm</code>  | A power log-normal continuous random variable.                     |
| <code>powernorm</code>     | A power normal continuous random variable.                         |
| <code>rdist</code>         | An R-distributed continuous random variable.                       |
| <code>reciprocal</code>    | A reciprocal continuous random variable.                           |
| <code>rayleigh</code>      | A Rayleigh continuous random variable.                             |
| <code>rice</code>          | A Rice continuous random variable.                                 |
| <code>recipinvgauss</code> | A reciprocal inverse Gaussian continuous random variable.          |
| <code>semicircular</code>  | A semicircular continuous random variable.                         |
| <code>skewnorm</code>      | A skew-normal random variable.                                     |
| <code>t</code>             | A Student's T continuous random variable.                          |
| <code>trapz</code>         | A trapezoidal continuous random variable.                          |
| <code>triang</code>        | A triangular continuous random variable.                           |
| <code>truncexpon</code>    | A truncated exponential continuous random variable.                |
| <code>truncnorm</code>     | A truncated normal continuous random variable.                     |
| <code>tukeylambda</code>   | A Tukey-Lambda continuous random variable.                         |
| <code>uniform</code>       | A uniform continuous random variable.                              |
| <code>vonmises</code>      | A Von Mises continuous random variable.                            |

`scipy.stats.alpha` = <scipy.stats.\_continuous\_distns.alpha\_gen object at 0x2b2318b8cf10>

An alpha continuous random variable.

As an instance of the `rv_continuous` class, `alpha` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `alpha` is:

$$\text{alpha.pdf}(x, a) = 1/(x^{**2} * \text{Phi}(a) * \text{sqrt}(2 * \text{pi})) * \exp(-1/2 * (a - 1/x)^{**2}),$$

where `Phi(alpha)` is the normal CDF,  $x > 0$ , and  $a > 0$ .

`alpha` takes `a` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `alpha.pdf(x, a, loc, scale)` is identically equivalent to `alpha.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(alpha.ppf(0.01, a),
...                 alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a),
...        'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = alpha.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                   |                                                                                                  |
|---------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>                                    | Random variates.                                                                                 |
| <code>pdf(x, a, loc=0, scale=1)</code>                                                            | Probability density function.                                                                    |
| <code>logpdf(x, a, loc=0, scale=1)</code>                                                         | Log of the probability density function.                                                         |
| <code>cdf(x, a, loc=0, scale=1)</code>                                                            | Cumulative distribution function.                                                                |
| <code>logcdf(x, a, loc=0, scale=1)</code>                                                         | Log of the cumulative distribution function.                                                     |
| <code>sf(x, a, loc=0, scale=1)</code>                                                             | Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate). |
| <code>logsf(x, a, loc=0, scale=1)</code>                                                          | Log of the survival function.                                                                    |
| <code>ppf(q, a, loc=0, scale=1)</code>                                                            | Percent point function (inverse of <code>cdf</code> — percentiles).                              |
| <code>isf(q, a, loc=0, scale=1)</code>                                                            | Inverse survival function (inverse of <code>sf</code> ).                                         |
| <code>moment(n, a, loc=0, scale=1)</code>                                                         | Non-central moment of order <i>n</i>                                                             |
| <code>stats(a, loc=0, scale=1, moments='mv')</code>                                               | Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').                                       |
| <code>entropy(a, loc=0, scale=1)</code>                                                           | (Differential) entropy of the RV.                                                                |

| <code>interval(alpha, a, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains <i>alpha</i> percent of the distribution                    |

`scipy.stats.anglit = <scipy.stats.continuous_distns.anglit_gen object at 0x2b2318be91d0>`

An `anglit` continuous random variable.

As an instance of the `rv_continuous` class, `anglit` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `anglit` is:

$$\text{anglit.pdf}(x) = \sin(2x + \pi/2) = \cos(2x),$$

for  $-\pi/4 \leq x \leq \pi/4$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `anglit.pdf(x, loc, scale)` is identically equivalent to `anglit.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import anglit
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(anglit.ppf(0.01),
...                 anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
...         'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.arcsine` = <scipy.stats.\_continuous\_distns.arcsine\_gen object at 0x2b2318be93d0>

An arcsine continuous random variable.

As an instance of the `rv_continuous` class, `arcsine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `arcsine` is:

$$\text{arcsine.pdf}(x) = 1 / (\pi * \sqrt{x * (1-x)})$$

for  $0 < x < 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `arcsine.pdf(x, loc, scale)` is identically equivalent to `arcsine.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```

>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(arcsine.ppf(0.01),
...                 arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
...         'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

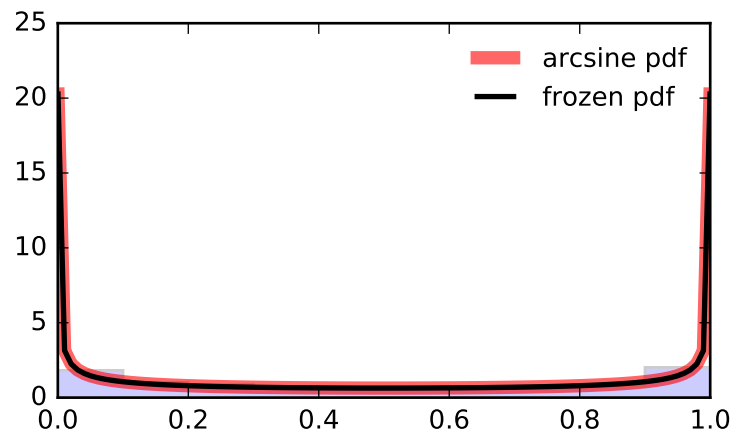

```
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.argus = <scipy.stats.continuous_distns.argus_gen object at 0x2b2318ee6d50>`

Argus distribution

As an instance of the `rv_continuous` class, `argus` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `argus` is:

$$\text{argus.pdf}(x, \text{chi}) = \text{chi}^3 / (\text{sqrt}(2\pi) * \text{Psi}(\text{chi})) * x * \text{sqrt}(1-x^2) * \exp(-0.5 * \text{chi}^2 * (1-x^2))$$

where:

$$\text{Psi}(\text{chi}) = \text{Phi}(\text{chi}) - \text{chi} * \text{phi}(\text{chi}) - 1/2$$

with `Phi` and `phi` being the CDF and PDF of a standard normal distribution, respectively.

`argus` takes `chi` as shape a parameter.

**References**

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `argus.pdf(x, chi, loc, scale)` is identically equivalent to `argus.pdf(y, chi) / scale` with `y = (x - loc) / scale`.

New in version 0.19.0.

[R555]

### Examples

```
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(argus.ppf(0.01, chi),
...                 argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi),
...        'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
True
```

Generate random numbers:

```
>>> r = argus.rvs(chi, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.beta` = <scipy.stats.continuous\_distns.beta\_gen object at 0x2b2318be9650>

A beta continuous random variable.

As an instance of the `rv_continuous` class, `beta` object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `beta` is:

$$\text{beta.pdf}(x, a, b) = \frac{\text{gamma}(a+b) * x^{a-1} * (1-x)^{b-1}}{\text{gamma}(a) * \text{gamma}(b)}$$

for  $0 < x < 1, a > 0, b > 0$ , where `gamma(z)` is the gamma function (`scipy.special.gamma`).

`beta` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `beta.pdf(x, a, b, loc, scale)` is identically equivalent to `beta.pdf(y, a, b) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(beta.ppf(0.01, a, b),
...                 beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.betaprime` = <scipy.stats.\_continuous\_distns.betaprime\_gen object at 0x2b2318be98d0>  
A beta prime continuous random variable.

As an instance of the `rv_continuous` class, `betaprime` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `betaprime` is:

$$\text{betaprime.pdf}(x, a, b) = x^{a-1} * (1+x)^{-a-b} / \text{beta}(a, b)$$

for  $x > 0, a > 0, b > 0$ , where `beta(a, b)` is the beta function (see `scipy.special.beta`).

`betaprime` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `betaprime.pdf(x, a, b, loc, scale)` is identically equivalent to `betaprime.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(betaprime.ppf(0.01, a, b),
...                 betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='betaprime pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = betaprime(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.bradford` = <scipy.stats.\_continuous\_distns.bradford\_gen object at 0x2b2318be9b50>  
 A Bradford continuous random variable.

As an instance of the `rv_continuous` class, `bradford` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `bradford` is:

$$\text{bradford.pdf}(x, c) = c / (k * (1+c*x)),$$

for  $0 < x < 1, c > 0$  and  $k = \log(1+c)$ .

`bradford` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `bradford.pdf(x, c, loc, scale)` is identically equivalent to `bradford.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(bradford.ppf(0.01, c),
...                 bradford.ppf(0.99, c), 100)
>>> ax.plot(x, bradford.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

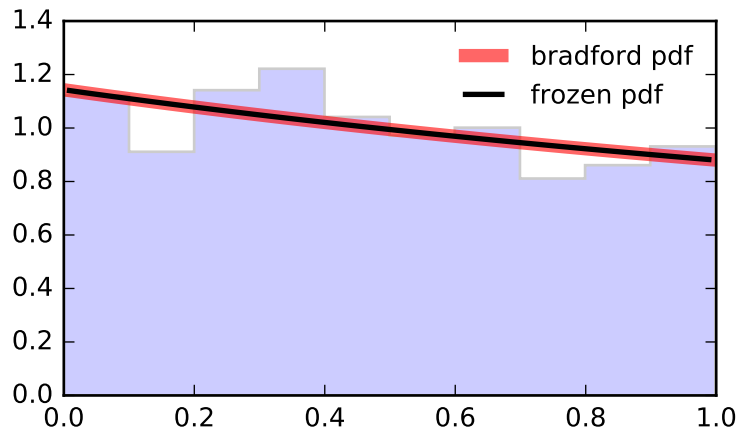

```
>>> vals = bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], bradford.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

```
scipy.stats.burr = <scipy.stats._continuous_distns.burr_gen object at 0x2b2318be9e10>
```

A Burr (Type III) continuous random variable.

As an instance of the `rv_continuous` class, `burr` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`fisk` a special case of either `burr` or `burr12` with  $d = 1$   
`burr12` Burr Type XII distribution

**Notes**

The probability density function for `burr` is:

```
burr.pdf(x, c, d) = c * d * x**(-c-1) * (1+x**(-c))**(-d-1)
```

for  $x > 0$ .

`burr` takes `c` and `d` as shape parameters.

This is the PDF corresponding to the third CDF given in Burr's list; specifically, it is equation (11) in Burr's paper [R561].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr.pdf(x, c, d, loc, scale)` is identically equivalent to `burr.pdf(y, c, d) / scale` with  $y = (x - loc) / scale$ .

**References**

[R561]

**Examples**

```
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 10.5, 4.3
>>> mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr.ppf(0.01, c, d),
...                 burr.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr.pdf(x, c, d),
...        'r-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.burr12 = <scipy.stats._continuous_distns.burr12_gen object at 0x2b2318bf60d0>`

A Burr (Type XII) continuous random variable.

As an instance of the `rv_continuous` class, `burr12` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

- `fisk` a special case of either `burr` or `burr12` with  $d = 1$
- `burr` Burr Type III distribution

**Notes**

The probability density function for `burr` is:

$$\text{burr12.pdf}(x, c, d) = c * d * x^{(c-1)} * (1+x^{(c)})^{-(d-1)}$$

for  $x > 0$ .

`burr12` takes `c` and `d` as shape parameters.

This is the PDF corresponding to the twelfth CDF given in Burr's list; specifically, it is equation (20) in Burr's paper [R562].

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr12.pdf(x, c, d, loc, scale)` is identically equivalent to `burr12.pdf(y, c, d) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [R563].

### References

[R562], [R563]

### Examples

```
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr12.ppf(0.01, c, d),
...                 burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr12 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr12.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>mean(c, d, loc=0, scale=1)</code>                                                             | Mean of the distribution.                                                                        |
| <code>var(c, d, loc=0, scale=1)</code>                                                              | Variance of the distribution.                                                                    |
| <code>std(c, d, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, c, d, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.cauchy` = <scipy.stats.continuous\_distns.cauchy\_gen object at 0x2b2318bf65d0>

A Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `cauchy` object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `cauchy` is:

```
cauchy.pdf(x) = 1 / (pi * (1 + x**2))
```

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cauchy.ppf(0.01),
...                 cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.chi` = <scipy.stats.continuous\_distns.chi\_gen object at 0x2b2318bf6810>

A chi continuous random variable.

As an instance of the `rv_continuous` class, `chi` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `chi` is:

```
chi.pdf(x, df) = x**(df-1) * exp(-x**2/2) / (2**(df/2-1) * gamma(df/2))
```

for  $x > 0$ .

Special cases of `chi` are:

- `chi(1, loc, scale)` is equivalent to `halfnorm`
- `chi(2, 0, scale)` is equivalent to `rayleigh`
- `chi(3, 0, scale)` is equivalent to `maxwell`

`chi` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi.pdf(x, df, loc, scale)` is identically equivalent to `chi.pdf(y, df) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi.ppf(0.01, df),
...                 chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.chi2 = <scipy.stats.continuous\_distns.chi2\_gen object at 0x2b2318bf6a90>

A chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `chi2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `chi2` is:

```
chi2.pdf(x, df) = 1 / (2*gamma(df/2)) * (x/2)**(df/2-1) * exp(-x/2)
```

`chi2` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi2.ppf(0.01, df),
...                 chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi2.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.cosine` = <scipy.stats.continuous\_distns.cosine\_gen object at 0x2b2318bf6d10>  
 A cosine continuous random variable.

As an instance of the `rv_continuous` class, `cosine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The cosine distribution is an approximation to the normal distribution. The probability density function for `cosine` is:

$$\text{cosine.pdf}(x) = 1/(2\pi) * (1+\cos(x))$$

for  $-\pi \leq x \leq \pi$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cosine.pdf(x, loc, scale)` is identically equivalent to `cosine.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cosine.ppf(0.01),
...                 cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x),
...        'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cosine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cosine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cosine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.dgamma = <scipy.stats.continuous_distns.dgamma_gen object at 0x2b2318bf6f10>`

A double gamma continuous random variable.

As an instance of the `rv_continuous` class, `dgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `dgamma` is:

$$\text{dgamma.pdf}(x, a) = 1 / (2 * \text{gamma}(a)) * \text{abs}(x) ** (a-1) * \text{exp}(-\text{abs}(x))$$

for  $a > 0$ .

`dgamma` takes `a` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dgamma.ppf(0.01, a),
...                 dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.dweibull` = <scipy.stats.continuous\_distns.dweibull\_gen object at 0x2b2318c031d0>  
 A double Weibull continuous random variable.

As an instance of the `rv_continuous` class, `dweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `dweibull` is:

$$\text{dweibull.pdf}(x, c) = c / 2 * \text{abs}(x)**(c-1) * \text{exp}(-\text{abs}(x)**c)$$

`dweibull` takes `d` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dweibull.pdf(x, c, loc, scale)` is identically equivalent to `dweibull.pdf(y, c) / scale` with `y = (x - loc) / scale`.

**Examples**

```
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 2.07
>>> mean, var, skew, kurt = dweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dweibull.ppf(0.01, c),
...                 dweibull.ppf(0.99, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

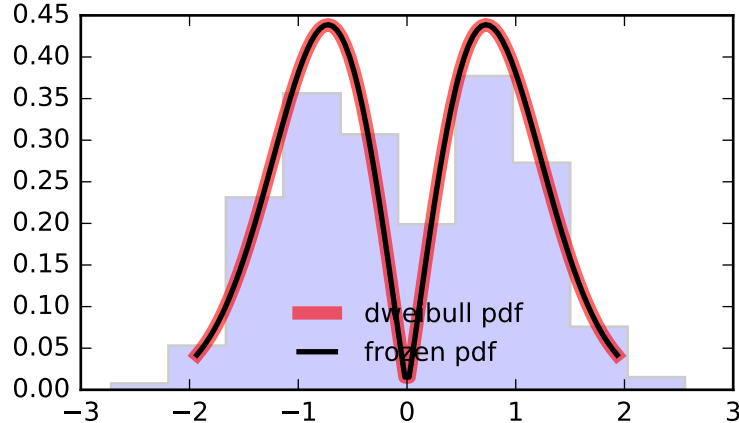

```
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.erlang = <scipy.stats.continuous_distns.erlang_gen object at 0x2b2318c1de90>`

An Erlang continuous random variable.

As an instance of the `rv_continuous` class, `erlang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

gamma

### Notes

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter  $a$  an integer. Note that this restriction is not enforced by `erlang`. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to `gamma` for examples.

### Methods

|                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

`scipy.stats.expon = <scipy.stats.continuous_distns.expon_gen object at 0x2b2318c03450>`

An exponential continuous random variable.

As an instance of the `rv_continuous` class, `expon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `expon` is:

$$\text{expon.pdf}(x) = \exp(-x)$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `expon.pdf(x, loc, scale)` is identically equivalent to `expon.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

A common parameterization for `expon` is in terms of the rate parameter `lambda`, such that  $\text{pdf} = \text{lambda} * \exp(-\text{lambda} * x)$ . This parameterization corresponds to using `scale = 1 / lambda`.

### Examples

```
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(expon.ppf(0.01),
...                 expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
...         'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
True
```

Generate random numbers:

```
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.exponnorm` = <`scipy.stats.continuous_distns.exponnorm_gen` object at `0x2b2318c03650`>  
 An exponentially modified Normal continuous random variable.

As an instance of the `rv_continuous` class, `exponnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `exponnorm` is:

```
exponnorm.pdf(x, K) =
    1/(2*K) exp(1/(2 * K**2)) exp(-x / K) * erfc-(x - 1/K) / sqrt(2))
```

where the shape parameter  $K > 0$ .

It can be thought of as the sum of a normally distributed random value with mean `loc` and sigma `scale` and an exponentially distributed random number with a pdf proportional to  $\exp(-\lambda * x)$  where  $\lambda = (K * scale)**(-1)$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent to `exponnorm.pdf(y, K) / scale` with  $y = (x - loc) / scale$ .

An alternative parameterization of this distribution (for example, in [Wikipedia](#)) involves three parameters,  $\mu$ ,  $\lambda$  and  $\sigma$ . In the present parameterization this corresponds to having `loc` and `scale` equal to  $\mu$  and  $\sigma$ , respectively, and shape parameter  $K = 1/\sigma\lambda$ .

New in version 0.16.0.

### Examples

```
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponnorm.ppf(0.01, K),
...                 exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
...         'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
True
```

Generate random numbers:

```
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.exponweib` = <scipy.stats.\_continuous\_distns.exponweib\_gen object at 0x2b2318c038d0>  
An exponentiated Weibull continuous random variable.

As an instance of the `rv_continuous` class, `exponweib` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `exponweib` is:

```
exponweib.pdf(x, a, c) =
    a * c * (1-exp(-x**c))**(a-1) * exp(-x**c)*x**(c-1)
```

for  $x > 0, a > 0, c > 0$ .

`exponweib` takes `a` and `c` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponweib.pdf(x, a, c, loc, scale)` is identically equivalent to `exponweib.pdf(y, a, c) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
...                 exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.exponpow` = <scipy.stats.\_continuous\_distns.exponpow\_gen object at 0x2b2318c03b50>  
An exponential power continuous random variable.

As an instance of the `rv_continuous` class, `exponpow` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `exponpow` is:

```
exponpow.pdf(x, b) = b * x**(b-1) * exp(1 + x**b - exp(x**b))
```

for  $x \geq 0, b > 0$ . Note that this is a different distribution from the exponential power distribution that is also known under the names “generalized normal” or “generalized Gaussian”.

`exponpow` takes `b` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponpow.pdf(x, b, loc, scale)` is identically equivalent to `exponpow.pdf(y, b) / scale` with  $y = (x - loc) / scale$ .

### References

<http://www.math.wm.edu/~leemis/chart/UDR/PDFs/Exponentialpower.pdf>

### Examples

```
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponpow.ppf(0.01, b),
...                 exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b),
...        'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>mean(b, loc=0, scale=1)</code>                                                              | Mean of the distribution.                                                                        |
| <code>var(b, loc=0, scale=1)</code>                                                               | Variance of the distribution.                                                                    |
| <code>std(b, loc=0, scale=1)</code>                                                               | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, b, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.f` = <scipy.stats.continuous\_distns.f\_gen object at 0x2b2318c11310>

An F continuous random variable.

As an instance of the `rv_continuous` class, `f` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `f` is:

$$F.\text{pdf}(x, \text{df1}, \text{df2}) = \frac{\text{df2}^{df2/2} * \text{df1}^{df1/2} * x^{df1/2-1}}{(\text{df2} + \text{df1} * x)^{df1/2 + df2/2} * B(\text{df1}/2, \text{df2}/2)}$$

for  $x > 0$ .

`f` takes `dfn` and `dfd` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `f.pdf(x, dfn, dfd, loc, scale)` is identically equivalent to `f.pdf(y, dfn, dfd) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(f.ppf(0.01, dfn, dfd),
...                 f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd),
...         'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.fatiguelife` = <scipy.stats.\_continuous\_distns.fatiguelife\_gen object at 0x2b2318c03dd0>  
A fatigue-life (Birnbbaum-Saunders) continuous random variable.

As an instance of the `rv_continuous` class, `fatiguelife` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `fatiguelife` is:

$$\text{fatiguelife.pdf}(x, c) = \frac{(x+1)}{(2*c*\sqrt{2*\pi*x**3})} * \exp(-(x-1)**2/(2*x*c**2))$$

for  $x > 0$ .

`fatiguelife` takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `fatiguelife.pdf(x, c, loc, scale)` is identically equivalent to `fatiguelife.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**References**

[R577]

*Examples*

```
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 29
>>> mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fatiguelife.ppf(0.01, c),
...                 fatiguelife.ppf(0.99, c), 100)
>>> ax.plot(x, fatiguelife.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fatiguelife pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fatiguelife(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fatiguelife.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.fisk = <scipy.stats.continuous_distns.fisk_gen object at 0x2b2318bf6350>`

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution, and equals the Burr distribution with  $d == 1$ .

`fisk` takes `c` as a shape parameter.

As an instance of the `rv_continuous` class, `fisk` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`burr`

**Notes**

The probability density function for `fisk` is:

$$\text{fisk.pdf}(x, c) = c * x^{-(c-1)} * (1 + x^{-(c)})^{-2}$$

for  $x > 0$ .

`fisk` takes `c` as a shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fisk.pdf(x, c, loc, scale)` is identically equivalent to `fisk.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fisk.ppf(0.01, c),
...                 fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fisk pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fisk(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fisk.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fisk.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fisk.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```
scipy.stats.foldcauchy = <scipy.stats._continuous_distns.foldcauchy_gen object at 0x2b2318c11090>
```

A folded Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `foldcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `foldcauchy` is:

$$\text{foldcauchy.pdf}(x, c) = 1/(\pi * (1+(x-c)**2)) + 1/(\pi * (1+(x+c)**2))$$

for  $x \geq 0$ .

`foldcauchy` takes `c` as a shape parameter.

### Examples

```
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 4.72
>>> mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldcauchy.ppf(0.01, c),
...                 foldcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, foldcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.foldnorm = <scipy.stats.continuous_distns.foldnorm_gen object at 0x2b2318c11590>`  
 A folded normal continuous random variable.

As an instance of the `rv_continuous` class, `foldnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `foldnorm` is:

```
foldnormal.pdf(x, c) = sqrt(2/pi) * cosh(c*x) * exp(-(x**2+c**2)/2)
```

for  $c \geq 0$ .

`foldnorm` takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `foldnorm.pdf(x, c, loc, scale)` is identically equivalent to `foldnorm.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.95
>>> mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldnorm.ppf(0.01, c),
...                 foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.frechet_r = <scipy.stats.continuous_distns.frechet_r_gen object at 0x2b2318c11810>`  
 A Fréchet right (or Weibull minimum) continuous random variable.

As an instance of the `rv_continuous` class, `frechet_r` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

**`weibull_min`**

The same distribution as `frechet_r`.

`frechet_l`, `weibull_max`

**Notes**

The probability density function for `frechet_r` is:

```
frechet_r.pdf(x, c) = c * x**(c-1) * exp(-x**c)
```

for  $x > 0, c > 0$ .

`frechet_r` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `frechet_r.pdf(x, c, loc, scale)` is identically equivalent to `frechet_r.pdf(y, c) / scale` with  $y = (x - loc) / scale$ .

**Examples**

```
>>> from scipy.stats import frechet_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.89
>>> mean, var, skew, kurt = frechet_r.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(frechet_r.ppf(0.01, c),
...                 frechet_r.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_r.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='frechet_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = frechet_r(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = frechet_r.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_r.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = frechet_r.rvs(c, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
    
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

```

scipy.stats.frechet_1 = <scipy.stats._continuous_distns.frechet_1_gen object at 0x2b2318c11cd0>
    
```

A Frechet left (or Weibull maximum) continuous random variable.

As an instance of the `rv_continuous` class, `frechet_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`weibull_max`

The same distribution as `frechet_l`.

`frechet_r`, `weibull_min`

**Notes**

The probability density function for `frechet_l` is:

$$\text{frechet\_l.pdf}(x, c) = c * (-x)**(c-1) * \exp(-(-x)**c)$$

for  $x < 0, c > 0$ .

`frechet_l` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `frechet_l.pdf(x, c, loc, scale)` is identically equivalent to `frechet_l.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import frechet_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.63
>>> mean, var, skew, kurt = frechet_l.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(frechet_l.ppf(0.01, c),
...                 frechet_l.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_l.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='frechet_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = frechet_l(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = frechet_l.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_l.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = frechet_l.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, c, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.genlogistic = <scipy.stats.continuous_distns.genlogistic_gen object at 0x2b2318c1d1d0>`  
 A generalized logistic continuous random variable.

As an instance of the `rv_continuous` class, `genlogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `genlogistic` is:

$$\text{genlogistic.pdf}(x, c) = c * \exp(-x) / (1 + \exp(-x))^{c+1}$$

for  $x > 0, c > 0$ .

`genlogistic` takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `genlogistic.pdf(x, c, loc, scale)` is identically equivalent to `genlogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genlogistic.ppf(0.01, c),
...                 genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genlogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.gennorm` = <scipy.stats.continuous\_distns.gennorm\_gen object at 0x2b2318ee6850>  
 A generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `gennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

- `laplace` Laplace distribution
- `norm` normal distribution

**Notes**

The probability density function for `gennorm` is [R587]:

$$\text{gennorm.pdf}(x, \text{beta}) = \frac{\text{beta}}{2 \cdot \text{gamma}(1/\text{beta})} \exp(-|x|**\text{beta})$$

`gennorm` takes `beta` as a shape parameter. For `beta = 1`, it is identical to a Laplace distribution. For `beta = 2`, it is identical to a normal distribution (with `scale=1/sqrt(2)`).

**References**

[R587]

### Examples

```
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gennorm.ppf(0.01, beta),
...                 gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

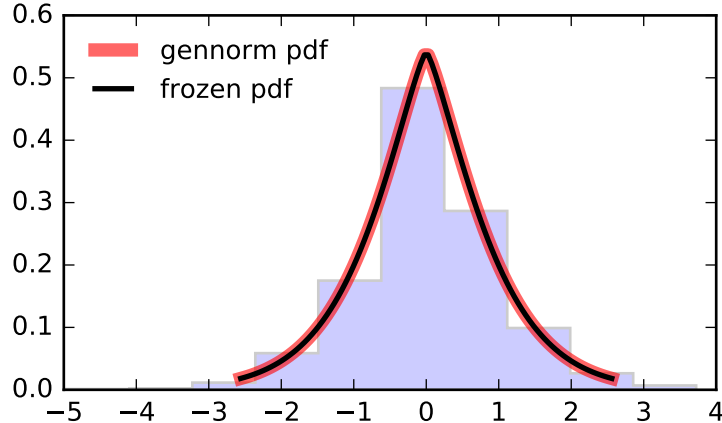

```
>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = gennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

`scipy.stats.genpareto` = <scipy.stats.continuous\_distns.genpareto\_gen object at 0x2b2318c1d450>  
 A generalized Pareto continuous random variable.

As an instance of the `rv_continuous` class, `genpareto` object inherits from it a collection of generic

methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `genpareto` is:

```
genpareto.pdf(x, c) = (1 + c * x)**(-1 - 1/c)
```

defined for  $x \geq 0$  if  $c \geq 0$ , and for  $0 \leq x \leq -1/c$  if  $c < 0$ .

`genpareto` takes  $c$  as a shape parameter.

For  $c == 0$ , `genpareto` reduces to the exponential distribution, `expon`:

```
genpareto.pdf(x, c=0) = exp(-x)
```

For  $c == -1$ , `genpareto` is uniform on  $[0, 1]$ :

```
genpareto.cdf(x, c=-1) = x
```

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genpareto.pdf(x, c, loc, scale)` is identically equivalent to `genpareto.pdf(y, c) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.1
>>> mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genpareto.ppf(0.01, c),
...                 genpareto.ppf(0.99, c), 100)
>>> ax.plot(x, genpareto.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genpareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genpareto(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genpareto.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

`scipy.stats.genexpon = <scipy.stats.continuous_distns.genexpon_gen object at 0x2b2318c1d6d0>`  
 A generalized exponential continuous random variable.

As an instance of the `rv_continuous` class, `genexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `genexpon` is:

$$\text{genexpon.pdf}(x, a, b, c) = (a + b * (1 - \exp(-c*x))) * \exp(-a - b * \exp(-c*x))$$

for  $x \geq 0, a, b, c > 0$ .

`genexpon` takes *a*, *b* and *c* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genexpon.pdf(x, a, b, c, loc, scale)` is identically equivalent to `genexpon.pdf(y, a, b, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

*Examples*

```
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b, c = 9.13, 16.2, 3.28
>>> mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genexpon.ppf(0.01, a, b, c),
...                 genexpon.ppf(0.99, a, b, c), 100)
>>> ax.plot(x, genexpon.pdf(x, a, b, c),
...         'r-', lw=5, alpha=0.6, label='genexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genexpon(a, b, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
>>> np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
True
```

Generate random numbers:

```
>>> r = genexpon.rvs(a, b, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>expect(func, args=(a, b, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code> | Expected value of a function (of one argument) with respect to the distribution.                 |
| <code>median(a, b, c, loc=0, scale=1)</code>                                                           | Median of the distribution.                                                                      |
| <code>mean(a, b, c, loc=0, scale=1)</code>                                                             | Mean of the distribution.                                                                        |
| <code>var(a, b, c, loc=0, scale=1)</code>                                                              | Variance of the distribution.                                                                    |
| <code>std(a, b, c, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, a, b, c, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.genextreme = <scipy.stats.continuous_distns.genextreme_gen object at 0x2b2318c1d990>`  
 A generalized extreme value continuous random variable.

As an instance of the `rv_continuous` class, `genextreme` object inherits from it a collection of generic

methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`gumbel_r`

**Notes**

For  $c=0$ , `genextreme` is equal to `gumbel_r`. The probability density function for `genextreme` is:

$$\text{genextreme.pdf}(x, c) = \begin{cases} \exp(-\exp(-x)) * \exp(-x), & \text{for } c=0 \\ \exp(-(1-c*x)**(1/c)) * (1-c*x)**(1/c-1), & \text{for } x \leq 1/c, c > 0 \end{cases}$$

Note that several sources and software packages use the opposite convention for the sign of the shape parameter  $c$ .

`genextreme` takes  $c$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genextreme.ppf(0.01, c),
...                 genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genextreme pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

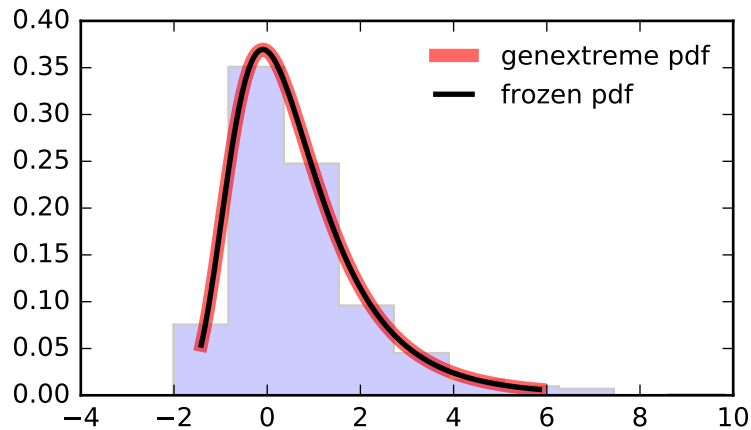

```
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genextreme.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.gausshyper` = <scipy.stats.\_continuous\_distns.gausshyper\_gen object at 0x2b2318e8f510>  
 A Gauss hypergeometric continuous random variable.

As an instance of the `rv_continuous` class, `gausshyper` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `gausshyper` is:

```
gausshyper.pdf(x, a, b, c, z) =
    C * x**(a-1) * (1-x)**(b-1) * (1+z*x)**(-c)
```

for  $0 \leq x \leq 1, a > 0, b > 0,$  and  $C = 1 / (B(a, b) F[2, 1](c, a; a+b; -z))$

`gausshyper` takes `a, b, c` and `z` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gausshyper.pdf(x, a, b, c, z, loc, scale)` is identically equivalent to `gausshyper.pdf(y, a, b, c, z) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
...                 gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
...         'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
True
```

Generate random numbers:

```
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>mean(a, b, c, z, loc=0, scale=1)</code>                                                             | Mean of the distribution.                                                                        |
| <code>var(a, b, c, z, loc=0, scale=1)</code>                                                              | Variance of the distribution.                                                                    |
| <code>std(a, b, c, z, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, a, b, c, z, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.gamma = <scipy.stats._continuous_distns.gamma_gen object at 0x2b2318c1dc10>`

A gamma continuous random variable.

As an instance of the `rv_continuous` class, `gamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`erlang`, `expon`

**Notes**

The probability density function for `gamma` is:

$$\text{gamma.pdf}(x, a) = x^{a-1} * \exp(-x) / \text{gamma}(a)$$

for  $x \geq 0, a > 0$ . Here `gamma(a)` refers to the gamma function.

`gamma` has a shape parameter *a* which needs to be set explicitly.

When *a* is an integer, `gamma` reduces to the Erlang distribution, and when *a*=1 to the exponential distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gamma.pdf(x, a, loc, scale)` is identically equivalent to `gamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gamma.ppf(0.01, a),
...                 gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = gamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.gengamma` = <scipy.stats.continuous\_distns.gengamma\_gen object at 0x2b2318e82150>  
 A generalized gamma continuous random variable.

As an instance of the `rv_continuous` class, `gengamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `gengamma` is:

```
gengamma.pdf(x, a, c) = abs(c) * x**(c*a-1) * exp(-x**c) / gamma(a)
```

for  $x \geq 0$ ,  $a > 0$ , and  $c \neq 0$ .

`gengamma` takes `a` and `c` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gengamma.pdf(x, a, c, loc, scale)` is identically equivalent to `gengamma.pdf(y, a, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gengamma.ppf(0.01, a, c),
...                 gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
...        'r-', lw=5, alpha=0.6, label='gengamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gengamma(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gengamma.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], gengamma.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = gengamma.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, a, c, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.genhalflogistic = <scipy.stats.continuous_distns.genhalflogistic_gen object at 0x2b2318e823d0>`  
 A generalized half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `genhalflogistic` object inherits from it a collection of

generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `genhalflogistic` is:

```
genhalflogistic.pdf(x, c) =
    2 * (1-c*x)**(1/c-1) / (1+(1-c*x)**(1/c))**2
```

for  $0 \leq x \leq 1/c$ , and  $c > 0$ .

`genhalflogistic` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
...                 genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genhalflogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>mean(c, loc=0, scale=1)</code>                                                              | Mean of the distribution.                                                                        |
| <code>var(c, loc=0, scale=1)</code>                                                               | Variance of the distribution.                                                                    |
| <code>std(c, loc=0, scale=1)</code>                                                               | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, c, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains <i>alpha</i> percent of the distribution                    |

`scipy.stats.gilbrat = <scipy.stats.continuous_distns.gilbrat_gen object at 0x2b2318ea26d0>`  
 A Gilbrat continuous random variable.

As an instance of the `rv_continuous` class, `gilbrat` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `gilbrat` is:

```
gilbrat.pdf(x) = 1/(x*sqrt(2*pi)) * exp(-1/2*(log(x))**2)
```

`gilbrat` is a special case of `lognorm` with `s = 1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gilbrat.ppf(0.01),
...                 gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.gompertz` = <scipy.stats.continuous\_distns.gompertz\_gen object at 0x2b2318e82650>

A Gompertz (or truncated Gumbel) continuous random variable.

As an instance of the `rv_continuous` class, `gompertz` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `gompertz` is:

```
gompertz.pdf(x, c) = c * exp(x) * exp(-c*(exp(x)-1))
```

for  $x \geq 0, c > 0$ .

`gompertz` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gompertz.pdf(x, c, loc, scale)` is identically equivalent to `gompertz.pdf(y, c) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gompertz.ppf(0.01, c),
...                 gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>var(c, loc=0, scale=1)</code>                                                               | Variance of the distribution.                                                                    |
| <code>std(c, loc=0, scale=1)</code>                                                               | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, c, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.gumbel_r = <scipy.stats.continuous_distns.gumbel_r_gen object at 0x2b2318e828d0>`

A right-skewed Gumbel continuous random variable.

As an instance of the `rv_continuous` class, `gumbel_r` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

```
gumbel_l, gompertz, genextreme
```

### Notes

The probability density function for `gumbel_r` is:

```
gumbel_r.pdf(x) = exp(-(x + exp(-x)))
```

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_r.pdf(x, loc, scale)` is identically equivalent to `gumbel_r.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_r.ppf(0.01),
...                 gumbel_r.ppf(0.99), 100)
>>> ax.plot(x, gumbel_r.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.halfcauchy = <scipy.stats.continuous_distns.halfcauchy_gen object at 0x2b2318e82cd0>`  
 A Half-Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `halfcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `halfcauchy` is:

```
halfcauchy.pdf(x) = 2 / (pi * (1 + x**2))
```

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import halfcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halfcauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfcauchy.ppf(0.01),
...                 halfcauchy.ppf(0.99), 100)
>>> ax.plot(x, halfcauchy.pdf(x),
...        'r-', lw=5, alpha=0.6, label='halfcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfcauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfcauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfcauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfcauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.halflogistic` = <scipy.stats.\_continuous\_distns.halflogistic\_gen object at 0x2b2318e82ed0>  
 A half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `halflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `halflogistic` is:

$$\text{halflogistic.pdf}(x) = 2 * \exp(-x) / (1+\exp(-x))^{**2} = 1/2 * \text{sech}(x/2)^{**2}$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halflogistic.pdf(x, loc, scale)` is identically equivalent to `halflogistic.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import halflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halflogistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halflogistic.ppf(0.01),
...                 halflogistic.ppf(0.99), 100)
>>> ax.plot(x, halflogistic.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halflogistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halflogistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halflogistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halflogistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.halfnorm = <scipy.stats.continuous_distns.halfnorm_gen object at 0x2b2318e8f110>`

A half-normal continuous random variable.

As an instance of the `rv_continuous` class, `halfnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `halfnorm` is:

```
halfnorm.pdf(x) = sqrt(2/pi) * exp(-x**2/2)
```

for  $x > 0$ .

`halfnorm` is a special case of `chi` with `df == 1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfnorm.pdf(x, loc, scale)` is identically equivalent to `halfnorm.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfnorm.ppf(0.01),
...                 halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfnorm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

`scipy.stats.halfgennorm` = <scipy.stats.continuous\_distns.halfgennorm\_gen object at 0x2b2318ee6ad0>  
 The upper half of a generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `halfgennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gennorm` generalized normal distribution  
`expon` exponential distribution  
`halfnorm` half normal distribution

### Notes

The probability density function for `halfgennorm` is:

$$\text{halfgennorm.pdf}(x, \text{beta}) = \frac{\text{beta}}{\text{gamma}(1/\text{beta})} \exp(-|x|**\text{beta})$$

`gennorm` takes `beta` as a shape parameter. For `beta = 1`, it is identical to an exponential distribution. For `beta = 2`, it is identical to a half normal distribution (with `scale=1/sqrt(2)`).

### References

[R588]

### Examples

```
>>> from scipy.stats import halfgennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta = 0.675
>>> mean, var, skew, kurt = halfgennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
...                 halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
...        'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfgennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = halfgennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

`scipy.stats.hypsecant` = <scipy.stats.\_continuous\_distns.hypsecant\_gen object at 0x2b2318e8f310>

A hyperbolic secant continuous random variable.

As an instance of the `rv_continuous` class, `hypsecant` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `hypsecant` is:

```
hypsecant.pdf(x) = 1/pi * sech(x)
```

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = hypsecant.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(hypsecant.ppf(0.01),
...                 hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
...        'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
True
```

Generate random numbers:

```
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.invgamma` = <scipy.stats.continuous\_distns.invgamma\_gen object at 0x2b2318e8f790>

An inverted gamma continuous random variable.

As an instance of the `rv_continuous` class, `invgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `invgamma` is:

```
invgamma.pdf(x, a) = x**(-a-1) / gamma(a) * exp(-1/x)
```

for  $x > 0$ ,  $a > 0$ .

`invgamma` takes `a` as a shape parameter.

`invgamma` is a special case of `gengamma` with `c == -1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgamma.pdf(x, a, loc, scale)` is identically equivalent to `invgamma.pdf(y, a) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgamma.ppf(0.01, a),
...                 invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
...        'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, a, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.invgauss = <scipy.stats.continuous_distns.invgauss_gen object at 0x2b2318e8fa50>`  
 An inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `invgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `invgauss` is:

```
invgauss.pdf(x, mu) = 1 / sqrt(2*pi*x**3) * exp(-(x-mu)**2/(2*x*mu**2))
```

for  $x > 0$ .

`invgauss` takes `mu` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgauss.pdf(x, mu, loc, scale)` is identically equivalent to `invgauss.pdf(y, mu) / scale` with  $y = (x - loc) / scale$ .

When `mu` is too small, evaluating the cumulative distribution function will be inaccurate due to `cdf(mu -> 0) = inf * 0`. NaNs are returned for `mu <= 0.0028`.

### Examples

```
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgauss.ppf(0.01, mu),
...                 invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
...        'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.invweibull = <scipy.stats.continuous_distns.invweibull_gen object at 0x2b2318e8fcd0>`  
An inverted Weibull continuous random variable.

As an instance of the `rv_continuous` class, `invweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `invweibull` is:

```
invweibull.pdf(x, c) = c * x**(-c-1) * exp(-x**(-c))
```

for  $x > 0, c > 0$ .

`invweibull` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c, loc, scale)` is identically equivalent to `invweibull.pdf(y, c) / scale` with  $y = (x - loc) / scale$ .

### References

F.R.S. de Gusmao, E.M.M Ortega and G.M. Cordeiro, “The generalized inverse Weibull distribution”, Stat. Papers, vol. 52, pp. 591-619, 2011.

### Examples

```
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invweibull.ppf(0.01, c),
...                 invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

```
scipy.stats.johnsonsb = <scipy.stats._continuous_distns.johnsonsb_gen object at 0x2b2318e8ff50>
```

A Johnson SB continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsb` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`johnsonsu`

**Notes**

The probability density function for `johnsonsb` is:

```
johnsonsb.pdf(x, a, b) = b / (x*(1-x)) * phi(a + b * log(x/(1-x)))
```

for  $0 < x < 1$  and  $a, b > 0$ , and `phi` is the normal pdf.

`johnsonsb` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsb.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsb.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 4.32, 3.18
>>> mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b),
...                 johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsb.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.johnsonsu` = <scipy.stats.continuous\_distns.johnsonsu\_gen object at 0x2b2318e9b210>  
A Johnson SU continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsu` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`johnsonsb`

**Notes**

The probability density function for `johnsonsu` is:

$$\text{johnsonsu.pdf}(x, a, b) = b / \sqrt{x^2 + 1} * \text{phi}(a + b * \log(x + \sqrt{x^2 + 1}))$$

for all  $x$ ,  $a, b > 0$ , and *phi* is the normal pdf.

`johnsonsu` takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `johnsonsu.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsu.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

*Examples*

```
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b),
...                 johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

| <code>mean(a, b, loc=0, scale=1)</code>                                                             | Mean of the distribution.                                                                        |
| <code>var(a, b, loc=0, scale=1)</code>                                                              | Variance of the distribution.                                                                    |
| <code>std(a, b, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, a, b, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.kappa4 = <scipy.stats.continuous_distns.kappa4_gen object at 0x2b2318ea2d50>`

Kappa 4 parameter distribution.

As an instance of the `rv_continuous` class, `kappa4` object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for kappa4 is:

$$\text{kappa4.pdf}(x, h, k) = (1.0 - k*x)**(1.0/k - 1.0) * (1.0 - h*(1.0 - k*x)**(1.0/k))**(1.0/h-1)$$

if h and k are not equal to 0.

