- info** [int] Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown

## Notes

The LGMRES algorithm [1] [2] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the *outer\_v* argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

## Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = lgmres(A, b)
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

## scipy.sparse.linalg.minres

`scipy.sparse.linalg.minres` (*A*, *b*, *x0=None*, *shift=0.0*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *show=False*, *check=False*)

Use MINimum RESidual iteration to solve  $Ax=b$

MINRES minimizes  $\text{norm}(A*x - b)$  for a real symmetric matrix *A*. Unlike the Conjugate Gradient method, *A* can be indefinite or singular.

If *shift*  $\neq 0$  then the method solves  $(A - \text{shift}*I)x = b$

### Parameters

- A** [{sparse matrix, dense matrix, LinearOperator}] The real symmetric N-by-N matrix of the linear system Alternatively, *A* can be a linear operator which can produce  $Ax$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

### Returns

- x** [{array, matrix}] The converged solution.
- info** [integer]

#### Provides convergence information:

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

### Other Parameters

<b>x0</b>	[[array, matrix]] Starting guess for the solution.
<b>tol</b>	[float] Tolerance to achieve. The algorithm terminates when the relative residual is below <i>tol</i> .
<b>maxiter</b>	[integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
<b>M</b>	[[sparse matrix, dense matrix, LinearOperator]] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
<b>callback</b>	[function] User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

## Examples

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import minres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> A = A + A.T
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = minres(A, b)
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

## scipy.sparse.linalg.qmr

scipy.sparse.linalg.**qmr**(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, callback=None, atol=None)

Use Quasi-Minimal Residual iteration to solve  $Ax = b$ .

### Parameters

<b>A</b>	[[sparse matrix, dense matrix, LinearOperator]] The real-valued N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce $Ax$ and $A^T x$ using, e.g., <code>scipy.sparse.linalg.LinearOperator</code> .
<b>b</b>	[[array, matrix]] Right hand side of the linear system. Has shape (N,) or (N,1).

### Returns

<b>x</b>	[[array, matrix]] The converged solution.
<b>info</b>	[integer]

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

**x0** [[array, matrix]] Starting guess for the solution.  
**tol, atol** [[float, optional]] Tolerances for convergence,  $\text{norm}(\text{residual}) \leq \max(\text{tol} \cdot \text{norm}(b), \text{atol})$ . The default for `atol` is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

**maxiter** [integer] Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.  
**M1** [{sparse matrix, dense matrix, LinearOperator}] Left preconditioner for A.  
**M2** [{sparse matrix, dense matrix, LinearOperator}] Right preconditioner for A. Used together with the left preconditioner M1. The matrix  $M1 * A * M2$  should have better conditioned than A alone.  
**callback** [function] User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

See also:

[LinearOperator](#)

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import qmr
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = qmr(A, b)
>>> print(exitCode)           # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

**scipy.sparse.linalg.gcrotmk**

`scipy.sparse.linalg.gcrotmk`(*A, b, x0=None, tol=1e-05, maxiter=1000, M=None, callback=None, m=20, k=None, CU=None, discard\_C=False, truncate='oldest', atol=None*)

Solve a matrix equation using flexible GCROT(m,k) algorithm.

**Parameters**

**A** [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce  $Ax$  using, e.g., `scipy.sparse.linalg.LinearOperator`.  
**b** [[array, matrix]] Right hand side of the linear system. Has shape (N,) or (N,1).  
**x0** [[array, matrix]] Starting guess for the solution.

**tol, atol** [float, optional] Tolerances for convergence,  $\text{norm}(\text{residual}) \leq \max(\text{tol} * \text{norm}(b), \text{atol})$ . The default for *atol* is *tol*.

**Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

**maxiter** [int, optional] Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.

**M** [{sparse matrix, dense matrix, LinearOperator}, optional] Preconditioner for A. The preconditioner should approximate the inverse of A. *gcrotmk* is a ‘flexible’ algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** [function, optional] User-supplied function to call after each iteration. It is called as *callback(xk)*, where *xk* is the current solution vector.