If h or k are zero then the pdf can be simplified:

h = 0 and k != 0:

$$\text{kappa4.pdf}(x, h, k) = (1.0 - k*x)**(1.0/k - 1.0) * \exp(-(1.0 - k*x)**(1.0/k))$$

h != 0 and k = 0:

$$\text{kappa4.pdf}(x, h, k) = \exp(-x) * (1.0 - h*\exp(-x))**(1.0/h - 1.0)$$

h = 0 and k = 0:

$$\text{kappa4.pdf}(x, h, k) = \exp(-x) * \exp(-\exp(-x))$$

kappa4 takes h and k as shape parameters.

The kappa4 distribution returns other distributions when certain h and k values are used.

| h    | k=0.0                   | k=1.0                  | -inf<=k<=inf                                  |
|------|-------------------------|------------------------|-----------------------------------------------|
| -1.0 | Logistic<br>logistic(x) |                        | Generalized Logistic(1)                       |
| 0.0  | Gumbel<br>gumbel_r(x)   | Reverse Exponential(2) | Generalized Extreme Value<br>genextreme(x, k) |
| 1.0  | Exponential<br>expon(x) | Uniform<br>uniform(x)  | Generalized Pareto<br>genpareto(x, -k)        |

1. There are at least five generalized logistic distributions. Four are described here: [https://en.wikipedia.org/wiki/Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Generalized_logistic_distribution) The “fifth” one is the one kappa4 should match which currently isn’t implemented in scipy: [https://en.wikipedia.org/wiki/Talk:Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Talk:Generalized_logistic_distribution) [http://www.mathwave.com/help/easyfit/html/analyses/distributions/gen\\_logistic.html](http://www.mathwave.com/help/easyfit/html/analyses/distributions/gen_logistic.html)

2. This distribution is currently not in scipy.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa4.pdf(x, h, k, loc, scale)` is identically equivalent to `kappa4.pdf(y, h, k) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
...                 kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
...        'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
True
```

Generate random numbers:

```
>>> r = kappa4.rvs(h, k, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>expect(func, args=(h, k), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code> | Expected value of a function (of one argument) with respect to the distribution.                 |
| <code>median(h, k, loc=0, scale=1)</code>                                                           | Median of the distribution.                                                                      |
| <code>mean(h, k, loc=0, scale=1)</code>                                                             | Mean of the distribution.                                                                        |
| <code>var(h, k, loc=0, scale=1)</code>                                                              | Variance of the distribution.                                                                    |
| <code>std(h, k, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, h, k, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.kappa3` = <scipy.stats.continuous\_distns.kappa3\_gen object at 0x2b2318ea2fd0>

Kappa 3 parameter distribution.

As an instance of the `rv_continuous` class, `kappa3` object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *kappa* is:

```
kappa3.pdf(x, a) =
    a*[a + x**a]**(-(a + 1)/a),    for ``x > 0``
    0.0,                            for ``x <= 0``
```

`kappa3` takes `a` as a shape parameter and `a > 0`.

B. Kumphon, “Maximum Entropy and Maximum Likelihood Estimation for the Three-Parameter Kappa Distribution”, *Open Journal of Statistics*, vol 2, 415-419 (2012) [http://file.scirp.org/pdf/OJS20120400011\\_95789012.pdf](http://file.scirp.org/pdf/OJS20120400011_95789012.pdf)

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa3.pdf(x, a, loc, scale)` is identically equivalent to `kappa3.pdf(y, a) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import kappa3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1
>>> mean, var, skew, kurt = kappa3.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa3.ppf(0.01, a),
...                 kappa3.ppf(0.99, a), 100)
>>> ax.plot(x, kappa3.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='kappa3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa3(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

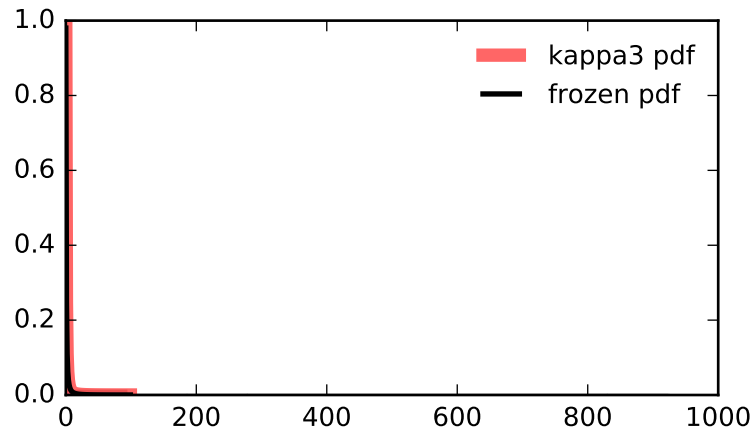

```
>>> vals = kappa3.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], kappa3.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = kappa3.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, a, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.ksone = <scipy.stats.continuous_distns.ksone_gen object at 0x2b2318b8c910>`

General Kolmogorov-Smirnov one-sided test.

As an instance of the `rv_continuous` class, `ksone` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import ksone
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n = 1e+03
>>> mean, var, skew, kurt = ksone.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ksone.ppf(0.01, n),
...                 ksone.ppf(0.99, n), 100)
>>> ax.plot(x, ksone.pdf(x, n),
...         'r-', lw=5, alpha=0.6, label='ksone pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ksone(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ksone.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], ksone.cdf(vals, n))
True
```

Generate random numbers:

```
>>> r = ksone.rvs(n, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>fit(data, n, loc=0, scale=1)</code>                                                         | Parameter estimates for generic data.                                                            |
| <code>expect(func, args=(n,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code> | Expected value of a function (of one argument) with respect to the distribution.                 |
| <code>median(n, loc=0, scale=1)</code>                                                            | Median of the distribution.                                                                      |
| <code>mean(n, loc=0, scale=1)</code>                                                              | Mean of the distribution.                                                                        |
| <code>var(n, loc=0, scale=1)</code>                                                               | Variance of the distribution.                                                                    |
| <code>std(n, loc=0, scale=1)</code>                                                               | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, n, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.kstwobign = <scipy.stats.continuous_distns.kstwobign_gen object at 0x2b2318b8cb10>`  
 Kolmogorov-Smirnov two-sided test for large *N*.

As an instance of the `rv_continuous` class, `kstwobign` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import kstwobign
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = kstwobign.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwobign.ppf(0.01),
...                 kstwobign.ppf(0.99), 100)
>>> ax.plot(x, kstwobign.pdf(x),
...         'r-', lw=5, alpha=0.6, label='kstwobign pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwobign()  
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kstwobign.ppf([0.001, 0.5, 0.999])  
>>> np.allclose([0.001, 0.5, 0.999], kstwobign.cdf(vals))  
True
```

Generate random numbers:

```
>>> r = kstwobign.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)  
>>> ax.legend(loc='best', frameon=False)  
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.laplace` = <scipy.stats.continuous\_distns.laplace\_gen object at 0x2b2318e9b490>  
 A Laplace continuous random variable.

As an instance of the `rv_continuous` class, `laplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `laplace` is:

$$\text{laplace.pdf}(x) = 1/2 * \exp(-\text{abs}(x))$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `laplace.pdf(x, loc, scale)` is identically equivalent to `laplace.pdf(y) / scale` with `y = (x - loc) / scale`.

**Examples**

```

>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```

>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')

```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace.ppf(0.01),
...                 laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x),
...         'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
True
```

Generate random numbers:

```
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.levy = <scipy.stats._continuous_distns.levy_gen object at 0x2b2318e9b590>`

A Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`levy_stable`, `levy_l`

**Notes**

The probability density function for `levy` is:

$$\text{levy.pdf}(x) = 1 / (x * \text{sqrt}(2 * \text{pi} * x)) * \text{exp}(-1 / (2 * x))$$

for  $x > 0$ .

This is the same as the Levy-stable distribution with  $a=1/2$  and  $b=1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy.pdf(x, loc, scale)` is identically equivalent to `levy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy.ppf(0.01),
...                 levy.ppf(0.99), 100)
>>> ax.plot(x, levy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

`scipy.stats.levy_1` = <scipy.stats.continuous\_distns.levy\_1\_gen object at 0x2b2318e9b890>

A left-skewed Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy_1` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

```
levy, levy_stable
```

### Notes

The probability density function for `levy_1` is:

$$\text{levy\_1.pdf}(x) = 1 / (\text{abs}(x) * \text{sqrt}(2 * \pi * \text{abs}(x))) * \text{exp}(-1 / (2 * \text{abs}(x)))$$

for  $x < 0$ .

This is the same as the Levy-stable distribution with  $a=1/2$  and  $b=-1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_1.pdf(x, loc, scale)` is identically equivalent to `levy_1.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import levy_1
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = levy_1.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_1.ppf(0.01),
...                 levy_1.ppf(0.99), 100)
>>> ax.plot(x, levy_1.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy_1 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_1()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy_1.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_1.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy_1.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

`scipy.stats.levy_stable` = <scipy.stats.continuous\_distns.levy\_stable\_gen object at 0x2b2318e9ba90>  
 A Levy-stable continuous random variable.

As an instance of the `rv_continuous` class, `levy_stable` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

```
levy, levy_l
```

### Notes

Levy-stable distribution (only random variates available – ignore other docs)

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_stable.pdf(x, alpha, beta, loc, scale)` is identically equivalent to `levy_stable.pdf(y, alpha, beta) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import levy_stable
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> alpha, beta = 0.357, -0.675
>>> mean, var, skew, kurt = levy_stable.stats(alpha, beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_stable.ppf(0.01, alpha, beta),
...                 levy_stable.ppf(0.99, alpha, beta), 100)
>>> ax.plot(x, levy_stable.pdf(x, alpha, beta),
...        'r-', lw=5, alpha=0.6, label='levy_stable pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_stable(alpha, beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy_stable.ppf([0.001, 0.5, 0.999], alpha, beta)
>>> np.allclose([0.001, 0.5, 0.999], levy_stable.cdf(vals, alpha, beta))
True
```

Generate random numbers:

```
>>> r = levy_stable.rvs(alpha, beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>expect(func, args=(alpha, beta), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code> | Expected value of a function (of one argument) with respect to the distribution.                 |
| <code>median(alpha, beta, loc=0, scale=1)</code>                                                           | Median of the distribution.                                                                      |
| <code>mean(alpha, beta, loc=0, scale=1)</code>                                                             | Mean of the distribution.                                                                        |
| <code>var(alpha, beta, loc=0, scale=1)</code>                                                              | Variance of the distribution.                                                                    |
| <code>std(alpha, beta, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, alpha, beta, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains <i>alpha</i> percent of the distribution                    |

`scipy.stats.logistic = <scipy.stats.continuous_distns.logistic_gen object at 0x2b2318e9bd10>`

A logistic (or Sech-squared) continuous random variable.

As an instance of the `rv_continuous` class, `logistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `logistic` is:

$$\text{logistic.pdf}(x) = \exp(-x) / (1 + \exp(-x))^{*2}$$

`logistic` is a special case of `genlogistic` with `c == 1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `logistic.pdf(x, loc, scale)` is identically equivalent to `logistic.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(logistic.ppf(0.01),
...                 logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x),
...         'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = logistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.loggamma` = <scipy.stats.continuous\_distns.loggamma\_gen object at 0x2b2318e9bf10>  
 A log gamma continuous random variable.

As an instance of the `rv_continuous` class, `loggamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `loggamma` is:

$$\text{loggamma.pdf}(x, c) = \exp(c \cdot x - \exp(x)) / \text{gamma}(c)$$

for all  $x, c > 0$ .

`loggamma` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loggamma.pdf(x, c, loc, scale)` is identically equivalent to `loggamma.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```

>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loggamma.ppf(0.01, c),
...                 loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.loglaplace` = <scipy.stats.continuous\_distns.loglaplace\_gen object at 0x2b2318ea21d0>  
 A log-Laplace continuous random variable.

As an instance of the `rv_continuous` class, `loglaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `loglaplace` is:

$$\begin{aligned} \text{loglaplace.pdf}(x, c) &= c / 2 * x^{c-1}, & \text{for } 0 < x < 1 \\ &= c / 2 * x^{-c-1}, & \text{for } x \geq 1 \end{aligned}$$

for  $c > 0$ .

`loglaplace` takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `loglaplace.pdf(x, c, loc, scale)` is identically equivalent to `loglaplace.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**References**

T.J. Kozubowski and K. Podgorski, “A log-Laplace growth rate model”, *The Mathematical Scientist*, vol. 28, pp. 49-60, 2003.

*Examples*

```
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loglaplace.ppf(0.01, c),
...                 loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.lognorm` = <scipy.stats.continuous\_distns.lognorm\_gen object at 0x2b2318ea2450>

A lognormal continuous random variable.

As an instance of the `rv_continuous` class, `lognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `lognorm` is:

$$\text{lognorm.pdf}(x, s) = 1 / (s*x*\text{sqrt}(2*\text{pi})) * \text{exp}(-1/2*(\text{log}(x)/s)**2)$$

for  $x > 0, s > 0$ .

`lognorm` takes `s` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lognorm.pdf(x, s, loc, scale)` is identically equivalent to `lognorm.pdf(y, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

A common parametrization for a lognormal random variable  $Y$  is in terms of the mean,  $\mu$ , and standard deviation,  $\sigma$ , of the unique normally distributed random variable  $X$  such that  $\exp(X) = Y$ . This parametrization corresponds to setting  $s = \sigma$  and  $\text{scale} = \exp(\mu)$ .

### Examples

```
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lognorm.ppf(0.01, s),
...                 lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s),
...        'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```
>>> r = lognorm.rvs(s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.lomax` = <scipy.stats.continuous\_distns.lomax\_gen object at 0x2b2318ec4290>

A Lomax (Pareto of the second kind) continuous random variable.

As an instance of the `rv_continuous` class, `lomax` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The Lomax distribution is a special case of the Pareto distribution, with (`loc=-1.0`).

The probability density function for `lomax` is:

```
lomax.pdf(x, c) = c / (1+x)**(c+1)
```

for  $x \geq 0, c > 0$ .

`lomax` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lomax.pdf(x, c, loc, scale)` is identically equivalent to `lomax.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lomax.ppf(0.01, c),
...                 lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='lomax pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = lomax.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```
scipy.stats.maxwell = <scipy.stats._continuous_distns.maxwell_gen object at 0x2b2318ea28d0>
```

A Maxwell continuous random variable.

As an instance of the `rv_continuous` class, `maxwell` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

A special case of a `chi` distribution, with `df = 3`, `loc = 0.0`, and given `scale = a`, where `a` is the parameter used in the Mathworld description [R606].

The probability density function for `maxwell` is:

$$\text{maxwell.pdf}(x) = \sqrt{2/\pi} x^{*2} * \exp(-x^{*2}/2)$$

for  $x > 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### References

[R606]

### Examples

```
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(maxwell.ppf(0.01),
...                 maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x),
...        'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True
```

Generate random numbers:

```
>>> r = maxwell.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.mielke = <scipy.stats._continuous_distns.mielke_gen object at 0x2b2318ea2ad0>`  
 A Mielke's Beta-Kappa continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `mielke` is:

$$\text{mielke.pdf}(x, k, s) = k * x^{k-1} / (1+x*s)^{k+1/s}$$

for  $x > 0$ .

`mielke` takes `k` and `s` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import mielke
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> k, s = 10.4, 3.6
>>> mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(mielke.ppf(0.01, k, s),
...                 mielke.ppf(0.99, k, s), 100)
>>> ax.plot(x, mielke.pdf(x, k, s),
...        'r-', lw=5, alpha=0.6, label='mielke pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = mielke(k, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
>>> np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
True
```

Generate random numbers:

```
>>> r = mielke.rvs(k, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.nakagami` = <scipy.stats.\_continuous\_distns.nakagami\_gen object at 0x2b2318eb7290>  
 A Nakagami continuous random variable.

As an instance of the `rv_continuous` class, `nakagami` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `nakagami` is:

$$\text{nakagami.pdf}(x, \text{nu}) = 2 * \text{nu} * \text{nu} / \text{gamma}(\text{nu}) * x^{2 * \text{nu} - 1} * \exp(-\text{nu} * x^2)$$

for  $x > 0, \text{nu} > 0$ .

`nakagami` takes `nu` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nakagami.pdf(x, nu, loc, scale)` is identically equivalent to `nakagami.pdf(y, nu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nakagami.ppf(0.01, nu),
...                 nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu),
...        'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.ncx2` = <scipy.stats.\_continuous\_distns.ncx2\_gen object at 0x2b2318eb7510>

A non-central chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `ncx2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `ncx2` is:

$$\text{ncx2.pdf}(x, \text{df}, \text{nc}) = \exp(-(\text{nc}+x)/2) * 1/2 * (x/\text{nc})^{((\text{df}-2)/4)} * I[(\text{df}-2)/2](\text{sqrt}(\text{nc}*x))$$

for  $x > 0$ .

`ncx2` takes `df` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncx2.pdf(x, df, nc, loc, scale)` is identically equivalent to `ncx2.pdf(y, df, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncx2.ppf(0.01, df, nc),
...                 ncx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc),
...        'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncx2.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncx2.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = ncx2.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.ncf` = <scipy.stats.\_continuous\_distns.ncf\_gen object at 0x2b2318eb7790>

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `ncf` is:

$$\text{ncf.pdf}(x, \text{df1}, \text{df2}, \text{nc}) = \exp(\text{nc}/2 + \text{nc} \cdot \text{df1} \cdot x / (2 \cdot (\text{df1} \cdot x + \text{df2}))) \cdot \text{df1}^{df1/2} \cdot \text{df2}^{df2/2} \cdot x^{df1/2-1} \cdot (\text{df2} + \text{df1} \cdot x)^{-(df1+df2)/2} \cdot \text{gamma}(\text{df1}/2) \cdot \text{gamma}(1+df2/2) \cdot L^{\{v1/2-1\}}_{\{v2/2\}}(-\text{nc} \cdot v1 \cdot x / (2 \cdot (v1 \cdot x + v2))) / (B(v1/2, v2/2) \cdot \text{gamma}((v1+v2)/2))$$

for `df1`, `df2`, `nc` > 0.

`ncf` takes `df1`, `df2` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncf.pdf(x, dfn, dfd, nc, loc, scale)` is identically equivalent to `ncf.pdf(y, dfn, dfd, nc) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc),
...                 ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc),
...         'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```

Generate random numbers:

```
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.nct` = <scipy.stats.continuous\_distns.nct\_gen object at 0x2b2318eb7cd0>

A non-central Student's T continuous random variable.

As an instance of the `rv_continuous` class, `nct` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `nct` is:

$$\text{nct.pdf}(x, df, nc) = \frac{df^{df/2} * \text{gamma}(df+1)}{2^{df} * \exp(nc^{df/2}) * (df+x^{df/2})^{df/2} * \text{gamma}(df/2)}$$

for  $df > 0$ .

`nct` takes `df` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nct.pdf(x, df, nc, loc, scale)` is identically equivalent to `nct.pdf(y, df, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 14, 0.24
>>> mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nct.ppf(0.01, df, nc),
...                 nct.ppf(0.99, df, nc), 100)
>>> ax.plot(x, nct.pdf(x, df, nc),
...         'r-', lw=5, alpha=0.6, label='nct pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nct(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nct.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = nct.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.norm = <scipy.stats._continuous_distns.norm_gen object at 0x2b2318b8cd10>`

A normal continuous random variable.

The location (`loc`) keyword specifies the mean. The scale (`scale`) keyword specifies the standard deviation.

As an instance of the `rv_continuous` class, `norm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `norm` is:

```
norm.pdf(x) = exp(-x**2/2)/sqrt(2*pi)
```

The survival function, `norm.sf`, is also referred to as the Q-function in some contexts (see, e.g., [Wikipedia's definition](#)).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norm.pdf(x, loc, scale)` is identically equivalent to `norm.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norm.ppf(0.01),
...                 norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
...        'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = norm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.pareto` = <scipy.stats.continuous\_distns.pareto\_gen object at 0x2b2318eb7f90>

A Pareto continuous random variable.

As an instance of the `rv_continuous` class, `pareto` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `pareto` is:

```
pareto.pdf(x, b) = b / x**(b+1)
```

for  $x \geq 1, b > 0$ .

`pareto` takes `b` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pareto.pdf(x, b, loc, scale)` is identically equivalent to `pareto.pdf(y, b) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pareto.ppf(0.01, b),
...                 pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='pareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.pearson3 = <scipy.stats.continuous_distns.pearson3_gen object at 0x2b2318ec4510>`

A pearson type III continuous random variable.

As an instance of the `rv_continuous` class, `pearson3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `pearson3` is:

```
pearson3.pdf(x, skew) = abs(beta) / gamma(alpha) *  
    (beta * (x - zeta))**(alpha - 1) * exp(-beta*(x - zeta))
```

where:

```
beta = 2 / (skew * stddev)  
alpha = (stddev * beta)**2  
zeta = loc - alpha / beta
```

`pearson3` takes `skew` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pearson3.pdf(x, skew, loc, scale)` is identically equivalent to `pearson3.pdf(y, skew) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import pearson3  
>>> import matplotlib.pyplot as plt  
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> skew = 0.1  
>>> mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pearson3.ppf(0.01, skew),  
...                pearson3.ppf(0.99, skew), 100)  
>>> ax.plot(x, pearson3.pdf(x, skew),  
...       'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pearson3(skew)  
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True
```

Generate random numbers:

```
>>> r = pearson3.rvs(skew, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.powerlaw = <scipy.stats._continuous_distns.powerlaw_gen object at 0x2b2318ec4790>`  
 A power-function continuous random variable.

As an instance of the `rv_continuous` class, `powerlaw` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `powerlaw` is:

$$\text{powerlaw.pdf}(x, a) = a * x^{(a-1)}$$

for  $0 \leq x \leq 1, a > 0$ .

`powerlaw` takes *a* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `powerlaw.pdf(x, a, loc, scale)` is identically equivalent to `powerlaw.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

`powerlaw` is a special case of `beta` with  $b == 1$ .

**Examples**

```
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlaw.ppf(0.01, a),
...                 powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='powerlaw pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = powerlaw.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.powerlognorm = <scipy.stats._continuous_distns.powerlognorm_gen object at 0x2b2318ec4a10>`  
 A power log-normal continuous random variable.

As an instance of the `rv_continuous` class, `powerlognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `powerlognorm` is:

$$\text{powerlognorm.pdf}(x, c, s) = c / (x*s) * \text{phi}(\log(x)/s) * (\text{Phi}(-\log(x)/s))^{c-1},$$

where `phi` is the normal pdf, and `Phi` is the normal cdf, and  $x > 0, s, c > 0$ .

`powerlognorm` takes `c` and `s` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlognorm.pdf(x, c, s, loc, scale)` is identically equivalent to `powerlognorm.pdf(y, c, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
...                 powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
...         'r-', lw=5, alpha=0.6, label='powerlognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```

Generate random numbers:

```
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, c, s, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.powernorm = <scipy.stats.continuous_distns.powernorm_gen object at 0x2b2318ec4c90>`  
 A power normal continuous random variable.

As an instance of the `rv_continuous` class, `powernorm` object inherits from it a collection of generic

methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `powernorm` is:

```
powernorm.pdf(x, c) = c * phi(x) * (Phi(-x))**(c-1)
```

where `phi` is the normal pdf, and `Phi` is the normal cdf, and  $x > 0, c > 0$ .

`powernorm` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powernorm.pdf(x, c, loc, scale)` is identically equivalent to `powernorm.pdf(y, c) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powernorm.ppf(0.01, c),
...                 powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='powernorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = powernorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.rdist = <scipy.stats.continuous_distns.rdist_gen object at 0x2b2318ec4f10>`

An R-distributed continuous random variable.

As an instance of the `rv_continuous` class, `rdist` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `rdist` is:

```
rdist.pdf(x, c) = (1-x**2)**(c/2-1) / B(1/2, c/2)
```

for  $-1 \leq x \leq 1, c > 0$ .

`rdist` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rdist.pdf(x, c, loc, scale)` is identically equivalent to `rdist.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.9
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rdist.ppf(0.01, c),
...                 rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.reciprocal` = <scipy.stats.continuous\_distns.reciprocal\_gen object at 0x2b2318ed13d0>  
 A reciprocal continuous random variable.

As an instance of the `rv_continuous` class, `reciprocal` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `reciprocal` is:

```
reciprocal.pdf(x, a, b) = 1 / (x*log(b/a))
```

for  $a \leq x \leq b, a, b > 0$ .

`reciprocal` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `reciprocal.pdf(x, a, b, loc, scale)` is identically equivalent to `reciprocal.pdf(y, a, b) / scale` with  $y = (x - loc) / scale$ .

**Examples**

```
>>> from scipy.stats import reciprocal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.00623, 1.01
>>> mean, var, skew, kurt = reciprocal.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(reciprocal.ppf(0.01, a, b),
...                 reciprocal.ppf(0.99, a, b), 100)
>>> ax.plot(x, reciprocal.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='reciprocal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = reciprocal(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = reciprocal.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], reciprocal.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = reciprocal.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, a, b, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains alpha percent of the distribution                           |

`scipy.stats.rayleigh = <scipy.stats.continuous_distns.rayleigh_gen object at 0x2b2318ed11d0>`  
 A Rayleigh continuous random variable.

As an instance of the `rv_continuous` class, `rayleigh` object inherits from it a collection of generic meth-

ods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `rayleigh` is:

```
rayleigh.pdf(r) = r * exp(-r**2/2)
```

for  $x \geq 0$ .

`rayleigh` is a special case of `chi` with `df == 2`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rayleigh.pdf(x, loc, scale)` is identically equivalent to `rayleigh.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rayleigh.ppf(0.01),
...                 rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x),
...         'r-', lw=5, alpha=0.6, label='rayleigh pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

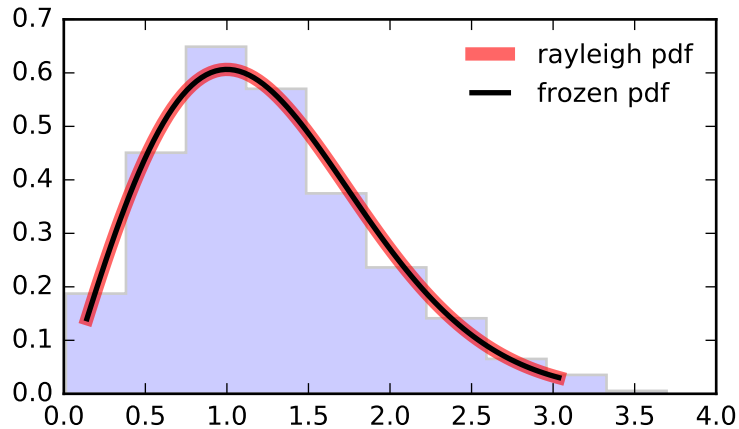

```
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
True
```

Generate random numbers:

```
>>> r = rayleigh.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.rice` = <scipy.stats\_continuous\_distns.rice\_gen object at 0x2b2318ed1650>

A Rice continuous random variable.

As an instance of the `rv_continuous` class, `rice` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `rice` is:

```
rice.pdf(x, b) = x * exp(-(x**2+b**2)/2) * I[0](x*b)
```

for  $x > 0, b > 0$ .

`rice` takes `b` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rice.pdf(x, b, loc, scale)` is identically equivalent to `rice.pdf(y, b) / scale` with  $y = (x - loc) / scale$ .

The Rice distribution describes the length,  $r$ , of a 2-D vector with components  $(U+u, V+v)$ , where  $U, V$  are constant,  $u, v$  are independent Gaussian random variables with standard deviation  $s$ . Let  $R = (U**2 + V**2)**0.5$ . Then the pdf of  $r$  is `rice.pdf(x, R/s, scale=s)`.

### Examples

```
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rice.ppf(0.01, b),
...                 rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = rice.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```
scipy.stats.recipinvgauss = <scipy.stats.continuous_distns.recipinvgauss_gen object at 0x2b2318ed18d0>
A reciprocal inverse Gaussian continuous random variable.
```

As an instance of the `rv_continuous` class, `recipinvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `recipinvgauss` is:

```
recipinvgauss.pdf(x, mu) = 1/sqrt(2*pi*x) * exp(-(1-mu*x)**2/(2*x*mu**2))
```

for  $x \geq 0$ .

`recipinvgauss` takes `mu` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `recipinvgauss.pdf(x, mu, loc, scale)` is identically equivalent to `recipinvgauss.pdf(y, mu) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu),
...                 recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu),
...         'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.semicircular = <scipy.stats.continuous_distns.semicircular_gen object at 0x2b2318ed1b50>`  
 A semicircular continuous random variable.

As an instance of the `rv_continuous` class, `semicircular` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `semicircular` is:

```
semicircular.pdf(x) = 2/pi * sqrt(1-x**2)
```

for  $-1 \leq x \leq 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `semicircular.pdf(x, loc, scale)` is identically equivalent to `semicircular.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(semicircular.ppf(0.01),
...                 semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x),
...         'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = semicircular()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))
True
```

Generate random numbers:

```
>>> r = semicircular.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.skewnorm` = <scipy.stats.continuous\_distns.skew\_norm\_gen object at 0x2b2318ed1d50>  
 A skew-normal random variable.

As an instance of the `rv_continuous` class, `skewnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The pdf is:

```
skewnorm.pdf(x, a) = 2*norm.pdf(x)*norm.cdf(ax)
```

`skewnorm` takes `a` as a skewness parameter. When `a=0` the distribution is identical to a normal distribution. `rvs` implements the method of [R636].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewnorm.pdf(x, a, loc, scale)` is identically equivalent to `skewnorm.pdf(y, a) / scale` with `y = (x - loc) / scale`.

### References

[R636]

### Examples

```
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(skewnorm.ppf(0.01, a),
...                 skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

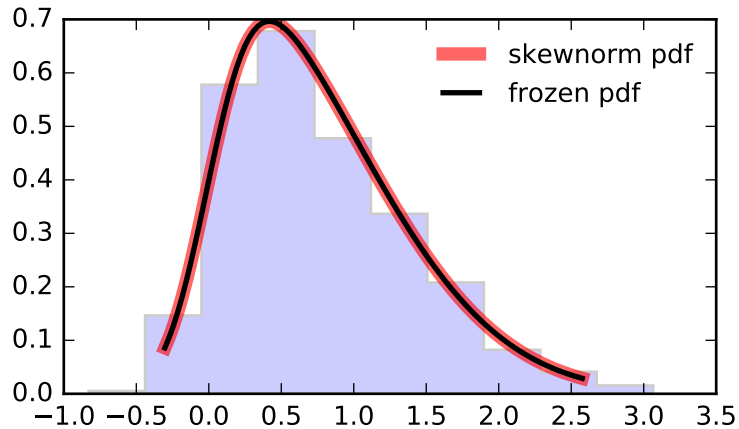

```
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.t` = <scipy.stats.continuous\_distns.t\_gen object at 0x2b2318eb7a50>

A Student's T continuous random variable.

As an instance of the `rv_continuous` class, `t` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for  $t$  is:

$$t.pdf(x, df) = \frac{\text{gamma}((df+1)/2)}{\sqrt{\pi \cdot df} * \text{gamma}(df/2) * (1+x**2/df)**((df+1)/2)}$$

for  $df > 0$ .

$t$  takes  $df$  as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `t.pdf(x, df, loc, scale)` is identically equivalent to `t.pdf(y, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(t.ppf(0.01, df),
...                 t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

`scipy.stats.trapz = <scipy.stats.continuous_distns.trapz_gen object at 0x2b2318ed2050>`

A trapezoidal continuous random variable.

As an instance of the `rv_continuous` class, `trapz` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The trapezoidal distribution can be represented with an up-sloping line from  $loc$  to  $(loc + c*scale)$ , then constant to  $(loc + d*scale)$  and then down-sloping from  $(loc + d*scale)$  to  $(loc+scale)$ .

`trapz` takes  $c$  and  $d$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `trapz.pdf(x, c, d, loc, scale)` is identically equivalent to `trapz.pdf(y, c, d) / scale` with  $y = (x - loc) / scale$ .

The standard form is in the range  $[0, 1]$  with  $c$  the mode. The location parameter shifts the start to  $loc$ . The scale parameter changes the width from 1 to  $scale$ .

### Examples

```
>>> from scipy.stats import trapz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapz.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(trapz.ppf(0.01, c, d),
...                 trapz.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapz.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='trapz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = trapz(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = trapz.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapz.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = trapz.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.triang` = <scipy.stats.continuous\_distns.triang\_gen object at 0x2b2318ed22d0>

A triangular continuous random variable.

As an instance of the `rv_continuous` class, `triang` object inherits from it a collection of generic methods

(see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The triangular distribution can be represented with an up-sloping line from `loc` to `(loc + c*scale)` and then downsloping for `(loc + c*scale)` to `(loc+scale)`.

`triang` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `triang.pdf(x, c, loc, scale)` is identically equivalent to `triang.pdf(y, c) / scale` with `y = (x - loc) / scale`.

The standard form is in the range `[0, 1]` with `c` the mode. The location parameter shifts the start to `loc`. The scale parameter changes the width from 1 to `scale`.

### Examples

```
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.158
>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(triang.ppf(0.01, c),
...                 triang.ppf(0.99, c), 100)
>>> ax.plot(x, triang.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='triang pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = triang(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.truncexpon = <scipy.stats.continuous_distns.truncexpon_gen object at 0x2b2318ed2550>`  
 A truncated exponential continuous random variable.

As an instance of the `rv_continuous` class, `truncexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `truncexpon` is:

$$\text{truncexpon.pdf}(x, b) = \exp(-x) / (1 - \exp(-b))$$

for  $0 < x < b$ .

`truncexpon` takes `b` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncexpon.pdf(x, b, loc, scale)` is identically equivalent to `truncexpon.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 4.69
>>> mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncexpon.ppf(0.01, b),
...                 truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.truncnorm` = <scipy.stats.continuous\_distns.truncnorm\_gen object at 0x2b2318ed27d0>  
 A truncated normal continuous random variable.

As an instance of the `rv_continuous` class, `truncnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The standard form of this distribution is a standard normal truncated to the range  $[a, b]$  — notice that  $a$  and  $b$  are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

```
a, b = (myclip_a - my_mean) / my_std, (myclip_b - my_mean) / my_std
```

`truncnorm` takes  $a$  and  $b$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncnorm.pdf(x, a, b, loc, scale)` is identically equivalent to `truncnorm.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncnorm.ppf(0.01, a, b),
...                 truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = truncnorm.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.tukeylambda = <scipy.stats.continuous_distns.tukeylambda_gen object at 0x2b2318ed2a50>`  
 A Tukey-Lambda continuous random variable.

As an instance of the `rv_continuous` class, `tukeylambda` object inherits from it a collection of generic

methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy (lam=-1)
- logistic (lam=0.0)
- approx Normal (lam=0.14)
- u-shape (lam = 0.5)
- uniform from -1 to 1 (lam = 1)

`tukeylambda` takes `lam` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `tukeylambda.pdf(x, lam, loc, scale)` is identically equivalent to `tukeylambda.pdf(y, lam) / scale` with  $y = (x - loc) / scale$ .

### Examples

```
>>> from scipy.stats import tukeylambda
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(tukeylambda.ppf(0.01, lam),
...                 tukeylambda.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambda.pdf(x, lam),
...         'r-', lw=5, alpha=0.6, label='tukeylambda pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = tukeylambda(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = tukeylambda.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambda.cdf(vals, lam))
True
```

Generate random numbers:

```
>>> r = tukeylambda.rvs(lam, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.uniform` = <scipy.stats\_continuous\_distns.uniform\_gen object at 0x2b2318ed2cd0>  
 A uniform continuous random variable.

This distribution is constant between *loc* and *loc* + *scale*.

As an instance of the `rv_continuous` class, `uniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(uniform.ppf(0.01),
...                 uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x),
...         'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
True
```

Generate random numbers:

```
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.vonmises = <scipy.stats._continuous_distns.vonmises_gen object at 0x2b2318ed2ed0>`  
 A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**`vonmises_line`**

The same distribution, defined on a  $[-\pi, \pi]$  segment of the real line.

**Notes**

If  $x$  is not in range or  $loc$  is not in range it assumes they are angles and converts them to  $[-\pi, \pi]$  equivalents.

The probability density function for `vonmises` is:

```
vonmises.pdf(x, kappa) = exp(kappa * cos(x)) / (2*pi*I[0](kappa))
```

for  $-\pi \leq x \leq \pi, \text{kappa} > 0$ .

`vonmises` takes `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises.pdf(y, kappa) / scale` with  $y = (x - loc) / scale$ .

**Examples**

```
>>> from scipy.stats import vonmises
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises.ppf(0.01, kappa),
...                 vonmises.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

```
rvs(kappa, loc=0, scale=1, size=1,
    random_state=None)
pdf(x, kappa, loc=0, scale=1)
logpdf(x, kappa, loc=0, scale=1)
cdf(x, kappa, loc=0, scale=1)
logcdf(x, kappa, loc=0, scale=1)

sf(x, kappa, loc=0, scale=1)

logsf(x, kappa, loc=0, scale=1)
ppf(q, kappa, loc=0, scale=1)
isf(q, kappa, loc=0, scale=1)

moment(n, kappa, loc=0, scale=1)
stats(kappa, loc=0, scale=1, moments='mv')

entropy(kappa, loc=0, scale=1)
fit(data, kappa, loc=0, scale=1)
expect(func, args=(kappa,), loc=0, scale=1,
        lb=None, ub=None, conditional=False,
        **kwds)
median(kappa, loc=0, scale=1)
mean(kappa, loc=0, scale=1)
var(kappa, loc=0, scale=1)
std(kappa, loc=0, scale=1)
interval(alpha, kappa, loc=0, scale=1)
```

Random variates.

Probability density function.

Log of the probability density function.

Cumulative distribution function.

Log of the cumulative distribution function.

Survival function (also defined as  $1 - \text{cdf}$ , but  $\text{sf}$  is sometimes more accurate).

Log of the survival function.

Percent point function (inverse of  $\text{cdf}$  — percentiles).

Inverse survival function (inverse of  $\text{sf}$ ).

Non-central moment of order  $n$

Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').

(Differential) entropy of the RV.

Parameter estimates for generic data.

Expected value of a function (of one argument) with respect to the distribution.

Median of the distribution.

Mean of the distribution.

Variance of the distribution.

Standard deviation of the distribution.

Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.vonmises_line` = <scipy.stats.continuous\_distns.vonmises\_gen object at 0x2b2318ee6190>  
A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises_line` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`vonmises_line`

The same distribution, defined on a  $[-\pi, \pi]$  segment of the real line.

**Notes**

If  $x$  is not in range or  $loc$  is not in range it assumes they are angles and converts them to  $[-\pi, \pi]$  equivalents.

The probability density function for `vonmises` is:

$$\text{vonmises.pdf}(x, \text{kappa}) = \exp(\text{kappa} * \cos(x)) / (2 * \pi * I_0(\text{kappa}))$$

for  $-\pi \leq x \leq \pi, \text{kappa} > 0$ .

`vonmises` takes `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises_line.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises_line.pdf(y, kappa) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

**Examples**

```
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises_line.ppf(0.01, kappa),
...                 vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='vonmises_line pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises_line.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.wald = <scipy.stats._continuous_distns.wald_gen object at 0x2b2318ee63d0>`

A Wald continuous random variable.

As an instance of the `rv_continuous` class, `wald` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `wald` is:

$$\text{wald.pdf}(x) = 1/\sqrt{2\pi x^3} * \exp(-(x-1)**2/(2*x))$$

for  $x > 0$ .

`wald` is a special case of `invgauss` with `mu == 1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wald.pdf(x, loc, scale)` is identically equivalent to `wald.pdf(y) / scale` with `y = (x - loc) / scale`.

**Examples**

```
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wald.ppf(0.01),
...                 wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x),
...         'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
True
```

Generate random numbers:

```
>>> r = wald.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

`scipy.stats.weibull_min` = <scipy.stats.continuous\_distns.frechet\_r\_gen object at 0x2b2318c11a90>  
A Fréchet right (or Weibull minimum) continuous random variable.

As an instance of the `rv_continuous` class, `weibull_min` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:****`weibull_min`**

The same distribution as `frechet_r`.

`frechet_l`, `weibull_max`

**Notes**

The probability density function for `frechet_r` is:

$$\text{frechet\_r.pdf}(x, c) = c * x^{c-1} * \exp(-x^c)$$

for  $x > 0, c > 0$ .

`frechet_r` takes *c* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `weibull_min.pdf(x, c, loc, scale)` is identically equivalent to `weibull_min.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_min.ppf(0.01, c),
...                 weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.weibull_max = <scipy.stats.continuous_distns.frechet_l_gen object at 0x2b2318c11f50>`  
 A Fréchet left (or Weibull maximum) continuous random variable.

As an instance of the `rv_continuous` class, `weibull_max` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

**`weibull_max`**

The same distribution as `frechet_l`.

`frechet_r`, `weibull_min`

**Notes**

The probability density function for `frechet_l` is:

```
frechet_l.pdf(x, c) = c * (-x)**(c-1) * exp(-(-x)**c)
```

for  $x < 0, c > 0$ .

`frechet_l` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_max.pdf(x, c, loc, scale)` is identically equivalent to `weibull_max.pdf(y, c) / scale` with  $y = (x - loc) / scale$ .

**Examples**

```
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_max.ppf(0.01, c),
...                 weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_max.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### Methods

```
scipy.stats.wrapcauchy = <scipy.stats._continuous_distns.wrapcauchy_gen object at 0x2b2318ee65d0>
```

A wrapped Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `wrapcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `wrapcauchy` is:

```
wrapcauchy.pdf(x, c) = (1-c**2) / (2*pi*(1+c**2-2*c*cos(x)))
```

for  $0 \leq x \leq 2\pi, 0 < c < 1$ .

`wrapcauchy` takes `c` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wrapcauchy.pdf(x, c, loc, scale)` is identically equivalent to `wrapcauchy.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.0311
>>> mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wrapcauchy.ppf(0.01, c),
...                 wrapcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, wrapcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wrapcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = wrapcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## 5.27.2 Multivariate distributions

|                                  |                                        |
|----------------------------------|----------------------------------------|
| <code>multivariate_normal</code> | A multivariate normal random variable. |
| <code>matrix_normal</code>       | A matrix normal random variable.       |
| <code>dirichlet</code>           | A Dirichlet random variable.           |
| <code>wishart</code>             | A Wishart random variable.             |
| <code>invwishart</code>          | An inverse Wishart random variable.    |
| <code>multinomial</code>         | A multinomial random variable.         |
| <code>special_ortho_group</code> | A matrix-valued SO(N) random variable. |
| <code>ortho_group</code>         | A matrix-valued O(N) random variable.  |
| <code>random_correlation</code>  | A random correlation matrix.           |

`scipy.stats.multivariate_normal` = <scipy.stats.\_multivariate.multivariate\_normal\_gen object at 0x2b23194d1c90>  
 A multivariate normal random variable.

The *mean* keyword specifies the mean. The *cov* keyword specifies the covariance matrix.

**Parameters** `x` : array\_like

Quantiles, with the last axis of *x* denoting the components.

`mean` : array\_like, optional

Mean of the distribution (default zero)

`cov` : array\_like, optional

Covariance matrix of the distribution (default one)

`allow_singular` : bool, optional

Whether to allow a singular covariance matrix. (Default: False)

`random_state` : None or int or np.random.RandomState instance, optional

If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” multivariate normal random variable:**

`rv = multivariate_normal(mean=None, cov=1, allow_singular=False)`

- Frozen object with the same methods but holding the given mean and covariance fixed.

### Notes

#### Setting the parameter mean to None is equivalent to having mean

be the zero-vector. The parameter *cov* can be a scalar, in which case the covariance matrix is the identity times that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array\_like.

The covariance matrix *cov* must be a (symmetric) positive semi-definite matrix. The determinant and inverse of *cov* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *cov* does not need to have full rank.

The probability density function for `multivariate_normal` is

$$f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp\left(-\frac{1}{2}(x - \mu)^T \Sigma^{-1}(x - \mu)\right),$$

where  $\mu$  is the mean,  $\Sigma$  the covariance matrix, and  $k$  is the dimension of the space where  $x$  takes values.

New in version 0.14.0.

*Examples*

```

>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal

>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([ 0.00108914,  0.01033349,  0.05946514,  0.20755375,  0.43939129,
        0.56418958,  0.43939129,  0.20755375,  0.05946514,  0.01033349])
>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)

```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```

>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))

```

**Methods**

|                                                                |                                                              |
|----------------------------------------------------------------|--------------------------------------------------------------|
| <code>pdf(x, mean=None, cov=1, allow_singular=False)</code>    | Probability density function.                                |
| <code>logpdf(x, mean=None, cov=1, allow_singular=False)</code> | Log of the probability density function.                     |
| <code>rvs(mean=None, cov=1, size=1, random_state=None)</code>  | Draw random samples from a multivariate normal distribution. |
| <code>entropy()</code>                                         | Compute the differential entropy of the multivariate normal. |

`scipy.stats.matrix_normal = <scipy.stats.multivariate.matrix_normal_gen object at 0x2b23194d1ed0>`  
 A matrix normal random variable.