**m** [int, optional] Number of inner FGMRES iterations per each outer iteration. Default: 20

**k** [int, optional] Number of vectors to carry between inner FGMRES iterations. According to [2], good values are around *m*. Default: *m*

**CU** [list of tuples, optional] List of tuples (*c*, *u*) which contain the columns of the matrices C and U in the GCROT(*m*,*k*) algorithm. For details, see [2]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The *c* elements in the tuples can be `None`, in which case the vectors are recomputed via  $c = A u$  on start and orthogonalized as described in [3].

**discard\_C** [bool, optional] Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.

**truncate** [{‘oldest’, ‘smallest’}, optional] Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [2] for detailed comparison. Default: ‘oldest’

**Returns**

**x** [array or matrix] The solution found.

**info** [int] Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations

**References**

[1], [2], [3]

Iterative methods for least-squares problems:

<code>lsqr(A, b[, damp, atol, btol, conlim, ...])</code>	Find the least-squares solution to a large, sparse, linear system of equations.
<code>lsmr(A, b[, damp, atol, btol, conlim, ...])</code>	Iterative solver for least-squares problems.

**scipy.sparse.linalg.lsqr**

```
scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=100000000.0,
                          iter_lim=None, show=False, calc_var=False, x0=None)
```

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves  $Ax = b$  or  $\min \|Ax - b\|^2$  or  $\min \|Ax - b\|^2 + d^2 \|x\|^2$ .

The matrix  $A$  may be square or rectangular (over-determined or under-determined), and may have any rank.

1. Unsymmetric equations -- solve  $A*x = b$
2. Linear least squares -- solve  $A*x = b$   
in the least-squares sense
3. Damped least squares -- solve  $\begin{pmatrix} A \\ \text{damp}*I \end{pmatrix} * x = \begin{pmatrix} b \\ 0 \end{pmatrix}$   
in the least-squares sense

**Parameters**

- A** [{sparse matrix, ndarray, LinearOperator}] Representation of an m-by-n matrix. Alternatively, A can be a linear operator which can produce  $Ax$  and  $A^T x$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** [array\_like, shape (m,)] Right-hand side vector b.
- damp** [float] Damping coefficient.
- atol, btol** [float, optional] Stopping tolerances. If both are  $1.0e-9$  (say), the final residual norm should be accurate to about 9 digits. (The final  $x$  will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of  $\text{damp}$ .)
- conlim** [float, optional] Another stopping tolerance. `lsqr` terminates if an estimate of  $\text{cond}(A)$  exceeds *conlim*. For compatible systems  $Ax = b$ , *conlim* could be as large as  $1.0e+12$  (say). For least-squares problems, *conlim* should be less than  $1.0e+8$ . Maximum precision can be obtained by setting  $\text{atol} = \text{btol} = \text{conlim} = \text{zero}$ , but the number of iterations may then be excessive.
- iter\_lim** [int, optional] Explicit limitation on number of iterations (for safety).
- show** [bool, optional] Display an iteration log.
- calc\_var** [bool, optional] Whether to estimate diagonals of  $(A^T A + \text{damp}^2 I)^{-1}$ .
- x0** [array\_like, shape (n), optional] Initial guess of  $x$ , if None zeros are used.  
New in version 1.0.0.

**Returns**

- x** [ndarray of float] The final solution.
- istop** [int] Gives the reason for termination. 1 means  $x$  is an approximate solution to  $Ax = b$ . 2 means  $x$  approximately solves the least-squares problem.
- itn** [int] Iteration number upon termination.
- r1norm** [float]  $\text{norm}(r)$ , where  $r = b - Ax$ .
- r2norm** [float]  $\sqrt{\text{norm}(r)^2 + \text{damp}^2 * \text{norm}(x)^2}$ . Equal to *r1norm* if  $\text{damp} == 0$ .
- anorm** [float] Estimate of Frobenius norm of  $A_{\text{bar}} = \begin{bmatrix} A \\ \text{damp}*I \end{bmatrix}$ .
- acond** [float] Estimate of  $\text{cond}(A_{\text{bar}})$ .
- arnorm** [float] Estimate of  $\text{norm}(A^T * r - \text{damp}^2 * x)$ .
- xnorm** [float]  $\text{norm}(x)$
- var** [ndarray of float] If *calc\_var* is True, estimates all diagonals of  $(A^T A)^{-1}$  (if  $\text{damp} == 0$ ) or more generally  $(A^T A + \text{damp}^2 I)^{-1}$ . This is well defined if  $A$  has full

column rank or  $\text{damp} > 0$ . (Not sure what var means if  $\text{rank}(A) < n$  and  $\text{damp} = 0$ .)

## Notes

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of  $A$  should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of  $A$  is very small or large compared to the other rows of  $A$ , the corresponding row of  $(A \ b)$  should be scaled up or down.

In problems 1 and 2, the solution  $x$  is easily recovered following column-scaling. Unless better information is known, the nonzero columns of  $A$  should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if  $\text{damp}$  is nonzero. However, the value of  $\text{damp}$  should be assigned only after attention has been paid to the scaling of  $A$ .

The parameter  $\text{damp}$  is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter  $\text{acon}$ , which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate  $x_0$  is known and if  $\text{damp} == 0$ , one could proceed as follows:

1. Compute a residual vector  $r_0 = b - A*x_0$ .
2. Use LSQR to solve the system  $A*dx = r_0$ .
3. Add the correction  $dx$  to obtain a final solution  $x = x_0 + dx$ .

This requires that  $x_0$  be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes  $k_1$  iterations to solve  $A*x = b$  and  $k_2$  iterations to solve  $A*dx = r_0$ . If  $x_0$  is “good”,  $\text{norm}(r_0)$  will be smaller than  $\text{norm}(b)$ . If the same stopping tolerances  $\text{atol}$  and  $\text{btol}$  are used for each system,  $k_1$  and  $k_2$  will be similar, but the final solution  $x_0 + dx$  should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value  $\text{btol}$  is suitable for  $A*x = b$ , the larger value  $\text{btol}*\text{norm}(b)/\text{norm}(r_0)$  should be suitable for  $A*dx = r_0$ .

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system  $M*x = b$  efficiently, where  $M$  approximates  $A$  in some helpful way (e.g.  $M - A$  has low rank or its elements are small relative to those of  $A$ ), LSQR may converge more rapidly on the system  $A*M(\text{inverse})*z = b$ , after which  $x$  can be recovered by solving  $M*x = z$ .

If  $A$  is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method ( $\text{cg}$ ) and/or SYMMLQ. SYMMLQ is an implementation of symmetric  $\text{cg}$  that applies to any symmetric  $A$  and will converge more rapidly than LSQR. If  $A$  is positive definite, there are other implementations of symmetric  $\text{cg}$  that require slightly less work per iteration than SYMMLQ (but will take the same number of iterations).

## References

[1], [2], [3]

## Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution  $[0, 0]$

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
The exact solution is x = 0
>>> istop
0
>>> x
array([ 0.,  0.]
```

The stopping code `istop=0` returned indicates that a vector of zeros was found as a solution. The returned solution `x` indeed contains  $[0, 0]$ . The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> r1norm
4.440892098500627e-16
```