The *mean* keyword specifies the mean. The *rowcov* keyword specifies the among-row covariance matrix. The ‘*colcov*’ keyword specifies the among-column covariance matrix.

**Parameters** **X** : array\_like  
 Quantiles, with the last two axes of *X* denoting the components.  
**mean** : array\_like, optional  
 Mean of the distribution (default: *None*)  
**rowcov** : array\_like, optional  
 Among-row covariance matrix of the distribution (default: *I*)  
**colcov** : array\_like, optional  
 Among-column covariance matrix of the distribution (default: *I*)  
**random\_state** : None or int or np.random.RandomState instance, optional  
 If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.  
**Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” matrix normal random variable:**  
**rv = matrix\_normal(mean=None, rowcov=1, colcov=1)**  
 •Frozen object with the same methods but holding the given mean and covariance fixed.

### Notes

**If mean is set to None then a matrix of zeros is used for the mean.**

The dimensions of this matrix are inferred from the shape of `rowcov` and `colcov`, if these are provided, or set to `I` if ambiguous.

`rowcov` and `colcov` can be two-dimensional array\_likes specifying the covariance matrices directly. Alternatively, a one-dimensional array will be interpreted as the entries of a diagonal matrix, and a scalar or zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by `rowcov` and `colcov` must be (symmetric) positive definite. If the samples in `X` are  $m \times n$ , then `rowcov` must be  $m \times m$  and `colcov` must be  $n \times n$ . `mean` must be the same shape as `X`.

The probability density function for `matrix_normal` is

$$f(X) = (2\pi)^{-\frac{mn}{2}} |U|^{-\frac{n}{2}} |V|^{-\frac{m}{2}} \exp\left(-\frac{1}{2} \text{Tr}[U^{-1}(X-M)V^{-1}(X-M)^T]\right),$$

where  $M$  is the mean,  $U$  the among-row covariance matrix,  $V$  the among-column covariance matrix.

The `allow_singular` behaviour of the `multivariate_normal` distribution is not currently supported. Covariance matrices must be full rank.

The `matrix_normal` distribution is closely related to the `multivariate_normal` distribution. Specifically, `Vec(X)` (the vector formed by concatenating the columns of `X`) has a multivariate normal distribution with mean `Vec(M)` and covariance  $V \otimes U$  (where  $\otimes$  is the Kronecker product). Sampling and pdf evaluation are  $\mathcal{O}(m^3 + n^3 + m^2n + mn^2)$  for the matrix normal, but  $\mathcal{O}(m^3n^3)$  for the equivalent multivariate normal, making this equivalent form algorithmically inefficient.

New in version 0.17.0.

### Examples

```
>>> from scipy.stats import matrix_normal

>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]])
>>> V = 0.3*np.identity(2); V
array([[ 0.3,  0. ],
       [ 0. ,  0.3]])
>>> X = M + 0.1; X
array([[ 0.1,  1.1],
       [ 2.1,  3.1],
       [ 4.1,  5.1]])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054

>>> # Equivalent multivariate normal
>>> from scipy.stats import multivariate_normal
>>> vectorised_X = X.T.flatten()
>>> equiv_mean = M.T.flatten()
>>> equiv_cov = np.kron(V,U)
```

```
>>> multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
0.023410202050005054
```

**Methods**

|                                                               |                                          |
|---------------------------------------------------------------|------------------------------------------|
| pdf(X, mean=None, rowcov=1, colcov=1)                         | Probability density function.            |
| logpdf(X, mean=None, rowcov=1, colcov=1)                      | Log of the probability density function. |
| rvs(mean=None, rowcov=1, colcov=1, size=1, random_state=None) | Draw random samples.                     |

scipy.stats.dirichlet = <scipy.stats.multivariate.dirichlet\_gen object at 0x2b23194d1f50>  
 A Dirichlet random variable.

The `alpha` keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

**Parameters** `x` : array\_like

Quantiles, with the last axis of `x` denoting the components.

**alpha** : array\_like

The concentration parameters. The number of entries determines the dimensionality of the distribution.

**random\_state** : None or int or np.random.RandomState instance, optional

If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:**

**rv = dirichlet(alpha)**

- Frozen object with the same methods but holding the given concentration parameters fixed.

**Notes**

Each  $\alpha$  entry must be positive. The distribution has only support on the simplex defined by

$$\sum_{i=1}^K x_i \leq 1$$

The probability density function for `dirichlet` is

$$f(x) = \frac{1}{B(\alpha)} \prod_{i=1}^K x_i^{\alpha_i - 1}$$

where

$$B(\alpha) = \frac{\prod_{i=1}^K \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^K \alpha_i)}$$

and  $\alpha = (\alpha_1, \dots, \alpha_K)$ , the concentration parameters and  $K$  is the dimension of the space where  $x$  takes values.

Note that the `dirichlet` interface is somewhat inconsistent. The array returned by the `rvs` function is transposed with respect to the format expected by the `pdf` and `logpdf`.

**Methods**

|                                       |                                                                 |
|---------------------------------------|-----------------------------------------------------------------|
| pdf(x, alpha)                         | Probability density function.                                   |
| logpdf(x, alpha)                      | Log of the probability density function.                        |
| rvs(alpha, size=1, random_state=None) | Draw random samples from a Dirichlet distribution.              |
| mean(alpha)                           | The mean of the Dirichlet distribution                          |
| var(alpha)                            | The variance of the Dirichlet distribution                      |
| entropy(alpha)                        | Compute the differential entropy of the Dirichlet distribution. |

`scipy.stats.wishart` = <scipy.stats.\_multivariate.wishart\_gen object at 0x2b23194d1f90>  
 A Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix).

**Parameters** `x` : array\_like

Quantiles, with the last axis of *x* denoting the components.

**df** : int

Degrees of freedom, must be greater than or equal to dimension of the scale matrix

**scale** : array\_like

Symmetric positive definite scale matrix of the distribution

**random\_state** : None or int or np.random.RandomState instance, optional

If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:**

**rv = wishart(df=1, scale=1)**

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

**See also:**

`invwishart`, `chi2`

**Notes**

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

$$W_p(\nu, \Sigma)$$

where  $\nu$  is the degrees of freedom and  $\Sigma$  is the  $p \times p$  scale matrix.

The probability density function for `wishart` has support over positive definite matrices *S*; if  $S \sim W_p(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|S|^{\frac{\nu-p-1}{2}}}{2^{\frac{\nu p}{2}} |\Sigma|^{\frac{\nu}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-tr(\Sigma^{-1}S)/2)$$

If  $S \sim W_p(\nu, \Sigma)$  (Wishart) then  $S^{-1} \sim W_p^{-1}(\nu, \Sigma^{-1})$  (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution  $W_1(\nu, 1)$  collapses to the  $\chi^2(\nu)$  distribution.

New in version 0.16.0.

**References**

[R652], [R653]

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2
>>> x = np.linspace(1e-5, 8, 100)
>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
array([ 0.00126156,  0.10892176,  0.14793434,  0.17400548,  0.1929669 ] )
>>> c = chi2.pdf(x, 3); c[:5]
array([ 0.00126156,  0.10892176,  0.14793434,  0.17400548,  0.1929669 ] )
>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

**Methods**

|                                                                                                           |                                                                                                                                                                                                                               |

`scipy.stats.invwishart = <scipy.stats._multivariate.invwishart_gen object at 0x2b23194db290>`  
 An inverse Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

**Parameters** *x*: array\_like  
 Quantiles, with the last axis of *x* denoting the components.  
*df*: int

Degrees of freedom, must be greater than or equal to dimension of the scale matrix

**scale** : array\_like

Symmetric positive definite scale matrix of the distribution

**random\_state** : None or int or np.random.RandomState instance, optional

If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:**

**rv = invwishart(df=1, scale=1)**

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

**See also:**

wishart

**Notes**

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted

$$W_p^{-1}(\nu, \Psi)$$

where  $\nu$  is the degrees of freedom and  $\Psi$  is the  $p \times p$  scale matrix.

The probability density function for `invwishart` has support over positive definite matrices  $S$ ; if  $S \sim W_p^{-1}(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|\Sigma|^{\frac{\nu}{2}}}{2^{\frac{\nu p}{2}} |S|^{\frac{\nu+p+1}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-\text{tr}(\Sigma S^{-1})/2)$$

If  $S \sim W_p^{-1}(\nu, \Psi)$  (inverse Wishart) then  $S^{-1} \sim W_p(\nu, \Psi^{-1})$  (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution  $W_1(\nu, 1)$  collapses to the inverse Gamma distribution with parameters shape =  $\frac{\nu}{2}$  and scale =  $\frac{1}{2}$ .

New in version 0.16.0.

**References**

[R589], [R590]

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import invwishart, invgamma
>>> x = np.linspace(0.01, 1, 100)
>>> iw = invwishart.pdf(x, df=6, scale=1)
>>> iw[:3]
array([ 1.20546865e-15,  5.42497807e-06,  4.45813929e-03])
>>> ig = invgamma.pdf(x, 6/2., scale=1./2)
>>> ig[:3]
array([ 1.20546865e-15,  5.42497807e-06,  4.45813929e-03])
>>> plt.plot(x, iw)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

**Methods**

|                                           |                                                           |
|-------------------------------------------|-----------------------------------------------------------|
| pdf(x, df, scale)                         | Probability density function.                             |
| logpdf(x, df, scale)                      | Log of the probability density function.                  |
| rvs(df, scale, size=1, random_state=None) | Draw random samples from an inverse Wishart distribution. |

`scipy.stats.multinomial` = <scipy.stats.\_multivariate.multinomial\_gen object at 0x2b23194db4d0>  
 A multinomial random variable.

**Parameters**

- x** : array\_like  
Quantiles, with the last axis of *x* denoting the components.
- n** : int  
Number of trials
- p** : array\_like  
Probability of a trial falling into each category; should sum to 1
- random\_state** : None or int or np.random.RandomState instance, optional  
If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**See also:**

- `scipy.stats.binom`  
The binomial distribution.
- `numpy.random.multinomial`  
Sampling from the multinomial distribution.

**Notes**

*n* should be a positive integer. Each element of *p* should be in the interval [0, 1] and the elements should sum to 1. If they do not sum to 1, the last element of the *p* array is not used and is replaced with the remaining probability left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the *n* and *p* parameters, returning a “frozen” multinomial random variable:

The probability mass function for `multinomial` is

$$f(x) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k},$$

supported on  $x = (x_1, \dots, x_k)$  where each  $x_i$  is a nonnegative integer and their sum is  $n$ .

New in version 0.19.0.

### Examples

```
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [0.3, 0.2, 0.5])
>>> rv.pmf([1, 3, 4])
0.0420000000000000072
```

The multinomial distribution for  $k = 2$  is identical to the corresponding binomial distribution (tiny numerical differences notwithstanding):

```
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[0.4, 0.6])
0.290303999999999973
>>> binom.pmf(3, 7, 0.4)
0.290304000000000012
```

The functions `pmf`, `logpmf`, `entropy`, and `cov` support broadcasting, under the convention that the vector parameters (`x` and `p`) are interpreted as if each row along the last axis is a single object. For instance:

```
>>> multinomial.pmf([[3, 4], [3, 5]], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```

Here, `x.shape == (2, 2)`, `n.shape == (2,)`, and `p.shape == (2,)`, but following the rules mentioned above they behave as if the rows `[3, 4]` and `[3, 5]` in `x` and `[.3, .7]` in `p` were a single object, and as if we had `x.shape = (2,)`, `n.shape = (2,)`, and `p.shape = ()`. To obtain the individual elements without broadcasting, we would do this:

```
>>> multinomial.pmf([3, 4], n=7, p=[.3, .7])
0.2268945
>>> multinomial.pmf([3, 5], 8, p=[.3, .7])
0.25412184
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `p.shape[-1]`. For example:

```
>>> multinomial.cov([4, 5], [[.3, .7], [.4, .6]])
array([[[ 0.84, -0.84],
        [-0.84, 0.84]],
       [[ 1.2, -1.2],
        [-1.2, 1.2 ]]])
```

In this example, `n.shape == (2,)` and `p.shape == (2, 2)`, and following the rules above, these broadcast as if `p.shape == (2,)`. Thus the result should also be of shape `(2,)`, but since each output is a  $2 \times 2$  matrix, the result in fact has shape `(2, 2, 2)`, where `result[0]` is equal to `multinomial.cov(n=4, p=[.3, .7])` and `result[1]` is equal to `multinomial.cov(n=5, p=[.4, .6])`.

**Methods**

|                                                   |                                                                |
|---------------------------------------------------|----------------------------------------------------------------|
| <code>pmf(x, n, p)</code>                         | Probability mass function.                                     |
| <code>logpmf(x, n, p)</code>                      | Log of the probability mass function.                          |
| <code>rvs(n, p, size=1, random_state=None)</code> | Draw random samples from a multinomial distribution.           |
| <code>entropy(n, p)</code>                        | Compute the entropy of the multinomial distribution.           |
| <code>cov(n, p)</code>                            | Compute the covariance matrix of the multinomial distribution. |

`scipy.stats.special_ortho_group = <scipy.stats.multivariate.special_ortho_group_gen object at 0x2b23194db310>`  
 A matrix-valued SO(N) random variable.

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)).

The *dim* keyword specifies the dimension N.

**Parameters** **dim** : scalar  
 Dimension of matrices

**Notes**

This class is wrapping the `random_rot` code from the MDP Toolkit, <https://github.com/mdp-toolkit/mdp-toolkit>

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)). The algorithm is described in the paper Stewart, G.W., “The efficient generation of random orthogonal matrices with an application to condition estimators”, SIAM Journal on Numerical Analysis, 17(3), pp. 403-409, 1980. For more information see [http://en.wikipedia.org/wiki/Orthogonal\\_matrix#Randomization](http://en.wikipedia.org/wiki/Orthogonal_matrix#Randomization)

See also the similar `ortho_group`.

**Examples**

```
>>> from scipy.stats import special_ortho_group
>>> x = special_ortho_group.rvs(3)

>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])

>>> import scipy.linalg
>>> scipy.linalg.det(x)
1.0
```

This generates one random matrix from SO(3). It is orthogonal and has a determinant of 1.

**Methods**

|                                                       |                                 |
|-------------------------------------------------------|---------------------------------|
| <code>rvs(dim=None, size=1, random_state=None)</code> | Draw random samples from SO(N). |
|-------------------------------------------------------|---------------------------------|

`scipy.stats.ortho_group = <scipy.stats.multivariate.ortho_group_gen object at 0x2b23194db490>`  
 A matrix-valued O(N) random variable.

Return a random orthogonal matrix, drawn from the O(N) Haar distribution (the only uniform distribution on O(N)).

The *dim* keyword specifies the dimension N.

**Parameters** **dim** : scalar  
 Dimension of matrices

**Notes**

This class is closely related to `special_ortho_group`.

Some care is taken to avoid numerical error, as per the paper by Mezzadri.

**References**

[R617]

**Examples**

```
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)

>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])

>>> import scipy.linalg
>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from  $O(3)$ . It is orthogonal and has a determinant of +1 or -1.

**Methods**

|                                                       |                                   |
|-------------------------------------------------------|-----------------------------------|
| <code>rvs(dim=None, size=1, random_state=None)</code> | Draw random samples from $O(N)$ . |
|-------------------------------------------------------|-----------------------------------|

`scipy.stats.random_correlation = <scipy.stats.multivariate.random_correlation_gen object at 0x2b23194db5d0>`  
A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The `eigs` keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

**Parameters** `eigs` : 1d ndarray  
Eigenvalues of correlation matrix.

**Notes**

Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single  $O(N)$  similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

**References**

[R628]

**Examples**

```
>>> from scipy.stats import random_correlation
>>> np.random.seed(514)
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5))
>>> x
array([[ 1.          , -0.20387311,  0.18366501, -0.04953711],
       [-0.20387311,  1.          , -0.24351129,  0.06703474],
       [ 0.18366501, -0.24351129,  1.          ,  0.38530195],
       [-0.04953711,  0.06703474,  0.38530195,  1.          ]])
```

```
>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([ 0.5,  0.8,  1.2,  1.5])
```

**Methods**

|                                                |                                                              |
|------------------------------------------------|--------------------------------------------------------------|
| <code>rvs(eigs=None, random_state=None)</code> | Draw random correlation matrices, all with eigenvalues eigs. |
|------------------------------------------------|--------------------------------------------------------------|

### 5.27.3 Discrete distributions

| <code>zipf</code>      | A Zipf discrete random variable.                              |

`scipy.stats.bernoulli` = <scipy.stats.\_discrete\_distns.bernoulli\_gen object at 0x2b2318c12cd0>  
 A Bernoulli discrete random variable.

As an instance of the `rv_discrete` class, `bernoulli` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `bernoulli` is:

$$\begin{aligned} \text{bernoulli.pmf}(k) &= 1-p && \text{if } k = 0 \\ &= p && \text{if } k = 1 \end{aligned}$$

for  $k$  in  $\{0, 1\}$ .

`bernoulli` takes  $p$  as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `bernoulli.pmf(k, p, loc)` is identically equivalent to `bernoulli.pmf(k - loc, p)`.

**Examples**

```
>>> from scipy.stats import bernoulli
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.3
>>> mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(bernoulli.ppf(0.01, p),
...               bernoulli.ppf(0.99, p))
>>> ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
>>> ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = bernoulli(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = bernoulli.cdf(x, p)
>>> np.allclose(x, bernoulli.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = bernoulli.rvs(p, size=1000)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.binom` = <scipy.stats\_discrete\_distns.binom\_gen object at 0x2b2318c12ad0>

A binomial discrete random variable.

As an instance of the `rv_discrete` class, `binom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `binom` is:

$$\text{binom.pmf}(k) = \text{choose}(n, k) * p^{**k} * (1-p)^{**(n-k)}$$

for  $k$  in  $\{0, 1, \dots, n\}$ .

`binom` takes `n` and `p` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `binom.pmf(k, n, p, loc)` is identically equivalent to `binom.pmf(k - loc, n, p)`.

**Examples**

```

>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```

>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')

```

Display the probability mass function (pmf):

```
>>> x = np.arange(binom.ppf(0.01, n, p),
...               binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = binom.rvs(n, p, size=1000)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.boltzmann = <scipy.stats._discrete_distns.boltzmann_gen object at 0x2b2318ef6cd0>`

A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the `rv_discrete` class, `boltzmann` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `boltzmann` is:

$$\text{boltzmann.pmf}(k) = (1 - \exp(-\lambda)) \exp(-\lambda * k) / (1 - \exp(-\lambda * N))$$

for  $k = 0, \dots, N-1$ .

`boltzmann` takes `lambda_` and `N` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `boltzmann.pmf(k, lambda_, N, loc)` is identically equivalent to `boltzmann.pmf(k - loc, lambda_, N)`.

**Examples**

```

>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```

>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')

```

Display the probability mass function (pmf):

```
>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N),
...               boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = boltzmann(lambda_, N)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = boltzmann.cdf(x, lambda_, N)
>>> np.allclose(x, boltzmann.ppf(prob, lambda_, N))
True
```

Generate random numbers:

```
>>> r = boltzmann.rvs(lambda_, N, size=1000)
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.dlaplace = <scipy.stats._discrete_distns.dlaplace_gen object at 0x2b2318f04310>`

A Laplacian discrete random variable.

As an instance of the `rv_discrete` class, `dlaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `dlaplace` is:

$$\text{dlaplace.pmf}(k) = \tanh(a/2) * \exp(-a * \text{abs}(k))$$

for  $a > 0$ .

`dlaplace` takes *a* as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `dlaplace.pmf(k, a, loc)` is identically equivalent to `dlaplace.pmf(k - loc, a)`.

### Examples

```

>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
                
```

Calculate a few first moments:

```

>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
                
```

Display the probability mass function (pmf):

```
>>> x = np.arange(dlaplace.ppf(0.01, a),
...               dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = dlaplace.cdf(x, a)
>>> np.allclose(x, dlaplace.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = dlaplace.rvs(a, size=1000)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.geom` = <scipy.stats.\_discrete\_distns.geom\_gen object at 0x2b2318ef6250>

A geometric discrete random variable.

As an instance of the `rv_discrete` class, `geom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `geom` is:

$$\text{geom.pmf}(k) = (1-p)^{k-1} * p$$

for  $k \geq 1$ .

`geom` takes `p` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `geom.pmf(k, p, loc)` is identically equivalent to `geom.pmf(k - loc, p)`.

**Examples**

```

>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```

>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')

```

Display the probability mass function (`pmf`):

```
>>> x = np.arange(geom.ppf(0.01, p),
...               geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = geom.rvs(p, size=1000)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`scipy.stats.hypergeom` = <scipy.stats.\_discrete\_distns.hypergeom\_gen object at 0x2b2318ef6390>

A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin. *M* is the total number of objects, *n* is total number of Type I objects. The random variate represents the number of Type I objects in *N* drawn without replacement from the total population.

As an instance of the `rv_discrete` class, `hypergeom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The symbols used to denote the shape parameters (*M*, *n*, and *N*) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$p(k, M, n, N) = \frac{\binom{n}{k} \binom{M-n}{N-k}}{\binom{M}{N}}$$

for  $k \in [\max(0, N - M + n), \min(n, N)]$ , where the binomial coefficients are defined as,

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}$$

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `hypergeom.pmf(k, M, n, N, loc)` is identically equivalent to `hypergeom.pmf(k - loc, M, n, N)`.

**Examples**

```
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```
>>> [M, n, N] = [20, 7, 12]
>>> rv = hypergeom(M, n, N)
>>> x = np.arange(0, n+1)
>>> pmf_dogs = rv.pmf(x)

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group of chosen animals')
>>> ax.set_ylabel('hypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use `hypergeom` methods directly. To for example obtain the cumulative distribution function, use:

```
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```
>>> R = hypergeom.rvs(M, n, N, size=10)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

`scipy.stats.logser = <scipy.stats.discrete_distns.logser_gen object at 0x2b2318ef6550>`

A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the `rv_discrete` class, `logser` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `logser` is:

$$\text{logser.pmf}(k) = - p^{**k} / (k * \log(1-p))$$

for  $k \geq 1$ .

`logser` takes `p` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

**Examples**

```

>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```

>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')

```

Display the probability mass function (pmf):

```
>>> x = np.arange(logser.ppf(0.01, p),
...               logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = logser.rvs(p, size=1000)
```

`scipy.stats.nbinom` = <scipy.stats.\_discrete\_distns.nbinom\_gen object at 0x2b2318c12f10>

A negative binomial discrete random variable.

As an instance of the `rv_discrete` class, `nbinom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for `nbinom` is:

$$\text{nbinom.pmf}(k) = \text{choose}(k+n-1, n-1) * p^{**n} * (1-p)^{**k}$$

for  $k \geq 0$ .

`nbinom` takes `n` and `p` as shape parameters where `n` is the number of successes, whereas `p` is the probability of a single success.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nbinom.pmf(k, n, p, loc)` is identically equivalent to `nbinom.pmf(k - loc, n, p)`.

**Examples**

```

>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```
>>> n, p = 0.4, 0.4
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(nbinom.ppf(0.01, n, p),
...               nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = nbinom.rvs(n, p, size=1000)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.planck = <scipy.stats._discrete_distns.planck_gen object at 0x2b2318ef6a90>`

A Planck discrete exponential random variable.

As an instance of the `rv_discrete` class, `planck` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `planck` is:

$$\text{planck.pmf}(k) = (1 - \exp(-\lambda)) * \exp(-\lambda * k)$$

for  $k * \lambda \geq 0$ .

`planck` takes `lambda_` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `planck.pmf(k, lambda_, loc)` is identically equivalent to `planck.pmf(k - loc, lambda_)`.

**Examples**

```

>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```

>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')

```

Display the probability mass function (pmf):

```
>>> x = np.arange(planck.ppf(0.01, lambda_),
...               planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))
True
```

Generate random numbers:

```
>>> r = planck.rvs(lambda_, size=1000)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.poisson` = <scipy.stats.\_discrete\_distns.poisson\_gen object at 0x2b2318ef6750>

A Poisson discrete random variable.

As an instance of the `rv_discrete` class, `poisson` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `poisson` is:

$$\text{poisson.pmf}(k) = \exp(-\mu) * \mu^{**k} / k!$$

for  $k \geq 0$ .

`poisson` takes `mu` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `poisson.pmf(k, mu, loc)` is identically equivalent to `poisson.pmf(k - loc, mu)`.

**Examples**

```

>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```

>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')

```

Display the probability mass function (pmf):

```
>>> x = np.arange(poisson.ppf(0.01, mu),
...               poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
>>> ax.vlines(x, 0, poisson.pmf(x, mu), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = poisson(mu)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:

```
>>> r = poisson.rvs(mu, size=1000)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.randint` = <scipy.stats.\_discrete\_distns.randint\_gen object at 0x2b2318ef6f90>

A uniform discrete random variable.

As an instance of the `rv_discrete` class, `randint` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `randint` is:

$$\text{randint.pmf}(k) = 1./(\text{high} - \text{low})$$

for  $k = \text{low}, \dots, \text{high} - 1$ .

`randint` takes `low` and `high` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `randint.pmf(k, low, high, loc)` is identically equivalent to `randint.pmf(k - loc, low, high)`.

**Examples**

```

>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```

>>> low, high = 7, 31
>>> mean, var, skew, kurt = randint.stats(low, high, moments='mvsk')

```

Display the probability mass function (pmf):

```
>>> x = np.arange(randint.ppf(0.01, low, high),
...               randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...         label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = randint.cdf(x, low, high)
>>> np.allclose(x, randint.ppf(prob, low, high))
True
```

Generate random numbers:

```
>>> r = randint.rvs(low, high, size=1000)
```

**Methods**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.skellam = <scipy.stats.discrete_distns.skellam_gen object at 0x2b2318f04610>`

A Skellam discrete random variable.

As an instance of the `rv_discrete` class, `skellam` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let  $k_1$  and  $k_2$  be two Poisson-distributed r.v. with expected values  $\lambda_{m1}$  and  $\lambda_{m2}$ . Then,  $k_1 - k_2$  follows a Skellam distribution with parameters  $\mu_1 = \lambda_{m1} - \rho \cdot \sqrt{\lambda_{m1} \cdot \lambda_{m2}}$  and  $\mu_2 = \lambda_{m2} - \rho \cdot \sqrt{\lambda_{m1} \cdot \lambda_{m2}}$ , where  $\rho$  is the correlation coefficient between  $k_1$  and  $k_2$ . If the two Poisson-distributed r.v. are independent then  $\rho = 0$ .

Parameters  $\mu_1$  and  $\mu_2$  must be strictly positive.

For details see: [http://en.wikipedia.org/wiki/Skellam\\_distribution](http://en.wikipedia.org/wiki/Skellam_distribution)

`skellam` takes  $\mu_1$  and  $\mu_2$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `skellam.pmf(k,  $\mu_1$ ,  $\mu_2$ , loc)` is identically equivalent to `skellam.pmf(k - loc,  $\mu_1$ ,  $\mu_2$ )`.

**Examples**

```

>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

```

Calculate a few first moments:

```
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2),
...               skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

### Methods

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`scipy.stats.zipf = <scipy.stats._discrete_distns.zipf_gen object at 0x2b2318f041d0>`

A Zipf discrete random variable.

As an instance of the `rv_discrete` class, `zipf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `zipf` is:

$$\text{zipf.pmf}(k, a) = 1 / (\zeta(a) * k^{**a})$$

for  $k \geq 1$ .

`zipf` takes `a` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `zipf.pmf(k, a, loc)` is identically equivalent to `zipf.pmf(k - loc, a)`.

### Examples

```

>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
                    
```

Calculate a few first moments:

```

>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
                    
```

Display the probability mass function (*pmf*):

```
>>> x = np.arange(zipf.ppf(0.01, a),
...               zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = zipf.cdf(x, a)
>>> np.allclose(x, zipf.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = zipf.rvs(a, size=1000)
```

*Methods*

|                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 5.27.4 Statistical functions

Several of these functions have a similar version in `scipy.stats.mstats` which work for masked arrays.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

```
scipy.stats.describe(a, axis=0, ddof=1, bias=True, nan_policy='propagate')
```

Computes several descriptive statistics of the passed array.

**Parameters**

- a** : array\_like  
Input data.
- axis** : int or None, optional  
Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- ddof** : int, optional  
Delta degrees of freedom (only for variance). Default is 1.
- bias** : bool, optional  
If False, then the skewness and kurtosis calculations are corrected for statistical bias.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- nobs** : int  
Number of observations (length of data along *axis*).
- minmax**: tuple of ndarrays or floats  
Minimum and maximum value of data array.
- mean** : ndarray or float  
Arithmetic mean of data along axis.
- variance** : ndarray or float  
Unbiased variance of the data along axis, denominator is number of observations minus one.
- skewness** : ndarray or float  
Skewness, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.
- kurtosis** : ndarray or float  
Kurtosis (Fisher). The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

**See also:**

`skew`, `kurtosis`

**Examples**

```
>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5, variance=9.1666666666666661,
               skewness=0.0, kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
               mean=array([ 2., 3.]), variance=array([ 2., 2.]),
               skewness=array([ 0., 0.]), kurtosis=array([-2., -2.]))
```

`scipy.stats.gmean(a, axis=0, dtype=None)`

Compute the geometric mean along the specified axis.

Returns the geometric average of the array elements. That is:  $n$ -th root of  $(x_1 * x_2 * \dots * x_n)$

**Parameters**

- a** : array\_like  
Input array or object that can be converted to an array.
- axis** : int or None, optional

Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array *a*.

**dtype** : dtype, optional  
 Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns** **gmean** : ndarray  
 see dtype parameter above

**See also:**

[\*numpy.mean\*](#) Arithmetic average

[\*numpy.average\*](#)

Weighted average

[\*hmean\*](#) Harmonic mean

**Notes**

The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

`scipy.stats.hmean(a, axis=0, dtype=None)`

Calculates the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

**Parameters** **a** : array\_like

Input array, masked array or object that can be converted to an array.

**axis** : int or None, optional

Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.

**dtype** : dtype, optional

Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns** **hmean** : ndarray

see *dtype* parameter above

**See also:**

[\*numpy.mean\*](#) Arithmetic average

[\*numpy.average\*](#)

Weighted average

[\*gmean\*](#) Geometric mean

**Notes**

The harmonic mean is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

`scipy.stats.kurtosis(a, axis=0, fisher=True, bias=True, nan_policy='propagate')`

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If `bias` is `False` then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

**Parameters**

- a** : array  
data for which the kurtosis is calculated
- axis** : int or None, optional  
Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array *a*.
- fisher** : bool, optional  
If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
- bias** : bool, optional  
If False, then the calculations are corrected for statistical bias.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- kurtosis** : array  
The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.

## References

[R601]

`scipy.stats.kurtosistest` (*a*, *axis*=0, *nan\_policy*='propagate')

Tests whether a dataset has normal kurtosis

This function tests the null hypothesis that the kurtosis of the population from which the sample was drawn is that of the normal distribution:  $kurtosis = 3(n-1)/(n+1)$ .

**Parameters**

- a** : array  
array of the sample data
- axis** : int or None, optional  
Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- statistic** : float  
The computed z-score for this test.
- pvalue** : float  
The 2-sided p-value for the hypothesis test

## Notes

Valid only for  $n > 20$ . The Z-score is set to 0 for bad entries. This function uses the method described in [R602].

## References

[R602]

`scipy.stats.mode` (*a*, *axis*=0, *nan\_policy*='propagate')

Returns an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

**Parameters**

- a** : array\_like  
n-dimensional array of which to find mode(s).
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- mode** : ndarray  
Array of modal values.
- count** : ndarray  
Array of counts for each mode.

**Examples**

```
>>> a = np.array([[6, 8, 3, 0],
...              [3, 2, 1, 7],
...              [8, 1, 8, 4],
...              [5, 3, 0, 5],
...              [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
(array([[3, 1, 0, 0]]), array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify axis=None:

```
>>> stats.mode(a, axis=None)
(array([3]), array([3]))
```

`scipy.stats.moment` (*a*, *moment=1*, *axis=0*, *nan\_policy='propagate'*)

Calculates the nth moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

**Parameters**

- a** : array\_like  
data
- moment** : int or array\_like of ints, optional  
order of central moment that is returned. Default is 1.
- axis** : int or None, optional  
Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- n-th central moment** : ndarray or float  
The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

See also:

[kurtosis](#), [skew](#), [describe](#)

**Notes**

The k-th central moment of a data sample is:

$$m_k = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^k$$

Where n is the number of samples and x-bar is the mean. This function uses exponentiation by squares [R609] for efficiency.

**References**

[R609]

`scipy.stats.normaltest` (*a*, *axis=0*, *nan\_policy='propagate'*)

Tests whether a sample differs from a normal distribution.

This function tests the null hypothesis that a sample comes from a normal distribution. It is based on D'Agostino and Pearson's [R614], [R615] test that combines skew and kurtosis to produce an omnibus test of normality.

**Parameters** **a** : array\_like

The array containing the data to be tested.

**axis** : int or None, optional

Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**statistic** : float or array  
 $s^2 + k^2$ , where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.

**pvalue** : float or array

A 2-sided chi squared probability for the hypothesis test.

**References**

[R614], [R615]

`scipy.stats.skew` (*a*, *axis=0*, *bias=True*, *nan\_policy='propagate'*)

Computes the skewness of a data set.

For normally distributed data, the skewness should be about 0. A skewness value > 0 means that there is more weight in the left tail of the distribution. The function `skewtest` can be used to determine if the skewness value is close enough to 0, statistically speaking.

**Parameters** **a** : ndarray

data

**axis** : int or None, optional

Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.

**bias** : bool, optional

If False, then the calculations are corrected for statistical bias.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**skewness** : ndarray  
The skewness of values along an axis, returning 0 where all values are equal.

### References

[R635]

`scipy.stats.skewtest` (*a*, *axis=0*, *nan\_policy='propagate'*)

Tests whether the skew is different from the normal distribution.

This function tests the null hypothesis that the skewness of the population that the sample was drawn from is the same as that of a corresponding normal distribution.

**Parameters**

- a** : array  
The data to be tested
- axis** : int or None, optional  
Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- statistic** : float  
The computed z-score for this test.
- pvalue** : float  
a 2-sided p-value for the hypothesis test

### Notes

The sample size must be at least 8.

### References

[R637]

`scipy.stats.kstat` (*data*, *n=2*)

Return the *n*th k-statistic (1<=*n*<=4 so far).

The *n*th k-statistic *k<sub>n</sub>* is the unique symmetric unbiased estimator of the *n*th cumulant *kappa<sub>n</sub>*.

**Parameters**

- data** : array\_like  
Input array. Note that n-D input gets flattened.
- n** : int, {1, 2, 3, 4}, optional  
Default is equal to 2.

**Returns**

- kstat** : float  
The *n*th k-statistic.

### See also:

***kstatvar*** Returns an unbiased estimator of the variance of the k-statistic.  
***moment*** Returns the *n*-th central moment about the mean for a sample.

### Notes

For a sample size *n*, the first few k-statistics are given by:

$$k_1 = \mu k_2 = \frac{n}{n-1} m_2 k_3 = \frac{n^2}{(n-1)(n-2)} m_3 k_4 = \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)}$$

where  $\mu$  is the sample mean,  $m_2$  is the sample variance, and  $m_i$  is the *i*-th sample central moment.

### References

<http://mathworld.wolfram.com/Cumulant.html>

**Examples**

```
>>> from scipy import stats
>>> rndm = np.random.RandomState(1234)
```

As sample size increases, n-th moment and n-th k-statistic converge to the same number (although they aren't identical). In the case of the normal distribution, they converge to zero.

```
>>> for n in [2, 3, 4, 5, 6, 7]:
...     x = rndm.normal(size=10**n)
...     m, k = stats.moment(x, 3), stats.kstat(x, 3)
...     print("%.3g %.3g %.3g" % (m, k, m-k))
-0.631 -0.651 0.0194
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```

`scipy.stats.kstatvar(data, n=2)`

Returns an unbiased estimator of the variance of the k-statistic.

See `kstat` for more details of the k-statistic.

**Parameters** `data` : array\_like  
Input array. Note that n-D input gets flattened.  
`n` : int, {1, 2}, optional  
Default is equal to 2.  
**Returns** `kstatvar` : float  
The nth k-statistic variance.

**See also:**

`kstat` Returns the n-th k-statistic.  
`moment` Returns the n-th central moment about the mean for a sample.

**Notes**

The variances of the first few k-statistics are given by:

$$\text{var}(k_1) = \frac{\kappa^2}{n} \text{var}(k_2) = \frac{\kappa^4}{n} + \frac{2\kappa_2^2}{n-1} \text{var}(k_3) = \frac{\kappa^6}{n} + \frac{9\kappa_2\kappa_4}{n-1} + \frac{9\kappa_3^2}{n-1} + \frac{6n\kappa_2^3}{(n-1)(n-2)} \text{var}(k_4) = \frac{\kappa^8}{n} + \frac{16\kappa_2\kappa_6}{n-1} + \frac{48\kappa_3\kappa_5}{n-1}$$

`scipy.stats.tmean(a, limits=None, inclusive=(True, True), axis=None)`

Compute the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given *limits*.

**Parameters** `a` : array\_like  
Array of values.  
`limits` : None or (lower limit, upper limit), optional  
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When `limits` is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.  
`inclusive` : (bool, bool), optional  
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**Returns** **tmean** : float **axis** : int or None, optional  
 Axis along which to compute test. Default is None.

**See also:**

[trim\\_mean](#) returns mean after trimming a proportion from both tails.

**Examples**

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3,17))
10.0
```

`scipy.stats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)  
 Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

**Parameters** **a** : array\_like  
 Array of values.

**limits** : None or (lower limit, upper limit), optional  
 Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** : (bool, bool), optional  
 A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional  
 Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** : int, optional  
 Delta degrees of freedom. Default is 1.

**Returns** **tvar** : float  
 Trimmed variance.

**Notes**

`tvar` computes the unbiased sample variance, i.e. it uses a correction factor  $n / (n - 1)$ .

**Examples**

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3,17))
20.0
```

`scipy.stats.tmin` (*a*, *lowerlimit=None*, *axis=0*, *inclusive=True*, *nan\_policy='propagate'*)  
 Compute the trimmed minimum

This function finds the minimum value of an array *a* along the specified axis, but only considering values greater than a specified lower limit.

**Parameters**

- a** : array\_like  
array of values
- lowerlimit** : None or float, optional  
Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional  
This flag determines whether values exactly equal to the lower limit are included. The default value is True.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- tmin** : float, int or ndarray

**Examples**

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0

>>> stats.tmin(x, 13)
13

>>> stats.tmin(x, 13, inclusive=False)
14
```

`scipy.stats.tmax` (*a*, *upperlimit=None*, *axis=0*, *inclusive=True*, *nan\_policy='propagate'*)  
Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- a** : array\_like  
array of values
- upperlimit** : None or float, optional  
Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional  
This flag determines whether values exactly equal to the upper limit are included. The default value is True.
- nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- tmax** : float, int or ndarray

*Examples*

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19

>>> stats.tmax(x, 13)
13

>>> stats.tmax(x, 13, inclusive=False)
12
```

`scipy.stats.tstd(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed sample standard deviation

This function finds the sample standard deviation of given values, ignoring values outside the given *limits*.

**Parameters**

- a** : array\_like  
array of values
- limits** : None or (lower limit, upper limit), optional  
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- inclusive** : (bool, bool), optional  
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** : int, optional  
Delta degrees of freedom. Default is 1.

**Returns**

- tstd** : float

*Notes*

`tstd` computes the unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

*Examples*

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161
>>> stats.tstd(x, (3, 17))
4.4721359549995796
```

`scipy.stats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

**Parameters**

- a** : array\_like  
array of values
- limits** : None or (lower limit, upper limit), optional

Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** : (bool, bool), optional

A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional

Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** : int, optional

Delta degrees of freedom. Default is 1.

**Returns** **tsem** : float

### Notes

`tsem` uses unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3, 17))
1.1547005383792515
```

`scipy.stats.variation(a, axis=0, nan_policy='propagate')`

Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.

**Parameters** **a** : array\_like

Input array.

**axis** : int or None, optional

Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**variation** : ndarray

The calculated variation along the requested axis.

### References

[R647]

`scipy.stats.find_repeats(arr)`

Find repeats and repeat counts.

**Parameters** **arr** : array\_like

Input array. This is cast to float64.

**Returns** **values** : ndarray

The unique values from the (flattened) input that are repeated.

**counts** : ndarray

Number of times the corresponding 'value' is repeated.

*Notes*

In numpy >= 1.9 `numpy.unique` provides similar functionality. The main difference is that `find_repeats` only returns repeated values.

*Examples*

```
>>> from scipy import stats
>>> stats.find_repeats([2, 1, 2, 3, 2, 2, 5])
RepeatedResults(values=array([ 2.]), counts=array([4]))

>>> stats.find_repeats([[10, 20, 1, 2], [5, 5, 4, 4]])
RepeatedResults(values=array([ 4.,  5.]), counts=array([2, 2]))
```

`scipy.stats.trim_mean(a, proportiontocut, axis=0)`

Return mean of array after trimming distribution from both tails.

If `proportiontocut = 0.1`, slices off ‘leftmost’ and ‘rightmost’ 10% of scores. The input is sorted before slicing. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off `proportiontocut`).

**Parameters**

- a** : array\_like  
Input array
- proportiontocut** : float  
Fraction to cut off of both tails of the distribution
- axis** : int or None, optional  
Axis along which the trimmed means are computed. Default is 0. If None, compute over the whole array *a*.

**Returns**

- trim\_mean** : ndarray  
Mean of trimmed array.

**See also:**

`trimboth`  
**tmean** compute the trimmed mean ignoring values outside given *limits*.

*Examples*

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.trim_mean(x, 0.1)
9.5
>>> x2 = x.reshape(5, 4)
>>> x2
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15],
       [16, 17, 18, 19]])
>>> stats.trim_mean(x2, 0.25)
array([ 8.,  9., 10., 11.])
>>> stats.trim_mean(x2, 0.25, axis=1)
array([ 1.5,  5.5,  9.5, 13.5, 17.5])
```

|                                                                |                                                                         |

`scipy.stats.cumfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Returns a cumulative frequency histogram, using the histogram function.

A cumulative histogram is a mapping that counts the cumulative number of observations in all of the bins up to the specified bin.

**Parameters**

- a** : array\_like  
Input array.
- numbins** : int, optional  
The number of bins to use for the histogram. Default is 10.
- defaultreallimits** : tuple (lower, upper), optional  
The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\text{min}() - s, a.\text{max}() + s)$ , where  $s = (1/2)(a.\text{max}() - a.\text{min}()) / (\text{numbins} - 1)$ .
- weights** : array\_like, optional  
The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

**Returns**

- cumcount** : ndarray  
Binned values of cumulative frequency.
- lowerlimit** : float  
Lower real limit
- binsize** : float  
Width of each bin.
- extrapoints** : int  
Extra points.

### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> x = [1, 4, 2, 1, 3, 1]
>>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
>>> res.cumcount
array([ 1.,  2.,  3.,  3.])
>>> res.extrapoints
3
```

Create a normal distribution with 1000 random values

```
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate cumulative frequencies

```
>>> res = stats.cumfreq(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size,
...                                 res.cumcount.size)
```

Plot histogram and cumulative histogram

```
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])

>>> plt.show()
```

`scipy.stats.histogram2(*args, **kwargs)`

`histogram2` is deprecated! `scipy.stats.histogram2` is deprecated in scipy 0.16.0; use `np.histogram2d` instead

Compute histogram using divisions in bins.

Count the number of times values from array *a* fall into numerical ranges defined by *bins*. Range *x* is given by  $\text{bins}[x] \leq \text{range}_x < \text{bins}[x+1]$  where  $x = 0, N$  and *N* is the length of the *bins* array. The last range is given by  $\text{bins}[N] \leq \text{range}_N < \text{infinity}$ . Values less than  $\text{bins}[0]$  are not included in the histogram.

**Parameters** *a* : array\_like of rank 1

The array of values to be assigned into bins

*bins*

[array\_like of rank 1] Defines the ranges of values to use during histogramming.

**Returns** `histogram2` : ndarray of rank 1

Each value represents the occurrences for a given bin (range) of values.

`scipy.stats.histogram(*args, **kwargs)`

`histogram` is deprecated! `scipy.stats.histogram` is deprecated in scipy 0.17.0; use `np.histogram` instead

`scipy.stats.itemfreq(a)`

Returns a 2-D array of item frequencies.

**Parameters** *a* : (N,) array\_like

**Returns** `itemfreq` : (K, 2) ndarray

Input array.  
A 2-D frequency table. Column 1 contains sorted, unique values from *a*, column 2 contains their respective counts.

**Examples**

```

>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
array([[ 0.,  2.],
       [ 1.,  4.],
       [ 2.,  2.],
       [ 4.,  1.],
       [ 5.,  1.]])
>>> np.bincount(a)
array([2, 4, 2, 0, 1, 1])

>>> stats.itemfreq(a/10.)
array([[ 0. ,  2. ],
       [ 0.1,  4. ],
       [ 0.2,  2. ],
       [ 0.4,  1. ],
       [ 0.5,  1. ]])

```

`scipy.stats.percentileofscore(a, score, kind='rank')`

The percentile rank of a score relative to a list of scores.

A `percentileofscore` of, for example, 80% means that 80% of the scores in *a* are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, *kind*.

**Parameters** *a* : array\_like

Array of scores to which *score* is compared.

**score** : int or float

Score that is compared to the elements in *a*.

**kind** : {'rank', 'weak', 'strict', 'mean'}, optional

This optional parameter specifies the interpretation of the resulting score:

- “rank”**: *Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores.*
- “weak”**: *This kind corresponds to the definition of a cumulative*

*distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score.*

- “strict”**: *Similar to “weak”, except that only values that are*

*strictly less than the given score are counted.*

- “mean”**: *The average of the “weak” and “strict” scores, often used in*

*testing. See*

[http://en.wikipedia.org/wiki/Percentile\\_rank](http://en.wikipedia.org/wiki/Percentile_rank)

**Returns** *pcos* : float

Percentile-position of score (0-100) relative to *a*.

**See also:**

`numpy.percentile`

**Examples**

Three-quarters of the given values lie below a given score:

```
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='strict')
40.0
```

But 4/5 values are less than or equal to 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='mean')
60.0
```

`scipy.stats.scoreatpercentile` (*a*, *per*, *limit*=(), *interpolation\_method*='fraction', *axis*=None)

Calculate the score at a given percentile of the input sequence.

For example, the score at *per*=50 is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of *interpolation*. If the parameter *limit* is provided, it should be a tuple (lower, upper) of two values.

**Parameters**

- a** : array\_like  
A 1-D array of values from which to extract score.
- per** : array\_like  
Percentile(s) at which to extract score. Values should be in range [0,100].
- limit** : tuple, optional  
Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of *a* outside this (closed) interval will be ignored.
- interpolation\_method** : {'fraction', 'lower', 'higher'}, optional  
This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*
  - fraction:  $i + (j - i) * \text{fraction}$  where *fraction* is the fractional part of the index surrounded by *i* and *j*.
  - lower: *i*.
  - higher: *j*.
- axis** : int, optional  
Axis along which the percentiles are computed. Default is None. If None, compute over the whole array *a*.

**Returns**

- score** : float or ndarray  
Score at percentile(s).

**See also:**

`percentileofscore`, `numpy.percentile`

**Notes**

This function will become obsolete in the future. For Numpy 1.9 and higher, `numpy.percentile` provides all the functionality that `scoreatpercentile` provides. And it's significantly faster. Therefore it's recommended to use `numpy.percentile` for users that have `numpy >= 1.9`.

**Examples**

```
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```

`scipy.stats.relfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Returns a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.

**Parameters**

- a** : array\_like  
Input array.
- numbins** : int, optional  
The number of bins to use for the histogram. Default is 10.
- defaultreallimits** : tuple (lower, upper), optional  
The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\text{min}() - s, a.\text{max}() + s)$ , where  $s = (1/2)(a.\text{max}() - a.\text{min}()) / (\text{numbins} - 1)$ .
- weights** : array\_like, optional  
The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

**Returns**

- frequency** : ndarray  
Binned values of relative frequency.
- lowerlimit** : float  
Lower real limit
- binsize** : float  
Width of each bin.
- extrapoints** : int  
Extra points.

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfreq(a, numbins=4)
>>> res.frequency
array([ 0.16666667, 0.5         , 0.16666667, 0.16666667])
>>> np.sum(res.frequency) # relative frequencies should add up to 1
1.0
```

Create a normal distribution with 1000 random values

```
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate relative frequencies

```
>>> res = stats.relfrac(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size,
...                                 res.frequency.size)
```

Plot relative frequency histogram

```
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.binsize)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

---

|                                                            |                                                                        |
|------------------------------------------------------------|------------------------------------------------------------------------|
| <code>binned_statistic(x, values[, statistic, ...])</code> | Compute a binned statistic for one or more sets of data.               |

---

`scipy.stats.binned_statistic(x, values, statistic='mean', bins=10, range=None)`

Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters** `x`: (N,) array\_like

A sequence of values to be binned.

**values** : (N,) array\_like or list of (N,) array\_like

The data on which the statistic will be computed. This must be the same shape as *x*, or a set of sequences - each the same shape as *x*. If *values* is a set of sequences, the statistic will be computed on each independently.

**statistic** : string or callable, optional

The statistic to compute (default is 'mean'). The following statistics are available:

- 'mean' : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- 'median' : compute the median of values for points within each bin. Empty bins will be represented by NaN.
- 'count' : compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
- 'sum' : compute the sum of values for points within each bin. This is identical to a weighted histogram.
- 'min' : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- 'max' : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- 'function' : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.

**bins** : int or sequence of scalars, optional

If *bins* is an int, it defines the number of equal-width bins in the given range (10 by default). If *bins* is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in *x* that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to `bins[-1]`. If the bin edges are specified, the number of bins will be,  $(nx = \text{len}(\text{bins}) - 1)$ .

**range** : (float, float) or [(float, float)], optional

The lower and upper range of the bins. If not provided, range is simply  $(x.\text{min}(), x.\text{max}())$ . Values outside the range are ignored.

#### Returns

**statistic** : array  
The values of the selected statistic in each bin.

**bin\_edges** : array of dtype float

Return the bin edges  $(\text{length}(\text{statistic}) + 1)$ .

**binnumber**: 1-D ndarray of ints

Indices of the bins (corresponding to *bin\_edges*) in which each value of *x* belongs. Same length as *values*. A binnumber of *i* means the corresponding value is between  $(\text{bin\_edges}[i-1], \text{bin\_edges}[i])$ .

#### See also:

`numpy.digitize`, `numpy.histogram`, `binned_statistic_2d`, `binned_statistic_dd`

#### Notes

All but the last (righthand-most) bin is half-open. In other words, if *bins* is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which includes 4.

New in version 0.11.0.

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

First some basic examples:

Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```
>>> values = [1.0, 1.0, 2.0, 1.5, 3.0]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
(array([ 4. ,  4.5]), array([ 1.,  4.,  7.]), array([1, 1, 1, 2, 2]))
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```
>>> values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
(array([[ 4. ,  4.5], [ 8. ,  9. ]]), array([ 1.,  4.,  7.]),
      array([1, 1, 1, 2, 2]))

>>> stats.binned_statistic([1, 2, 1, 2, 4], np.arange(5), statistic='mean',
...                        bins=3)
(array([ 1.,  2.,  4.]), array([ 1.,  2.,  3.,  4.]),
      array([1, 2, 1, 2, 3]))
```

As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```
>>> windspeed = 8 * np.random.rand(500)
>>> boatspeed = .3 * windspeed**.5 + .2 * np.random.rand(500)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed,
...   boatspeed, statistic='median', bins=[1,2,3,4,5,6,7])
>>> plt.figure()
>>> plt.plot(windspeed, boatspeed, 'b.', label='raw data')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=5,
...          label='binned statistic of data')
>>> plt.legend()
```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

```
>>> low_boatspeed = boatspeed[binnumber == 0]
```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```
>>> x = np.linspace(0, 5, num=500)
>>> x_pdf = stats.maxwell.pdf(x)
>>> samples = stats.maxwell.rvs(size=10000)

>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf,
...   statistic='mean', bins=25)
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2
```

```

>>> plt.figure()
>>> plt.hist(samples, bins=50, normed=True, histtype='stepfilled',
...         alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
...         label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()

```

`scipy.stats.binned_statistic_2d(x, y, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)`

Compute a bidimensional binned statistic for one or more sets of data.

This is a generalization of a `histogram2d` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters**

**x** : (N,) array\_like  
A sequence of values to be binned along the first dimension.

**y** : (N,) array\_like  
A sequence of values to be binned along the second dimension.

**values** : (N,) array\_like or list of (N,) array\_like  
The data on which the statistic will be computed. This must be the same shape as *x*, or a list of sequences - each with the same shape as *x*. If *values* is such a list, the statistic will be computed on each independently.

**statistic** : string or callable, optional  
The statistic to compute (default is 'mean'). The following statistics are available:

- 'mean' : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- 'median' : compute the median of values for points within each bin. Empty bins will be represented by NaN.
- 'count' : compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
- 'sum' : compute the sum of values for points within each bin. This is identical to a weighted histogram.
- 'min' : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- 'max' : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- 'function' : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.

**bins** : int or [int, int] or array\_like or [array, array], optional  
The bin specification:

- the number of bins for the two dimensions ( $nx = ny = bins$ ),
- the number of bins in each dimension ( $nx, ny = bins$ ),
- the bin edges for the two dimensions ( $x\_edge = y\_edge = bins$ ),
- the bin edges in each dimension ( $x\_edge, y\_edge = bins$ ).

If the bin edges are specified, the number of bins will be, ( $nx = len(x\_edge) - 1$ ,  $ny = len(y\_edge) - 1$ ).

**range** : (2,2) array\_like, optional  
The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the *bins* parameters):  $[[xmin, xmax], [ymin, ymax]]$ . All values outside of this range will be considered outliers and not tallied in the histogram.

**expand\_binnumbers** : bool, optional  
'False' (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. 'True': the returned *binnumber* is 'unraveled' into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section.

**Returns**

**statistic** : (nx, ny) ndarray  
New in version 0.17.0.  
The values of the selected statistic in each two-dimensional bin.

**x\_edge** : (nx + 1) ndarray  
The bin edges along the first dimension.

**y\_edge** : (ny + 1) ndarray  
The bin edges along the second dimension.

**binnumber** : (N,) array of ints or (2,N) ndarray of ints  
This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

**See also:**

`numpy.digitize`, `numpy.histogram2d`, `binned_statistic`, `binned_statistic_dd`

**Notes**

**Binedges:** All but the last (righthand-most) bin is half-open. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which *includes* 4.

**binnumber:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (D\_edge[i-1], D\_edge[i]), where 'D' is either 'x' or 'y'.

New in version 0.11.0.

**Examples**

```
>>> from scipy import stats
```

Calculate the counts with explicit bin-edges:

```
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny])
>>> ret.statistic
array([[ 2.,  1.],
       [ 1.,  0.]])
```

The bin in which each sample is placed is given by the *binnumber* returned parameter. By default, these are the linearized bin indices:

```
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the *expand\_binnumbers* parameter:

```
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny],
...                                 expand_binnumbers=True)
>>> ret.binnumber
array([[1, 1, 1, 2],
       [1, 2, 1, 1]])
```

Which shows that the first three elements belong in the xbin 1, and the fourth into xbin 2; and so on for y.

`scipy.stats.binned_statistic_dd`(*sample*, *values*, *statistic*='mean', *bins*=10, *range*=None, *expand\_binnumbers*=False)

Compute a multidimensional binned statistic for a set of data.

This is a generalization of a `histogramdd` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

**Parameters**

**sample** : array\_like  
 Data to histogram passed as a sequence of D arrays of length N, or as an (N,D) array.

**values** : (N,) array\_like or list of (N,) array\_like  
 The data on which the statistic will be computed. This must be the same shape as *x*, or a list of sequences - each with the same shape as *x*. If *values* is such a list, the statistic will be computed on each independently.

**statistic** : string or callable, optional  
 The statistic to compute (default is 'mean'). The following statistics are available:

- 'mean' : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- 'median' : compute the median of values for points within each bin. Empty bins will be represented by NaN.
- 'count' : compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
- 'sum' : compute the sum of values for points within each bin. This is identical to a weighted histogram.
- 'min' : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- 'max' : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- 'function' : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.

**bins** : sequence or int, optional  
 The bin specification must be in one of the following forms:

- A sequence of arrays describing the bin edges along each dimension.
- The number of bins for each dimension ( $n_x, n_y, \dots = \text{bins}$ ).
- The number of bins for all dimensions ( $n_x = n_y = \dots = \text{bins}$ ).

**range** : sequence, optional  
 A sequence of lower and upper bin edges to be used if the edges are not given explicitly in *bins*. Defaults to the minimum and maximum values along each dimension.

**expand\_binnumbers** : bool, optional  
 'False' (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. 'True': the returned *binnumber* is 'unraveled' into a shape (D,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section of [binned\\_statistic\\_2d](#).

**Returns**

**statistic** : ndarray, shape( $n_x1, n_x2, n_x3, \dots$ )  
 New in version 0.17.0.  
 The values of the selected statistic in each two-dimensional bin.

**bin\_edges** : list of ndarrays  
 A list of D arrays describing the ( $n_xi + 1$ ) bin edges for each dimension.

**binnumber** : (N,) array of ints or (D,N) ndarray of ints  
 This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

See also:

`numpy.digitize`, `numpy.histogramdd`, `binned_statistic`, `binned_statistic_2d`

### Notes

**Binedges:** All but the last (righthand-most) bin is half-open in each dimension. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which *includes* 4.

**binnumber:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (D,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (bin\_edges[D][i-1], bin\_edges[D][i]), for each dimension 'D'.

New in version 0.11.0.

`scipy.stats.obrientransform(*args)`

Computes the O'Brien transform on input data (any number of arrays).

Used to test for homogeneity of variance prior to running one-way stats. Each array in *\*args* is one level of a factor. If `f_oneway` is run on the transformed data and found significant, the variances are unequal. From Maxwell and Delaney [R616], p.112.

**Parameters** `args` : tuple of array\_like

**Returns** `obrientransform` : ndarray

Any number of arrays.  
Transformed data for use in an ANOVA. The first dimension of the result corresponds to the sequence of transformed arrays. If the arrays given are all 1-D of the same length, the return value is a 2-D array; otherwise it is a 1-D array of type object, with each element being an ndarray.

### References

[R616]

### Examples

We'll test the following data sets for differences in their variance.

```
>>> x = [10, 11, 13, 9, 7, 12, 12, 9, 10]
>>> y = [13, 21, 5, 10, 8, 14, 10, 12, 7, 15]
```

Apply the O'Brien transform to the data.

```
>>> from scipy.stats import obrientransform
>>> tx, ty = obrientransform(x, y)
```

Use `scipy.stats.f_oneway` to apply a one-way ANOVA test to the transformed data.

```
>>> from scipy.stats import f_oneway
>>> F, p = f_oneway(tx, ty)
>>> p
0.1314139477040335
```

If we require that  $p < 0.05$  for significance, we cannot conclude that the variances are different.

`scipy.stats.signaltonoise(*args, **kwargs)`  
`signaltonoise` is deprecated! `scipy.stats.signaltonoise` is deprecated in scipy 0.16.0

The signal-to-noise ratio of the input data.

Returns the signal-to-noise ratio of  $a$ , here defined as the mean divided by the standard deviation.

**Parameters**    **a** : array\_like

An array\_like object containing the sample data.

**axis**

[int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array  $a$ .

**ddof**

[int, optional] Degrees of freedom correction for standard deviation. Default is 0.

**Returns**        **s2n** : ndarray

The mean to standard deviation ratio(s) along *axis*, or 0 where the standard deviation is 0.

`scipy.stats.bayes_mvs(data, alpha=0.9)`

Bayesian confidence intervals for the mean, var, and std.

**Parameters**    **data** : array\_like

Input data, if multi-dimensional it is flattened to 1-D by `bayes_mvs`. Requires 2 or more data points.

**alpha** : float, optional

Probability that the returned confidence interval contains the true parameter.

**Returns**        **mean\_cntr, var\_cntr, std\_cntr** : tuple

The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

`(center, (lower, upper))`

with *center* the mean of the conditional pdf of the value given the data, and *(lower, upper)* a confidence interval, centered on the median, containing the estimate to a probability  $\alpha$ .

**See also:**

`mvstdist`

**Notes**

Each tuple of mean, variance, and standard deviation estimates represent the `(center, (lower, upper))` with *center* the mean of the conditional pdf of the value given the data and `(lower, upper)` is a confidence interval centered on the median, containing the estimate to a probability  $\alpha$ .

Converts data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey's prior for variance and std.

Equivalent to `tuple((x.mean(), x.interval(alpha)) for x in mvstdist(dat))`

**References**

T.E. Oliphant, "A Bayesian perspective on estimating mean, variance, and standard-deviation from data", <http://scholarsarchive.byu.edu/facpub/278>, 2006.

### Examples

First a basic example to demonstrate the outputs:

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.1036502226125329, 10.896349777387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.7823367265645143, 4.9456146050146295))
```

Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.hist(data, bins=100, normed=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated mean')
>>> ax.axvspan(res_mean.minmax[0], res_mean.minmax[1], facecolor='r',
...           alpha=0.2, label=r'Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated scale')
>>> ax.axvspan(res_std.minmax[0], res_std.minmax[1], facecolor='g', alpha=0.2,
...           label=r'Estimated scale (95% limits)')

>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()
```

`scipy.stats.mvstdist` (*data*)

‘Frozen’ distributions for mean, variance, and standard deviation of data.

**Parameters** **data** : array\_like  
 Input array. Converted to 1-D using `ravel`. Requires 2 or more data-points.

**Returns** **mdist** : “frozen” distribution object  
 Distribution object representing the mean of the data

**vdist** : “frozen” distribution object  
 Distribution object representing the variance of the data

**sdist** : “frozen” distribution object  
 Distribution object representing the standard deviation of the data

**See also:**

[bayes\\_mvs](#)

**Notes**

The return values from `bayes_mvs(data)` is equivalent to `tuple((x.mean(), x.interval(0.90)) for x in mvstdist(data))`.

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from [bayes\\_mvs](#).

**References**

T.E. Oliphant, “A Bayesian perspective on estimating mean, variance, and standard-deviation from data”, <http://scholarsarchive.byu.edu/facpub/278>, 2006.

**Examples**

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvstdist(data)
```

We now have frozen distribution objects “mean”, “var” and “std” that we can examine:

```
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

`scipy.stats.sem` (*a*, *axis=0*, *ddof=1*, *nan\_policy='propagate'*)

Calculates the standard error of the mean (or standard error of measurement) of the values in the input array.

**Parameters** **a** : array\_like  
 An array containing the values for which the standard error is returned.

**axis** : int or None, optional  
 Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** : int, optional  
 Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

**nan\_policy** : { ‘propagate’, ‘raise’, ‘omit’ }, optional

**Returns** `s` : ndarray or float

Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

The standard error of the mean in the sample(s), along the input axis.

**Notes**

The default value for *ddof* is different to the default (0) used by other *ddof* containing routines, such as `np.std` and `np.nanstd`.

**Examples**

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5, 4)
>>> stats.sem(a)
array([ 2.8284,  2.8284,  2.8284,  2.8284])
```

Find standard error across the whole array, using n degrees of freedom:

```
>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628
```

`scipy.stats.zmap(scores, compare, axis=0, ddof=0)`

Calculates the relative z-scores.

Returns an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

**Parameters**

- scores** : array\_like  
The input for which z-scores are calculated.
- compare** : array\_like  
The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as *scores*.
- axis** : int or None, optional  
Axis over which mean and variance of *compare* are calculated. Default is 0. If None, compute over the whole array *scores*.
- ddof** : int, optional  
Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns** `zscore` : array\_like  
Z-scores, in the same shape as *scores*.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

**Examples**

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
```

`scipy.stats.zscore(a, axis=0, ddof=0)`

Calculates the z score of each value in the sample, relative to the sample mean and standard deviation.

**Parameters**

- a** : array\_like  
An array like object containing the sample data.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** : int, optional  
Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
The z-scores, standardized by mean and standard deviation of input array *a*.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

**Examples**

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...              0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```
>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...              [ 0.7149,  0.0775,  0.6072,  0.9656],
...              [ 0.6341,  0.1403,  0.9759,  0.4064],
...              [ 0.5918,  0.6948,  0.904 ,  0.3721],
...              [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823, -1.28415119,  1.07259584,  0.40420358],
       [  0.33048416, -1.37380874,  0.04251374,  1.00081084],
       [  0.26796377, -1.12598418,  1.23283094, -0.37481053],
       [ -0.22095197,  0.24468594,  1.19042819, -1.21416216],
       [ -0.82780366,  1.4457416 , -0.43867764, -0.1792603 ]])
```

`scipy.stats.iqr(x, axis=None, rng=(25, 75), scale='raw', nan_policy='propagate', interpolation='linear', keepdims=False)`

Compute the interquartile range of the data along the specified axis.

The interquartile range (IQR) is the difference between the 75th and 25th percentile of the data. It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers [R592].

The `rng` parameter allows this function to compute other percentile ranges than the actual IQR. For example, setting `rng=(0, 100)` is equivalent to `numpy.ptp`.

The IQR of an empty array is `np.nan`.

New in version 0.18.0.

**Parameters**

- x** : array\_like  
Input array or object that can be converted to an array.
- axis** : int or sequence of int, optional

Axis along which the range is computed. The default is to compute the IQR for the entire array.

**rng** : Two-element sequence containing floats in range of [0,100] optional

Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important.

**scale** : scalar or str, optional

The numerical value of scale will be divided out of the final result. The following string values are recognized:

• **'raw'** : No scaling, just return the raw IQR. **'normal'** : Scale by  $2\sqrt{2} \operatorname{erf}^{-1}(\frac{1}{2}) \approx 1.349$ .

The default is 'raw'. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that `out / scale` is a valid operation. The output dimensions depend on the input array, *x*, the *axis* argument, and the *keepdims* flag.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**interpolation** : {'linear', 'lower', 'higher', 'midpoint', 'nearest'}, optional

Specifies the interpolation method to use when the percentile boundaries lie between two data points *i* and *j*:

- **'linear'** :  $[i + (j - i) * fraction]$ , where *fraction* is the fractional part of the index surrounded by *i* and *j*.
- **'lower'** : *i*.
- **'higher'** : *j*.
- **'nearest'** : *i* or *j* whichever is nearest.
- **'midpoint'** :  $(i + j) / 2$ .

Default is 'linear'.

**keepdims** : bool, optional

If this is set to *True*, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array *x*.

**Returns**

**iqr** : scalar or ndarray

If *axis=None*, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

**See also:**

`numpy.std`, `numpy.var`

**Notes**

This function is heavily dependent on the version of `numpy` that is installed. Versions greater than 1.11.0b3 are highly recommended, as they include a number of enhancements and fixes to `numpy.percentile` and `numpy.nanpercentile` that affect the operation of this function. The following modifications apply:

**Below 1.10.0** [*nan\_policy* is poorly defined.] The default behavior of `numpy.percentile` is used for 'propagate'. This is a hybrid of 'omit' and 'propagate' that mostly yields a skewed version of 'omit' since NaNs are sorted to the end of the data. A warning is raised if there are NaNs in the data.

**Below 1.9.0:** `numpy.nanpercentile` does not exist.

This means that `numpy.percentile` is used regardless of *nan\_policy* and a warning is issued. See previous item for a description of the behavior.

**Below 1.9.0:** *keepdims* and *interpolation* are not supported.

The keywords get ignored with a warning if supplied with non-default values. However, multiple axes are still supported.

[R591], [R592], [R593]

**Examples**

```
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> iqr(x)
4.0
>>> iqr(x, axis=0)
array([ 3.5,  2.5,  1.5])
>>> iqr(x, axis=1)
array([ 3.,  1.])
>>> iqr(x, axis=1, keepdims=True)
array([[ 3.],
       [ 1.]])
```

---

|                                                      |                                                                        |
|------------------------------------------------------|------------------------------------------------------------------------|
| <code>sigmaclip(a[, low, high])</code>               | Iterative sigma-clipping of array elements.                            |
| <code>threshold(*args, **kwds)</code>                | <code>threshold</code> is deprecated!                                  |
| <code>trimboth(a, proportiontocut[, axis])</code>    | Slices off a proportion of items from both ends of an array.           |
| <code>triml(a, proportiontocut[, tail, axis])</code> | Slices off a proportion from ONE end of the passed array distribution. |

---

`scipy.stats.sigmaclip(a, low=4.0, high=4.0)`

Iterative sigma-clipping of array elements.

The output array contains only those elements of the input array *c* that satisfy the conditions

$$\text{mean}(c) - \text{std}(c) * \text{low} < c < \text{mean}(c) + \text{std}(c) * \text{high}$$

Starting from the full sample, all elements outside the critical range are removed. The iteration continues with a new critical range until no elements are outside the range.

- Parameters**
- a** : array\_like  
Data array, will be raveled if not 1-D.
  - low** : float, optional  
Lower bound factor of sigma clipping. Default is 4.
  - high** : float, optional  
Upper bound factor of sigma clipping. Default is 4.
- Returns**
- clipped** : ndarray  
Input array with clipped elements removed.
  - lower** : float  
Lower threshold value use for clipping.
  - upper** : float  
Upper threshold value use for clipping.

**Examples**

```
>>> from scipy.stats import sigmaclip
>>> a = np.concatenate((np.linspace(9.5, 10.5, 31),
...                    np.linspace(0, 20, 5)))
>>> fact = 1.5
>>> c, low, upp = sigmaclip(a, fact, fact)
>>> c
```

```

array([ 9.96666667, 10.          , 10.03333333, 10.          ])
>>> c.var(), c.std()
(0.0005555555555555165, 0.023570226039551501)
>>> low, c.mean() - fact*c.std(), c.min()
(9.9646446609406727, 9.9646446609406727, 9.9666666666666668)
>>> upp, c.mean() + fact*c.std(), c.max()
(10.035355339059327, 10.035355339059327, 10.033333333333333)

>>> a = np.concatenate((np.linspace(9.5, 10.5, 11),
...                       np.linspace(-100, -50, 3)))
>>> c, low, upp = sigmaclip(a, 1.8, 1.8)
>>> (c == np.linspace(9.5, 10.5, 11)).all()
True

```

`scipy.stats.threshold(*args, **kws)`

`threshold` is deprecated! `stats.threshold` is deprecated in scipy 0.17.0

Clip array to a given value.

Similar to `numpy.clip()`, except that values less than *threshmin* or greater than *threshmax* are replaced by *newval*, instead of by *threshmin* and *threshmax* respectively.

**Parameters** `a` : array\_like

Data to threshold.

***threshmin*** [float, int or None, optional] Minimum threshold, defaults to

***threshmax*** [float, int or None, optional] Maximum threshold, defaults to

***newval*** [float or int, optional] Value to put in place of values in *a* outside of bounds. Defaults to 0.

**Returns** `out` : ndarray

The clipped input array, with values less than *threshmin* or greater than *threshmax* replaced with *newval*.

### Examples

```

>>> a = np.array([9, 9, 6, 3, 1, 6, 1, 0, 0, 8])
>>> from scipy import stats
>>> stats.threshold(a, threshmin=2, threshmax=8, newval=-1)
array([-1, -1, 6, 3, -1, 6, -1, -1, -1, 8])

```

`scipy.stats.trimboth(a, proportiontocut, axis=0)`

Slices off a proportion of items from both ends of an array.

Slices off the passed proportion of items from both ends of the passed array (i.e., with *proportiontocut* = 0.1, slices leftmost 10% **and** rightmost 10% of scores). The trimmed values are the lowest and highest ones. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off ‘*proportiontocut*’).

**Parameters** `a` : array\_like

Data to trim.

***proportiontocut*** : float

Proportion (in range 0-1) of total data set to trim of each end.

***axis*** : int or None, optional

Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

**Returns** `out` : ndarray

Trimmed version of array *a*. The order of the trimmed content is undefined.

See also:

`trim_mean`

### Examples

```
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trimboth(a, 0.1)
>>> b.shape
(16,)
```

`scipy.stats.trim1(a, proportiontocut, tail='right', axis=0)`

Slices off a proportion from ONE end of the passed array distribution.

If `proportiontocut = 0.1`, slices off ‘leftmost’ or ‘rightmost’ 10% of scores. The lowest or highest values are trimmed (depending on the tail). Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off `proportiontocut`).

**Parameters**

- a** : array\_like  
Input array
- proportiontocut** : float  
Fraction to cut off of ‘left’ or ‘right’ of distribution
- tail** : {‘left’, ‘right’}, optional  
Defaults to ‘right’.
- axis** : int or None, optional  
Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

**Returns**

- trim1** : ndarray  
Trimmed version of array *a*. The order of the trimmed content is undefined.

---

`scipy.stats.f_oneway(*args)`

Performs a 1-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The test is applied to samples from two or more groups, possibly with differing sizes.

**Parameters**

- sample1, sample2, ...** : array\_like  
The sample measurements for each group.

**Returns**

- statistic** : float  
The computed F-value of the test.
- pvalue** : float  
The associated p-value from the F-distribution.

### Notes

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

1. The samples are independent.

2. Each sample is from a normally distributed population.
3. The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test (`scipy.stats.kruskal`) although with some loss of power.

The algorithm is from Heiman[2], pp.394-7.

`scipy.stats.pearsonr` (*x*, *y*)

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson's correlation requires that each dataset be normally distributed, and not necessarily zero-mean. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

### References

<http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation>

`scipy.stats.spearmanr` (*a*, *b=None*, *axis=0*, *nan\_policy='propagate'*)

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**    **a, b** : 1D or 2D array\_like, *b* is optional

One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under *axis*, below. Both arrays need to have the same length in the *axis* dimension.

**axis** : int or None, optional

If *axis*=0 (default), then each column represents a variable, with observations in the rows. If *axis*=1, the relationship is transposed: each row represents a variable, while the columns contain observations. If *axis*=None, then both arrays will be raveled.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**correlation** : float or ndarray (2-D square)

Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters. Correlation matrix is square with length equal to total number of variables (columns or rows) in *a* and *b* combined.

**pvalue** : float

The two-sided p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated, has same dimension as rho.

### Notes

Changes in scipy 0.8.0: rewrite to add tie-handling, and axis.

```

`scipy.stats.pointbiserialr(x, y)`

Calculates a point biserial correlation coefficient and its p-value.

The point biserial correlation is used to measure the relationship between a binary variable,  $x$ , and a continuous variable,  $y$ . Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a deterministic relationship.

This function uses a shortcut formula but produces the same result as `pearsonr`.

**Parameters**

- x** : array\_like of bools  
Input array.
- y** : array\_like  
Input array.

**Returns**

- correlation** : float  
R value
- pvalue** : float  
2-tailed p-value

### Notes

`pointbiserialr` uses a t-test with  $n-1$  degrees of freedom. It is equivalent to `pearsonr`.

The value of the point-biserial correlation can be calculated from:

$$r_{pb} = \frac{\bar{Y}_1 - \bar{Y}_0}{s_y} \sqrt{\frac{N_1 N_2}{N(N-1)}}$$

Where  $Y_0$  and  $Y_1$  are means of the metric observations coded 0 and 1 respectively;  $N_0$  and  $N_1$  are number of observations coded 0 and 1 respectively;  $N$  is the total number of observations and  $s_y$  is the standard deviation of all the metric observations.

A value of  $r_{pb}$  that is significantly different from zero is completely equivalent to a significant difference in means between the two groups. Thus, an independent groups t Test with  $N - 2$  degrees of freedom may be used to test whether  $r_{pb}$  is nonzero. The relation between the t-statistic for comparing two independent groups and

$r_{pb}$  is given by:

$$t = \sqrt{N - 2} \frac{r_{pb}}{\sqrt{1 - r_{pb}^2}}$$

### Examples

```
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pointbiserialr(a, b)
(0.8660254037844386, 0.011724811003954652)
>>> stats.pearsonr(a, b)
(0.86602540378443871, 0.011724811003954626)
>>> np.corrcoef(a, b)
array([[ 1.          ,  0.8660254 ],
       [ 0.8660254,  1.          ]])
```

`scipy.stats.kendalltau(x, y, initial_lexsort=None, nan_policy='propagate')`

Calculates Kendall's tau, a correlation measure for ordinal data.

Kendall's tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, values close to -1 indicate strong disagreement. This is the 1945 “tau-b” version of Kendall's tau [R596], which can account for ties and which reduces to the 1938 “tau-a” version [R595] in absence of ties.

**Parameters** `x, y` : array\_like

Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

**initial\_lexsort** : bool, optional

Unused (deprecated).

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that if the input contains nan 'omit' delegates to `mstats_basic.kendalltau()`, which has a different implementation.

**Returns**

**correlation** : float

The tau statistic.

**pvalue** : float

The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association,  $\tau = 0$ .

**See also:**

***spearmanr*** Calculates a Spearman rank-order correlation coefficient.

***theilslopes***

Computes the Theil-Sen estimator for a set of points (x, y).

***weightedtau***

Computes a weighted version of Kendall's tau.

**Notes**

The definition of Kendall's tau that is used is [R596]:

$$\tau = (P - Q) / \sqrt{(P + Q + T) * (P + Q + U)}$$

where P is the number of concordant pairs, Q the number of discordant pairs, T the number of ties only in  $x$ , and U the number of ties only in  $y$ . If a tie occurs for the same pair in both  $x$  and  $y$ , it is not added to either T or U.

### Examples

```
>>> from scipy import stats
>>> x1 = [12, 2, 1, 12, 2]
>>> x2 = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.kendalltau(x1, x2)
>>> tau
-0.47140452079103173
>>> p_value
0.2827454599327748
```

`scipy.stats.weightedtau(x, y, rank=True, weigher=None, additive=True)`

Computes a weighted version of Kendall's  $\tau$ .

The weighted  $\tau$  is a weighted version of Kendall's  $\tau$  in which exchanges of high weight are more influential than exchanges of low weight. The default parameters compute the additive hyperbolic version of the index,  $\tau_h$ , which has been shown to provide the best balance between important and unimportant elements [R648].

The weighting is defined by means of a rank array, which assigns a nonnegative rank to each element, and a weigher function, which assigns a weight based from the rank to each element. The weight of an exchange is then the sum or the product of the weights of the ranks of the exchanged elements. The default parameters compute  $\tau_h$ : an exchange between elements with rank  $r$  and  $s$  (starting from zero) has weight  $1/(r+1) + 1/(s+1)$ .

Specifying a rank array is meaningful only if you have in mind an external criterion of importance. If, as it usually happens, you do not have in mind a specific rank, the weighted  $\tau$  is defined by averaging the values obtained using the decreasing lexicographical rank by  $(x, y)$  and by  $(y, x)$ . This is the behavior with default parameters.

Note that if you are computing the weighted  $\tau$  on arrays of ranks, rather than of scores (i.e., a larger value implies a lower rank) you must negate the ranks, so that elements of higher rank are associated with a larger value.

**Parameters** `x, y` : array\_like

Arrays of scores, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

**rank** : array\_like of ints or bool, optional

A nonnegative rank assigned to each element. If it is None, the decreasing lexicographical rank by  $(x, y)$  will be used: elements of higher rank will be those with larger  $x$ -values, using  $y$ -values to break ties (in particular, swapping  $x$  and  $y$  will give a different result). If it is False, the element indices will be used directly as ranks. The default is True, in which case this function returns the average of the values obtained using the decreasing lexicographical rank by  $(x, y)$  and by  $(y, x)$ .

**weigher** : callable, optional

The weigher function. Must map nonnegative integers (zero representing the most important element) to a nonnegative weight. The default, None, provides hyperbolic weighing, that is, rank  $r$  is mapped to weight  $1/(r+1)$ .

**additive** : bool, optional

**Returns**

**correlation** : float  
 If True, the weight of an exchange is computed by adding the weights of the ranks of the exchanged elements; otherwise, the weights are multiplied. The default is True.  
 The weighted  $\tau$  correlation index.

**pvalue** : float  
 Presently `np.nan`, as the null statistics is unknown (even in the additive hyperbolic case).

**See also:**

**kendalltau** Calculates Kendall's tau.  
**spearmanr** Calculates a Spearman rank-order correlation coefficient.  
**theilslopes**  
 Computes the Theil-Sen estimator for a set of points (x, y).

**Notes**

This function uses an  $O(n \log n)$ , mergesort-based algorithm [R648] that is a weighted extension of Knight's algorithm for Kendall's  $\tau$  [R649]. It can compute Shieh's weighted  $\tau$  [R650] between rankings without ties (i.e., permutations) by setting *additive* and *rank* to False, as the definition given in [R648] is a generalization of Shieh's.

NaNs are considered the smallest possible score.

New in version 0.19.0.

**Examples**

```
>>> from scipy import stats
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
>>> p_value
nan
>>> tau, p_value = stats.weightedtau(x, y, additive=False)
>>> tau
-0.62205716951801038
```

NaNs are considered the smallest possible score:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, np.nan]
>>> tau, _ = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
```

This is exactly Kendall's tau:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, _ = stats.weightedtau(x, y, weigher=lambda x: 1)
>>> tau
-0.47140452079103173
```

```

>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> stats.weightedtau(x, y, rank=None)
WeightedTauResult(correlation=-0.4157652301037516, pvalue=nan)
>>> stats.weightedtau(y, x, rank=None)
WeightedTauResult(correlation=-0.71813413296990281, pvalue=nan)

```

`scipy.stats.linregress(x, y=None)`

Calculate a linear least-squares regression for two sets of measurements.

|                   |                          |                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>x, y</b> : array_like | Two sets of measurements. Both arrays should have the same length. If only x is given (and y=None), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension. |
| <b>Returns</b>    | <b>slope</b> : float     | slope of the regression line                                                                                                                                                                                                                                                   |
|                   | <b>intercept</b> : float | intercept of the regression line                                                                                                                                                                                                                                               |
|                   | <b>rvalue</b> : float    | correlation coefficient                                                                                                                                                                                                                                                        |
|                   | <b>pvalue</b> : float    | two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero.                                                                                                                                                                                       |
|                   | <b>stderr</b> : float    | Standard error of the estimated gradient.                                                                                                                                                                                                                                      |

See also:

[`scipy.optimize.curve\_fit`](#)

Use non-linear least squares to fit a function to data.

[`scipy.optimize.leastsq`](#)

Minimize the sum of squares of a set of equations.

**Examples**

```

>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = np.random.random(10)
>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)

```

To get coefficient of determination (`r_squared`)

```

>>> print("r-squared:", r_value**2)
('r-squared:', 0.080402268539028335)

```

Plot the data along with the fitted line

```

>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()

```

`scipy.stats.theilslopes` ( $y, x=None, \alpha=0.95$ )

Computes the Theil-Sen estimator for a set of points  $(x, y)$ .

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

**Parameters**

- y** : array\_like  
Dependent variable.
- x** : array\_like or None, optional  
Independent variable. If None, use `arange(len(y))` instead.
- alpha** : float, optional  
Confidence degree between 0 and 1. Default is 95% confidence. Note that `alpha` is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

**Returns**

- medslope** : float  
Theil slope.
- medintercept** : float  
Intercept of the Theil line, as  $\text{median}(y) - \text{medslope} * \text{median}(x)$ .
- lo\_slope** : float  
Lower bound of the confidence interval on `medslope`.
- up\_slope** : float  
Upper bound of the confidence interval on `medslope`.

### Notes

The implementation of `theilslopes` follows [R639]. The intercept is not defined in [R639], and here it is defined as  $\text{median}(y) - \text{medslope} * \text{median}(x)$ , which is given in [R641]. Other definitions of the intercept exist in the literature. A confidence interval for the intercept is not given as this question is not addressed in [R639].

### References

[R639], [R640], [R641]

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10 # add outliers
>>> y[-5:] -= 7
```

Compute the slope, intercept and 90% confidence interval. For comparison, also compute the least-squares fit with `linregress`:

```
>>> res = stats.theilslopes(y, x, 0.90)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Theil-Sen regression line is shown in red, with the dashed red lines illustrating the confidence interval of the slope (note that the dashed red lines are not the confidence interval of the regression as the confidence interval of the intercept is not included). The green line shows the least-squares fit for comparison.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, res[1] + res[2] * x, 'r--')
>>> ax.plot(x, res[1] + res[3] * x, 'r--')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

`scipy.stats.f_value` (\*args, \*\*kws)

`f_value` is deprecated! `stats.f_value` deprecated in scipy 0.17.0

Returns an F-statistic for a restricted vs. unrestricted model.

**Parameters** **ER** : float

*ER is the sum of squared residuals for the restricted model*

or null hypothesis

**EF** [float]

**EF is the sum of squared residuals for the unrestricted model**

| <b>Returns</b>                                                 | <b>F-statistic</b> : float | $\frac{dFR}{dF}$ | [int] $dFR$ is the degrees of freedom in the restricted model<br>[int] $dF$ is the degrees of freedom in the unrestricted model<br>or alternate hypothesis |

`scipy.stats.ttest_1samp(a, popmean, axis=0, nan_policy='propagate')`

Calculates the T-test for the mean of ONE group of scores.

This is a two-sided test for the null hypothesis that the expected value (mean) of a sample of independent observations *a* is equal to the given population mean, *popmean*.

**Parameters**

- a** : array\_like  
sample observation
- popmean** : float or array\_like  
expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension
- axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole array *a*.
- nan\_policy** : { 'propagate', 'raise', 'omit' }, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- statistic** : float or array  
t-statistic
- pvalue** : float or array  
two-tailed p-value

**Examples**

```
>>> from scipy import stats
```

```
>>> np.random.seed(7654567) # fix seed to get the same result
>>> rvs = stats.norm.rvs(loc=5, scale=10, size=(50,2))
```

Test if mean of random sample is equal to true mean, and different mean. We reject the null hypothesis in the second case and don't reject it in the first case.

```
>>> stats.ttest_1samp(rvs, 5.0)
(array([-0.68014479, -0.04323899]), array([ 0.49961383,  0.96568674]))
>>> stats.ttest_1samp(rvs, 0.0)
(array([ 2.77025808,  4.11038784]), array([ 0.00789095,  0.00014999]))
```

Examples using axis and non-scalar dimension for population mean.

```
>>> stats.ttest_1samp(rvs, [5.0, 0.0])
(array([-0.68014479,  4.11038784]), array([ 4.99613833e-01,  1.49986458e-04]))
>>> stats.ttest_1samp(rvs.T, [5.0, 0.0], axis=1)
(array([-0.68014479,  4.11038784]), array([ 4.99613833e-01,  1.49986458e-04]))
>>> stats.ttest_1samp(rvs, [[5.0], [0.0]])
(array([[ -0.68014479, -0.04323899],
        [ 2.77025808,  4.11038784]]), array([[ 4.99613833e-01,  9.65686743e-01],
        [ 7.89094663e-03,  1.49986458e-04]]))
```

`scipy.stats.ttest_ind(a, b, axis=0, equal_var=True, nan_policy='propagate')`

Calculates the T-test for the means of *two independent* samples of scores.

This is a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

**Parameters** **a, b** : array\_like

The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).

**axis** : int or None, optional

Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

**equal\_var** : bool, optional

If True (default), perform a standard independent 2 sample test that assumes equal population variances [R643]. If False, perform Welch's t-test, which does not assume equal population variance [R644].

New in version 0.11.0.

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns** **statistic** : float or array

The calculated t-statistic.

**pvalue** : float or array

The two-tailed p-value.

### Notes

We can use this test, if we observe two independent samples from the same or different population, e.g. exam scores of boys and girls or of two ethnic groups. The test measures whether the average (expected) value differs significantly across samples. If we observe a large p-value, for example larger than 0.05 or 0.1, then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages.

## References

[R643], [R644]

## Examples

```
>>> from scipy import stats
>>> np.random.seed(12345678)
```

Test with sample with identical means:

```
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> stats.ttest_ind(rvs1, rvs2)
(0.26833823296239279, 0.78849443369564776)
>>> stats.ttest_ind(rvs1, rvs2, equal_var = False)
(0.26833823296239279, 0.78849452749500748)
```

`ttest_ind` underestimates p for unequal variances:

```
>>> rvs3 = stats.norm.rvs(loc=5, scale=20, size=500)
>>> stats.ttest_ind(rvs1, rvs3)
(-0.46580283298287162, 0.64145827413436174)
>>> stats.ttest_ind(rvs1, rvs3, equal_var = False)
(-0.46580283298287162, 0.64149646246569292)
```

When  $n1 \neq n2$ , the equal variance t-statistic is no longer equal to the unequal variance t-statistic:

```
>>> rvs4 = stats.norm.rvs(loc=5, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs4)
(-0.99882539442782481, 0.3182832709103896)
>>> stats.ttest_ind(rvs1, rvs4, equal_var = False)
(-0.69712570584654099, 0.48716927725402048)
```

T-test with different means, variance, and n:

```
>>> rvs5 = stats.norm.rvs(loc=8, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs5)
(-1.4679669854490653, 0.14263895620529152)
>>> stats.ttest_ind(rvs1, rvs5, equal_var = False)
(-0.94365973617132992, 0.34744170334794122)
```

`scipy.stats.ttest_ind_from_stats` (*mean1*, *std1*, *nobs1*, *mean2*, *std2*, *nobs2*, *equal\_var=True*)

T-test for means of two independent samples from descriptive statistics.

This is a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values.

**Parameters**

- mean1** : array\_like  
The mean(s) of sample 1.
- std1** : array\_like  
The standard deviation(s) of sample 1.
- nobs1** : array\_like  
The number(s) of observations of sample 1.
- mean2** : array\_like  
The mean(s) of sample 2
- std2** : array\_like  
The standard deviations(s) of sample 2.

**nobs2** : array\_like  
The number(s) of observations of sample 2.

**equal\_var** : bool, optional  
If True (default), perform a standard independent 2 sample test that assumes equal population variances [R645]. If False, perform Welch's t-test, which does not assume equal population variance [R646].

**Returns**

**statistic** : float or array  
The calculated t-statistics

**pvalue** : float or array  
The two-tailed p-value.

**See also:**

`scipy.stats.ttest_ind`

**Notes**

New in version 0.16.0.

**References**

[R645], [R646]

`scipy.stats.ttest_rel(a, b, axis=0, nan_policy='propagate')`

Calculates the T-test on TWO RELATED samples of scores, a and b.

This is a two-sided test for the null hypothesis that 2 related or repeated samples have identical average (expected) values.

**Parameters**

**a, b** : array\_like  
The arrays must have the same shape.

**axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole arrays, a, and b.

**nan\_policy** : { 'propagate', 'raise', 'omit' }, optional  
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**statistic** : float or array  
t-statistic

**pvalue** : float or array  
two-tailed p-value

**Notes**

Examples for the use are scores of the same set of student in different exams, or repeated sampling from the same units. The test measures whether the average score differs significantly across samples (e.g. exams). If we observe a large p-value, for example greater than 0.05 or 0.1 then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages. Small p-values are associated with large t-statistics.

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(12345678) # fix random seed to get same numbers
```

```

>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = (stats.norm.rvs(loc=5, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs2)
(0.24101764965300962, 0.80964043445811562)
>>> rvs3 = (stats.norm.rvs(loc=8, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs3)
(-3.9995108708727933, 7.3082402191726459e-005)
    
```

`scipy.stats.kstest` (*rvs*, *cdf*, *args*=(), *N*=20, *alternative*='two-sided', *mode*='approx')

Perform the Kolmogorov-Smirnov test for goodness of fit.