As indicated by `istop=1`, `lsqr` found a solution obeying the tolerance limits. The given solution  $[1, -1]$  obviously solves the equation. The remaining return values include information about the number of iterations (`itn=1`) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333,  0.00333333])
>>> r1norm
0.005773502691896255
```

`istop` indicates that the system is inconsistent and thus `x` is rather an approximate solution to the corresponding least-squares problem. `r1norm` contains the norm of the minimal residual that was found.

**scipy.sparse.linalg.lsmr**

`scipy.sparse.linalg.lsmr(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False, x0=None)`

Iterative solver for least-squares problems.

`lsmr` solves the system of linear equations  $Ax = b$ . If the system is inconsistent, it solves the least-squares problem  $\min \|b - Ax\|_2$ .  $A$  is a rectangular matrix of dimension  $m$ -by- $n$ , where all cases are allowed:  $m = n$ ,  $m > n$ , or  $m < n$ .  $b$  is a vector of length  $m$ . The matrix  $A$  may be dense or sparse (usually sparse).

**Parameters**

- A** `[{matrix, sparse matrix, ndarray, LinearOperator}]` Matrix  $A$  in the linear system. Alternatively,  $A$  can be a linear operator which can produce  $Ax$  and  $A^H x$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** `[array_like, shape (m,)]` Vector  $b$  in the linear system.
- damp** `[float]` Damping factor for regularized least-squares. `lsmr` solves the regularized least-squares problem:

$$\min \begin{pmatrix} \|b - (A) x\| \\ \|(0) \quad (damp * I)\| \end{pmatrix}_2$$

- where `damp` is a scalar. If `damp` is `None` or `0`, the system is solved without regularization.
- atol, btol** `[float, optional]` Stopping tolerances. `lsmr` continues iterations until a certain backward error estimate is smaller than some quantity depending on `atol` and `btol`. Let  $r = b - Ax$  be the residual vector for the current approximate solution  $x$ . If  $Ax = b$  seems to be consistent, `lsmr` terminates when  $\text{norm}(r) \leq \text{atol} * \text{norm}(A) * \text{norm}(x) + \text{btol} * \text{norm}(b)$ . Otherwise, `lsmr` terminates when  $\text{norm}(A^H r) \leq \text{atol} * \text{norm}(A) * \text{norm}(r)$ . If both tolerances are  $1.0e-6$  (say), the final  $\text{norm}(r)$  should be accurate to about 6 digits. (The final  $x$  will usually have fewer correct digits, depending on  $\text{cond}(A)$  and the size of  $\text{LAMBDA}$ .) If `atol` or `btol` is `None`, a default value of  $1.0e-6$  will be used. Ideally, they should be estimates of the relative error in the entries of  $A$  and  $b$  respectively. For example, if the entries of  $A$  have 7 correct digits, set `atol = 1e-7`. This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.
- conlim** `[float, optional]` `lsmr` terminates if an estimate of  $\text{cond}(A)$  exceeds `conlim`. For compatible systems  $Ax = b$ , `conlim` could be as large as  $1.0e+12$  (say). For least-squares problems, `conlim` should be less than  $1.0e+8$ . If `conlim` is `None`, the default value is  $1e+8$ . Maximum precision can be obtained by setting `atol = btol = conlim = 0`, but the number of iterations may then be excessive.
- maxiter** `[int, optional]` `lsmr` terminates if the number of iterations reaches `maxiter`. The default is `maxiter = min(m, n)`. For ill-conditioned systems, a larger value of `maxiter` may be needed.
- show** `[bool, optional]` Print iterations logs if `show=True`.
- x0** `[array_like, shape (n,), optional]` Initial guess of  $x$ , if `None` zeros are used. New in version 1.0.0.

**Returns**

- x** `[ndarray of float]` Least-square solution returned.
- istop** `[int]` `istop` gives the reason for stopping:

```
istop = 0 means x=0 is a solution. If x0 was given,
↳ then x=x0 is a
    solution.
    = 1 means x is an approximate solution to A*x = B,
    according to atol and btol.
```

(continues on next page)

(continued from previous page)

```

    = 2 means x approximately solves the least-squares_
↪problem
    according to atol.
    = 3 means COND(A) seems to be greater than CONLIM.
    = 4 is the same as 1 with atol = btol = eps_
↪(machine
    precision)
    = 5 is the same as 2 with atol = eps.
    = 6 is the same as 3 with CONLIM = 1/eps.
    = 7 means ITN reached maxiter before the other_
↪stopping
    conditions were satisfied.

```

**itn** [int] Number of iterations used.  
**normr** [float] norm( $b - Ax$ )  
**normar** [float] norm( $A^H (b - Ax)$ )  
**norma** [float] norm( $A$ )  
**conda** [float] Condition number of  $A$ .  
**normx** [float] norm( $x$ )

## Notes

New in version 0.11.0.

## References

[1], [2]

## Examples

```

>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)

```

The first example has the trivial solution  $[0, 0]$

```

>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
0
>>> x
array([ 0.,  0.])

```

The stopping code `istop=0` returned indicates that a vector of zeros was found as a solution. The returned solution  $x$  indeed contains  $[0, 0]$ . The next example has a non-trivial solution:

```

>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
1

```

(continues on next page)

(continued from previous page)

```
>>> x
array([ 1., -1.])
>>> itn
1
>>> normr
4.440892098500627e-16
```

As indicated by *istop=1*, *lsmr* found a solution obeying the tolerance limits. The given solution  $[1., -1.]$  obviously solves the equation. The remaining return values include information about the number of iterations (*itm=1*) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333,  0.00333333])
>>> normr
0.005773502691896255
```

*istop* indicates that the system is inconsistent and thus  $x$  is rather an approximate solution to the corresponding least-squares problem. *normr* contains the minimal distance that was found.

## 6.24.5 Matrix factorizations

Eigenvalue problems:

<code>eigs(A[, k, M, sigma, which, v0, ncv, ...])</code>	Find $k$ eigenvalues and eigenvectors of the square matrix $A$ .
<code>eigsh(A[, k, M, sigma, which, v0, ncv, ...])</code>	Find $k$ eigenvalues and eigenvectors of the real symmetric square matrix or complex Hermitian matrix $A$ .
<code>lobpcg(A, X[, B, M, Y, tol, maxiter, ...])</code>	Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

### scipy.sparse.linalg.eigs

`scipy.sparse.linalg.eigs` ( $A$ ,  $k=6$ ,  $M=None$ ,  $sigma=None$ ,  $which='LM'$ ,  $v0=None$ ,  $ncv=None$ ,  $maxiter=None$ ,  $tol=0$ ,  $return_eigenvectors=True$ ,  $Minv=None$ ,  $OPinv=None$ ,  $OPpart=None$ )

Find  $k$  eigenvalues and eigenvectors of the square matrix  $A$ .

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

If  $M$  is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$

#### Parameters

<b>A</b>	[ndarray, sparse matrix or LinearOperator] An array, sparse matrix, or LinearOperator representing the operation $A * x$ , where $A$ is a real or complex square matrix.
<b>k</b>	[int, optional] The number of eigenvalues and eigenvectors desired. $k$ must be smaller than $N-1$ . It is not possible to compute all eigenvectors of a matrix.
<b>M</b>	[ndarray, sparse matrix or LinearOperator, optional] An array, sparse matrix, or LinearOperator representing the operation $M*x$ for the generalized eigenvalue problem $A * x = w * M * x.$ <p><math>M</math> must represent a real symmetric matrix if <math>A</math> is real, and must represent a complex Hermitian matrix if <math>A</math> is complex. For best results, the data type of <math>M</math> should be the same as that of <math>A</math>. Additionally:</p> <p>If <math>\sigma</math> is None, <math>M</math> is positive definite</p> <p>If <math>\sigma</math> is specified, <math>M</math> is positive semi-definite</p> <p>If <math>\sigma</math> is None, <code>eigs</code> requires an operator to compute the solution of the linear equation <math>M * x = b</math>. This is done internally via a (sparse) LU decomposition for an explicit matrix <math>M</math>, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator <code>Minv</code>, which gives <math>x = Minv * b = M^{-1} * b</math>.</p>
<b>sigma</b>	[real or complex, optional] Find eigenvalues near $\sigma$ using shift-invert mode. This requires an operator to compute the solution of the linear system $[A - \sigma * M] * x = b$ , where $M$ is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices $A$ & $M$ , or via an iterative solver if either $A$ or $M$ is a general linear operator. Alternatively, the user can supply the matrix or operator <code>OPinv</code> , which gives $x = OPinv * b = [A - \sigma * M]^{-1} * b$ . For a real matrix $A$ , shift-invert can either be done in imaginary mode or real mode, specified by the parameter <code>OPpart</code> ('r' or 'i'). Note that when $\sigma$ is specified, the keyword 'which' (below) refers to the shifted eigenvalues $w'[i]$ where: <p><b>If <math>A</math> is real and <code>OPpart == 'r'</code> (default),</b></p> $w'[i] = 1/2 * [1/(w[i]-\sigma) + 1/(w[i]-\text{conj}(\sigma))].$ <p><b>If <math>A</math> is real and <code>OPpart == 'i'</code>,</b></p> $w'[i] = 1/2i * [1/(w[i]-\sigma) - 1/(w[i]-\text{conj}(\sigma))].$ <p>If <math>A</math> is complex, <math>w'[i] = 1/(w[i]-\sigma)</math>.</p>
<b>v0</b>	[ndarray, optional] Starting vector for iteration. Default: random
<b>ncv</b>	[int, optional] The number of Lanczos vectors generated $ncv$ must be greater than $k$ ; it is recommended that $ncv > 2*k$ . Default: $\min(n, \max(2*k + 1, 20))$
<b>which</b>	[str, ['LM'   'SM'   'LR'   'SR'   'LI'   'SI'], optional] Which $k$ eigenvectors and eigenvalues to find: <p>'LM' : largest magnitude</p> <p>'SM' : smallest magnitude</p> <p>'LR' : largest real part</p> <p>'SR' : smallest real part</p> <p>'LI' : largest imaginary part</p> <p>'SI' : smallest imaginary part</p> <p>When <math>\sigma \neq \text{None}</math>, 'which' refers to the shifted eigenvalues <math>w'[i]</math> (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.</p>
<b>maxiter</b>	[int, optional] Maximum number of Arnoldi update iterations allowed Default: $n*10$
<b>tol</b>	[float, optional] Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.
<b>return_eigenvectors</b>	[bool, optional] Return eigenvectors (True) in addition to eigenvalues
<b>Minv</b>	[ndarray, sparse matrix or LinearOperator, optional] See notes in <code>M</code> , above.
<b>OPinv</b>	[ndarray, sparse matrix or LinearOperator, optional] See notes in <code>sigma</code> , above.
<b>OPpart</b>	[{'r' or 'i'}, optional] See notes in <code>sigma</code> , above

**Returns**

**w** [ndarray] Array of  $k$  eigenvalues.  
**v** [ndarray] An array of  $k$  eigenvectors.  $v[:, i]$  is the eigenvector corresponding to the eigenvalue  $w[i]$ .

**Raises**

**ArpackNoConvergence**

When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

**See also:**

**eigsh**

eigenvalues and eigenvectors for symmetric matrix  $A$

**svds**

singular value decomposition for a matrix  $A$

**Notes**

This function is a wrapper to the ARPACK [1] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [2].

**References**

[1], [2]

**Examples**

Find 6 eigenvectors of the identity matrix:

```
>>> from scipy.sparse.linalg import eigs
>>> id = np.eye(13)
>>> vals, vecs = eigs(id, k=6)
>>> vals
array([ 1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j,  1.+0.j])
>>> vecs.shape
(13, 6)
```

**scipy.sparse.linalg.eigsh**

`scipy.sparse.linalg.eigsh`( $A$ ,  $k=6$ ,  $M=None$ ,  $sigma=None$ ,  $which='LM'$ ,  $v0=None$ ,  $ncv=None$ ,  $maxiter=None$ ,  $tol=0$ ,  $return_eigenvectors=True$ ,  $Minv=None$ ,  $OPinv=None$ ,  $mode='normal'$ )

Find  $k$  eigenvalues and eigenvectors of the real symmetric square matrix or complex Hermitian matrix  $A$ .

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

If  $M$  is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

Note that there is no specialized routine for the case when  $A$  is a complex Hermitian matrix. In this case, `eigsh()` will call `eigs()` and return the real parts of the eigenvalues thus obtained.

**Parameters**

- A** [ndarray, sparse matrix or LinearOperator] A square operator representing the operation  $A * x$ , where  $A$  is real symmetric or complex Hermitian. For buckling mode (see below)  $A$  must additionally be positive-definite.
- k** [int, optional] The number of eigenvalues and eigenvectors desired.  $k$  must be smaller than  $N$ . It is not possible to compute all eigenvectors of a matrix.

**Returns**

- w** [array] Array of  $k$  eigenvalues.
- v** [array] An array representing the  $k$  eigenvectors. The column  $v[:, i]$  is the eigenvector corresponding to the eigenvalue  $w[i]$ .