This performs a test of the distribution  $G(x)$  of an observed random variable against a given distribution  $F(x)$ . Under the null hypothesis the two distributions are identical,  $G(x)=F(x)$ . The alternative hypothesis can be either 'two-sided' (default), 'less' or 'greater'. The KS test is only valid for continuous distributions.

**Parameters**    **rvs** : str, array or callable

If a string, it should be the name of a distribution in `scipy.stats`. If an array, it should be a 1-D array of observations of random variables. If a callable, it should be a function to generate random variables; it is required to have a keyword argument *size*.

**cdf** : str or callable

If a string, it should be the name of a distribution in `scipy.stats`. If *rvs* is a string then *cdf* can be False or the same as *rvs*. If a callable, that callable is used to calculate the cdf.

**args** : tuple, sequence, optional

Distribution parameters, used if *rvs* or *cdf* are strings.

**N** : int, optional

Sample size if *rvs* is string or callable. Default is 20.

**alternative** : {'two-sided', 'less', 'greater'}, optional

Defines the alternative hypothesis (see explanation above). Default is 'two-sided'.

**mode** : 'approx' (default) or 'asympt', optional

Defines the distribution used for calculating the p-value.

- 'approx' : use approximation to exact distribution of test statistic,
- 'asympt' : use asymptotic distribution of test statistic

**Returns**    **statistic** : float

KS test statistic, either D, D+ or D-.

**pvalue** : float

One-tailed or two-tailed p-value.

### Notes

In the one-sided test, the alternative is that the empirical cumulative distribution function of the random variable is "less" or "greater" than the cumulative distribution function  $F(x)$  of the hypothesis,  $G(x) \leq F(x)$ , resp.  $G(x) \geq F(x)$ .

### Examples

```

>>> from scipy import stats

>>> x = np.linspace(-15, 15, 9)
>>> stats.kstest(x, 'norm')
(0.44435602715924361, 0.038850142705171065)
    
```

```
>>> np.random.seed(987654321) # set random seed to get the same result
>>> stats.kstest('norm', False, N=100)
(0.058352892479417884, 0.88531190944151261)
```

The above lines are equivalent to:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.norm.rvs(size=100), 'norm')
(0.058352892479417884, 0.88531190944151261)
```

#### Test against one-sided alternative hypothesis

Shift distribution to larger values, so that  $\text{cdf}_{\text{dgp}}(x) < \text{norm.cdf}(x)$ :

```
>>> np.random.seed(987654321)
>>> x = stats.norm.rvs(loc=0.2, size=100)
>>> stats.kstest(x, 'norm', alternative = 'less')
(0.12464329735846891, 0.040989164077641749)
```

Reject equal distribution against alternative hypothesis: less

```
>>> stats.kstest(x, 'norm', alternative = 'greater')
(0.0072115233216311081, 0.98531158590396395)
```

Don't reject equal distribution against alternative hypothesis: greater

```
>>> stats.kstest(x, 'norm', mode='asympt')
(0.12464329735846891, 0.08944488871182088)
```

#### Testing *t* distributed random variables against normal distribution

With 100 degrees of freedom the *t* distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(100, size=100), 'norm')
(0.072018929165471257, 0.67630062862479168)
```

With 3 degrees of freedom the *t* distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(3, size=100), 'norm')
(0.131016895759829, 0.058826222555312224)
```

`scipy.stats.chisquare` (*f\_obs*, *f\_exp*=None, *ddof*=0, *axis*=0)

Calculates a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

**Parameters** **f\_obs** : array\_like

Observed frequencies in each category.

**f\_exp** : array\_like, optional

Expected frequencies in each category. By default the categories are assumed to be equally likely.

**ddof** : int, optional

“Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of *ddof* is 0.

**axis** : int or None, optional  
 The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If axis is None, all values in *f\_obs* are treated as a single data set. Default is 0.

**Returns** **chisq** : float or ndarray  
 The chi-squared test statistic. The value is a float if *axis* is None or *f\_obs* and *f\_exp* are 1-D.

**p** : float or ndarray  
 The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

**See also:**

`power_divergence`, `mstats.chisquare`

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom,  $k-1$ , are for the case when no parameters of the distribution are estimated. If  $p$  parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are  $k-1-p$ . If the parameters are estimated in a different way, then the dof can be between  $k-1-p$  and  $k-1$ . However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

**References**

[R567], [R568]

**Examples**

When just *f\_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With *f\_exp* the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting *axis*=None, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

*ddof* is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with *ddof*.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

*f\_obs* and *f\_exp* are also broadcast. In the following, *f\_obs* has shape (6,) and *f\_exp* has shape (2, 6), so the result of broadcasting *f\_obs* and *f\_exp* has shape (2, 6). To compute the desired chi-squared statistics, we use *axis=1*:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...           f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...           axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

`scipy.stats.power_divergence` (*f\_obs*, *f\_exp*=None, *ddof*=0, *axis*=0, *lambda\_*=None)

Cressie-Read power divergence statistic and goodness of fit test.

This function tests the null hypothesis that the categorical data has the given frequencies, using the Cressie-Read power divergence statistic.

**Parameters** **f\_obs** : array\_like

Observed frequencies in each category.

**f\_exp** : array\_like, optional

Expected frequencies in each category. By default the categories are assumed to be equally likely.

**ddof** : int, optional

“Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of *ddof* is 0.

**axis** : int or None, optional

The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If axis is None, all values in *f\_obs* are treated as a single data set. Default is 0.

**lambda\_** : float or str, optional

*lambda\_* gives the power in the Cressie-Read power divergence statistic. The default is 1. For convenience, *lambda\_* may be assigned one of the following strings, in which case the corresponding numerical value is used:

| String           | Value | Description                                                                                                   |
|------------------|-------|---------------------------------------------------------------------------------------------------------------|
| "pearson"        | 1     | Pearson's chi-squared statistic. In this case, the function is equivalent to <code>`stats.chisquare`</code> . |
| "log-likelihood" | 0     | Log-likelihood ratio. Also known as the G-test [R623]_.                                                       |
| "freeman-tukey"  | -1/2  | Freeman-Tukey statistic.                                                                                      |

|                      |     |                                  |
|----------------------|-----|----------------------------------|
| "mod-log-likelihood" | -1  | Modified log-likelihood ratio.   |
| "neyman"             | -2  | Neyman's statistic.              |
| "cressie-read"       | 2/3 | The power recommended in [R625]. |

**Returns**

**statistic** : float or ndarray  
 The Cressie-Read power divergence test statistic. The value is a float if *axis* is None or if *f\_obs* and *f\_exp* are 1-D.

**pvalue** : float or ndarray  
 The p-value of the test. The value is a float if *ddof* and the return value *stat* are scalars.

**See also:**

`chisquare`

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

When *lambda\_* is less than zero, the formula for the statistic involves dividing by *f\_obs*, so a warning or error may be generated if any value in *f\_obs* is 0.

Similarly, a warning or error may be generated if any value in *f\_exp* is zero when *lambda\_* >= 0.

The default degrees of freedom, k-1, are for the case when no parameters of the distribution are estimated. If p parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are k-1-p. If the parameters are estimated in a different way, then the dof can be between k-1-p and k-1. However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

This function handles masked arrays. If an element of *f\_obs* or *f\_exp* is masked, then data at that position is ignored, and does not count towards the size of the data set.

New in version 0.13.0.

**References**

[R621], [R622], [R623], [R624], [R625]

**Examples**

(See `chisquare` for more examples.)

When just *f\_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies. Here we perform a G-test (i.e. use the log-likelihood ratio statistic):

```
>>> from scipy.stats import power_divergence
>>> power_divergence([16, 18, 16, 14, 12, 12], lambda_='log-likelihood')
(2.006573162632538, 0.84823476779463769)
```

The expected frequencies can be given with the *f\_exp* argument:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[16, 16, 16, 16, 16, 8],
...                  lambda_='log-likelihood')
(3.3281031458963746, 0.6495419288047497)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> power_divergence(obs, lambda_="log-likelihood")
(array([ 2.00657316,  6.77634498]), array([ 0.84823477,  0.23781225]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> power_divergence(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> power_divergence(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the test statistic with `ddof`.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

`f_obs` and `f_exp` are also broadcast. In the following, `f_obs` has shape (6,) and `f_exp` has shape (2, 6), so the result of broadcasting `f_obs` and `f_exp` has shape (2, 6). To compute the desired chi-squared statistics, we must use `axis=1`:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[[16, 16, 16, 16, 16, 8],
...                          [8, 20, 20, 16, 12, 12]],
...                  axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

`scipy.stats.ks_2samp(data1, data2)`

Computes the Kolmogorov-Smirnov statistic on 2 samples.

This is a two-sided test for the null hypothesis that 2 independent samples are drawn from the same continuous distribution.

|                   |                                                                                                                                                                       |

| <b>Returns</b>    | <b>statistic</b> : float<br>KS statistic                                                                                                                              |
|                   | <b>pvalue</b> : float<br>two-tailed p-value                                                                                                                           |

### Notes

This tests whether 2 samples are drawn from the same distribution. Note that, like in the case of the one-sample K-S test, the distribution is assumed to be continuous.

This is the two-sided test, one-sided tests are not implemented. The test uses the two-sided asymptotic Kolmogorov-Smirnov distribution.

If the K-S statistic is small or the p-value is high, then we cannot reject the hypothesis that the distributions of the two samples are the same.

*Examples*

```
>>> from scipy import stats
>>> np.random.seed(12345678) #fix random seed to get the same result
>>> n1 = 200 # size of first sample
>>> n2 = 300 # size of second sample
```

For a different distribution, we can reject the null hypothesis since the pvalue is below 1%:

```
>>> rvs1 = stats.norm.rvs(size=n1, loc=0., scale=1)
>>> rvs2 = stats.norm.rvs(size=n2, loc=0.5, scale=1.5)
>>> stats.ks_2samp(rvs1, rvs2)
(0.20833333333333337, 4.6674975515806989e-005)
```

For a slightly different distribution, we cannot reject the null hypothesis at a 10% or lower alpha since the p-value at 0.144 is higher than 10%

```
>>> rvs3 = stats.norm.rvs(size=n2, loc=0.01, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs3)
(0.10333333333333333, 0.14498781825751686)
```

For an identical distribution, we cannot reject the null hypothesis since the p-value is high, 41%:

```
>>> rvs4 = stats.norm.rvs(size=n2, loc=0.0, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs4)
(0.07999999999999996, 0.41126949729859719)
```

`scipy.stats.mannwhitneyu(x, y, use_continuity=True, alternative=None)`

Computes the Mann-Whitney rank test on samples x and y.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>x, y</b> : array_like<br>Array of samples, should be one-dimensional.                                                                                                                                                                                                                                                                                                                                                                                     |
|                   | <b>use_continuity</b> : bool, optional<br>Whether a continuity correction (1/2.) should be taken into account. Default is True.                                                                                                                                                                                                                                                                                                                              |
|                   | <b>alternative</b> : None (deprecated), 'less', 'two-sided', or 'greater'<br>Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults to None, which results in a p-value half the size of the 'two-sided' p-value and a different U statistic. The default behavior is not the same as using 'less' or 'greater': it only exists for backward compatibility and is deprecated. |
| <b>Returns</b>    | <b>statistic</b> : float<br>The Mann-Whitney U statistic, equal to min(U for x, U for y) if <i>alternative</i> is equal to None (deprecated; exists for backward compatibility), and U for y otherwise.                                                                                                                                                                                                                                                      |
|                   | <b>pvalue</b> : float<br>p-value assuming an asymptotic normal distribution. One-sided or two-sided, depending on the choice of <i>alternative</i> .                                                                                                                                                                                                                                                                                                         |

*Notes*

Use only when the number of observation in each sample is > 20 and you have 2 independent samples of ranks. Mann-Whitney U is significant if the u-obtained is LESS THAN or equal to the critical value of U.

This test corrects for ties and by default uses a continuity correction.

`scipy.stats.tiecorrect(rankvals)`

Tie correction factor for ties in the Mann-Whitney U and Kruskal-Wallis H tests.

**Parameters** **rankvals** : array\_like  
A 1-D sequence of ranks. Typically this will be the array returned by `stats.rankdata`.

**Returns** **factor** : float  
Correction factor for U or H.

**See also:****rankdata** Assign ranks to the data**mannwhitneyu**

Mann-Whitney rank test

**kruskal** Kruskal-Wallis H test**References**

[R642]

**Examples**

```
>>> from scipy.stats import tiecorrect, rankdata
>>> tiecorrect([1, 2.5, 2.5, 4])
0.9
>>> ranks = rankdata([1, 3, 2, 4, 5, 7, 2, 8, 4])
>>> ranks
array([ 1. ,  4. ,  2.5,  5.5,  7. ,  8. ,  2.5,  9. ,  5.5])
>>> tiecorrect(ranks)
0.9833333333333333
```

`scipy.stats.rankdata(a, method='average')`

Assign ranks to data, dealing with ties appropriately.

Ranks begin at 1. The *method* argument controls how ranks are assigned to equal values. See [R629] for further discussion of ranking methods.

**Parameters** **a** : array\_like  
The array of values to be ranked. The array is first flattened.

**method** : str, optional  
The method used to assign ranks to tied elements. The options are ‘average’, ‘min’, ‘max’, ‘dense’ and ‘ordinal’.

**‘average’**: The average of the ranks that would have been assigned to all the tied values is assigned to each value.

**‘min’**: The minimum of the ranks that would have been assigned to all the tied values is assigned to each value. (This is also referred to as “competition” ranking.)

**‘max’**: The maximum of the ranks that would have been assigned to all the tied values is assigned to each value.

**‘dense’**: Like ‘min’, but the rank of the next highest element is assigned the rank immediately after those assigned to the tied elements.

**‘ordinal’**: All values are given a distinct rank, corresponding to the order that the values occur in *a*.

The default is ‘average’.

**Returns** **ranks** : ndarray  
An array of length equal to the size of *a*, containing rank scores.

**References**

[R629]

*Examples*

```
>>> from scipy.stats import rankdata
>>> rankdata([0, 2, 3, 2])
array([ 1. ,  2.5,  4. ,  2.5])
>>> rankdata([0, 2, 3, 2], method='min')
array([ 1,  2,  4,  2])
>>> rankdata([0, 2, 3, 2], method='max')
array([ 1,  3,  4,  3])
>>> rankdata([0, 2, 3, 2], method='dense')
array([ 1,  2,  3,  2])
>>> rankdata([0, 2, 3, 2], method='ordinal')
array([ 1,  2,  4,  3])
```

`scipy.stats.ranksums(x, y)`

Compute the Wilcoxon rank-sum statistic for two samples.

The Wilcoxon rank-sum test tests the null hypothesis that two sets of measurements are drawn from the same distribution. The alternative hypothesis is that values in one sample are more likely to be larger than the values in the other sample.

This test should be used to compare two samples from continuous distributions. It does not handle ties between measurements in *x* and *y*. For tie-handling and an optional continuity correction see `scipy.stats.mannwhitneyu`.

**Parameters** `x,y` : array\_like  
The data from the two samples

**Returns** `statistic` : float  
The test statistic under the large-sample approximation that the rank sum statistic is normally distributed

`pvalue` : float  
The two-sided p-value of the test

*References*

[R630]

`scipy.stats.wilcoxon(x, y=None, zero_method='wilcox', correction=False)`

Calculate the Wilcoxon signed-rank test.

The Wilcoxon signed-rank test tests the null hypothesis that two related paired samples come from the same distribution. In particular, it tests whether the distribution of the differences *x* - *y* is symmetric about zero. It is a non-parametric version of the paired T-test.

**Parameters** `x` : array\_like  
The first set of measurements.

`y` : array\_like, optional  
The second set of measurements. If *y* is not given, then the *x* array is considered to be the differences between the two sets of measurements.

**zero\_method** : string, {"pratt", "wilcox", "zsplit"}, optional

**"pratt"**: Pratt treatment: includes zero-differences in the ranking process (more conservative)

**"wilcox"**: Wilcox treatment: discards all zero-differences

**"zsplit"**: Zero rank split: just like Pratt, but splitting the zero rank between positive and negative ones

**correction** : bool, optional  
If True, apply continuity correction by adjusting the Wilcoxon rank statistic by 0.5 towards the mean value when computing the z-statistic. Default is False.

**Returns** `statistic` : float

The sum of the ranks of the differences above or below zero, whichever is smaller.

**pvalue** : float

The two-sided p-value for the test.

### Notes

Because the normal approximation is used for the calculations, the samples used should be large. A typical rule is to require that  $n > 20$ .

### References

[R651]

`scipy.stats.kruskal` (\*args, \*\*kwargs)

Compute the Kruskal-Wallis H-test for independent samples

The Kruskal-Wallis H-test tests the null hypothesis that the population median of all of the groups are equal. It is a non-parametric version of ANOVA. The test works on 2 or more independent samples, which may have different sizes. Note that rejecting the null hypothesis does not indicate which of the groups differs. Post-hoc comparisons between groups are required to determine which groups are different.

**Parameters** **sample1, sample2, ...** : array\_like

Two or more arrays with the sample measurements can be given as arguments.

**nan\_policy** : { 'propagate', 'raise', 'omit' }, optional

Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns** **statistic** : float

The Kruskal-Wallis H statistic, corrected for ties

**pvalue** : float

The p-value for the test using the assumption that H has a chi square distribution

### See also:

[`f\_oneway`](#) 1-way ANOVA

[`mannwhitneyu`](#)

Mann-Whitney rank test on two samples.

[`friedmanchisquare`](#)

Friedman test for repeated measurements

### Notes

Due to the assumption that H has a chi square distribution, the number of samples in each group must not be too small. A typical rule is that each sample must have at least 5 measurements.

### References

### Examples

```
>>> from scipy import stats
>>> x = [1, 3, 5, 7, 9]
>>> y = [2, 4, 6, 8, 10]
>>> stats.kruskal(x, y)
KruskalResult(statistic=0.27272727272727337, pvalue=0.60150813444058948)
```

```
>>> x = [1, 1, 1]
>>> y = [2, 2, 2]
>>> z = [2, 2]
>>> stats.kruskal(x, y, z)
KruskalResult(statistic=7.0, pvalue=0.030197383422318501)
```

`scipy.stats.friedmanchisquare` (\*args)

Computes the Friedman test for repeated measurements

The Friedman test tests the null hypothesis that repeated measurements of the same individuals have the same distribution. It is often used to test for consistency among measurements obtained in different ways. For example, if two measurement techniques are used on the same set of individuals, the Friedman test can be used to determine if the two measurement techniques are consistent.

**Parameters** **measurements1, measurements2, measurements3...** : array\_like  
 Arrays of measurements. All of the arrays must have the same number of elements. At least 3 sets of measurements must be given.

**Returns** **statistic** : float  
 the test statistic, correcting for ties

**pvalue** : float  
 the associated p-value assuming that the test statistic has a chi squared distribution

**Notes**

Due to the assumption that the test statistic has a chi squared distribution, the p-value is only reliable for  $n > 10$  and more than 6 repeated measurements.

**References**

[R582]

`scipy.stats.combine_pvalues` (pvalues, method='fisher', weights=None)

Methods for combining the p-values of independent tests bearing upon the same hypothesis.

**Parameters** **pvalues** : array\_like, 1-D  
 Array of p-values assumed to come from independent tests.

**method** : { 'fisher', 'stouffer' }, optional  
 Name of method to use to combine p-values. The following methods are available:

- "fisher": Fisher's method (Fisher's combined probability test), the default.
- "stouffer": Stouffer's Z-score method.

**weights** : array\_like, 1-D, optional  
 Optional array of weights used only for Stouffer's Z-score method.

**Returns** **statistic**: float  
 The statistic calculated by the specified method: - "fisher": The chi-squared statistic - "stouffer": The Z-score

**pval**: float  
 The combined p-value.

**Notes**

Fisher's method (also known as Fisher's combined probability test) [R569] uses a chi-squared statistic to compute a combined p-value. The closely related Stouffer's Z-score method [R570] uses Z-scores rather than p-values. The advantage of Stouffer's method is that it is straightforward to introduce weights, which can make Stouffer's method more powerful than Fisher's method when the p-values are from studies of different size [R571] [R572].

Fisher's method may be extended to combine p-values from dependent tests [R573]. Extensions such as Brown's method and Kost's method are not currently implemented.

New in version 0.15.0.

`scipy.stats.jarque_bera` (x)

Perform the Jarque-Bera goodness of fit test on sample data.

The Jarque-Bera test tests whether the sample data has the skewness and kurtosis matching a normal distribution.

Note that this test only works for a large enough number of data samples (>2000) as the test statistic asymptotically has a Chi-squared distribution with 2 degrees of freedom.

`scipy.stats.ansari` (x, y)

Perform the Ansari-Bradley test for equal scale parameters

The Ansari-Bradley test is a non-parametric test for the equality of the scale parameter of the distributions from

which two samples were drawn.

**Parameters** `x, y` : array\_like  
 arrays of sample data

**Returns** **statistic** : float  
 The Ansari-Bradley test statistic

**pvalue** : float  
 The p-value of the hypothesis test

**See also:**

[\*fligner\*](#) A non-parametric test for the equality of k variances  
[\*mood\*](#) A non-parametric test for the equality of two scale parameters

**Notes**

The p-value given is exact when the sample sizes are both less than 55 and there are no ties, otherwise a normal approximation for the p-value is used.

**References**

[R554]

`scipy.stats.bartlett` (\*args)  
 Perform Bartlett's test for equal variances

Bartlett's test tests the null hypothesis that all input samples are from populations with equal variances. For samples from significantly non-normal populations, Levene's test [`levene`](#) is more robust.

**Parameters** **sample1, sample2,...** : array\_like  
 arrays of sample data. May be different lengths.

**Returns** **statistic** : float  
 The test statistic.

**pvalue** : float  
 The p-value of the test.

**See also:**

[\*fligner\*](#) A non-parametric test for the equality of k variances  
[\*levene\*](#) A robust parametric test for equality of k variances

**Notes**

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [R558].

[R556], [R557], [R558], [R559]

`scipy.stats.levene` (\*args, \*\*kws)  
 Perform Levene test for equal variances.

The Levene test tests the null hypothesis that all input samples are from populations with equal variances. Levene's test is an alternative to Bartlett's test [`bartlett`](#) in the case where there are significant deviations from normality.

**Parameters** **sample1, sample2, ...** : array\_like  
 The sample data, possibly with different lengths

**center** : {'mean', 'median', 'trimmed'}, optional  
 Which function of the data to use in the test. The default is 'median'.

**proportiontocut** : float, optional

When *center* is ‘trimmed’, this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.

**Returns**

**statistic** : float  
The test statistic.

**pvalue** : float  
The p-value for the test.

**Notes**

Three variations of Levene’s test are possible. The possibilities and their recommended usages are:

- ‘median’ : Recommended for skewed (non-normal) distributions>
- ‘mean’ : Recommended for symmetric, moderate-tailed distributions.
- ‘trimmed’ : Recommended for heavy-tailed distributions.

**References**

[R603], [R604], [R605]

`scipy.stats.shapiro` (*x*, *a=None*, *reta=False*)

Perform the Shapiro-Wilk test for normality.

The Shapiro-Wilk test tests the null hypothesis that the data was drawn from a normal distribution.

**Parameters**

**x** : array\_like  
Array of sample data.

**a** : array\_like, optional  
Array of internal parameters used in the calculation. If these are not given, they will be computed internally. If *x* has length *n*, then *a* must have length *n*/2.

**reta** : bool, optional  
Whether or not to return the internally computed *a* values. The default is False.

**Returns**

**W** : float  
The test statistic.

**p-value** : float  
The p-value for the hypothesis test.

**a** : array\_like, optional  
If *reta* is True, then these are the internally computed “a” values that may be passed into this function on future calls.

**See also:**

**anderson** The Anderson-Darling test for normality

**kstest** The Kolmogorov-Smirnov test for goodness of fit.

**Notes**

The algorithm used is described in [R634] but censoring parameters as described are not implemented. For *N* > 5000 the *W* test statistic is accurate but the p-value may not be.

The chance of rejecting the null hypothesis when it is true is close to 5% regardless of sample size.

**References**

[R631], [R632], [R633], [R634]

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(12345678)
```

```
>>> x = stats.norm.rvs(loc=5, scale=3, size=100)
>>> stats.shapiro(x)
(0.9772805571556091, 0.08144091814756393)
```

`scipy.stats.anderson(x, dist='norm')`

Anderson-Darling test for data coming from a particular distribution

The Anderson-Darling test is a modification of the Kolmogorov- Smirnov test `kstest` for the null hypothesis that a sample is drawn from a population that follows a particular distribution. For the Anderson-Darling test, the critical values depend on which distribution is being tested against. This function works for normal, exponential, logistic, or Gumbel (Extreme Value Type I) distributions.

**Parameters** `x` : array\_like  
array of sample data

**dist** : {'norm', 'expon', 'logistic', 'gumbel', 'gumbel\_l', 'gumbel\_r', 'extreme1'}, optional the type of distribution to test against. The default is 'norm' and 'extreme1', 'gumbel\_l' and 'gumbel' are synonyms.

**Returns** **statistic** : float  
The Anderson-Darling test statistic

**critical\_values** : list  
The critical values for this distribution

**significance\_level** : list  
The significance levels for the corresponding critical values in percents. The function returns critical values for a differing set of significance levels depending on the distribution that is being tested against.

#### Notes

Critical values provided are for the following significance levels:

##### *normal/exponential*

15%, 10%, 5%, 2.5%, 1%

*logistic* 25%, 10%, 5%, 2.5%, 1%, 0.5%

*Gumbel* 25%, 10%, 5%, 2.5%, 1%

If A2 is larger than these critical values then for the corresponding significance level, the null hypothesis that the data come from the chosen distribution can be rejected.

#### References

[R547], [R548], [R549], [R550], [R551], [R552]

`scipy.stats.anderson_ksamp(samples, midrank=True)`

The Anderson-Darling test for k-samples.

The k-sample Anderson-Darling test is a modification of the one-sample Anderson-Darling test. It tests the null hypothesis that k-samples are drawn from the same population without having to specify the distribution function of that population. The critical values depend on the number of samples.

**Parameters** **samples** : sequence of 1-D array\_like  
Array of sample data in arrays.

**midrank** : bool, optional  
Type of Anderson-Darling test which is computed. Default (True) is the midrank test applicable to continuous and discrete populations. If False, the right side empirical distribution is used.

**Returns** **statistic** : float  
Normalized k-sample Anderson-Darling test statistic.

**critical\_values** : array  
The critical values for significance levels 25%, 10%, 5%, 2.5%, 1%.

**significance\_level** : float

**Raises** **ValueError** An approximate significance level at which the null hypothesis for the provided samples can be rejected.  
If less than 2 samples are provided, a sample is empty, or no distinct observations are in the samples.

**See also:**

`ks_2samp` 2 sample Kolmogorov-Smirnov test  
`anderson` 1 sample Anderson-Darling test

**Notes**

[R553] Defines three versions of the k-sample Anderson-Darling test: one for continuous distributions and two for discrete distributions, in which ties between samples may occur. The default of this routine is to compute the version based on the midrank empirical distribution function. This test is applicable to continuous and discrete data. If midrank is set to False, the right side empirical distribution is used for a test for discrete data. According to [R553], the two discrete test statistics differ only slightly if a few collisions due to round-off errors occur in the test not adjusted for ties between samples.

New in version 0.14.0.

**References**

[R553]

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(314159)
```

The null hypothesis that the two random samples come from the same distribution can be rejected at the 5% level because the returned test value is greater than the critical value for 5% (1.961) but not at the 2.5% level. The interpolation gives an approximate significance level of 3.1%:

```
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(loc=0.5, size=30)])
(2.4615796189876105,
 array([ 0.325,  1.226,  1.961,  2.718,  3.752]),
 0.03134990135800783)
```

The null hypothesis cannot be rejected for three samples from an identical distribution. The approximate p-value (87%) has to be computed by extrapolation and may not be very accurate:

```
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(size=30), np.random.normal(size=20)])
(-0.73091722665244196,
 array([ 0.44925884,  1.3052767 ,  1.9434184 ,  2.57696569,  3.41634856]),
 0.8789283903979661)
```

`scipy.stats.binom_test` (*x*, *n=None*, *p=0.5*, *alternative='two-sided'*)

Perform a test that the probability of success is *p*.

This is an exact, two-sided test of the null hypothesis that the probability of success in a Bernoulli experiment is *p*.

**Parameters** **x** : integer or array\_like  
the number of successes, or if *x* has length 2, it is the number of successes and the number of failures.

**n** : integer  
the number of trials. This is ignored if `x` gives both the number of successes and failures

**p** : float, optional  
The hypothesized probability of success.  $0 \leq p \leq 1$ . The default value is  $p = 0.5$

**alternative** : { 'two-sided', 'greater', 'less' }, optional  
Indicates the alternative hypothesis. The default value is 'two-sided'.

**Returns** **p-value** : float  
The p-value of the hypothesis test

### References

[R560]

`scipy.stats.fligner` (\*args, \*\*kwargs)  
Perform Fligner-Killeen test for equality of variance.

Fligner's test tests the null hypothesis that all input samples are from populations with equal variances. Fligner-Killeen's test is distribution free when populations are identical [R579].

**Parameters** **sample1, sample2, ...** : array\_like  
Arrays of sample data. Need not be the same length.

**center** : { 'mean', 'median', 'trimmed' }, optional  
Keyword argument controlling which function of the data is used in computing the test statistic. The default is 'median'.

**proportiontocut** : float, optional  
When `center` is 'trimmed', this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.

**Returns** **statistic** : float  
The test statistic.

**pvalue** : float  
The p-value for the hypothesis test.

### See also:

**bartlett** A parametric test for equality of  $k$  variances in normal samples

**levene** A robust parametric test for equality of  $k$  variances

### Notes

As with Levene's test there are three variants of Fligner's test that differ by the measure of central tendency used in the test. See `levene` for more information.

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [R580].

`scipy.stats.median_test` (\*args, \*\*kwargs)  
Mood's median test.

Test that two or more samples come from populations with the same median.

Let  $n = \text{len}(\text{args})$  be the number of samples. The "grand median" of all the data is computed, and a contingency table is formed by classifying the values in each sample as being above or below the grand median. The contingency table, along with `correction` and `lambda_`, are passed to `scipy.stats.chi2_contingency` to compute the test statistic and p-value.

**Parameters**

**sample1, sample2, ...** : array\_like  
 The set of samples. There must be at least two samples. Each sample must be a one-dimensional sequence containing at least one value. The samples are not required to have the same length.

**ties** : str, optional  
 Determines how values equal to the grand median are classified in the contingency table. The string must be one of:

```
"below":
    Values equal to the grand median are counted as "below".
"above":
    Values equal to the grand median are counted as "above".
"ignore":
    Values equal to the grand median are not counted.
```

The default is "below".

**correction** : bool, optional  
 If True, *and* there are just two samples, apply Yates' correction for continuity when computing the test statistic associated with the contingency table. Default is True.

**lambda\_** : float or str, optional.  
 By default, the statistic computed in this test is Pearson's chi-squared statistic. *lambda\_* allows a statistic from the Cressie-Read power divergence family to be used instead. See [power\\_divergence](#) for details. Default is 1 (Pearson's chi-squared statistic).

**nan\_policy** : {'propagate', 'raise', 'omit'}, optional  
 Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**stat** : float  
 The test statistic. The statistic that is returned is determined by *lambda\_*. The default is Pearson's chi-squared statistic.

**p** : float  
 The p-value of the test.

**m** : float  
 The grand median.

**table** : ndarray  
 The contingency table. The shape of the table is (2, n), where n is the number of samples. The first row holds the counts of the values above the grand median, and the second row holds the counts of the values below the grand median. The table allows further analysis with, for example, `scipy.stats.chi2_contingency`, or with `scipy.stats.fisher_exact` if there are two samples, without having to recompute the table. If *nan\_policy* is "propagate" and there are nans in the input, the return value for *table* is None.

**See also:**

[kruskal](#) Compute the Kruskal-Wallis H-test for independent samples.  
[mannwhitneyu](#) Computes the Mann-Whitney rank test on samples x and y.

**Notes**

New in version 0.15.0.

## References

[R607], [R608]

## Examples

A biologist runs an experiment in which there are three groups of plants. Group 1 has 16 plants, group 2 has 15 plants, and group 3 has 17 plants. Each plant produces a number of seeds. The seed counts for each group are:

```
Group 1: 10 14 14 18 20 22 24 25 31 31 32 39 43 43 48 49
Group 2: 28 30 31 33 34 35 36 40 44 55 57 61 91 92 99
Group 3:  0  3  9 22 23 25 25 33 34 34 40 45 46 48 62 67 84
```

The following code applies Mood's median test to these samples.

```
>>> g1 = [10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 43, 48, 49]
>>> g2 = [28, 30, 31, 33, 34, 35, 36, 40, 44, 55, 57, 61, 91, 92, 99]
>>> g3 = [0, 3, 9, 22, 23, 25, 25, 33, 34, 34, 40, 45, 46, 48, 62, 67, 84]
>>> from scipy.stats import median_test
>>> stat, p, med, tbl = median_test(g1, g2, g3)
```

The median is

```
>>> med
34.0
```

and the contingency table is

```
>>> tbl
array([[ 5, 10,  7],
       [11,  5, 10]])
```

$p$  is too large to conclude that the medians are not the same:

```
>>> p
0.12609082774093244
```

The "G-test" can be performed by passing `lambda_="log-likelihood"` to `median_test`.

```
>>> g, p, med, tbl = median_test(g1, g2, g3, lambda_="log-likelihood")
>>> p
0.12224779737117837
```

The median occurs several times in the data, so we'll get a different result if, for example, `ties="above"` is used:

```
>>> stat, p, med, tbl = median_test(g1, g2, g3, ties="above")
>>> p
0.063873276069553273
```

```
>>> tbl
array([[ 5, 11,  9],
       [11,  4,  8]])
```

This example demonstrates that if the data set is not large and there are values equal to the median, the  $p$ -value can be sensitive to the choice of *ties*.

`scipy.stats.mood(x, y, axis=0)`

Perform Mood's test for equal scale parameters.

Mood's two-sample test for scale parameters is a non-parametric test for the null hypothesis that two samples are drawn from the same distribution with the same scale parameter.

**Parameters**

- x, y** : array\_like  
Arrays of sample data.
- axis** : int, optional  
The axis along which the samples are tested. *x* and *y* can be of different length along *axis*. If *axis* is None, *x* and *y* are flattened and the test is done on all values in the flattened arrays.

**Returns**

- z** : scalar or ndarray  
The z-score for the hypothesis test. For 1-D inputs a scalar is returned.
- p-value** : scalar ndarray  
The p-value for the hypothesis test.

**See also:**

**fligner** A non-parametric test for the equality of k variances  
**ansari** A non-parametric test for the equality of 2 variances  
**bartlett** A parametric test for equality of k variances in normal samples  
**levene** A parametric test for equality of k variances

**Notes**

The data are assumed to be drawn from probability distributions  $f(x)$  and  $f(x/s) / s$  respectively, for some probability density function  $f$ . The null hypothesis is that  $s == 1$ .

For multi-dimensional arrays, if the inputs are of shapes  $(n_0, n_1, n_2, n_3)$  and  $(n_0, m_1, n_2, n_3)$ , then if  $axis=1$ , the resulting  $z$  and  $p$  values will have shape  $(n_0, n_2, n_3)$ . Note that  $n_1$  and  $m_1$  don't have to be equal, but the other dimensions do.

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(1234)
>>> x2 = np.random.randn(2, 45, 6, 7)
>>> x1 = np.random.randn(2, 30, 6, 7)
>>> z, p = stats.mood(x1, x2, axis=1)
>>> p.shape
(2, 6, 7)
```

Find the number of points where the difference in scale is not significant:

```
>>> (p > 0.1).sum()
74
```

Perform the test with different scales:

```
>>> x1 = np.random.randn(2, 30)
>>> x2 = np.random.randn(2, 35) * 10.0
>>> stats.mood(x1, x2, axis=1)
(array([-5.7178125, -5.25342163]), array([ 1.07904114e-08,  1.49299218e-07]))
```

`scipy.stats.boxcox(x, lmbda=None, alpha=None)`

Return a positive dataset transformed by a Box-Cox power transformation.

**Parameters** `x` : ndarray

Input array. Should be 1-dimensional.

**lmbda** : {None, scalar}, optional

If `lmbda` is not None, do the transformation for that value.

If `lmbda` is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument.

**alpha** : {None, float}, optional

If `alpha` is not None, return the  $100 * (1 - \alpha)\%$  confidence interval for `lmbda` as the third output argument. Must be between 0.0 and 1.0.

**Returns**

**boxcox** : ndarray

Box-Cox power transformed array.

**maxlog** : float, optional

If the `lmbda` parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.

**(min\_ci, max\_ci)** : tuple of float, optional

If `lmbda` parameter is None and `alpha` is not None, this returned tuple of floats represents the minimum and maximum confidence limits given `alpha`.

**See also:**

`probplot`, `boxcox_normplot`, `boxcox_normmax`, `boxcox_llf`

**Notes**

The Box-Cox transform is given by:

$$y = \begin{cases} (x^{*\text{lmbda}} - 1) / \text{lmbda}, & \text{for } \text{lmbda} > 0 \\ \log(x), & \text{for } \text{lmbda} = 0 \end{cases}$$

`boxcox` requires the input data to be positive. Sometimes a Box-Cox transformation provides a shift parameter to achieve this; `boxcox` does not. Such a shift parameter is equivalent to adding a positive constant to `x` before calling `boxcox`.

The confidence limits returned when `alpha` is provided give the interval where:

$$llf(\hat{\lambda}) - llf(\lambda) < \frac{1}{2}\chi^2(1 - \alpha, 1),$$

with `llf` the log-likelihood function and  $\chi^2$  the chi-squared function.

**References**

G.E.P. Box and D.R. Cox, “An Analysis of Transformations”, Journal of the Royal Statistical Society B, 26, 211-252 (1964).

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `boxcox` to transform the data so it's closest to normal:

```
>>> ax2 = fig.add_subplot(212)
>>> xt, _ = stats.boxcox(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Box-Cox transformation')

>>> plt.show()
```

```
scipy.stats.boxcox_normmax(x, brack=(-2.0, 2.0), method='pearsonr')
```

Compute optimal Box-Cox transform parameter for input data.

**Parameters** `x` : array\_like

Input array.

**brack** : 2-tuple, optional

The starting interval for a downhill bracket search with `optimize.brent`. Note that this is in most cases not critical; the final result is allowed to be outside this bracket.

**method** : str, optional

The method to determine the optimal transform parameter (`boxcox` lambda parameter). Options are:

**'pearsonr'** (default)

Maximizes the Pearson correlation coefficient between  $y = \text{boxcox}(x)$  and the expected values for  $y$  if  $x$  would be normally-distributed.

**'mle'**

Minimizes the log-likelihood `boxcox_llf`. This is the method used in `boxcox`.

**Returns** `maxlog` : float or ndarray  
 Use all optimization methods available, and return all results. Useful to compare different methods.  
 The optimal transform parameter found. An array instead of a scalar for `method='all'`.

**See also:**

`boxcox`, `boxcox_llf`, `boxcox_normplot`

**Examples**

```

>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234) # make this example reproducible
    
```

Generate some data and determine optimal lambda in various ways:

```

>>> x = stats.loggamma.rvs(5, size=30) + 5
>>> y, lmax_mle = stats.boxcox(x)
>>> lmax_pearsonr = stats.boxcox_normmax(x)

>>> lmax_mle
7.177...
>>> lmax_pearsonr
7.916...
>>> stats.boxcox_normmax(x, method='all')
array([ 7.91667384,  7.17718692])

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax_mle, color='r')
>>> ax.axvline(lmax_pearsonr, color='g', ls='--')

>>> plt.show()
    
```

`scipy.stats.boxcox_llf(lmb, data)`

The boxcox log-likelihood function.

**Parameters**

- lmb** : scalar  
Parameter for Box-Cox transformation. See `boxcox` for details.
- data** : array\_like  
Data to calculate Box-Cox log-likelihood for. If *data* is multi-dimensional, the log-likelihood is calculated along the first axis.

**Returns**

- llf** : float or ndarray  
Box-Cox log-likelihood of *data* given *lmb*. A float for 1-D *data*, an array otherwise.

**See also:**

`boxcox`, `probplot`, `boxcox_normplot`, `boxcox_normmax`

**Notes**

The Box-Cox log-likelihood function is defined here as

$$llf = (\lambda - 1) \sum_i (\log(x_i)) - N/2 \log(\sum_i (y_i - \bar{y})^2 / N),$$

where  $y$  is the Box-Cox transformed input data  $x$ .

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
>>> np.random.seed(1245)
```

Generate some random variates and calculate Box-Cox log-likelihood values for them for a range of `lmbda` values:

```
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lmbda in enumerate(lmbdas):
...     llf[ii] = stats.boxcox_llf(lmbda, x)
```

Also find the optimal `lmbda` value with `boxcox`:

```
>>> x_most_normal, lmbda_optimal = stats.boxcox(x)
```

Plot the log-likelihood as function of `lmbda`. Add the optimal `lmbda` as a horizontal line to check that that's really the optimum:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.boxcox_llf(lmbda_optimal, x), color='r')
>>> ax.set_xlabel('lmbda parameter')
>>> ax.set_ylabel('Box-Cox log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `boxcox` looks closest to normal:

```

>>> locs = [3, 10, 4] # 'lower left', 'center', 'lower right'
>>> for lmbda, loc in zip([-1, lmbda_optimal, 9], locs):
...     xt = stats.boxcox(x, lmbda=lmbda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title('$\lambda=%1.2f$' % lmbda)

>>> plt.show()
    
```

`scipy.stats.entropy(pk, qk=None, base=None)`

Calculate the entropy of a distribution for given probability values.

If only probabilities  $pk$  are given, the entropy is calculated as  $S = -\sum(pk * \log(pk), axis=0)$ .

If  $qk$  is not None, then compute the Kullback-Leibler divergence  $S = \sum(pk * \log(pk / qk), axis=0)$ .

This routine will normalize  $pk$  and  $qk$  if they don't sum to 1.

**Parameters**

- pk** : sequence  
Defines the (discrete) distribution.  $pk[i]$  is the (possibly unnormalized) probability of event  $i$ .
- qk** : sequence, optional  
Sequence against which the relative entropy is computed. Should be in the same format as  $pk$ .
- base** : float, optional  
The logarithmic base to use, defaults to  $e$  (natural logarithm).

**Returns**

- S** : float  
The calculated entropy.

---

`chisqprob(*args, **kwds)`    `chisqprob` is deprecated!  
`betai(*args, **kwds)`        `betai` is deprecated!

---

`scipy.stats.chisqprob(*args, **kws)`

`chisqprob` is deprecated! `stats.chisqprob` is deprecated in scipy 0.17.0; use `stats.distributions.chi2.sf` instead.

Probability value (1-tail) for the Chi<sup>2</sup> probability distribution.

Broadcasting rules apply.

**Parameters** `chisq` : array\_like or float > 0

**Returns** `chisqprob` : ndarray  
`df` : array\_like or float, probably int >= 1

The area from `chisq` to infinity under the Chi<sup>2</sup> probability distribution with degrees of freedom `df`.

`scipy.stats.betainc(*args, **kws)`

`betainc` is deprecated! `stats.betainc` is deprecated in scipy 0.17.0; use `special.betainc` instead

Returns the incomplete beta function.

$I_x(a,b) = 1/B(a,b) * (\text{Integral}(0,x) \text{ of } t^{a-1}(1-t)^{b-1} dt)$

where  $a,b > 0$  and  $B(a,b) = G(a)G(b)/(G(a+b))$  where  $G(a)$  is the gamma function of  $a$ .

The standard broadcasting rules apply to  $a$ ,  $b$ , and  $x$ .

**Parameters** `a` : array\_like or float > 0

`b` : array\_like or float > 0

`x` [array\_like or float] `x` will be clipped to be no greater than 1.0 .

**Returns** `betainc` : ndarray

Incomplete beta function.

## 5.27.5 Circular statistical functions

---

`circmean(samples[, high, low, axis])` Compute the circular mean for samples in a range.

`circvar(samples[, high, low, axis])` Compute the circular variance for samples assumed to be in a range

`circstd(samples[, high, low, axis])` Compute the circular standard deviation for samples assumed to be in the range [low to high]

---

`scipy.stats.circmean(samples, high=6.283185307179586, low=0, axis=None)`

Compute the circular mean for samples in a range.

**Parameters** `samples` : array\_like

Input array.

**high** : float or int, optional

High boundary for circular mean range. Default is  $2 * \pi$ .

**low** : float or int, optional

Low boundary for circular mean range. Default is 0.

**axis** : int, optional

Axis along which means are computed. The default is to compute the mean of the flattened array.

**Returns** `circmean` : float

Circular mean.

`scipy.stats.circvar(samples, high=6.283185307179586, low=0, axis=None)`

Compute the circular variance for samples assumed to be in a range

**Parameters** `samples` : array\_like

Input array.

**low** : float or int, optional

Low boundary for circular variance range. Default is 0.

**high** : float or int, optional

**Returns** **axis** : int, optional  
 High boundary for circular variance range. Default is  $2\pi$ .  
 Axis along which variances are computed. The default is to compute the variance of the flattened array.  
**circvar** : float  
 Circular variance.

**Notes**

This uses a definition of circular variance that in the limit of small angles returns a number close to the ‘linear’ variance.

`scipy.stats.circstd` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None)  
 Compute the circular standard deviation for samples assumed to be in the range [low to high].

**Parameters** **samples** : array\_like  
 Input array.  
**low** : float or int, optional  
 Low boundary for circular standard deviation range. Default is 0.  
**high** : float or int, optional  
 High boundary for circular standard deviation range. Default is  $2\pi$ .  
**axis** : int, optional  
 Axis along which standard deviations are computed. The default is to compute the standard deviation of the flattened array.  
**Returns** **circstd** : float  
 Circular standard deviation.

**Notes**

This uses a definition of circular standard deviation that in the limit of small angles returns a number close to the ‘linear’ standard deviation.

### 5.27.6 Contingency table functions

---

|                                                                         |                                                                      |
|-------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>chi2_contingency</code> (observed[, correction, <b>lambda_</b> ]) | Chi-square test of independence of variables in a contingency table. |
| <code>contingency.expected_freq</code> (observed)                       | Compute the expected frequencies from a contingency table.           |
| <code>contingency.margins</code> (a)                                    | Return a list of the marginal sums of the array <i>a</i> .           |
| <code>fisher_exact</code> (table[, alternative])                        | Performs a Fisher exact test on a 2x2 contingency table.             |

---

`scipy.stats.chi2_contingency` (*observed*, *correction*=True, *lambda\_*=None)  
 Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table [R564] *observed*. The expected frequencies are computed based on the marginal sums under the assumption of independence; see `scipy.stats.contingency.expected_freq`. The number of degrees of freedom is (expressed using numpy functions and attributes):

$$\text{dof} = \text{observed.size} - \text{sum}(\text{observed.shape}) + \text{observed.ndim} - 1$$

**Parameters** **observed** : array\_like  
 The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.  
**correction** : bool, optional

If True, *and* the degrees of freedom is 1, apply Yates' correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.

**lambda\_** : float or str, optional.

By default, the statistic computed in this test is Pearson's chi-squared statistic [R565]. *lambda\_* allows a statistic from the Cressie-Read power divergence family [R566] to be used instead. See [power\\_divergence](#) for details.

**Returns**

**chi2** : float

The test statistic.

**p** : float

The p-value of the test

**dof** : int

Degrees of freedom

**expected** : ndarray, same shape as *observed*

The expected frequencies, based on the marginal sums of the table.

**See also:**

[contingency.expected\\_freq](#), [fisher\\_exact](#), [chisquare](#), [power\\_divergence](#)

**Notes**

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequency in each cell is at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of *observed* is two or more. Applying the test to a one-dimensional table will always result in *expected* equal to *observed* and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.

Like `stats.chisquare`, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates' correction was not required, one could use `stats.chisquare`. That is, if one calls:

```
chi2, p, dof, ex = chi2_contingency(obs, correction=False)
```

then the following is true:

```
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(),
                             ddof=obs.size - 1 - dof)
```

The *lambda\_* argument was added in version 0.13.0 of `scipy`.

**References**

[R564], [R565], [R566]

**Examples**

A two-way example (2 x 3):

```
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20], [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777,
 0.24935220877729619,
 2,
```

```
array([[ 12.,  12.,  16.],
       [ 18.,  18.,  24.]])
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```
>>> g, p, dof, expctd = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```
>>> obs = np.array(
...     [[[[12, 17],
...         [11, 16]],
...         [[11, 12],
...         [15, 16]]],
...     [[[[23, 15],
...         [30, 22]],
...         [[14, 17],
...         [15, 16]]]])
>>> chi2_contingency(obs)
(8.7584514426741897,
 0.64417725029295503,
 11,
 array([[[[ 14.15462386,  14.15462386],
           [ 16.49423111,  16.49423111]],
         [[ 11.2461395 ,  11.2461395 ],
         [ 13.10500554,  13.10500554]]],
        [[ 19.5591166 ,  19.5591166 ],
         [ 22.79202844,  22.79202844]],
        [[ 15.54012004,  15.54012004],
         [ 18.10873492,  18.10873492]]]])
```

`scipy.stats.contingency.expected_freq`(*observed*)

Compute the expected frequencies from a contingency table.

Given an n-dimensional contingency table of observed frequencies, compute the expected frequencies for the table based on the marginal sums under the assumption that the groups associated with each dimension are independent.

**Parameters**    **observed** : array\_like  
The table of observed frequencies. (While this function can handle a 1-D array, that case is trivial. Generally *observed* is at least 2-D.)

**Returns**        **expected** : ndarray of float64  
The expected frequencies, based on the marginal sums of the table. Same shape as *observed*.

**Examples**

```
>>> observed = np.array([[10, 10, 20],[20, 20, 20]])
>>> from scipy.stats import expected_freq
>>> expected_freq(observed)
array([[ 12.,  12.,  16.],
       [ 18.,  18.,  24.]])
```

`scipy.stats.contingency.margins`(*a*)

Return a list of the marginal sums of the array *a*.

**Parameters**    **a** : ndarray

**Returns** **margsums** : list of ndarrays  
 The array for which to compute the marginal sums.  
 A list of length *a.ndim*. *margsums[k]* is the result of summing *a* over all axes except *k*; it has the same number of dimensions as *a*, but the length of each axis except axis *k* will be 1.

### Examples

```
>>> a = np.arange(12).reshape(2, 6)
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11]])
>>> m0, m1 = margins(a)
>>> m0
array([[15],
       [51]])
>>> m1
array([[ 6,  8, 10, 12, 14, 16]])

>>> b = np.arange(24).reshape(2, 3, 4)
>>> m0, m1, m2 = margins(b)
>>> m0
array([[[ 66]],
       [[210]])]
>>> m1
array([[[ 60],
       [ 92],
       [124]])]
>>> m2
array([[[60, 66, 72, 78]])]
```

`scipy.stats.fisher_exact` (*table*, *alternative='two-sided'*)

Performs a Fisher exact test on a 2x2 contingency table.

**Parameters**

- table** : array\_like of ints  
A 2x2 contingency table. Elements should be non-negative integers.
- alternative** : {'two-sided', 'less', 'greater'}, optional  
Which alternative hypothesis to the null hypothesis the test uses. Default is 'two-sided'.

**Returns**

- oddsratio** : float  
This is prior odds ratio and not a posterior estimate.
- p\_value** : float  
P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

**See also:**

[\*chi2\\_contingency\*](#)

Chi-square test of independence of variables in a contingency table.

### Notes

The calculated odds ratio is different from the one R uses. This scipy implementation returns the (more common) “unconditional Maximum Likelihood Estimate”, while R uses the “conditional Maximum Likelihood Estimate”.

For tables with large numbers, the (inexact) chi-square test implemented in the function [\*chi2\\_contingency\*](#) can also be used.

*Examples*

Say we spend a few days counting whales and sharks in the Atlantic and Indian oceans. In the Atlantic ocean we find 8 whales and 1 shark, in the Indian ocean 2 whales and 5 sharks. Then our contingency table is:

|        | Atlantic | Indian |
|--------|----------|--------|
| whales | 8        | 2      |
| sharks | 1        | 5      |

We use this table to find the p-value:

```
>>> import scipy.stats as stats
>>> oddsratio, pvalue = stats.fisher_exact([[8, 2], [1, 5]])
>>> pvalue
0.0349...
```

The probability that we would observe this or an even more imbalanced ratio by chance is about 3.5%. A commonly used significance level is 5%—if we adopt that, we can therefore conclude that our observed imbalance is statistically significant; whales prefer the Atlantic while sharks prefer the Indian ocean.

### 5.27.7 Plot-tests

---

|                                                              |                                                                           |
|--------------------------------------------------------------|---------------------------------------------------------------------------|
| <code>ppcc_max(x[, brack, dist])</code>                      | Calculate the shape parameter that maximizes the PPCC                     |
| <code>ppcc_plot(x, a, b[, dist, plot, N])</code>             | Calculate and optionally plot probability plot correlation coefficient.   |
| <code>probplot(x[, sparams, dist, fit, plot, rvalue])</code> | Calculate quantiles for a probability plot, and optionally show the plot. |
| <code>boxcox_normplot(x, la, lb[, plot, N])</code>           | Compute parameters for a Box-Cox normality plot, optionally show it.      |

---

```
scipy.stats.ppcc_max(x, brack=(0.0, 1.0), dist='tukeylambda')
Calculate the shape parameter that maximizes the PPCC
```

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. `ppcc_max` returns the shape parameter that would maximize the probability plot correlation coefficient for the given data to a one-parameter family of distributions.

**Parameters**

- x** : array\_like  
Input array.
- brack** : tuple, optional  
Triple (a,b,c) where (a<b<c). If bracket consists of two numbers (a, c) then they are assumed to be a starting interval for a downhill bracket search (see `scipy.optimize.brent`).
- dist** : str or stats.distributions instance, optional  
Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted. The default is `'tukeylambda'`.

**Returns**

- shape\_value** : float  
The shape parameter at which the probability plot correlation coefficient reaches its max value.

**See also:**

`ppcc_plot`, `probplot`, `boxcox`

*Notes*

The `brack` keyword serves as a starting point which is useful in corner cases. One can use a plot to obtain a rough visual estimate of the location for the maximum to start the search near it.

## References

[R626], [R627]

## Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```
>>> from scipy import stats
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000,
...                           random_state=1234567) + 1e4
```

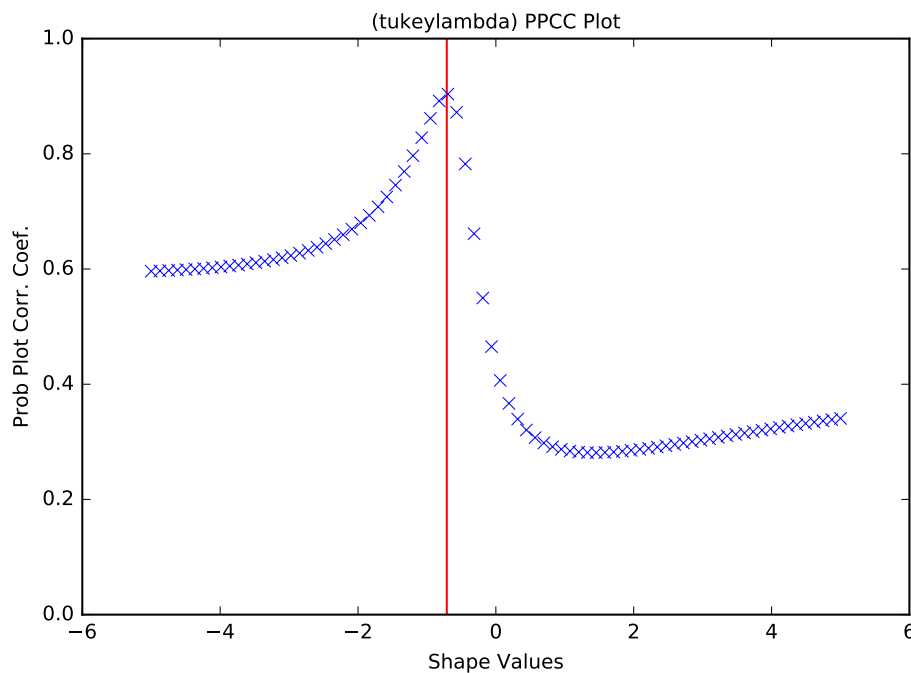

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(8, 6))
>>> ax = fig.add_subplot(111)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax)
```

We calculate the value where the shape should reach its maximum and a red line is drawn there. The line should coincide with the highest point in the ppcc\_plot.

```
>>> max = stats.ppcc_max(x)
>>> ax.vlines(max, 0, 1, colors='r', label='Expected shape value')

>>> plt.show()
```

```
scipy.stats.ppcc_plot(x, a, b, dist='tukeylambda', plot=None, N=80)
```

Calculate and optionally plot probability plot correlation coefficient.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. It cannot be used for distributions without shape parameters (like the normal distribution) or with multiple shape parameters.

By default a Tukey-Lambda distribution (`stats.tukeylambda`) is used. A Tukey-Lambda PPCC plot interpolates from long-tailed to short-tailed distributions via an approximately normal one, and is therefore particularly useful in practice.

**Parameters**

- x** : array\_like  
Input array.
- a, b** : scalar  
Lower and upper bounds of the shape parameter to use.
- dist** : str or stats.distributions instance, optional  
Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted. The default is `'tukeylambda'`.
- plot** : object, optional  
If given, plots PPCC against the shape parameter. `plot` is an object that has to have methods `"plot"` and `"text"`. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is `None`, which means that no plot is created.
- N** : int, optional  
Number of points on the horizontal axis (equally distributed from `a` to `b`).

**Returns**

- svals** : ndarray  
The shape values for which `ppcc` was calculated.
- ppcc** : ndarray  
The calculated probability plot correlation coefficient values.

**See also:**

`ppcc_max`, `probplot`, `boxcox_normplot`, `tukeylambda`

### References

J.J. Filliben, "The Probability Plot Correlation Coefficient Test for Normality", *Technometrics*, Vol. 17, pp. 111-117, 1975.

### Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234567)
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```
>>> fig = plt.figure(figsize=(12, 4))
>>> ax1 = fig.add_subplot(131)
>>> ax2 = fig.add_subplot(132)
>>> ax3 = fig.add_subplot(133)
>>> res = stats.probplot(x, plot=ax1)
>>> res = stats.boxcox_normplot(x, -5, 5, plot=ax2)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax3)
```

```
>>> ax3.vlines(-0.7, 0, 1, colors='r', label='Expected shape value')
>>> plt.show()
```

```
scipy.stats.probplot(x, sparams=(), dist='norm', fit=True, plot=None, rvalue=False)
Calculate quantiles for a probability plot, and optionally show the plot.
```

Generates a probability plot of sample data against the quantiles of a specified theoretical distribution (the normal distribution by default). `probplot` optionally calculates a best-fit line for the data and plots the results using Matplotlib or a given plot function.

**Parameters** `x` : array\_like

Sample/response data from which `probplot` creates the plot.

**sparams** : tuple, optional

Distribution-specific shape parameters (shape parameters plus location and scale).

**dist** : str or stats.distributions instance, optional

Distribution or distribution function name. The default is 'norm' for a normal probability plot. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted.

**fit** : bool, optional

Fit a least-squares regression (best-fit) line to the sample data if True (default).

**plot** : object, optional

If given, plots the quantiles and least squares fit. `plot` is an object that has to have methods "plot" and "text". The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

**Returns**

**(osm, osr)** : tuple of ndarrays

Tuple of theoretical quantiles (`osm`, or order statistic medians) and ordered responses (`osr`). `osr` is simply sorted input `x`. For details on how `osm` is calculated see the Notes section.

**(slope, intercept, r)** : tuple of floats, optional

Tuple containing the result of the least-squares fit, if that is performed by `probplot`. `r` is the square root of the coefficient of determination. If `fit=False` and `plot=None`, this tuple is not returned.

### Notes

Even if `plot` is given, the figure is not shown or saved by `probplot`; `plt.show()` or `plt.savefig('filename.png')` should be used after calling `probplot`.

`probplot` generates a probability plot, which should not be confused with a Q-Q or a P-P plot. Statsmodels has more extensive functionality of this type, see `statsmodels.api.ProbPlot`.

The formula used for the theoretical quantiles (horizontal axis of the probability plot) is Filliben's estimate:

```
quantiles = dist.ppf(val), for
    0.5**(1/n),                for i = n
    val = (i - 0.3175) / (n + 0.365), for i = 2, ..., n-1
    1 - 0.5**(1/n),          for i = 1
```

where  $i$  indicates the  $i$ -th ordered value and  $n$  is the total number of values.

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> nsample = 100
>>> np.random.seed(7654321)
```

A  $t$  distribution with small degrees of freedom:

```
>>> ax1 = plt.subplot(221)
>>> x = stats.t.rvs(3, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A  $t$  distribution with larger degrees of freedom:

```
>>> ax2 = plt.subplot(222)
>>> x = stats.t.rvs(25, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A mixture of two normal distributions with broadcasting:

```
>>> ax3 = plt.subplot(223)
>>> x = stats.norm.rvs(loc=[0,5], scale=[1,1.5],
...                   size=(nsample//2,2)).ravel()
>>> res = stats.probplot(x, plot=plt)
```

A standard normal distribution:

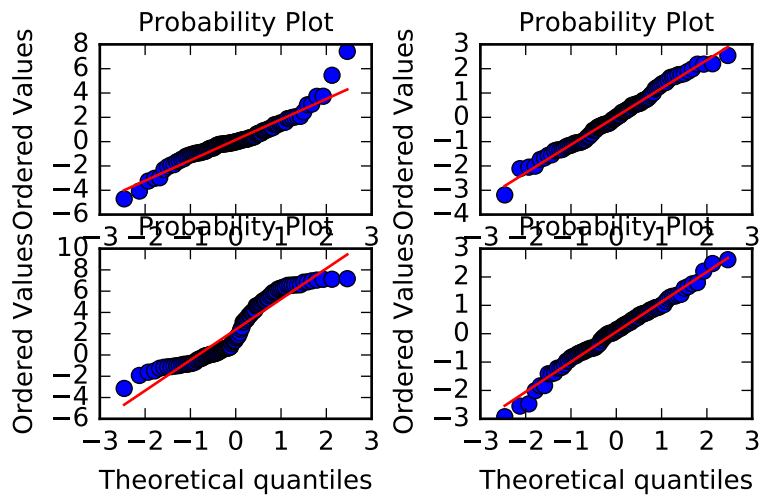

```
>>> ax4 = plt.subplot(224)
>>> x = stats.norm.rvs(loc=0, scale=1, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

Produce a new figure with a loggamma distribution, using the `dist` and `sparams` keywords:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = stats.loggamma.rvs(c=2.5, size=500)
>>> res = stats.probplot(x, dist=stats.loggamma, sparams=(2.5,), plot=ax)
>>> ax.set_title("Probplot for loggamma dist with shape parameter 2.5")
```

Show the results with Matplotlib:

```
>>> plt.show()
```

`scipy.stats.boxcox_normplot` (*x*, *la*, *lb*, *plot=None*, *N=80*)

Compute parameters for a Box-Cox normality plot, optionally show it.

A Box-Cox normality plot shows graphically what the best transformation parameter is to use in `boxcox` to obtain a distribution that is close to normal.

**Parameters** *x* : array\_like

Input array.

**la, lb** : scalar

The lower and upper bounds for the `lambda` values to pass to `boxcox` for Box-Cox transformations. These are also the limits of the horizontal axis of the plot if that is generated.

**plot** : object, optional

If given, plots the quantiles and least squares fit. *plot* is an object that has to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

**Returns**

- N** : int, optional  
Number of points on the horizontal axis (equally distributed from *la* to *lb*).
- lmbdas** : ndarray  
The *lambda* values for which a Box-Cox transform was done.
- ppcc** : ndarray  
Probability Plot Correlation Coefficient, as obtained from `probplot` when fitting the Box-Cox transformed input *x* against a normal distribution.

**See also:**

`probplot`, `boxcox`, `boxcox_normmax`, `boxcox_illf`, `ppcc_max`

**Notes**

Even if *plot* is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('figname.png')` should be used after calling `probplot`.

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some non-normally distributed data, and create a Box-Cox plot:

```
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal *lambda* to transform *x* and plot it in the same plot:

```
>>> _, maxlog = stats.boxcox(x)
>>> ax.axvline(maxlog, color='r')

>>> plt.show()
```

## 5.27.8 Masked statistics functions

### Statistical functions for masked arrays (`scipy.stats.mstats`)

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in `scipy.stats` but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

|                                                                |                                                                                  |
|----------------------------------------------------------------|----------------------------------------------------------------------------------|
| <code>argstoarray(*args)</code>                                | Constructs a 2D array from a group of sequences.                                 |
| <code>betai(*args, **kwargs)</code>                            | <code>betai</code> is deprecated!                                                |
| <code>chisquare(f_obs[, f_exp, ddof, axis])</code>             | Calculates a one-way chi square test.                                            |
| <code>count_tied_groups(x[, use_missing])</code>               | Counts the number of tied values.                                                |
| <code>describe(a[, axis, ddof, bias])</code>                   | Computes several descriptive statistics of the passed array.                     |
| <code>f_oneway(*args)</code>                                   | Performs a 1-way ANOVA, returning an F-value and probability given any nu        |
| <code>f_value_wilks_lambda(*args, **kwargs)</code>             | <code>f_value_wilks_lambda</code> is deprecated!                                 |
| <code>find_repeats(arr)</code>                                 | Find repeats in arr and return a tuple (repeats, repeat_count).                  |
| <code>friedmanchisquare(*args)</code>                          | Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA.          |
| <code>kendalltau(x, y[, use_ties, use_missing])</code>         | Computes Kendall's rank correlation tau on two variables <i>x</i> and <i>y</i> . |
| <code>kendalltau_seasonal(x)</code>                            | Computes a multivariate Kendall's rank correlation tau, for seasonal data.       |
| <code>kruskalwallis(*args)</code>                              | Compute the Kruskal-Wallis H-test for independent samples                        |
| <code>ks_twosamp(data1, data2[, alternative])</code>           | Computes the Kolmogorov-Smirnov test on two samples.                             |
| <code>kurtosis(a[, axis, fisher, bias])</code>                 | Computes the kurtosis (Fisher or Pearson) of a dataset.                          |
| <code>kurtosistest(a[, axis])</code>                           | Tests whether a dataset has normal kurtosis                                      |
| <code>linregress(x[, y])</code>                                | Calculate a linear least-squares regression for two sets of measurements.        |
| <code>mannwhitneyu(x, y[, use_continuity])</code>              | Computes the Mann-Whitney statistic                                              |
| <code>plotting_positions(data[, alpha, beta])</code>           | Returns plotting positions (or empirical percentile points) for the data.        |
| <code>mode(a[, axis])</code>                                   | Returns an array of the modal (most common) value in the passed array.           |
| <code>moment(a[, moment, axis])</code>                         | Calculates the nth moment about the mean for a sample.                           |
| <code>mquantiles(a[, prob, alphap, betap, axis, limit])</code> | Computes empirical quantiles for a data array.                                   |
| <code>msign(x)</code>                                          | Returns the sign of <i>x</i> , or 0 if <i>x</i> is masked.                       |
| <code>normaltest(a[, axis])</code>                             | Tests whether a sample differs from a normal distribution.                       |
| <code>obrientransform(*args)</code>                            | Computes a transform on input data (any number of columns).                      |
| <code>pearsonr(x, y)</code>                                    | Calculates a Pearson correlation coefficient and the p-value for testing non-co  |
| <code>plotting_positions(data[, alpha, beta])</code>           | Returns plotting positions (or empirical percentile points) for the data.        |
| <code>pointbiserialr(x, y)</code>                              | Calculates a point biserial correlation coefficient and its p-value.             |
| <code>rankdata(data[, axis, use_missing])</code>               | Returns the rank (also known as order statistics) of each data point along the g |
| <code>scoreatpercentile(data, per[, limit, ...])</code>        | Calculate the score at the given 'per' percentile of the sequence a.             |
| <code>sem(a[, axis, ddof])</code>                              | Calculates the standard error of the mean of the input array.                    |
| <code>signaltonoise(*args, **kwargs)</code>                    | <code>signaltonoise</code> is deprecated!                                        |
| <code>skew(a[, axis, bias])</code>                             | Computes the skewness of a data set.                                             |
| <code>skewtest(a[, axis])</code>                               | Tests whether the skew is different from the normal distribution.                |
| <code>spearmanr(x, y[, use_ties])</code>                       | Calculates a Spearman rank-order correlation coefficient and the p-value to te   |
| <code>theilslopes(y[, x, alpha])</code>                        | Computes the Theil-Sen estimator for a set of points ( <i>x</i> , <i>y</i> ).    |
| <code>threshold(*args, **kwargs)</code>                        | <code>threshold</code> is deprecated!                                            |
| <code>tmax(a[, upperlimit, axis, inclusive])</code>            | Compute the trimmed maximum                                                      |
| <code>tmean(a[, limits, inclusive, axis])</code>               | Compute the trimmed mean.                                                        |
| <code>tmin(a[, lowerlimit, axis, inclusive])</code>            | Compute the trimmed minimum                                                      |
| <code>trim(a[, limits, inclusive, relative, axis])</code>      | Trims an array by masking the data outside some given limits.                    |
| <code>trima(a[, limits, inclusive])</code>                     | Trims an array by masking the data outside some given limits.                    |
| <code>trimboth(data[, proportiontocut, inclusive, ...])</code> | Trims the smallest and largest data values.                                      |
| <code>trimmed_stde(a[, limits, inclusive, axis])</code>        | Returns the standard error of the trimmed mean along the given axis.             |
| <code>trimmr(a[, limits, inclusive, axis])</code>              | Trims an array by masking some proportion of the data on each end.               |

Table 5.297 – continued from previous page

|                                                               |                                                                                                |
|---------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| <code>trimtail(data[, proportiontocut, tail, ...])</code>     | Trims the data by masking values from one tail.                                                |
| <code>tsem(a[, limits, inclusive, axis, ddof])</code>         | Compute the trimmed standard error of the mean.                                                |
| <code>ttest_onesamp(a, popmean[, axis])</code>                | Calculates the T-test for the mean of ONE group of scores.                                     |
| <code>ttest_ind(a, b[, axis, equal_var])</code>               | Calculates the T-test for the means of TWO INDEPENDENT samples of scores.                      |
| <code>ttest_onesamp(a, popmean[, axis])</code>                | Calculates the T-test for the mean of ONE group of scores.                                     |
| <code>ttest_rel(a, b[, axis])</code>                          | Calculates the T-test on TWO RELATED samples of scores, a and b.                               |
| <code>tvar(a[, limits, inclusive, axis, ddof])</code>         | Compute the trimmed variance                                                                   |
| <code>variation(a[, axis])</code>                             | Computes the coefficient of variation, the ratio of the biased standard deviation to the mean. |
| <code>winsorize(a[, limits, inclusive, inplace, axis])</code> | Returns a Winsorized version of the input array.                                               |
| <code>zmap(scores, compare[, axis, ddof])</code>              | Calculates the relative z-scores.                                                              |
| <code>zscore(a[, axis, ddof])</code>                          | Calculates the z score of each value in the sample, relative to the sample mean.               |
| <code>compare_medians_ms(group_1, group_2[, axis])</code>     | Compares the medians from two independent groups along the given axis.                         |
| <code>gmean(a[, axis, dtype])</code>                          | Compute the geometric mean along the specified axis.                                           |
| <code>hdmedian(data[, axis, var])</code>                      | Returns the Harrell-Davis estimate of the median along the given axis.                         |
| <code>hdquantiles(data[, prob, axis, var])</code>             | Computes quantile estimates with the Harrell-Davis method.                                     |
| <code>hdquantiles_sd(data[, prob, axis])</code>               | The standard error of the Harrell-Davis quantile estimates by jackknife.                       |
| <code>hmean(a[, axis, dtype])</code>                          | Calculates the harmonic mean along the specified axis.                                         |
| <code>idealfourths(data[, axis])</code>                       | Returns an estimate of the lower and upper quartiles.                                          |
| <code>kruskal(*args)</code>                                   | Compute the Kruskal-Wallis H-test for independent samples                                      |
| <code>ks_2samp(data1, data2[, alternative])</code>            | Computes the Kolmogorov-Smirnov test on two samples.                                           |
| <code>median_cihs(data[, alpha, axis])</code>                 | Computes the alpha-level confidence interval for the median of the data.                       |
| <code>meppf(data[, alpha, beta])</code>                       | Returns plotting positions (or empirical percentile points) for the data.                      |
| <code>mjci(data[, prob, axis])</code>                         | Returns the Maritz-Jarrett estimators of the standard error of selected experim                |
| <code>mquantiles_cimj(data[, prob, alpha, axis])</code>       | Computes the alpha confidence interval for the selected quantiles of the data,                 |
| <code>rsh(data[, points])</code>                              | Evaluates Rosenblatt’s shifted histogram estimators for each point on the data                 |
| <code>sen_seasonal_slopes(x)</code>                           |                                                                                                |
| <code>trimmed_mean(a[, limits, inclusive, ...])</code>        |                                                                                                |
| <code>trimmed_mean_ci(data[, limits, inclusive, ...])</code>  | Selected confidence interval of the trimmed mean along the given axis.                         |
| <code>trimmed_std(a[, limits, inclusive, ...])</code>         |                                                                                                |
| <code>trimmed_var(a[, limits, inclusive, ...])</code>         |                                                                                                |
| <code>ttest_1samp(a, popmean[, axis])</code>                  | Calculates the T-test for the mean of ONE group of scores.                                     |

`scipy.stats.mstats.argstoarray(*args)`  
 Constructs a 2D array from a group of sequences.

Sequences are filled with missing values to match the length of the longest sequence.

**Parameters** `args` : sequences

**Returns** `argstoarray` : `MaskedArray` Group of sequences.

A ( $m \times n$ ) masked array, where  $m$  is the number of arguments and  $n$  the length of the longest argument.

**Notes**

`numpy.ma.row_stack` has identical behavior, but is called with a sequence of sequences.

`scipy.stats.mstats.betainc(*args, **kwds)`

`betainc` is deprecated! `mstats.betainc` is deprecated in scipy 0.17.0; use `special.betainc` instead.

`betainc()` is deprecated in scipy 0.17.0.

For details about this function, see `stats.betainc`.

`scipy.stats.mstats.chisquare(f_obs, f_exp=None, ddof=0, axis=0)`

Calculates a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

**Parameters**

- f\_obs** : array\_like  
Observed frequencies in each category.
- f\_exp** : array\_like, optional  
Expected frequencies in each category. By default the categories are assumed to be equally likely.
- ddof** : int, optional  
“Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of *ddof* is 0.
- axis** : int or None, optional  
The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If axis is None, all values in *f\_obs* are treated as a single data set. Default is 0.

**Returns**

- chisq** : float or ndarray  
The chi-squared test statistic. The value is a float if *axis* is None or *f\_obs* and *f\_exp* are 1-D.
- p** : float or ndarray  
The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

**See also:**

power\_divergence, mstats.chisquare

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom,  $k-1$ , are for the case when no parameters of the distribution are estimated. If  $p$  parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are  $k-1-p$ . If the parameters are estimated in a different way, then the dof can be between  $k-1-p$  and  $k-1$ . However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

**References**

[R610], [R611]

**Examples**

When just *f\_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With *f\_exp* the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
```

```
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with `ddof`.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

`f_obs` and `f_exp` are also broadcast. In the following, `f_obs` has shape (6,) and `f_exp` has shape (2, 6), so the result of broadcasting `f_obs` and `f_exp` has shape (2, 6). To compute the desired chi-squared statistics, we use `axis=1`:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...           f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...           axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

`scipy.stats.mstats.count_tied_groups(x, use_missing=False)`

Counts the number of tied values.

|                   |                                                                                     |
|-------------------|-------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>x</b> : sequence<br>Sequence of data on which to counts the ties                 |
|                   | <b>use_missing</b> : bool, optional<br>Whether to consider missing values as tied.  |
| <b>Returns</b>    | <b>count_tied_groups</b> : dict<br>Returns a dictionary (nb of ties: nb of groups). |

### Examples

```
>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}
```

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

```
>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 2, 3: 1}
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}
```

`scipy.stats.mstats.describe` (*a*, *axis=0*, *ddof=0*, *bias=True*)

Computes several descriptive statistics of the passed array.

**Parameters**

- a** : array\_like  
Data array
- axis** : int or None, optional  
Axis along which to calculate statistics. Default 0. If None, compute over the whole array *a*.
- ddof** : int, optional  
degree of freedom (default 0); note that default ddof is different from the same routine in `stats.describe`
- bias** : bool, optional  
If False, then the skewness and kurtosis calculations are corrected for statistical bias.

**Returns**

- nobs** : int  
(size of the data (discarding missing values))
- minmax** : (int, int)  
min, max
- mean** : float  
arithmetic mean
- variance** : float  
unbiased variance
- skewness** : float  
biased skewness
- kurtosis** : float  
biased kurtosis

### Examples

```
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult(nobs=array(3), minmax=(masked_array(data = 0,
            mask = False,
            fill_value = 999999)
, masked_array(data = 2,
            mask = False,
            fill_value = 999999)
), mean=1.0, variance=0.66666666666666663, skewness=masked_array(data = 0.0,
            mask = False,
            fill_value = 1e+20)
, kurtosis=-1.5)
```

`scipy.stats.mstats.f_oneway` (\*args)

Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

Usage: `f_oneway(*args)`, where *\*args* is 2 or more arrays, one per treatment group.

**Returns**

- statistic** : float  
The computed F-value of the test.
- pvalue** : float  
The associated p-value from the F-distribution.

`scipy.stats.mstats.f_value_wilks_lambda` (\*args, \*\*kws)

`f_value_wilks_lambda` is deprecated! `mstats.f_value_wilks_lambda` deprecated in scipy 0.17.0

*Calculation of Wilks lambda F-statistic for multivariate data, per Maxwell & Delaney p.657.*

`scipy.stats.mstats.find_repeats(arr)`

Find repeats in arr and return a tuple (repeats, repeat\_count).

The input is cast to float64. Masked values are discarded.

**Parameters** **arr** : sequence  
 Input array. The array is flattened if it is not 1D.

**Returns** **repeats** : ndarray  
 Array of repeated values.

**counts** : ndarray  
 Array of counts.

`scipy.stats.mstats.friedmanchisquare(*args)`

Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first n treatments are taken into account, where n is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.

**Returns** **statistic** : float  
 the test statistic.

**pvalue** : float  
 the associated p-value.

`scipy.stats.mstats.kendalltau(x, y, use_ties=True, use_missing=False)`

Computes Kendall's rank correlation tau on two variables x and y.

**Parameters** **x** : sequence  
 First data list (for example, time).

**y** : sequence  
 Second data list.

**use\_ties** : {True, False}, optional  
 Whether ties correction should be performed.

**use\_missing** : {False, True}, optional  
 Whether missing data should be allocated a rank of 0 (False) or the average rank (True)

**Returns** **correlation** : float  
 Kendall tau

**pvalue** : float  
 Approximate 2-side p-value.

`scipy.stats.mstats.kendalltau_seasonal(x)`

Computes a multivariate Kendall's rank correlation tau, for seasonal data.

**Parameters** **x** : 2-D ndarray  
 Array of seasonal data, with seasons in columns.

`scipy.stats.mstats.kruskalwallis(*args)`

Compute the Kruskal-Wallis H-test for independent samples

**Parameters** **sample1, sample2, ...** : array\_like  
 Two or more arrays with the sample measurements can be given as arguments.

**Returns** **statistic** : float  
 The Kruskal-Wallis H statistic, corrected for ties

**pvalue** : float

The p-value for the test using the assumption that H has a chi square distribution

### Notes

For more details on `kruskal`, see `stats.kruskal`.

`scipy.stats.mstats.ks_twosamp` (*data1*, *data2*, *alternative='two-sided'*)

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

|                   |                                                                   |                                                               |
|-------------------|-------------------------------------------------------------------|---------------------------------------------------------------|
| <b>Parameters</b> | <b>data1</b> : array_like                                         | First data set                                                |
|                   | <b>data2</b> : array_like                                         | Second data set                                               |
|                   | <b>alternative</b> : { 'two-sided', 'less', 'greater' }, optional | Indicates the alternative hypothesis. Default is 'two-sided'. |
| <b>Returns</b>    | <b>d</b> : float                                                  | Value of the Kolmogorov Smirnov test                          |
|                   | <b>p</b> : float                                                  | Corresponding p-value.                                        |

`scipy.stats.mstats.kurtosis` (*a*, *axis=0*, *fisher=True*, *bias=True*)

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If *bias* is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

|                   |                                     |                                                                                                                                  |
|-------------------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>a</b> : array                    | data for which the kurtosis is calculated                                                                                        |
|                   | <b>axis</b> : int or None, optional | Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array <i>a</i> .                      |
|                   | <b>fisher</b> : bool, optional      | If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).                  |
|                   | <b>bias</b> : bool, optional        | If False, then the calculations are corrected for statistical bias.                                                              |
| <b>Returns</b>    | <b>kurtosis</b> : array             | The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition. |

### Notes

For more details about `kurtosis`, see `stats.kurtosis`.

`scipy.stats.mstats.kurtosistest` (*a*, *axis=0*)

Tests whether a dataset has normal kurtosis

|                   |                                     |                                                                                                  |
|-------------------|-------------------------------------|--------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>a</b> : array                    | array of the sample data                                                                         |
|                   | <b>axis</b> : int or None, optional | Axis along which to compute test. Default is 0. If None, compute over the whole array <i>a</i> . |
| <b>Returns</b>    | <b>statistic</b> : float            | The computed z-score for this test.                                                              |

**pvalue** : float  
The 2-sided p-value for the hypothesis test

#### Notes

For more details about `kurtosistest`, see `stats.kurtosistest`.

`scipy.stats.mstats.linregress` (*x*, *y=None*)

Calculate a linear least-squares regression for two sets of measurements.

**Parameters**    **x, y** : array\_like  
Two sets of measurements. Both arrays should have the same length. If only *x* is given (and *y=None*), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension.

**Returns**        **slope** : float  
slope of the regression line

**intercept** : float  
intercept of the regression line

**rvalue** : float  
correlation coefficient

**pvalue** : float  
two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero.

**stderr** : float  
Standard error of the estimated gradient.

#### See also:

[`scipy.optimize.curve\_fit`](#)

Use non-linear least squares to fit a function to data.

[`scipy.optimize.leastsq`](#)

Minimize the sum of squares of a set of equations.

#### Notes

Missing values are considered pair-wise: if a value is missing in *x*, the corresponding value in *y* is masked.

#### Examples

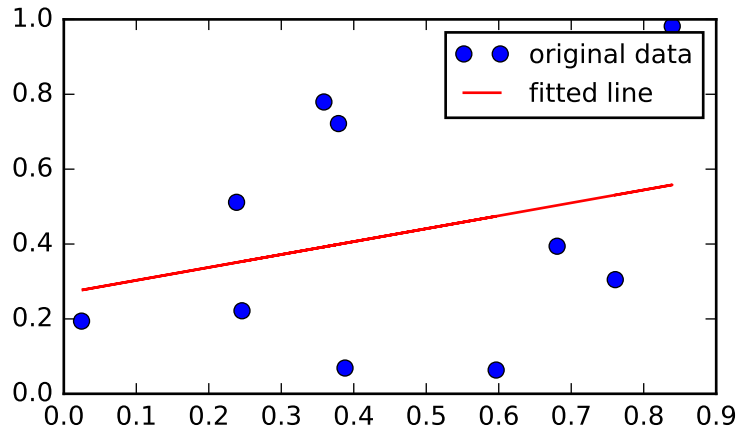

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = np.random.random(10)
>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)
```

To get coefficient of determination (`r_squared`)

```
>>> print("r-squared:", r_value**2)
('r-squared:', 0.080402268539028335)
```

Plot the data along with the fitted line

```
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

`scipy.stats.mstats.mannwhitneyu(x, y, use_continuity=True)`

Computes the Mann-Whitney statistic

Missing values in  $x$  and/or  $y$  are discarded.

**Parameters**  $x$  : sequence

Input

$y$  : sequence

Input

**use\_continuity** : {True, False}, optional

Whether a continuity correction (1/2.) should be taken into account.

**Returns**

**statistic** : float

The Mann-Whitney statistics

**pvalue** : float

Approximate p-value assuming a normal distribution.

`scipy.stats.mstats.plotting_positions(data, alpha=0.4, beta=0.4)`

Returns plotting positions (or empirical percentile points) for the data.

Plotting positions are defined as  $(i-\alpha)/(n+1-\alpha-\beta)$ , where:

- $i$  is the rank order statistics
- $n$  is the number of unmasked values along the given axis
- $\alpha$  and  $\beta$  are two parameters.

Typical values for  $\alpha$  and  $\beta$  are:

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5) :  $p(k) = (k-1/2)/n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k/(n+1)$ , Weibull (R type 6)
- (1,1) :  $p(k) = (k-1)/(n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3)/(n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8)/(n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM

•(.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

- data** : array\_like  
Input data, as a sequence or array of dimension at most 2.
- alpha** : float, optional  
Plotting positions parameter. Default is 0.4.
- beta** : float, optional  
Plotting positions parameter. Default is 0.4.

**Returns**

- positions** : MaskedArray  
The calculated plotting positions.

`scipy.stats.mstats.mode(a, axis=0)`

Returns an array of the modal (most common) value in the passed array.

**Parameters**

- a** : array\_like  
n-dimensional array of which to find mode(s).
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**Returns**

- mode** : ndarray  
Array of modal values.
- count** : ndarray  
Array of counts for each mode.

**Notes**

For more details, see `stats.mode`.

`scipy.stats.mstats.moment(a, moment=1, axis=0)`

Calculates the *n*th moment about the mean for a sample.

**Parameters**

- a** : array\_like  
data
- moment** : int, optional  
order of central moment that is returned
- axis** : int or None, optional  
Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.

**Returns**

- n-th central moment** : ndarray or float  
The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**Notes**

For more details about `moment`, see `stats.moment`.

`scipy.stats.mstats.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())`

Computes empirical quantiles for a data array.

Samples quantile are defined by  $Q(p) = (1-\gamma)*x[j] + \gamma*x[j+1]$ , where  $x[j]$  is the *j*-th order statistic, and  $\gamma$  is a function of  $j = \text{floor}(n*p + m)$ ,  $m = \text{alphap} + p*(1 - \text{alphap} - \text{betap})$  and  $g = n*p + m - j$ .

Reinterpreting the above equations to compare to **R** lead to the equation:  $p(k) = (k - \text{alphap}) / (n + 1 - \text{alphap} - \text{betap})$

**Typical values of (alphap,betap) are:**

•(0,1) :  $p(k) = k/n$  : linear interpolation of cdf (**R** type 4)

- (.5,.5) :  $p(k) = (k - 1/2.) / n$  : piecewise linear function (**R** type 5)
- (0,0) :  $p(k) = k / (n+1)$  : (**R** type 6)
- (1,1) :  $p(k) = (k-1) / (n-1)$  :  $p(k) = \text{mode}[F(x[k])]$ . (**R** type 7, **R** default)
- (1/3,1/3) :  $p(k) = (k-1/3) / (n+1/3)$  : Then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (**R** type 8)
- (3/8,3/8) :  $p(k) = (k-3/8) / (n+1/4)$  : Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (**R** type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35) : APL, used with PWM

**Parameters**

**a** : array\_like  
Input data, as a sequence or array of dimension at most 2.

**prob** : array\_like, optional  
List of quantiles to compute.

**alphap** : float, optional  
Plotting positions parameter, default is 0.4.

**betap** : float, optional  
Plotting positions parameter, default is 0.4.

**axis** : int, optional  
Axis along which to perform the trimming. If None (default), the input array is first flattened.

**limit** : tuple, optional  
Tuple of (lower, upper) values. Values of  $a$  outside this open interval are ignored.

**Returns**

**mquantiles** : MaskedArray  
An array containing the calculated quantiles.

### Notes

This formulation is very similar to **R** except the calculation of  $m$  from **alphap** and **betap**, where in **R**  $m$  is defined with each type.

### Examples

```
>>> from scipy.stats.mstats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([ 19.2,  40. ,  42.8])
```

Using a 2D array, specifying axis and limit.

```
>>> data = np.array([[ 6.,  7.,  1.],
...                  [ 47., 15.,  2.],
...                  [ 49., 36.,  3.],
...                  [ 15., 39.,  4.],
...                  [ 42., 40., -999.],
...                  [ 41., 41., -999.],
...                  [  7., -999., -999.],
...                  [ 39., -999., -999.],
...                  [ 43., -999., -999.],
...                  [ 40., -999., -999.],
...                  [ 36., -999., -999.]])
```

```
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[ 19.2  14.6   1.45]
 [ 40.   37.5   2.5 ]
 [ 42.8  40.05  3.55]]

>>> data[:, 2] = -999.
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]
```

`scipy.stats.mstats.msign(x)`

Returns the sign of x, or 0 if x is masked.

`scipy.stats.mstats.normaltest(a, axis=0)`

Tests whether a sample differs from a normal distribution.

**Parameters** `a` : array\_like

The array containing the data to be tested.

**axis** : int or None, optional

Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

**Returns**

**statistic** : float or array  
 $s^2 + k^2$ , where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.

**pvalue** : float or array

A 2-sided chi squared probability for the hypothesis test.

**Notes**

For more details about `normaltest`, see `stats.normaltest`.

`scipy.stats.mstats.obrientransform(*args)`

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in *\*args* is one level of a factor. If an `f_oneway()` run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA

`scipy.stats.mstats.pearsonr(x, y)`

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson's correlation requires that each dataset be normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters** `x` : 1-D array\_like

Input

`y` : 1-D array\_like

Input

**Returns**

**pearsonr** : float  
 Pearson's correlation coefficient, 2-tailed p-value.

## References

<http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation>

`scipy.stats.mstats.plotting_positions` (*data*, *alpha*=0.4, *beta*=0.4)

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as  $(i-\alpha)/(n+1-\alpha-\beta)$ , where:*

- *i* is the rank order statistics
- *n* is the number of unmasked values along the given axis
- *alpha* and *beta* are two parameters.

*Typical values for alpha and beta are:*

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5) :  $p(k) = (k-1/2)/n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k/(n+1)$ , Weibull (R type 6)
- (1,1) :  $p(k) = (k-1)/(n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3)/(n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of *x*. (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8)/(n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if *x* is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

**data** : array\_like  
Input data, as a sequence or array of dimension at most 2.

**alpha** : float, optional  
Plotting positions parameter. Default is 0.4.

**beta** : float, optional  
Plotting positions parameter. Default is 0.4.

**Returns**

**positions** : MaskedArray  
The calculated plotting positions.

`scipy.stats.mstats.pointbiserialr` (*x*, *y*)

Calculates a point biserial correlation coefficient and its p-value.

**Parameters**

**x** : array\_like of bools  
Input array.

**y** : array\_like  
Input array.

**Returns**

**correlation** : float  
R value

**pvalue** : float  
2-tailed p-value

## Notes

Missing values are considered pair-wise: if a value is missing in *x*, the corresponding value in *y* is masked.

For more details on `pointbiserialr`, see `stats.pointbiserialr`.

`scipy.stats.mstats.rankdata` (*data*, *axis*=None, *use\_missing*=False)

Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if `use_missing` is False, or set to the average rank of the unmasked values if `use_missing` is True.

**Parameters**

- data** : sequence  
Input data. The data is transformed to a masked array
- axis** : {None,int}, optional  
Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2
- use\_missing** : bool, optional  
Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

`scipy.stats.mstats.scoreatpercentile` (*data, per, limit=(), alphap=0.4, betap=0.4*)

Calculate the score at the given 'per' percentile of the sequence a. For example, the score at per=50 is the median.

This function is a shortcut to `mquantile`

`scipy.stats.mstats.sem` (*a, axis=0, ddof=1*)

Calculates the standard error of the mean of the input array.

Also sometimes called standard error of measurement.

**Parameters**

- a** : array\_like  
An array containing the values for which the standard error is returned.
- axis** : int or None, optional  
If axis is None, ravel *a* first. If axis is an integer, this will be the axis over which to operate. Defaults to 0.
- ddof** : int, optional  
Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

**Returns**

- s** : ndarray or float  
The standard error of the mean in the sample(s), along the input axis.

### Notes

The default value for `ddof` changed in `scipy` 0.15.0 to be consistent with `stats.sem` as well as with the most common definition used (like in the R documentation).

### Examples

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5, 4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903 2.8284271247461903 2.8284271247461903
 2.8284271247461903]
```

Find standard error across the whole array, using n degrees of freedom:

```
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

`scipy.stats.mstats.signaltonoise` (*\*args, \*\*kws*)

`signaltonoise` is deprecated! `mstats.signaltonoise` is deprecated in `scipy` 0.16.0

*Calculates the signal-to-noise ratio, as the ratio of the mean over standard deviation along the given axis.*

**Parameters**

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>data</b> : sequence | Input data                                                                                                              |
| <b>axis</b>            | [[0, int], optional] Axis along which to compute. If None, the computation is performed on a flat version of the array. |

`scipy.stats.mstats.skew(a, axis=0, bias=True)`

Computes the skewness of a data set.

**Parameters**

|                                     |                                                                                                         |
|-------------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>a</b> : ndarray                  | data                                                                                                    |
| <b>axis</b> : int or None, optional | Axis along which skewness is calculated. Default is 0. If None, compute over the whole array <i>a</i> . |
| <b>bias</b> : bool, optional        | If False, then the calculations are corrected for statistical bias.                                     |

**Returns**

|                           |                                                                               |
|---------------------------|-------------------------------------------------------------------------------|
| <b>skewness</b> : ndarray | The skewness of values along an axis, returning 0 where all values are equal. |
|---------------------------|-------------------------------------------------------------------------------|

#### Notes

For more details about `skew`, see `stats.skew`.

`scipy.stats.mstats.skewtest(a, axis=0)`

Tests whether the skew is different from the normal distribution.

**Parameters**

|                                     |                                                                                                            |
|-------------------------------------|------------------------------------------------------------------------------------------------------------|
| <b>a</b> : array                    | The data to be tested                                                                                      |
| <b>axis</b> : int or None, optional | Axis along which statistics are calculated. Default is 0. If None, compute over the whole array <i>a</i> . |

**Returns**

|                          |                                           |
|--------------------------|-------------------------------------------|
| <b>statistic</b> : float | The computed z-score for this test.       |
| <b>pvalue</b> : float    | a 2-sided p-value for the hypothesis test |

#### Notes

For more details about `skewtest`, see `stats.skewtest`.

`scipy.stats.mstats.spearmanr(x, y, use_ties=True)`

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

Missing values are discarded pair-wise: if a value is missing in *x*, the corresponding value in *y* is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

|                       |                                     |
|-----------------------|-------------------------------------|
| <b>x</b> : array_like | The length of <i>x</i> must be > 2. |
| <b>y</b> : array_like |                                     |

The length of *y* must be > 2.

**Returns**

- use\_ties** : bool, optional  
Whether the correction for ties should be computed.
- correlation** : float  
Spearman correlation coefficient
- pvalue** : float  
2-tailed p-value.

**References**

[CRCProbStat2000] section 14.7

`scipy.stats.mstats.theilslopes` (*y*, *x=None*, *alpha=0.95*)

Computes the Theil-Sen estimator for a set of points (*x*, *y*).

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

**Parameters**

- y** : array\_like  
Dependent variable.
- x** : array\_like or None, optional  
Independent variable. If None, use `arange(len(y))` instead.
- alpha** : float, optional  
Confidence degree between 0 and 1. Default is 95% confidence. Note that *alpha* is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

**Returns**

- medslope** : float  
Theil slope.
- medintercept** : float  
Intercept of the Theil line, as `median(y) - medslope*median(x)`.
- lo\_slope** : float  
Lower bound of the confidence interval on *medslope*.
- up\_slope** : float  
Upper bound of the confidence interval on *medslope*.

**Notes**

For more details on `theilslopes`, see `stats.theilslopes`.

`scipy.stats.mstats.threshold` (*\*args*, *\*\*kws*)

`threshold` is deprecated! `mstats.threshold` is deprecated in scipy 0.17.0

Clip array to a given value.

Similar to `numpy.clip()`, except that values less than *threshmin* or greater than *threshmax* are replaced by *newval*, instead of by *threshmin* and *threshmax* respectively.

**Parameters**

- a** : ndarray  
Input data
- threshmin** : [{None, float}, optional]  
Lower threshold. If None, set to the minimum value.
- threshmax** : [{None, float}, optional]  
Upper threshold. If None, set to the maximum value.
- newval** : [{0, float}, optional]  
Value outside the thresholds.

**Returns**

- threshold** : ndarray  
Returns *a*, with values less than *threshmin* and values greater *threshmax* replaced with *newval*.

`scipy.stats.mstats.tmax(a, upperlimit=None, axis=0, inclusive=True)`

Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- a** : array\_like  
array of values
- upperlimit** : None or float, optional  
Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional  
This flag determines whether values exactly equal to the upper limit are included. The default value is True.

**Returns**

- tmax** : float, int or ndarray

#### Notes

For more details on `tmax`, see `stats.tmax`.

`scipy.stats.mstats.tmean(a, limits=None, inclusive=(True, True), axis=None)`

Compute the trimmed mean.

**Parameters**

- a** : array\_like  
Array of values.
- limits** : None or (lower limit, upper limit), optional  
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- inclusive** : (bool, bool), optional  
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** : int or None, optional  
Axis along which to operate. If None, compute over the whole array. Default is None.

**Returns**

- tmean** : float

#### Notes

For more details on `tmean`, see `stats.tmean`.

`scipy.stats.mstats.tmin(a, lowerlimit=None, axis=0, inclusive=True)`

Compute the trimmed minimum

**Parameters**

- a** : array\_like  
array of values
- lowerlimit** : None or float, optional  
Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional

**Returns** `tmin` : float, int or ndarray

This flag determines whether values exactly equal to the lower limit are included. The default value is True.

**Notes**

For more details on `tmin`, see `stats.tmin`.

`scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), relative=False, axis=None)`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters** `a` : sequence

Input array

**limits** : {None, tuple}, optional

If *relative* is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If *relative* is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting *n* the number of unmasked data before trimming, the (*n*\*limits[0])th smallest data and the (*n*\*limits[1])th largest data are masked, and the total number of unmasked data after trimming is *n*\*(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed

**inclusive** : {(bool, bool) tuple}, optional

If *relative* is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If *relative* is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

**relative** : bool, optional

Whether to consider the limits as absolute values (False) or proportions to cut (True).

**axis** : int, optional

Axis along which to trim.

**Examples**

```
>>> from scipy.stats.mstats import trim
>>> z = [ 1, 2, 3, 4, 5, 6, 7, 8, 9,10]
>>> print(trim(z, (3,8)))
[-- -- 3 4 5 6 7 8 -- --]
>>> print(trim(z, (0.1,0.2), relative=True))
[-- 2 3 4 5 6 7 8 -- --]
```

`scipy.stats.mstats.trimma(a, limits=None, inclusive=(True, True))`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters** `a` : array\_like

Input array.

**limits** : {None, tuple}, optional

Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.

**inclusive** : (bool, bool) tuple, optional

Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.

`scipy.stats.mstats.trimboth` (*data*, *proportiontocut*=0.2, *inclusive*=(*True*, *True*), *axis*=*None*)

Trims the smallest and largest data values.

Trims the *data* by masking the `int` (`proportiontocut * n`) smallest and `int` (`proportiontocut * n`) largest values of data along the given axis, where *n* is the number of unmasked values before trimming.

**Parameters** **data** : ndarray

Data to trim.

**proportiontocut** : float, optional

Percentage of trimming (as a float between 0 and 1). If *n* is the number of unmasked values before trimming, the number of values after trimming is  $(1 - 2 * \text{proportiontocut}) * n$ . Default is 0.2.

**inclusive** : {(bool, bool) tuple}, optional

Tuple indicating whether the number of data being masked on each side should be rounded (*True*) or truncated (*False*).

**axis** : int, optional

Axis along which to perform the trimming. If *None*, the input array is first flattened.

`scipy.stats.mstats.trimmed_std` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *axis*=*None*)

Returns the standard error of the trimmed mean along the given axis.

**Parameters** **a** : sequence

Input array

**limits** : {(0.1,0.1), tuple of float}, optional

tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.

If *n* is the number of unmasked data before trimming, the values smaller than  $n * \text{limits}[0]$  and the values larger than  $n * \text{limits}[1]$  are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . In each case, the value of one limit can be set to *None* to indicate an open interval. If *limits* is *None*, no trimming is performed.

**inclusive** : {(bool, bool) tuple} optional

Tuple indicating whether the number of data being masked on each side should be rounded (*True*) or truncated (*False*).

**axis** : int, optional

Axis along which to trim.

**Returns** **trimmed\_std** : scalar or ndarray

`scipy.stats.mstats.trimr` (*a*, *limits*=*None*, *inclusive*=(*True*, *True*), *axis*=*None*)

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

**Parameters** **a** : sequence

Input array.

**limits** : {None, tuple}, optional

Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting *n* the number of unmasked data before trimming, the  $(n * \text{limits}[0])$ th smallest data and the  $(n * \text{limits}[1])$ th largest data are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . The value of one limit can be set to *None* to indicate an open interval.

**inclusive** : {(True, True) tuple}, optional

Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.

**axis** : {None,int}, optional

Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

`scipy.stats.mstats.trimtail` (*data*, *proportiontocut*=0.2, *tail*='left', *inclusive*=(True, True), *axis*=None)

Trims the data by masking values from one tail.

**Parameters** **data** : array\_like

Data to trim.

**proportiontocut** : float, optional

Percentage of trimming. If *n* is the number of unmasked values before trimming, the number of values after trimming is  $(1 - \text{proportiontocut}) * n$ . Default is 0.2.

**tail** : {'left','right'}, optional

If 'left' the *proportiontocut* lowest values will be masked. If 'right' the *proportiontocut* highest values will be masked. Default is 'left'.

**inclusive** : {(bool, bool) tuple}, optional

Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).

**axis** : int, optional

Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

**Returns** **trimtail** : ndarray

Returned array of same shape as *data* with masked tail values.

`scipy.stats.mstats.tsem` (*a*, *limits*=None, *inclusive*=(True, True), *axis*=0, *ddof*=1)

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

**Parameters** **a** : array\_like

array of values

**limits** : None or (lower limit, upper limit), optional

Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** : (bool, bool), optional

A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional

Axis along which to operate. If None, compute over the whole array. Default is zero.

**ddof** : int, optional

Delta degrees of freedom. Default is 1.

**Returns** **tsem** : float

### Notes

For more details on `tsem`, see `stats.tsem`.

`scipy.stats.mstats.ttest_onesamp` (*a*, *popmean*, *axis*=0)

Calculates the T-test for the mean of ONE group of scores.

**Parameters** **a** : array\_like

sample observation

**popmean** : float or array\_like  
 expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension

**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole array

**Returns** **statistic** : float or array  
<sup>*a*</sup>  
 t-statistic

**pvalue** : float or array  
 two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

`scipy.stats.mstats.ttest_ind(a, b, axis=0, equal_var=True)`  
 Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

**Parameters** **a, b** : array\_like  
 The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).

**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

**equal\_var** : bool, optional  
 If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch's t-test, which does not assume equal population variance. .. versionadded:: 0.17.0

**Returns** **statistic** : float or array  
 The calculated t-statistic.

**pvalue** : float or array  
 The two-tailed p-value.

**Notes**

For more details on `ttest_ind`, see `stats.ttest_ind`.

`scipy.stats.mstats.ttest_onesamp(a, popmean, axis=0)`  
 Calculates the T-test for the mean of ONE group of scores.

**Parameters** **a** : array\_like  
 sample observation

**popmean** : float or array\_like  
 expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension

**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole array

**Returns** **statistic** : float or array  
<sup>*a*</sup>  
 t-statistic

**pvalue** : float or array  
 two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

`scipy.stats.mstats.ttest_rel(a, b, axis=0)`  
 Calculates the T-test on TWO RELATED samples of scores, a and b.

**Parameters** **a, b** : array\_like  
 The arrays must have the same shape.  
**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole arrays,  
**Returns** **statistic** : float or array  
*a*, and *b*.  
 t-statistic  
**pvalue** : float or array  
 two-tailed p-value

**Notes**

For more details on `ttest_rel`, see `stats.ttest_rel`.

`scipy.stats.mstats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

**Parameters** **a** : array\_like  
 Array of values.  
**limits** : None or (lower limit, upper limit), optional  
 Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.  
**inclusive** : (bool, bool), optional  
 A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).  
**axis** : int or None, optional  
 Axis along which to operate. If None, compute over the whole array. Default is zero.  
**ddof** : int, optional  
 Delta degrees of freedom. Default is 1.  
**Returns** **tvar** : float  
 Trimmed variance.

**Notes**

For more details on `tvar`, see `stats.tvar`.

`scipy.stats.mstats.variation` (*a*, *axis=0*)

Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.

**Parameters** **a** : array\_like  
 Input array.  
**axis** : int or None, optional  
 Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.  
**Returns** **variation** : ndarray  
 The calculated variation along the requested axis.

**Notes**

For more details about `variation`, see `stats.variation`.

`scipy.stats.mstats.winsorize` (*a*, *limits=None*, *inclusive=(True, True)*, *inplace=False*, *axis=None*)

Returns a Winsorized version of the input array.

The `(limits[0])`th lowest values are set to the `(limits[0])`th percentile, and the `(limits[1])`th highest values are set to the `(1 - limits[1])`th percentile. Masked values are skipped.

**Parameters**

- a** : sequence  
Input array.
- limits** : {None, tuple of float}, optional  
Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting `n` the number of unmasked data before trimming, the `(n*limits[0])`th smallest data and the `(n*limits[1])`th largest data are masked, and the total number of unmasked data after trimming is `n*(1.-sum(limits))`. The value of one limit can be set to None to indicate an open interval.
- inclusive** : {(True, True) tuple}, optional  
Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- inplace** : {False, True}, optional  
Whether to winsorize in place (True) or to use a copy (False)
- axis** : {None, int}, optional  
Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

### Notes

This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

`scipy.stats.mstats.zmap(scores, compare, axis=0, ddof=0)`  
Calculates the relative z-scores.

Returns an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

**Parameters**

- scores** : array\_like  
The input for which z-scores are calculated.
- compare** : array\_like  
The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as `scores`.
- axis** : int or None, optional  
Axis over which mean and variance of `compare` are calculated. Default is 0. If None, compute over the whole array `scores`.
- ddof** : int, optional  
Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
Z-scores, in the same shape as `scores`.

### Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses `asanyarray` instead of `asarray` for parameters).

### Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
```

`scipy.stats.mstats.zscore(a, axis=0, ddof=0)`

Calculates the z score of each value in the sample, relative to the sample mean and standard deviation.

**Parameters**

- a** : array\_like  
An array like object containing the sample data.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** : int, optional  
Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
The z-scores, standardized by mean and standard deviation of input array *a*.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

**Examples**

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...              0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```
>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...              [ 0.7149,  0.0775,  0.6072,  0.9656],
...              [ 0.6341,  0.1403,  0.9759,  0.4064],
...              [ 0.5918,  0.6948,  0.904 ,  0.3721],
...              [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823, -1.28415119,  1.07259584,  0.40420358],
       [  0.33048416, -1.37380874,  0.04251374,  1.00081084],
       [  0.26796377, -1.12598418,  1.23283094, -0.37481053],
       [ -0.22095197,  0.24468594,  1.19042819, -1.21416216],
       [ -0.82780366,  1.4457416 , -0.43867764, -0.1792603 ]])
```

`scipy.stats.mstats.compare_medians_ms(group_1, group_2, axis=None)`

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

**Parameters**

- group\_1** : array\_like  
First dataset.
- group\_2** : array\_like  
Second dataset.
- axis** : int, optional  
Axis along which the medians are estimated. If None, the arrays are flattened. If *axis* is not None, then *group\_1* and *group\_2* should have the same shape.

**Returns**

- compare\_medians\_ms** : {float, ndarray}  
If *axis* is None, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of *group\_1* along *axis*.

`scipy.stats.mstats.gmean` (*a*, *axis=0*, *dtype=None*)

Compute the geometric mean along the specified axis.

Returns the geometric average of the array elements. That is:  $n$ -th root of  $(x_1 * x_2 * \dots * x_n)$

**Parameters**

- a** : array\_like  
Input array or object that can be converted to an array.
- axis** : int or None, optional  
Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** : dtype, optional  
Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- gmean** : ndarray  
see dtype parameter above

**See also:**

`numpy.mean` Arithmetic average

`numpy.average`

Weighted average

`hmean`

Harmonic mean

**Notes**

The geometric average is computed over a single dimension of the input array, *axis=0* by default, or all values in the array if *axis=None*. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

`scipy.stats.mstats.hdmedian` (*data*, *axis=-1*, *var=False*)

Returns the Harrell-Davis estimate of the median along the given axis.

**Parameters**

- data** : ndarray  
Data array.
- axis** : int, optional  
Axis along which to compute the quantiles. If None, use a flattened array.
- var** : bool, optional  
Whether to return the variance of the estimate.

`scipy.stats.mstats.hdquantiles` (*data*, *prob=[0.25, 0.5, 0.75]*, *axis=None*, *var=False*)

Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

**Parameters**

- data** : array\_like  
Data array.
- prob** : sequence, optional  
Sequence of quantiles to compute.
- axis** : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.
- var** : bool, optional  
Whether to return the variance of the estimate.

**Returns**

- hdquantiles** : MaskedArray  
A (p,) array of quantiles (if *var* is False), or a (2,p) array of quantiles and variances (if *var* is True), where *p* is the number of quantiles.

`scipy.stats.mstats.hdquantiles_sd` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

The standard error of the Harrell-Davis quantile estimates by jackknife.

**Parameters**

- data** : array\_like  
Data array.
- prob** : sequence, optional  
Sequence of quantiles to compute.
- axis** : int, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

- hdquantiles\_sd** : MaskedArray  
Standard error of the Harrell-Davis quantile estimates.

`scipy.stats.mstats.hmean` (*a*, *axis*=0, *dtype*=None)

Calculates the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

**Parameters**

- a** : array\_like  
Input array, masked array or object that can be converted to an array.
- axis** : int or None, optional  
Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** : dtype, optional  
Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- hmean** : ndarray  
see *dtype* parameter above

**See also:**

[\*numpy.mean\*](#) Arithmetic average

[\*numpy.average\*](#)

Weighted average

[\*gmean\*](#)

Geometric mean

**Notes**

The harmonic mean is computed over a single dimension of the input array, *axis*=0 by default, or all values in the array if *axis*=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

`scipy.stats.mstats.idealfourths` (*data*, *axis*=None)

Returns an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

**Parameters**

- data** : array\_like  
Input array.
- axis** : int, optional  
Axis along which the quartiles are estimated. If None, the arrays are flattened.

**Returns**

- idealfourths** : {list of floats, masked array}  
Returns the two internal values that divide *data* into four parts using the ideal fourths algorithm either along the flattened array (if *axis* is None) or along *axis* of *data*.

`scipy.stats.mstats.kruskal(*args)`

Compute the Kruskal-Wallis H-test for independent samples

**Parameters** `sample1, sample2, ...` : array\_like  
Two or more arrays with the sample measurements can be given as arguments.

**Returns** `statistic` : float  
The Kruskal-Wallis H statistic, corrected for ties

`pvalue` : float  
The p-value for the test using the assumption that H has a chi square distribution

#### Notes

For more details on `kruskal`, see `stats.kruskal`.

`scipy.stats.mstats.ks_2samp(data1, data2, alternative='two-sided')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters** `data1` : array\_like  
First data set

`data2` : array\_like  
Second data set

`alternative` : {'two-sided', 'less', 'greater'}, optional  
Indicates the alternative hypothesis. Default is 'two-sided'.

**Returns** `d` : float  
Value of the Kolmogorov Smirnov test

`p` : float  
Corresponding p-value.

`scipy.stats.mstats.median_cihs(data, alpha=0.05, axis=None)`

Computes the alpha-level confidence interval for the median of the data.

Uses the Hettmasperger-Sheather method.

**Parameters** `data` : array\_like  
Input data. Masked values are discarded. The input should be 1D only, or `axis` should be set to None.

`alpha` : float, optional  
Confidence level of the intervals.

`axis` : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

**Returns** `median_cihs`  
Alpha level confidence interval.

`scipy.stats.mstats.meppf(data, alpha=0.4, beta=0.4)`

Returns plotting positions (or empirical percentile points) for the data.

**Plotting positions are defined as  $(i-\alpha)/(n+1-\alpha-\beta)$ , where:**

- `i` is the rank order statistics
- `n` is the number of unmasked values along the given axis
- `alpha` and `beta` are two parameters.

**Typical values for alpha and beta are:**

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5) :  $p(k) = (k-1/2)/n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k/(n+1)$ , Weibull (R type 6)

- (1,1) :  $p(k) = (k-1) / (n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3) / (n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8) / (n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

**data** : array\_like  
Input data, as a sequence or array of dimension at most 2.

**alpha** : float, optional  
Plotting positions parameter. Default is 0.4.

**beta** : float, optional  
Plotting positions parameter. Default is 0.4.

**Returns**

**positions** : MaskedArray  
The calculated plotting positions.

`scipy.stats.mstats.mjci` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

**Parameters**

**data** : ndarray  
Data array.

**prob** : sequence, optional  
Sequence of quantiles to compute.

**axis** : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

`scipy.stats.mstats.mquantiles_cimj` (*data*, *prob*=[0.25, 0.5, 0.75], *alpha*=0.05, *axis*=None)

Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

**Parameters**

**data** : ndarray  
Data array.

**prob** : sequence, optional  
Sequence of quantiles to compute.

**alpha** : float, optional  
Confidence level of the intervals.

**axis** : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

`scipy.stats.mstats.rsh` (*data*, *points*=None)

Evaluates Rosenblatt's shifted histogram estimators for each point on the dataset 'data'.

**Parameters**

**data** : sequence  
Input data. Masked values are ignored.

**points** : sequence or None, optional  
Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.

`scipy.stats.mstats.sen_seasonal_slopes` (*x*)

`scipy.stats.mstats.trimmed_mean` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *relative*=True, *axis*=None)

`scipy.stats.mstats.trimmed_mean_ci` (*data*, *limits*=(0.2, 0.2), *inclusive*=(True, True), *alpha*=0.05, *axis*=None)

Selected confidence interval of the trimmed mean along the given axis.

**Parameters**

- data** : array\_like  
Input data.
- limits** : {None, tuple}, optional  
None or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If *n* is the number of unmasked data before trimming, then (*n* \* *limits*[0])th smallest data and (*n* \* *limits*[1])th largest data are masked. The total number of unmasked data after trimming is *n* \* (1. - sum(*limits*)). The value of one limit can be set to None to indicate an open interval.  
Defaults to (0.2, 0.2).
- inclusive** : (2,) tuple of boolean, optional  
If *relative*==False, tuple indicating whether values exactly equal to the absolute limits are allowed. If *relative*==True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).  
Defaults to (True, True).
- alpha** : float, optional  
Confidence level of the intervals.  
Defaults to 0.05.
- axis** : int, optional  
Axis along which to cut. If None, uses a flattened version of *data*.  
Defaults to None.

**Returns**

- trimmed\_mean\_ci** : (2,) ndarray  
The lower and upper confidence intervals of the trimmed data.

`scipy.stats.mstats.trimmed_std` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *relative*=True, *axis*=None, *ddof*=0)

`scipy.stats.mstats.trimmed_var` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *relative*=True, *axis*=None, *ddof*=0)

`scipy.stats.mstats.ttest_1samp` (*a*, *popmean*, *axis*=0)

Calculates the T-test for the mean of ONE group of scores.

**Parameters**

- a** : array\_like  
sample observation
- popmean** : float or array\_like  
expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension
- axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole array

**Returns**

- statistic** : float or array  
*a*.  
t-statistic
- pvalue** : float or array  
two-tailed p-value

#### Notes

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

### 5.27.9 Univariate and multivariate kernel density estimation (`scipy.stats.kde`)

---

`gaussian_kde(dataset[, bw_method])` Representation of a kernel-density estimate using Gaussian kernels.

---

**class** `scipy.stats.gaussian_kde` (*dataset*, *bw\_method=None*)  
Representation of a kernel-density estimate using Gaussian kernels.

Kernel density estimation is a way to estimate the probability density function (PDF) of a random variable in a non-parametric way. `gaussian_kde` works for both uni-variate and multi-variate data. It includes automatic bandwidth determination. The estimation works best for a unimodal distribution; bimodal or multi-modal distributions tend to be oversmoothed.

**Parameters**

- dataset** : array\_like  
Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).
- bw\_method** : str, scalar or callable, optional  
The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If a scalar, this will be used directly as *kde.factor*. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), ‘scott’ is used. See Notes for more details.

#### Notes

Bandwidth selection strongly influences the estimate obtained from the KDE (much more so than the actual shape of the kernel). Bandwidth selection can be done by a “rule of thumb”, by cross-validation, by “plug-in methods” or by other means; see [R585], [R586] for reviews. `gaussian_kde` uses a rule of thumb, the default is Scott’s Rule.

Scott’s Rule [R583], implemented as `scotts_factor`, is:

$$n^{**(-1./ (d+4))},$$

with  $n$  the number of data points and  $d$  the number of dimensions. Silverman’s Rule [R584], implemented as `silverman_factor`, is:

$$(n * (d + 2) / 4.)^{**(-1. / (d + 4))}.$$

Good general descriptions of kernel density estimation can be found in [R583] and [R584], the mathematics for this multi-dimensional implementation can be found in [R583].

#### References

[R583], [R584], [R585], [R586]

#### Examples

Generate some random two-dimensional data:

```
>>> from scipy import stats
>>> def measure(n):
...     "Measurement model, return two coupled measurements."
...     m1 = np.random.normal(size=n)
...     m2 = np.random.normal(scale=0.5, size=n)
...     return m1+m2, m1-m2
```

```
>>> m1, m2 = measure(2000)
>>> xmin = m1.min()
>>> xmax = m1.max()
>>> ymin = m2.min()
>>> ymax = m2.max()
```

Perform a kernel density estimate on the data:

```
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel(positions).T, X.shape)
```

Plot the results:

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
...           extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()
```

#### Attributes

| dataset    | (ndarray) The dataset with which <code>gaussian_kde</code> was initialized.                                                      |
| d          | (int) Number of dimensions.                                                                                                      |
| n          | (int) Number of datapoints.                                                                                                      |
| factor     | (float) The bandwidth factor, obtained from <code>kde.covariance_factor</code> , with which the covariance matrix is multiplied. |
| covariance | (ndarray) The covariance matrix of <code>dataset</code> , scaled by the calculated bandwidth ( <code>kde.factor</code> ).        |
| inv_cov    | (ndarray) The inverse of <code>covariance</code> .                                                                               |

*Methods*

|                                                               |                                                                                                                           |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>evaluate(points)</code>                                 | Evaluate the estimated pdf on a set of points.                                                                            |
| <code>__call__(points)</code>                                 | Evaluate the estimated pdf on a set of points.                                                                            |
| <code>integrate_gaussian(mean, cov)</code>                    | Multiply estimated density by a multivariate Gaussian and integrate over the whole space.                                 |
| <code>integrate_box_1d(low, high)</code>                      | Computes the integral of a 1D pdf between two bounds.                                                                     |
| <code>integrate_box(low_bounds, high_bounds[, maxpts])</code> | Computes the integral of a pdf over a rectangular interval.                                                               |
| <code>integrate_kde(other)</code>                             | Computes the integral of the product of this kernel density estimate with another kernel density estimate.                |
| <code>pdf(x)</code>                                           | Evaluate the estimated pdf on a provided set of points.                                                                   |
| <code>logpdf(x)</code>                                        | Evaluate the log of the estimated pdf on a provided set of points.                                                        |
| <code>resample([size])</code>                                 | Randomly sample a dataset from the estimated pdf.                                                                         |
| <code>set_bandwidth([bw_method])</code>                       | Compute the estimator bandwidth with given method.                                                                        |
| <code>covariance_factor()</code>                              | Computes the coefficient ( <i>kde.factor</i> ) that multiplies the data covariance matrix to get the estimator bandwidth. |

`gaussian_kde.evaluate(points)`  
 Evaluate the estimated pdf on a set of points.

**Parameters** **points** : (# of dimensions, # of points)-array  
 Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

**Returns** **values** : (# of points,)-array  
 The values at each point.

**Raises** **ValueError** : if the dimensionality of the input points is different than the dimensionality of the KDE.

`gaussian_kde.__call__(points)`  
 Evaluate the estimated pdf on a set of points.

**Parameters** **points** : (# of dimensions, # of points)-array  
 Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

**Returns** **values** : (# of points,)-array  
 The values at each point.

**Raises** **ValueError** : if the dimensionality of the input points is different than the dimensionality of the KDE.

`gaussian_kde.integrate_gaussian(mean, cov)`  
 Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

**Parameters** **mean** : array\_like  
 A 1-D array, specifying the mean of the Gaussian.

**cov** : array\_like  
 A 2-D array, specifying the covariance matrix of the Gaussian.

**Returns** **result** : scalar  
 The value of the integral.

**Raises** **ValueError**  
 If the mean or covariance of the input Gaussian differs from the KDE's dimensionality.

`gaussian_kde.integrate_box_1d(low, high)`  
 Computes the integral of a 1D pdf between two bounds.

**Parameters** **low** : scalar  
 Lower bound of integration.

**high** : scalar  
 Upper bound of integration.

**Returns** **value** : scalar  
 The result of the integral.

**Raises** **ValueError**  
 If the KDE is over more than one dimension.

`gaussian_kde.integrate_box` (*low\_bounds*, *high\_bounds*, *maxpts=None*)

Computes the integral of a pdf over a rectangular interval.

**Parameters**

- low\_bounds** : array\_like  
A 1-D array containing the lower bounds of integration.
- high\_bounds** : array\_like  
A 1-D array containing the upper bounds of integration.
- maxpts** : int, optional  
The maximum number of points to use for integration.

**Returns**

- value** : scalar  
The result of the integral.

`gaussian_kde.integrate_kde` (*other*)

Computes the integral of the product of this kernel density estimate with another.

**Parameters**

- other** : gaussian\_kde instance  
The other kde.

**Returns**

- value** : scalar  
The result of the integral.

**Raises**

- ValueError**  
If the KDEs have different dimensionality.

`gaussian_kde.pdf` (*x*)

Evaluate the estimated pdf on a provided set of points.

#### Notes

This is an alias for `gaussian_kde.evaluate`. See the `evaluate` docstring for more details.

`gaussian_kde.logpdf` (*x*)

Evaluate the log of the estimated pdf on a provided set of points.

`gaussian_kde.resample` (*size=None*)

Randomly sample a dataset from the estimated pdf.

**Parameters**

- size** : int, optional  
The number of samples to draw. If not provided, then the size is the same as the underlying dataset.

**Returns**

- resample** : (self.d, *size*) ndarray  
The sampled dataset.

`gaussian_kde.set_bandwidth` (*bw\_method=None*)

Compute the estimator bandwidth with given method.

The new bandwidth calculated after a call to `set_bandwidth` is used for subsequent evaluations of the estimated density.

**Parameters**

- bw\_method** : str, scalar or callable, optional  
The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as *kde.factor*. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), nothing happens; the current *kde.covariance\_factor* method is kept.

#### Notes

New in version 0.11.

*Examples*

```

>>> import scipy.stats as stats
>>> x1 = np.array([-7, -5, 1, 4, 5.])
>>> kde = stats.gaussian_kde(x1)
>>> xs = np.linspace(-10, 10, num=50)
>>> y1 = kde(xs)
>>> kde.set_bandwidth(bw_method='silverman')
>>> y2 = kde(xs)
>>> kde.set_bandwidth(bw_method=kde.factor / 3.)
>>> y3 = kde(xs)

>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.plot(x1, np.ones(x1.shape) / (4. * x1.size), 'bo',
...        label='Data points (rescaled)')
>>> ax.plot(xs, y1, label='Scott (default)')
>>> ax.plot(xs, y2, label='Silverman')
>>> ax.plot(xs, y3, label='Const (1/3 * Silverman)')
>>> ax.legend()
>>> plt.show()

```

`gaussian_kde.covariance_factor()`

Computes the coefficient (*kde.factor*) that multiplies the data covariance matrix to obtain the kernel covariance matrix. The default is `scotts_factor`. A subclass can overwrite this method to provide a different method, or set it through a call to `kde.set_bandwidth`.

For many more stat related functions install the software R and the interface package rpy.

## 5.28 Statistical functions for masked arrays (`scipy.stats.mstats`)

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in `scipy.stats` but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

|                                                                |                                                                                  |
|----------------------------------------------------------------|----------------------------------------------------------------------------------|
| <code>argstoarray(*args)</code>                                | Constructs a 2D array from a group of sequences.                                 |
| <code>betai(*args, **kwds)</code>                              | <code>betai</code> is deprecated!                                                |
| <code>chisquare(f_obs[, f_exp, ddof, axis])</code>             | Calculates a one-way chi square test.                                            |
| <code>count_tied_groups(x[, use_missing])</code>               | Counts the number of tied values.                                                |
| <code>describe(a[, axis, ddof, bias])</code>                   | Computes several descriptive statistics of the passed array.                     |
| <code>f_oneway(*args)</code>                                   | Performs a 1-way ANOVA, returning an F-value and probability given any nu        |
| <code>f_value_wilks_lambda(*args, **kwds)</code>               | <code>f_value_wilks_lambda</code> is deprecated!                                 |
| <code>find_repeats(arr)</code>                                 | Find repeats in arr and return a tuple (repeats, repeat_count).                  |
| <code>friedmanchisquare(*args)</code>                          | Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA.          |
| <code>kendalltau(x, y[, use_ties, use_missing])</code>         | Computes Kendall's rank correlation tau on two variables $x$ and $y$ .           |
| <code>kendalltau_seasonal(x)</code>                            | Computes a multivariate Kendall's rank correlation tau, for seasonal data.       |
| <code>kruskalwallis(*args)</code>                              | Compute the Kruskal-Wallis H-test for independent samples                        |
| <code>ks_twosamp(data1, data2[, alternative])</code>           | Computes the Kolmogorov-Smirnov test on two samples.                             |
| <code>kurtosis(a[, axis, fisher, bias])</code>                 | Computes the kurtosis (Fisher or Pearson) of a dataset.                          |
| <code>kurtosistest(a[, axis])</code>                           | Tests whether a dataset has normal kurtosis                                      |
| <code>linregress(x[, y])</code>                                | Calculate a linear least-squares regression for two sets of measurements.        |
| <code>mannwhitneyu(x, y[, use_continuity])</code>              | Computes the Mann-Whitney statistic                                              |
| <code>plotting_positions(data[, alpha, beta])</code>           | Returns plotting positions (or empirical percentile points) for the data.        |
| <code>mode(a[, axis])</code>                                   | Returns an array of the modal (most common) value in the passed array.           |
| <code>moment(a[, moment, axis])</code>                         | Calculates the nth moment about the mean for a sample.                           |
| <code>mquantiles(a[, prob, alphap, betap, axis, limit])</code> | Computes empirical quantiles for a data array.                                   |
| <code>msign(x)</code>                                          | Returns the sign of $x$ , or 0 if $x$ is masked.                                 |
| <code>normaltest(a[, axis])</code>                             | Tests whether a sample differs from a normal distribution.                       |
| <code>obrientransform(*args)</code>                            | Computes a transform on input data (any number of columns).                      |
| <code>pearsonr(x, y)</code>                                    | Calculates a Pearson correlation coefficient and the p-value for testing non-co  |
| <code>plotting_positions(data[, alpha, beta])</code>           | Returns plotting positions (or empirical percentile points) for the data.        |
| <code>pointbiserialr(x, y)</code>                              | Calculates a point biserial correlation coefficient and its p-value.             |
| <code>rankdata(data[, axis, use_missing])</code>               | Returns the rank (also known as order statistics) of each data point along the g |
| <code>scoreatpercentile(data, per[, limit, ...])</code>        | Calculate the score at the given 'per' percentile of the sequence a.             |
| <code>sem(a[, axis, ddof])</code>                              | Calculates the standard error of the mean of the input array.                    |
| <code>signaltonoise(*args, **kwds)</code>                      | <code>signaltonoise</code> is deprecated!                                        |
| <code>skew(a[, axis, bias])</code>                             | Computes the skewness of a data set.                                             |
| <code>skewtest(a[, axis])</code>                               | Tests whether the skew is different from the normal distribution.                |
| <code>spearmanr(x, y[, use_ties])</code>                       | Calculates a Spearman rank-order correlation coefficient and the p-value to te   |
| <code>theilslopes(y[, x, alpha])</code>                        | Computes the Theil-Sen estimator for a set of points ( $x$ , $y$ ).              |
| <code>threshold(*args, **kwds)</code>                          | <code>threshold</code> is deprecated!                                            |
| <code>tmax(a[, upperlimit, axis, inclusive])</code>            | Compute the trimmed maximum                                                      |
| <code>tmean(a[, limits, inclusive, axis])</code>               | Compute the trimmed mean.                                                        |
| <code>tmin(a[, lowerlimit, axis, inclusive])</code>            | Compute the trimmed minimum                                                      |
| <code>trim(a[, limits, inclusive, relative, axis])</code>      | Trims an array by masking the data outside some given limits.                    |
| <code>trima(a[, limits, inclusive])</code>                     | Trims an array by masking the data outside some given limits.                    |
| <code>trimboth(data[, proportiontocut, inclusive, ...])</code> | Trims the smallest and largest data values.                                      |
| <code>trimmed_stde(a[, limits, inclusive, axis])</code>        | Returns the standard error of the trimmed mean along the given axis.             |
| <code>trimr(a[, limits, inclusive, axis])</code>               | Trims an array by masking some proportion of the data on each end.               |
| <code>trimtail(data[, proportiontocut, tail, ...])</code>      | Trims the data by masking values from one tail.                                  |
| <code>tsem(a[, limits, inclusive, axis, ddof])</code>          | Compute the trimmed standard error of the mean.                                  |
| <code>ttest_onesamp(a, popmean[, axis])</code>                 | Calculates the T-test for the mean of ONE group of scores.                       |
| <code>ttest_ind(a, b[, axis, equal_var])</code>                | Calculates the T-test for the means of TWO INDEPENDENT samples of scor           |
| <code>ttest_onesamp(a, popmean[, axis])</code>                 | Calculates the T-test for the mean of ONE group of scores.                       |
| <code>ttest_rel(a, b[, axis])</code>                           | Calculates the T-test on TWO RELATED samples of scores, a and b.                 |
| <code>tvar(a[, limits, inclusive, axis, ddof])</code>          | Compute the trimmed variance                                                     |
| <code>variation(a[, axis])</code>                              | Computes the coefficient of variation, the ratio of the biased standard deviatio |

|                                                               |                                                                                  |
|---------------------------------------------------------------|----------------------------------------------------------------------------------|
| <code>winsorize(a[, limits, inclusive, inplace, axis])</code> | Returns a Winsorized version of the input array.                                 |
| <code>zmap(scores, compare[, axis, ddof])</code>              | Calculates the relative z-scores.                                                |
| <code>zscore(a[, axis, ddof])</code>                          | Calculates the z score of each value in the sample, relative to the sample mean. |
| <code>compare_medians_ms(group_1, group_2[, axis])</code>     | Compares the medians from two independent groups along the given axis.           |
| <code>gmean(a[, axis, dtype])</code>                          | Compute the geometric mean along the specified axis.                             |
| <code>hdmedian(data[, axis, var])</code>                      | Returns the Harrell-Davis estimate of the median along the given axis.           |
| <code>hdquantiles(data[, prob, axis, var])</code>             | Computes quantile estimates with the Harrell-Davis method.                       |
| <code>hdquantiles_sd(data[, prob, axis])</code>               | The standard error of the Harrell-Davis quantile estimates by jackknife.         |
| <code>hmean(a[, axis, dtype])</code>                          | Calculates the harmonic mean along the specified axis.                           |
| <code>idealfourths(data[, axis])</code>                       | Returns an estimate of the lower and upper quartiles.                            |
| <code>kruskal(*args)</code>                                   | Compute the Kruskal-Wallis H-test for independent samples                        |
| <code>ks_2samp(data1, data2[, alternative])</code>            | Computes the Kolmogorov-Smirnov test on two samples.                             |
| <code>median_cihs(data[, alpha, axis])</code>                 | Computes the alpha-level confidence interval for the median of the data.         |
| <code>meppf(data[, alpha, beta])</code>                       | Returns plotting positions (or empirical percentile points) for the data.        |
| <code>mjci(data[, prob, axis])</code>                         | Returns the Maritz-Jarrett estimators of the standard error of selected experim  |
| <code>mquantiles_cimj(data[, prob, alpha, axis])</code>       | Computes the alpha confidence interval for the selected quantiles of the data,   |
| <code>rsh(data[, points])</code>                              | Evaluates Rosenblatt’s shifted histogram estimators for each point on the data   |
| <code>sen_seasonal_slopes(x)</code>                           |                                                                                  |
| <code>trimmed_mean(a[, limits, inclusive, ...])</code>        |                                                                                  |
| <code>trimmed_mean_ci(data[, limits, inclusive, ...])</code>  | Selected confidence interval of the trimmed mean along the given axis.           |
| <code>trimmed_std(a[, limits, inclusive, ...])</code>         |                                                                                  |
| <code>trimmed_var(a[, limits, inclusive, ...])</code>         |                                                                                  |
| <code>ttest_1samp(a, popmean[, axis])</code>                  | Calculates the T-test for the mean of ONE group of scores.                       |

`scipy.stats.mstats.argstoarray(*args)`

Constructs a 2D array from a group of sequences.

Sequences are filled with missing values to match the length of the longest sequence.

**Parameters** `args` : sequences

**Returns** `argstoarray` : `Group of sequences`  
`MaskedArray`

A ( $m \times n$ ) masked array, where  $m$  is the number of arguments and  $n$  the length of the longest argument.

**Notes**

`numpy.ma.row_stack` has identical behavior, but is called with a sequence of sequences.

`scipy.stats.mstats.betainc(*args, **kws)`

`betainc` is deprecated! `mstats.betainc` is deprecated in scipy 0.17.0; use `special.betainc` instead.

`betainc()` is deprecated in scipy 0.17.0.

For details about this function, see `stats.betainc`.

`scipy.stats.mstats.chisquare(f_obs, f_exp=None, ddof=0, axis=0)`

Calculates a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

**Parameters** `f_obs` : array\_like

Observed frequencies in each category.

`f_exp` : array\_like, optional

Expected frequencies in each category. By default the categories are assumed to be equally likely.

`ddof` : int, optional

“Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of *ddof* is 0.

**axis** : int or None, optional  
The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If axis is None, all values in *f\_obs* are treated as a single data set. Default is 0.

**Returns** **chisq** : float or ndarray  
The chi-squared test statistic. The value is a float if *axis* is None or *f\_obs* and *f\_exp* are 1-D.

**p** : float or ndarray  
The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

**See also:**

`power_divergence`, `mstats.chisquare`

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom,  $k-1$ , are for the case when no parameters of the distribution are estimated. If  $p$  parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are  $k-1-p$ . If the parameters are estimated in a different way, then the dof can be between  $k-1-p$  and  $k-1$ . However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

**References**

[R610], [R611]

**Examples**

When just *f\_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With *f\_exp* the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting *axis*=None, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

*ddof* is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with *ddof*.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

*f\_obs* and *f\_exp* are also broadcast. In the following, *f\_obs* has shape (6,) and *f\_exp* has shape (2, 6), so the result of broadcasting *f\_obs* and *f\_exp* has shape (2, 6). To compute the desired chi-squared statistics, we use *axis=1*:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...           f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...           axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

`scipy.stats.mstats.count_tied_groups(x, use_missing=False)`

Counts the number of tied values.

**Parameters**

- x** : sequence  
Sequence of data on which to counts the ties
- use\_missing** : bool, optional  
Whether to consider missing values as tied.

**Returns**

- count\_tied\_groups** : dict  
Returns a dictionary (nb of ties: nb of groups).

### Examples

```
>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}
```

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

```
>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 2, 3: 1}
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}
```

`scipy.stats.mstats.describe(a, axis=0, ddof=0, bias=True)`

Computes several descriptive statistics of the passed array.

**Parameters**

- a** : array\_like  
Data array
- axis** : int or None, optional

Axis along which to calculate statistics. Default 0. If None, compute over the whole array *a*.

**ddof** : int, optional  
degree of freedom (default 0); note that default ddof is different from the same routine in stats.describe

**bias** : bool, optional  
If False, then the skewness and kurtosis calculations are corrected for statistical bias.

**Returns**

**nobs** : int  
(size of the data (discarding missing values))

**minmax** : (int, int)  
min, max

**mean** : float  
arithmetic mean

**variance** : float  
unbiased variance

**skewness** : float  
biased skewness

**kurtosis** : float  
biased kurtosis

### Examples

```
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult(nobs=array(3), minmax=(masked_array(data = 0,
            mask = False,
            fill_value = 999999)
, masked_array(data = 2,
            mask = False,
            fill_value = 999999)
), mean=1.0, variance=0.66666666666666663, skewness=masked_array(data = 0.0,
            mask = False,
            fill_value = 1e+20)
, kurtosis=-1.5)
```

`scipy.stats.mstats.f_oneway(*args)`

Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

Usage: `f_oneway(*args)`, where `*args` is 2 or more arrays, one per treatment group.

**Returns**

**statistic** : float  
The computed F-value of the test.

**pvalue** : float  
The associated p-value from the F-distribution.

`scipy.stats.mstats.f_value_wilks_lambda(*args, **kws)`

`f_value_wilks_lambda` is deprecated! `mstats.f_value_wilks_lambda` deprecated in scipy 0.17.0

*Calculation of Wilks lambda F-statistic for multivariate data, per Maxwell & Delaney p.657.*

`scipy.stats.mstats.find_repeats(arr)`

Find repeats in `arr` and return a tuple (repeats, repeat\_count).

The input is cast to float64. Masked values are discarded.

**Parameters** **arr** : sequence

**Returns**

**repeats** : ndarray  
Input array. The array is flattened if it is not 1D.  
Array of repeated values.

**counts** : ndarray  
Array of counts.

`scipy.stats.mstats.friedmanchisquare(*args)`

Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first  $n$  treatments are taken into account, where  $n$  is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.

**Returns**

**statistic** : float  
the test statistic.

**pvalue** : float  
the associated p-value.

`scipy.stats.mstats.kendalltau(x, y, use_ties=True, use_missing=False)`

Computes Kendall's rank correlation tau on two variables  $x$  and  $y$ .

**Parameters**

**x** : sequence  
First data list (for example, time).

**y** : sequence  
Second data list.

**use\_ties** : {True, False}, optional  
Whether ties correction should be performed.

**use\_missing** : {False, True}, optional  
Whether missing data should be allocated a rank of 0 (False) or the average rank (True)

**Returns**

**correlation** : float  
Kendall tau

**pvalue** : float  
Approximate 2-side p-value.

`scipy.stats.mstats.kendalltau_seasonal(x)`

Computes a multivariate Kendall's rank correlation tau, for seasonal data.

**Parameters**

**x** : 2-D ndarray  
Array of seasonal data, with seasons in columns.

`scipy.stats.mstats.kruskalwallis(*args)`

Compute the Kruskal-Wallis H-test for independent samples

**Parameters**

**sample1, sample2, ...** : array\_like  
Two or more arrays with the sample measurements can be given as arguments.

**Returns**

**statistic** : float  
The Kruskal-Wallis H statistic, corrected for ties

**pvalue** : float  
The p-value for the test using the assumption that H has a chi square distribution

**Notes**

For more details on `kruskal`, see `stats.kruskal`.

`scipy.stats.mstats.ks_twosamp` (*data1*, *data2*, *alternative='two-sided'*)

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

|                   |                                                                 |                                                               |
|-------------------|-----------------------------------------------------------------|---------------------------------------------------------------|
| <b>Parameters</b> | <b>data1</b> : array_like                                       | First data set                                                |
|                   | <b>data2</b> : array_like                                       | Second data set                                               |
|                   | <b>alternative</b> : {'two-sided', 'less', 'greater'}, optional | Indicates the alternative hypothesis. Default is 'two-sided'. |
| <b>Returns</b>    | <b>d</b> : float                                                | Value of the Kolmogorov Smirnov test                          |
|                   | <b>p</b> : float                                                | Corresponding p-value.                                        |

`scipy.stats.mstats.kurtosis` (*a*, *axis=0*, *fisher=True*, *bias=True*)

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If *bias* is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

|                   |                                     |                                                                                                                                  |
|-------------------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>a</b> : array                    | data for which the kurtosis is calculated                                                                                        |
|                   | <b>axis</b> : int or None, optional | Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array <i>a</i> .                      |
|                   | <b>fisher</b> : bool, optional      | If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).                  |
|                   | <b>bias</b> : bool, optional        | If False, then the calculations are corrected for statistical bias.                                                              |
| <b>Returns</b>    | <b>kurtosis</b> : array             | The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition. |

**Notes**

For more details about `kurtosis`, see `stats.kurtosis`.

`scipy.stats.mstats.kurtosistest` (*a*, *axis=0*)

Tests whether a dataset has normal kurtosis

|                   |                                     |                                                                                                  |
|-------------------|-------------------------------------|--------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>a</b> : array                    | array of the sample data                                                                         |
|                   | <b>axis</b> : int or None, optional | Axis along which to compute test. Default is 0. If None, compute over the whole array <i>a</i> . |
| <b>Returns</b>    | <b>statistic</b> : float            | The computed z-score for this test.                                                              |
|                   | <b>pvalue</b> : float               | The 2-sided p-value for the hypothesis test                                                      |

### Notes

For more details about `kurtosistest`, see `stats.kurtosistest`.

`scipy.stats.mstats.linregress(x, y=None)`

Calculate a linear least-squares regression for two sets of measurements.

|                   |                          |                                                                                                                                                                                                                                                                                                           |
|-------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>x, y</b> : array_like | Two sets of measurements. Both arrays should have the same length. If only <code>x</code> is given (and <code>y=None</code> ), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension. |
| <b>Returns</b>    | <b>slope</b> : float     | slope of the regression line                                                                                                                                                                                                                                                                              |
|                   | <b>intercept</b> : float | intercept of the regression line                                                                                                                                                                                                                                                                          |
|                   | <b>rvalue</b> : float    | correlation coefficient                                                                                                                                                                                                                                                                                   |
|                   | <b>pvalue</b> : float    | two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero.                                                                                                                                                                                                                  |
|                   | <b>stderr</b> : float    | Standard error of the estimated gradient.                                                                                                                                                                                                                                                                 |

See also:

`scipy.optimize.curve_fit`

Use non-linear least squares to fit a function to data.

`scipy.optimize.leastsq`

Minimize the sum of squares of a set of equations.

### Notes

Missing values are considered pair-wise: if a value is missing in `x`, the corresponding value in `y` is masked.

### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = np.random.random(10)
>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)
```

To get coefficient of determination (`r_squared`)

```
>>> print("r-squared:", r_value**2)
('r-squared:', 0.080402268539028335)
```

Plot the data along with the fitted line

```
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

`scipy.stats.mstats.mannwhitneyu(x, y, use_continuity=True)`

Computes the Mann-Whitney statistic

Missing values in  $x$  and/or  $y$  are discarded.

**Parameters**  $x$  : sequence

Input

$y$  : sequence

Input

**use\_continuity** : {True, False}, optional

Whether a continuity correction (1/2.) should be taken into account.

**Returns**

**statistic** : float

The Mann-Whitney statistics

**pvalue** : float

Approximate p-value assuming a normal distribution.

`scipy.stats.mstats.plotting_positions(data, alpha=0.4, beta=0.4)`

Returns plotting positions (or empirical percentile points) for the data.

Plotting positions are defined as  $(i - \alpha) / (n + 1 - \alpha - \beta)$ , where:

- $i$  is the rank order statistics
- $n$  is the number of unmasked values along the given axis
- $\alpha$  and  $\beta$  are two parameters.

Typical values for  $\alpha$  and  $\beta$  are:

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5) :  $p(k) = (k - 1/2) / n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k / (n + 1)$ , Weibull (R type 6)
- (1,1) :  $p(k) = (k - 1) / (n - 1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k - 1/3) / (n + 1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (R type 8)
- (3/8,3/8):  $p(k) = (k - 3/8) / (n + 1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM

•(.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

- data** : array\_like  
Input data, as a sequence or array of dimension at most 2.
- alpha** : float, optional  
Plotting positions parameter. Default is 0.4.
- beta** : float, optional  
Plotting positions parameter. Default is 0.4.

**Returns**

- positions** : MaskedArray  
The calculated plotting positions.

`scipy.stats.mstats.mode(a, axis=0)`

Returns an array of the modal (most common) value in the passed array.

**Parameters**

- a** : array\_like  
n-dimensional array of which to find mode(s).
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**Returns**

- mode** : ndarray  
Array of modal values.
- count** : ndarray  
Array of counts for each mode.

**Notes**

For more details, see `stats.mode`.

`scipy.stats.mstats.moment(a, moment=1, axis=0)`

Calculates the *n*th moment about the mean for a sample.

**Parameters**

- a** : array\_like  
data
- moment** : int, optional  
order of central moment that is returned
- axis** : int or None, optional  
Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.

**Returns**

- n-th central moment** : ndarray or float  
The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**Notes**

For more details about `moment`, see `stats.moment`.

`scipy.stats.mstats.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())`

Computes empirical quantiles for a data array.

Samples quantile are defined by  $Q(p) = (1-\gamma) * x[j] + \gamma * x[j+1]$ , where  $x[j]$  is the *j*-th order statistic, and  $\gamma$  is a function of  $j = \text{floor}(n * p + m)$ ,  $m = \text{alphap} + p * (1 - \text{alphap} - \text{betap})$  and  $g = n * p + m - j$ .

Reinterpreting the above equations to compare to **R** lead to the equation:  $p(k) = (k - \text{alphap}) / (n + 1 - \text{alphap} - \text{betap})$

**Typical values of (alphap,betap) are:**

•(0,1) :  $p(k) = k/n$  : linear interpolation of cdf (**R** type 4)

- (.5,.5) :  $p(k) = (k - 1/2.) / n$  : piecewise linear function (**R** type 5)
- (0,0) :  $p(k) = k / (n+1)$  : (**R** type 6)
- (1,1) :  $p(k) = (k-1) / (n-1)$  :  $p(k) = \text{mode}[F(x[k])]$ . (**R** type 7, **R** default)
- (1/3,1/3) :  $p(k) = (k-1/3) / (n+1/3)$  : Then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (**R** type 8)
- (3/8,3/8) :  $p(k) = (k-3/8) / (n+1/4)$  : Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (**R** type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35) : APL, used with PWM

**Parameters**

**a** : array\_like  
Input data, as a sequence or array of dimension at most 2.

**prob** : array\_like, optional  
List of quantiles to compute.

**alphap** : float, optional  
Plotting positions parameter, default is 0.4.

**betap** : float, optional  
Plotting positions parameter, default is 0.4.

**axis** : int, optional  
Axis along which to perform the trimming. If None (default), the input array is first flattened.

**limit** : tuple, optional  
Tuple of (lower, upper) values. Values of  $a$  outside this open interval are ignored.

**Returns**

**mquantiles** : MaskedArray  
An array containing the calculated quantiles.

### Notes

This formulation is very similar to **R** except the calculation of  $m$  from **alphap** and **betap**, where in **R**  $m$  is defined with each type.

### References

[R612], [R613]

### Examples

```
>>> from scipy.stats.mstats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([ 19.2,  40. ,  42.8])
```

Using a 2D array, specifying axis and limit.

```
>>> data = np.array([[ 6.,  7.,  1.],
...                 [ 47., 15.,  2.],
...                 [ 49., 36.,  3.],
...                 [ 15., 39.,  4.],
...                 [ 42., 40., -999.],
...                 [ 41., 41., -999.],
...                 [  7., -999., -999.],
...                 [ 39., -999., -999.],
...                 [ 43., -999., -999.],
...                 [ 40., -999., -999.],
...                 [ 36., -999., -999.]])
```

```
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[ 19.2  14.6   1.45]
 [ 40.   37.5   2.5 ]
 [ 42.8  40.05  3.55]]

>>> data[:, 2] = -999.
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]
```

`scipy.stats.mstats.msign(x)`

Returns the sign of *x*, or 0 if *x* is masked.

`scipy.stats.mstats.normaltest(a, axis=0)`

Tests whether a sample differs from a normal distribution.

**Parameters** *a* : array\_like

The array containing the data to be tested.

**axis** : int or None, optional

Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

**Returns**

**statistic** : float or array  
 $s^2 + k^2$ , where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.

**pvalue** : float or array

A 2-sided chi squared probability for the hypothesis test.

**Notes**

For more details about `normaltest`, see `stats.normaltest`.

`scipy.stats.mstats.obrientransform(*args)`

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in *\*args* is one level of a factor. If an `f_oneway()` run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA

`scipy.stats.mstats.pearsonr(x, y)`

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson's correlation requires that each dataset be normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters** *x* : 1-D array\_like

Input

*y* : 1-D array\_like

**Returns**

**pearsonr** : float

Pearson's correlation coefficient, 2-tailed p-value.

`scipy.stats.mstats.plotting_positions` (*data*, *alpha*=0.4, *beta*=0.4)

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as  $(i-\alpha)/(n+1-\alpha-\beta)$ , where:*

- *i* is the rank order statistics
- *n* is the number of unmasked values along the given axis
- *alpha* and *beta* are two parameters.

*Typical values for alpha and beta are:*

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5) :  $p(k) = (k-1/2)/n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k/(n+1)$ , Weibull (R type 6)
- (1,1) :  $p(k) = (k-1)/(n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3)/(n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of *x*. (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8)/(n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if *x* is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

**data** : array\_like  
Input data, as a sequence or array of dimension at most 2.

**alpha** : float, optional  
Plotting positions parameter. Default is 0.4.

**beta** : float, optional  
Plotting positions parameter. Default is 0.4.

**Returns**

**positions** : MaskedArray  
The calculated plotting positions.

`scipy.stats.mstats.pointbiserialr` (*x*, *y*)

Calculates a point biserial correlation coefficient and its p-value.

**Parameters**

**x** : array\_like of bools  
Input array.

**y** : array\_like  
Input array.

**Returns**

**correlation** : float  
R value

**pvalue** : float  
2-tailed p-value

## Notes

Missing values are considered pair-wise: if a value is missing in *x*, the corresponding value in *y* is masked.

For more details on `pointbiserialr`, see `stats.pointbiserialr`.

`scipy.stats.mstats.rankdata` (*data*, *axis*=None, *use\_missing*=False)

Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if `use_missing` is False, or set to the average rank of the unmasked values if `use_missing` is True.

**Parameters**

- data** : sequence  
Input data. The data is transformed to a masked array
- axis** : {None,int}, optional  
Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2
- use\_missing** : bool, optional  
Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

`scipy.stats.mstats.scoreatpercentile` (*data, per, limit=(), alphap=0.4, betap=0.4*)

Calculate the score at the given 'per' percentile of the sequence a. For example, the score at per=50 is the median.

This function is a shortcut to `mquantile`

`scipy.stats.mstats.sem` (*a, axis=0, ddof=1*)

Calculates the standard error of the mean of the input array.

Also sometimes called standard error of measurement.

**Parameters**

- a** : array\_like  
An array containing the values for which the standard error is returned.
- axis** : int or None, optional  
If axis is None, ravel *a* first. If axis is an integer, this will be the axis over which to operate. Defaults to 0.
- ddof** : int, optional  
Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

**Returns**

- s** : ndarray or float  
The standard error of the mean in the sample(s), along the input axis.

### Notes

The default value for `ddof` changed in scipy 0.15.0 to be consistent with `stats.sem` as well as with the most common definition used (like in the R documentation).

### Examples

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5, 4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903 2.8284271247461903 2.8284271247461903
 2.8284271247461903]
```

Find standard error across the whole array, using n degrees of freedom:

```
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

`scipy.stats.mstats.signaltonoise` (*\*args, \*\*kws*)

`signaltonoise` is deprecated! `mstats.signaltonoise` is deprecated in scipy 0.16.0

*Calculates the signal-to-noise ratio, as the ratio of the mean over standard deviation along the given axis.*

**Parameters**

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>data</b> : sequence | Input data                                                                                                              |
| <b>axis</b>            | [[0, int], optional] Axis along which to compute. If None, the computation is performed on a flat version of the array. |

`scipy.stats.mstats.skew(a, axis=0, bias=True)`

Computes the skewness of a data set.

**Parameters**

|                                     |                                                                                                         |
|-------------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>a</b> : ndarray                  | data                                                                                                    |
| <b>axis</b> : int or None, optional | Axis along which skewness is calculated. Default is 0. If None, compute over the whole array <i>a</i> . |
| <b>bias</b> : bool, optional        | If False, then the calculations are corrected for statistical bias.                                     |

**Returns**

|                           |                                                                               |
|---------------------------|-------------------------------------------------------------------------------|
| <b>skewness</b> : ndarray | The skewness of values along an axis, returning 0 where all values are equal. |
|---------------------------|-------------------------------------------------------------------------------|

#### Notes

For more details about `skew`, see `stats.skew`.

`scipy.stats.mstats.skewtest(a, axis=0)`

Tests whether the skew is different from the normal distribution.

**Parameters**

|                                     |                                                                                                            |
|-------------------------------------|------------------------------------------------------------------------------------------------------------|
| <b>a</b> : array                    | The data to be tested                                                                                      |
| <b>axis</b> : int or None, optional | Axis along which statistics are calculated. Default is 0. If None, compute over the whole array <i>a</i> . |

**Returns**

|                          |                                           |
|--------------------------|-------------------------------------------|
| <b>statistic</b> : float | The computed z-score for this test.       |
| <b>pvalue</b> : float    | a 2-sided p-value for the hypothesis test |

#### Notes

For more details about `skewtest`, see `stats.skewtest`.

`scipy.stats.mstats.spearmanr(x, y, use_ties=True)`

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

Missing values are discarded pair-wise: if a value is missing in *x*, the corresponding value in *y* is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

|                       |                                     |
|-----------------------|-------------------------------------|
| <b>x</b> : array_like | The length of <i>x</i> must be > 2. |
| <b>y</b> : array_like |                                     |

The length of *y* must be > 2.

**Returns**

- use\_ties** : bool, optional  
Whether the correction for ties should be computed.
- correlation** : float  
Spearman correlation coefficient
- pvalue** : float  
2-tailed p-value.

[CRCProbStat2000] section 14.7

`scipy.stats.mstats.theilslopes` (*y*, *x=None*, *alpha=0.95*)

Computes the Theil-Sen estimator for a set of points (*x*, *y*).

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

**Parameters**

- y** : array\_like  
Dependent variable.
- x** : array\_like or None, optional  
Independent variable. If None, use `arange(len(y))` instead.
- alpha** : float, optional  
Confidence degree between 0 and 1. Default is 95% confidence. Note that *alpha* is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

**Returns**

- medslope** : float  
Theil slope.
- medintercept** : float  
Intercept of the Theil line, as `median(y) - medslope*median(x)`.
- lo\_slope** : float  
Lower bound of the confidence interval on *medslope*.
- up\_slope** : float  
Upper bound of the confidence interval on *medslope*.

**Notes**

For more details on `theilslopes`, see `stats.theilslopes`.

`scipy.stats.mstats.threshold` (*\*args*, *\*\*kws*)

`threshold` is deprecated! `mstats.threshold` is deprecated in scipy 0.17.0

Clip array to a given value.

Similar to `numpy.clip()`, except that values less than *threshmin* or greater than *threshmax* are replaced by *newval*, instead of by *threshmin* and *threshmax* respectively.

**Parameters**

- a** : ndarray  
Input data
- threshmin** : [{None, float}, optional]  
Lower threshold. If None, set to the minimum value.
- threshmax** : [{None, float}, optional]  
Upper threshold. If None, set to the maximum value.
- newval** : [{0, float}, optional]  
Value outside the thresholds.

**Returns**

- threshold** : ndarray  
Returns *a*, with values less than *threshmin* and values greater *threshmax* replaced with *newval*.

`scipy.stats.mstats.tmax(a, upperlimit=None, axis=0, inclusive=True)`

Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- a** : array\_like  
array of values
- upperlimit** : None or float, optional  
Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional  
This flag determines whether values exactly equal to the upper limit are included. The default value is True.

**Returns**

- tmax** : float, int or ndarray

#### Notes

For more details on `tmax`, see `stats.tmax`.

`scipy.stats.mstats.tmean(a, limits=None, inclusive=(True, True), axis=None)`

Compute the trimmed mean.

**Parameters**

- a** : array\_like  
Array of values.
- limits** : None or (lower limit, upper limit), optional  
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- inclusive** : (bool, bool), optional  
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** : int or None, optional  
Axis along which to operate. If None, compute over the whole array. Default is None.

**Returns**

- tmean** : float

#### Notes

For more details on `tmean`, see `stats.tmean`.

`scipy.stats.mstats.tmin(a, lowerlimit=None, axis=0, inclusive=True)`

Compute the trimmed minimum

**Parameters**

- a** : array\_like  
array of values
- lowerlimit** : None or float, optional  
Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** : {True, False}, optional

**Returns** `tmin` : float, int or ndarray

This flag determines whether values exactly equal to the lower limit are included. The default value is True.

**Notes**

For more details on `tmin`, see `stats.tmin`.

`scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), relative=False, axis=None)`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters** `a` : sequence  
 Input array

`limits` : {None, tuple}, optional  
 If `relative` is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If `relative` is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting `n` the number of unmasked data before trimming, the  $(n*\text{limits}[0])$ th smallest data and the  $(n*\text{limits}[1])$ th largest data are masked, and the total number of unmasked data after trimming is  $n*(1-\text{sum}(\text{limits}))$ . In each case, the value of one limit can be set to None to indicate an open interval. If `limits` is None, no trimming is performed

`inclusive` : {(bool, bool) tuple}, optional  
 If `relative` is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If `relative` is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

`relative` : bool, optional  
 Whether to consider the limits as absolute values (False) or proportions to cut (True).

`axis` : int, optional  
 Axis along which to trim.

**Examples**

```
>>> from scipy.stats.mstats import trim
>>> z = [ 1, 2, 3, 4, 5, 6, 7, 8, 9,10]
>>> print(trim(z, (3,8)))
[-- -- 3 4 5 6 7 8 -- --]
>>> print(trim(z, (0.1,0.2), relative=True))
[-- 2 3 4 5 6 7 8 -- --]
```

`scipy.stats.mstats.trimma(a, limits=None, inclusive=(True, True))`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters** `a` : array\_like  
 Input array.

`limits` : {None, tuple}, optional  
 Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.

`inclusive` : (bool, bool) tuple, optional

Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.

`scipy.stats.mstats.trimboth` (*data*, *proportiontocut*=0.2, *inclusive*=(*True*, *True*), *axis*=*None*)

Trims the smallest and largest data values.

Trims the *data* by masking the `int` (`proportiontocut * n`) smallest and `int` (`proportiontocut * n`) largest values of data along the given axis, where *n* is the number of unmasked values before trimming.

**Parameters**    **data** : ndarray

Data to trim.

**proportiontocut** : float, optional

Percentage of trimming (as a float between 0 and 1). If *n* is the number of unmasked values before trimming, the number of values after trimming is  $(1 - 2 * \text{proportiontocut}) * n$ . Default is 0.2.

**inclusive** : {(bool, bool) tuple}, optional

Tuple indicating whether the number of data being masked on each side should be rounded (*True*) or truncated (*False*).

**axis** : int, optional

Axis along which to perform the trimming. If *None*, the input array is first flattened.

`scipy.stats.mstats.trimmed_stde` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *axis*=*None*)

Returns the standard error of the trimmed mean along the given axis.

**Parameters**    **a** : sequence

Input array

**limits** : {(0.1,0.1), tuple of float}, optional

tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.

If *n* is the number of unmasked data before trimming, the values smaller than  $n * \text{limits}[0]$  and the values larger than  $n * \text{limits}[1]$  are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . In each case, the value of one limit can be set to *None* to indicate an open interval. If *limits* is *None*, no trimming is performed.

**inclusive** : {(bool, bool) tuple} optional

Tuple indicating whether the number of data being masked on each side should be rounded (*True*) or truncated (*False*).

**axis** : int, optional

Axis along which to trim.

**Returns**        **trimmed\_stde** : scalar or ndarray

`scipy.stats.mstats.trimr` (*a*, *limits*=*None*, *inclusive*=(*True*, *True*), *axis*=*None*)

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

**Parameters**    **a** : sequence

Input array.

**limits** : {None, tuple}, optional

Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting *n* the number of unmasked data before trimming, the  $(n * \text{limits}[0])$ th smallest data and the  $(n * \text{limits}[1])$ th largest data are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . The value of one limit can be set to *None* to indicate an open interval.

**inclusive** : {(True, True) tuple}, optional

Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.

**axis** : {None,int}, optional

Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

`scipy.stats.mstats.trimtail` (*data*, *proportiontocut*=0.2, *tail*='left', *inclusive*=(True, True), *axis*=None)

Trims the data by masking values from one tail.

**Parameters** **data** : array\_like

Data to trim.

**proportiontocut** : float, optional

Percentage of trimming. If *n* is the number of unmasked values before trimming, the number of values after trimming is  $(1 - \text{proportiontocut}) * n$ . Default is 0.2.

**tail** : {'left','right'}, optional

If 'left' the *proportiontocut* lowest values will be masked. If 'right' the *proportiontocut* highest values will be masked. Default is 'left'.

**inclusive** : {(bool, bool) tuple}, optional

Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).

**axis** : int, optional

Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

**Returns** **trimtail** : ndarray

Returned array of same shape as *data* with masked tail values.

`scipy.stats.mstats.tsem` (*a*, *limits*=None, *inclusive*=(True, True), *axis*=0, *ddof*=1)

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

**Parameters** **a** : array\_like

array of values

**limits** : None or (lower limit, upper limit), optional

Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** : (bool, bool), optional

A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** : int or None, optional

Axis along which to operate. If None, compute over the whole array. Default is zero.

**ddof** : int, optional

Delta degrees of freedom. Default is 1.

**Returns** **tsem** : float

### Notes

For more details on `tsem`, see `stats.tsem`.

`scipy.stats.mstats.ttest_onesamp` (*a*, *popmean*, *axis*=0)

Calculates the T-test for the mean of ONE group of scores.

**Parameters** **a** : array\_like

sample observation  
**popmean** : float or array\_like  
 expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension  
**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole array

**Returns** **statistic** : float or array  
<sup>*a*</sup>  
 t-statistic  
**pvalue** : float or array  
 two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

`scipy.stats.mstats.ttest_ind(a, b, axis=0, equal_var=True)`  
 Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

**Parameters** **a, b** : array\_like  
 The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).  
**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.  
**equal\_var** : bool, optional  
 If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch's t-test, which does not assume equal population variance. .. versionadded:: 0.17.0

**Returns** **statistic** : float or array  
 The calculated t-statistic.  
**pvalue** : float or array  
 The two-tailed p-value.

**Notes**

For more details on `ttest_ind`, see `stats.ttest_ind`.

`scipy.stats.mstats.ttest_onesamp(a, popmean, axis=0)`  
 Calculates the T-test for the mean of ONE group of scores.

**Parameters** **a** : array\_like  
 sample observation  
**popmean** : float or array\_like  
 expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension  
**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole array

**Returns** **statistic** : float or array  
<sup>*a*</sup>  
 t-statistic  
**pvalue** : float or array  
 two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

`scipy.stats.mstats.ttest_rel(a, b, axis=0)`  
 Calculates the T-test on TWO RELATED samples of scores, a and b.

**Parameters** **a, b** : array\_like  
 The arrays must have the same shape.  
**axis** : int or None, optional  
 Axis along which to compute test. If None, compute over the whole arrays,  
**Returns** **statistic** : float or array  
*a*, and *b*.  
 t-statistic  
**pvalue** : float or array  
 two-tailed p-value

**Notes**

For more details on `ttest_rel`, see `stats.ttest_rel`.

`scipy.stats.mstats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

**Parameters** **a** : array\_like  
 Array of values.  
**limits** : None or (lower limit, upper limit), optional  
 Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.  
**inclusive** : (bool, bool), optional  
 A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).  
**axis** : int or None, optional  
 Axis along which to operate. If None, compute over the whole array. Default is zero.  
**ddof** : int, optional  
 Delta degrees of freedom. Default is 1.  
**Returns** **tvar** : float  
 Trimmed variance.

**Notes**

For more details on `tvar`, see `stats.tvar`.

`scipy.stats.mstats.variation` (*a*, *axis=0*)

Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.

**Parameters** **a** : array\_like  
 Input array.  
**axis** : int or None, optional  
 Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.  
**Returns** **variation** : ndarray  
 The calculated variation along the requested axis.

**Notes**

For more details about `variation`, see `stats.variation`.

`scipy.stats.mstats.winsorize` (*a*, *limits=None*, *inclusive=(True, True)*, *inplace=False*, *axis=None*)

Returns a Winsorized version of the input array.

The `(limits[0])`th lowest values are set to the `(limits[0])`th percentile, and the `(limits[1])`th highest values are set to the `(1 - limits[1])`th percentile. Masked values are skipped.

**Parameters**

- a** : sequence  
Input array.
- limits** : {None, tuple of float}, optional  
Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting `n` the number of unmasked data before trimming, the `(n*limits[0])`th smallest data and the `(n*limits[1])`th largest data are masked, and the total number of unmasked data after trimming is `n*(1.-sum(limits))`. The value of one limit can be set to None to indicate an open interval.
- inclusive** : {(True, True) tuple}, optional  
Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- inplace** : {False, True}, optional  
Whether to winsorize in place (True) or to use a copy (False)
- axis** : {None, int}, optional  
Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

### Notes

This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

`scipy.stats.mstats.zmap(scores, compare, axis=0, ddof=0)`  
Calculates the relative z-scores.

Returns an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

**Parameters**

- scores** : array\_like  
The input for which z-scores are calculated.
- compare** : array\_like  
The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as `scores`.
- axis** : int or None, optional  
Axis over which mean and variance of `compare` are calculated. Default is 0. If None, compute over the whole array `scores`.
- ddof** : int, optional  
Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
Z-scores, in the same shape as `scores`.

### Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses `asanyarray` instead of `asarray` for parameters).

### Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
```

`scipy.stats.mstats.zscore(a, axis=0, ddof=0)`

Calculates the z score of each value in the sample, relative to the sample mean and standard deviation.

**Parameters**

- a** : array\_like  
An array like object containing the sample data.
- axis** : int or None, optional  
Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** : int, optional  
Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

- zscore** : array\_like  
The z-scores, standardized by mean and standard deviation of input array *a*.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

**Examples**

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...              0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```
>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...              [ 0.7149,  0.0775,  0.6072,  0.9656],
...              [ 0.6341,  0.1403,  0.9759,  0.4064],
...              [ 0.5918,  0.6948,  0.904 ,  0.3721],
...              [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823, -1.28415119,  1.07259584,  0.40420358],
       [  0.33048416, -1.37380874,  0.04251374,  1.00081084],
       [  0.26796377, -1.12598418,  1.23283094, -0.37481053],
       [ -0.22095197,  0.24468594,  1.19042819, -1.21416216],
       [ -0.82780366,  1.4457416 , -0.43867764, -0.1792603 ]])
```

`scipy.stats.mstats.compare_medians_ms(group_1, group_2, axis=None)`

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

**Parameters**

- group\_1** : array\_like  
First dataset.
- group\_2** : array\_like  
Second dataset.
- axis** : int, optional  
Axis along which the medians are estimated. If None, the arrays are flattened. If *axis* is not None, then *group\_1* and *group\_2* should have the same shape.

**Returns**

- compare\_medians\_ms** : {float, ndarray}  
If *axis* is None, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of *group\_1* along *axis*.

`scipy.stats.mstats.gmean` (*a*, *axis=0*, *dtype=None*)

Compute the geometric mean along the specified axis.

Returns the geometric average of the array elements. That is:  $n$ -th root of  $(x_1 * x_2 * \dots * x_n)$

**Parameters**

- a** : array\_like  
Input array or object that can be converted to an array.
- axis** : int or None, optional  
Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** : dtype, optional  
Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- gmean** : ndarray  
see dtype parameter above

**See also:**

`numpy.mean` Arithmetic average

`numpy.average`

Weighted average

`hmean`

Harmonic mean

**Notes**

The geometric average is computed over a single dimension of the input array, *axis=0* by default, or all values in the array if *axis=None*. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

`scipy.stats.mstats.hdmedian` (*data*, *axis=-1*, *var=False*)

Returns the Harrell-Davis estimate of the median along the given axis.

**Parameters**

- data** : ndarray  
Data array.
- axis** : int, optional  
Axis along which to compute the quantiles. If None, use a flattened array.
- var** : bool, optional  
Whether to return the variance of the estimate.

`scipy.stats.mstats.hdquantiles` (*data*, *prob=[0.25, 0.5, 0.75]*, *axis=None*, *var=False*)

Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

**Parameters**

- data** : array\_like  
Data array.
- prob** : sequence, optional  
Sequence of quantiles to compute.
- axis** : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.
- var** : bool, optional  
Whether to return the variance of the estimate.

**Returns**

- hdquantiles** : MaskedArray  
A (p,) array of quantiles (if *var* is False), or a (2,p) array of quantiles and variances (if *var* is True), where *p* is the number of quantiles.

`scipy.stats.mstats.hdquantiles_sd` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

The standard error of the Harrell-Davis quantile estimates by jackknife.

**Parameters**

- data** : array\_like  
Data array.
- prob** : sequence, optional  
Sequence of quantiles to compute.
- axis** : int, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

- hdquantiles\_sd** : MaskedArray  
Standard error of the Harrell-Davis quantile estimates.

`scipy.stats.mstats.hmean` (*a*, *axis*=0, *dtype*=None)

Calculates the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

**Parameters**

- a** : array\_like  
Input array, masked array or object that can be converted to an array.
- axis** : int or None, optional  
Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** : dtype, optional  
Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- hmean** : ndarray  
see *dtype* parameter above

See also:

[\*numpy.mean\*](#) Arithmetic average  
[\*numpy.average\*](#) Weighted average  
[\*gmean\*](#) Geometric mean

**Notes**

The harmonic mean is computed over a single dimension of the input array, *axis*=0 by default, or all values in the array if *axis*=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

`scipy.stats.mstats.idealfourths` (*data*, *axis*=None)

Returns an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

**Parameters**

- data** : array\_like  
Input array.
- axis** : int, optional  
Axis along which the quartiles are estimated. If None, the arrays are flattened.

**Returns**

- idealfourths** : {list of floats, masked array}  
Returns the two internal values that divide *data* into four parts using the ideal fourths algorithm either along the flattened array (if *axis* is None) or along *axis* of *data*.

`scipy.stats.mstats.kruskal(*args)`

Compute the Kruskal-Wallis H-test for independent samples

**Parameters** `sample1, sample2, ...` : array\_like  
Two or more arrays with the sample measurements can be given as arguments.

**Returns** `statistic` : float  
The Kruskal-Wallis H statistic, corrected for ties

`pvalue` : float  
The p-value for the test using the assumption that H has a chi square distribution

#### Notes

For more details on `kruskal`, see `stats.kruskal`.

`scipy.stats.mstats.ks_2samp(data1, data2, alternative='two-sided')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters** `data1` : array\_like  
First data set

`data2` : array\_like  
Second data set

`alternative` : {'two-sided', 'less', 'greater'}, optional  
Indicates the alternative hypothesis. Default is 'two-sided'.

**Returns** `d` : float  
Value of the Kolmogorov Smirnov test

`p` : float  
Corresponding p-value.

`scipy.stats.mstats.median_cihs(data, alpha=0.05, axis=None)`

Computes the alpha-level confidence interval for the median of the data.

Uses the Hettmasperger-Sheather method.

**Parameters** `data` : array\_like  
Input data. Masked values are discarded. The input should be 1D only, or `axis` should be set to None.

`alpha` : float, optional  
Confidence level of the intervals.

`axis` : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

**Returns** `median_cihs`  
Alpha level confidence interval.

`scipy.stats.mstats.meppf(data, alpha=0.4, beta=0.4)`

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as  $(i-\alpha)/(n+1-\alpha-\beta)$ , where:*

- $i$  is the rank order statistics
- $n$  is the number of unmasked values along the given axis
- $\alpha$  and  $\beta$  are two parameters.

*Typical values for alpha and beta are:*

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5) :  $p(k) = (k-1/2)/n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k/(n+1)$ , Weibull (R type 6)

- (1,1) :  $p(k) = (k-1)/(n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3)/(n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8)/(n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

**data** : array\_like  
Input data, as a sequence or array of dimension at most 2.

**alpha** : float, optional  
Plotting positions parameter. Default is 0.4.

**beta** : float, optional  
Plotting positions parameter. Default is 0.4.

**Returns**

**positions** : MaskedArray  
The calculated plotting positions.

`scipy.stats.mstats.mjci` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

**Parameters**

**data** : ndarray  
Data array.

**prob** : sequence, optional  
Sequence of quantiles to compute.

**axis** : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

`scipy.stats.mstats.mquantiles_cimj` (*data*, *prob*=[0.25, 0.5, 0.75], *alpha*=0.05, *axis*=None)

Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

**Parameters**

**data** : ndarray  
Data array.

**prob** : sequence, optional  
Sequence of quantiles to compute.

**alpha** : float, optional  
Confidence level of the intervals.

**axis** : int or None, optional  
Axis along which to compute the quantiles. If None, use a flattened array.

`scipy.stats.mstats.rsh` (*data*, *points*=None)

Evaluates Rosenblatt's shifted histogram estimators for each point on the dataset 'data'.

**Parameters**

**data** : sequence  
Input data. Masked values are ignored.

**points** : sequence or None, optional  
Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.

`scipy.stats.mstats.sen_seasonal_slopes` (*x*)

`scipy.stats.mstats.trimmed_mean` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *relative*=True, *axis*=None)

`scipy.stats.mstats.trimmed_mean_ci` (*data*, *limits*=(0.2, 0.2), *inclusive*=(True, True), *alpha*=0.05, *axis*=None)

Selected confidence interval of the trimmed mean along the given axis.

**Parameters**

- data** : array\_like  
Input data.
- limits** : {None, tuple}, optional  
None or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If *n* is the number of unmasked data before trimming, then (*n* \* *limits*[0])th smallest data and (*n* \* *limits*[1])th largest data are masked. The total number of unmasked data after trimming is *n* \* (1. - sum(*limits*)). The value of one limit can be set to None to indicate an open interval.  
Defaults to (0.2, 0.2).
- inclusive** : (2,) tuple of boolean, optional  
If *relative*==False, tuple indicating whether values exactly equal to the absolute limits are allowed. If *relative*==True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).  
Defaults to (True, True).
- alpha** : float, optional  
Confidence level of the intervals.  
Defaults to 0.05.
- axis** : int, optional  
Axis along which to cut. If None, uses a flattened version of *data*.  
Defaults to None.

**Returns**

- trimmed\_mean\_ci** : (2,) ndarray  
The lower and upper confidence intervals of the trimmed data.

`scipy.stats.mstats.trimmed_std` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *relative*=True, *axis*=None, *ddof*=0)

`scipy.stats.mstats.trimmed_var` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *relative*=True, *axis*=None, *ddof*=0)

`scipy.stats.mstats.ttest_1samp` (*a*, *popmean*, *axis*=0)

Calculates the T-test for the mean of ONE group of scores.

**Parameters**

- a** : array\_like  
sample observation
- popmean** : float or array\_like  
expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension
- axis** : int or None, optional  
Axis along which to compute test. If None, compute over the whole array

**Returns**

- statistic** : float or array  
*a*.  
t-statistic
- pvalue** : float or array  
two-tailed p-value

#### Notes

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

## 5.29 Low-level callback functions

Some functions in SciPy take as arguments callback functions, which can either be python callables or low-level compiled functions. Using compiled callback functions can improve performance somewhat by avoiding wrapping data in Python objects.

Such low-level functions in Scipy are wrapped in `LowLevelCallable` objects, which can be constructed from function pointers obtained from ctypes, cffi, Cython, or contained in Python `PyCapsule` objects.

---

`LowLevelCallable`    Low-level callback function.

---

**class** `scipy.LowLevelCallable`

Low-level callback function.

**Parameters**

- function** : {PyCapsule, ctypes function pointer, cffi function pointer}  
Low-level callback function.
- user\_data** : {PyCapsule, ctypes void pointer, cffi void pointer}  
User data to pass on to the callback function.
- signature** : str, optional  
Signature of the function. If omitted, determined from *function*, if possible.

### Notes

The argument `function` can be one of:

- PyCapsule, whose name contains the C function signature
- ctypes function pointer
- cffi function pointer

The signature of the low-level callback must match one of those expected by the routine it is passed to.

If constructing low-level functions from a PyCapsule, the name of the capsule must be the corresponding signature, in the format:

```
return_type (arg1_type, arg2_type, ...)
```

For example:

```
"void (double)"
"double (double, int *, void *)"
```

The context of a PyCapsule passed in as `function` is used as `user_data`, if an explicit value for `user_data` was not given.

### Attributes

|                        |                            |
|------------------------|----------------------------|
| <code>function</code>  | Callback function given    |
| <code>user_data</code> | User data given            |
| <code>signature</code> | Signature of the function. |

### Methods

---

`from_cython(module, name[, user_data, signature])`    Create a low-level callback function from an exported Cython function.

---

**classmethod** `LowLevelCallable.from_cython` (*module*, *name*, *user\_data=None*, *signature=None*)

Create a low-level callback function from an exported Cython function.

**Parameters**

- module** : module  
Cython module where the exported function resides
- name** : str  
Name of the exported function
- user\_data** : {PyCapsule, ctypes void pointer, cffi void pointer}, optional  
User data to pass on to the callback function.
- signature** : str, optional  
Signature of the function. If omitted, determined from *function*.

**See also:**

Functions accepting low-level callables:

`scipy.integrate.quad`, `scipy.ndimage.generic_filter`, `scipy.ndimage.generic_filter1d`,  
`scipy.ndimage.geometric_transform`