**Other Parameters**

- M** [An  $N \times N$  matrix, array, sparse matrix, or linear operator representing] the operation  $M @ x$  for the generalized eigenvalue problem  
 $A @ x = w * M @ x$ .  
 $M$  must represent a real symmetric matrix if  $A$  is real, and must represent a complex Hermitian matrix if  $A$  is complex. For best results, the data type of  $M$  should be the same as that of  $A$ . Additionally:  
 If  $\sigma$  is None,  $M$  is symmetric positive definite.  
 If  $\sigma$  is specified,  $M$  is symmetric positive semi-definite.  
 In buckling mode,  $M$  is symmetric indefinite.
- sigma** [real] Find eigenvalues near  $\sigma$  using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - \sigma * M] x = b$ , where  $M$  is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices  $A$  &  $M$ , or via an iterative solver if either  $A$  or  $M$  is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives  $x = OPinv @ b = [A - \sigma * M]^{-1} @ b$ . Note that when  $\sigma$  is specified, the keyword 'which' refers to the shifted eigenvalues  $w'[i]$  where:  
 if mode == 'normal',  $w'[i] = 1 / (w[i] - \sigma)$ .  
 if mode == 'cayley',  $w'[i] = (w[i] + \sigma) / (w[i] - \sigma)$ .  
 if mode == 'buckling',  $w'[i] = w[i] / (w[i] - \sigma)$ .  
 (see further discussion in 'mode' below)
- v0** [ndarray, optional] Starting vector for iteration. Default: random
- ncv** [int, optional] The number of Lanczos vectors generated `ncv` must be greater than  $k$  and smaller than  $n$ ; it is recommended that  $ncv > 2*k$ . Default:  $\min(n, \max(2*k + 1, 20))$
- which** [str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']] If  $A$  is a complex Hermitian matrix, 'BE' is invalid. Which  $k$  eigenvectors and eigenvalues to find:  
 'LM' : Largest (in magnitude) eigenvalues.  
 'SM' : Smallest (in magnitude) eigenvalues.  
 'LA' : Largest (algebraic) eigenvalues.  
 'SA' : Smallest (algebraic) eigenvalues.  
 'BE' : Half ( $k/2$ ) from each end of the spectrum.

When  $k$  is odd, return one more ( $k/2+1$ ) from the high end. When  $\sigma \neq \text{None}$ , ‘which’ refers to the shifted eigenvalues  $w'[i]$  (see discussion in ‘sigma’, above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** [int, optional] Maximum number of Arnoldi update iterations allowed. Default:  $n*10$   
**tol** [float] Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.  
**Minv** [N x N matrix, array, sparse matrix, or LinearOperator] See notes in *M*, above.  
**OPinv** [N x N matrix, array, sparse matrix, or LinearOperator] See notes in *sigma*, above.  
**return\_eigenvectors**

[bool] Return eigenvectors (True) in addition to eigenvalues. This value determines the order in which eigenvalues are sorted. The sort order is also dependent on the *which* variable.

**For which = ‘LM’ or ‘SA’:**

If *return\_eigenvectors* is True, eigenvalues are sorted by algebraic value.

If *return\_eigenvectors* is False, eigenvalues are sorted by absolute value.

**For which = ‘BE’ or ‘LA’:**

eigenvalues are always sorted by algebraic value.

**For which = ‘SM’:**

If *return\_eigenvectors* is True, eigenvalues are sorted by algebraic value.

If *return\_eigenvectors* is False, eigenvalues are sorted by decreasing absolute value.

**mode** [string [‘normal’ | ‘buckling’ | ‘cayley’]] Specify strategy to use for shift-invert mode. This argument applies only for real-valued *A* and  $\sigma \neq \text{None}$ . For shift-invert mode, ARPACK internally solves the eigenvalue problem  $OP * x'[i] = w'[i] * B * x'[i]$  and transforms the resulting Ritz vectors  $x'[i]$  and Ritz values  $w'[i]$  into the desired eigenvectors and eigenvalues of the problem  $A * x[i] = w[i] * M * x[i]$ . The modes are as follows:

**‘normal’:**  $OP = [A - \sigma * M]^{-1} @ M$ ,  $B = M$ ,  $w'[i] = 1 / (w[i] - \sigma)$

**‘buckling’:**

$OP = [A - \sigma * M]^{-1} @ A$ ,  $B = A$ ,  $w'[i] = w[i] / (w[i] - \sigma)$

**‘cayley’:**  $OP = [A - \sigma * M]^{-1} @ [A + \sigma * M]$ ,  $B = M$ ,  $w'[i] = (w[i] + \sigma) / (w[i] - \sigma)$

The choice of mode will affect which eigenvalues are selected by the keyword ‘which’, and can also impact the stability of convergence (see [2] for a discussion).

### Raises

#### ArpackNoConvergence

When the requested convergence is not obtained.

The currently converged eigenvalues and eigenvectors can be found as *eigenvalues* and *eigenvectors* attributes of the exception object.

See also:

#### eigs

eigenvalues and eigenvectors for a general (nonsymmetric) matrix *A*

#### svds

singular value decomposition for a matrix *A*

## Notes

This function is a wrapper to the ARPACK [1] SSEUPD and DSEUPD functions which use the Implicitly Restarted Lanczos Method to find the eigenvalues and eigenvectors [2].

## References

[1], [2]

## Examples

```
>>> from scipy.sparse.linalg import eigsh
>>> identity = np.eye(13)
>>> eigenvalues, eigenvectors = eigsh(identity, k=6)
>>> eigenvalues
array([1., 1., 1., 1., 1., 1.])
>>> eigenvectors.shape
(13, 6)
```

## scipy.sparse.linalg.lobpcg

`scipy.sparse.linalg.lobpcg`(*A*, *X*, *B=None*, *M=None*, *Y=None*, *tol=None*, *maxiter=None*, *largest=True*, *verbosityLevel=0*, *retLambdaHistory=False*, *retResidualNormsHistory=False*)

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

### Parameters

- A** [[sparse matrix, dense matrix, LinearOperator]] The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.
- X** [ndarray, float32 or float64] Initial approximation to the *k* eigenvectors (non-sparse). If *A* has `shape=(n, n)` then *X* should have `shape=(n, k)`.
- B** [[dense matrix, sparse matrix, LinearOperator], optional] The right hand side operator in a generalized eigenproblem. By default, `B = Identity`. Often called the “mass matrix”.
- M** [[dense matrix, sparse matrix, LinearOperator], optional] Preconditioner to *A*; by default `M = Identity`. *M* should approximate the inverse of *A*.
- Y** [ndarray, float32 or float64, optional] *n*-by-`sizeY` matrix of constraints (non-sparse), `sizeY < n`. The iterations will be performed in the *B*-orthogonal complement of the column-space of *Y*. *Y* must be full rank.
- tol** [scalar, optional] Solver tolerance (stopping criterion). The default is `tol=n*sqrt(eps)`.
- maxiter** [int, optional] Maximum number of iterations. The default is `maxiter = 20`.
- largest** [bool, optional] When True, solve for the largest eigenvalues, otherwise the smallest.
- verbosityLevel** [int, optional] Controls solver output. The default is `verbosityLevel=0`.
- retLambdaHistory** [bool, optional] Whether to return eigenvalue history. Default is False.
- retResidualNormsHistory** [bool, optional] Whether to return history of residual norms. Default is False.

### Returns

<b>w</b>	[ndarray] Array of $k$ eigenvalues
<b>v</b>	[ndarray] An array of $k$ eigenvectors. $v$ has the same shape as $X$ .
<b>lambdas</b>	[list of ndarray, optional] The eigenvalue history, if <code>retLambdaHistory</code> is True.
<b>rnorms</b>	[list of ndarray, optional] The history of residual norms, if <code>retResidualNormsHistory</code> is True.

## Notes

If both `retLambdaHistory` and `retResidualNormsHistory` are True, the return tuple has the following format (lambda, V, lambda history, residual norms history).

In the following  $n$  denotes the matrix size and  $m$  the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size  $3m$  on every iteration by calling the “standard” dense eigensolver, so if  $m$  is not small enough compared to  $n$ , it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. `numpy` or `scipy` function in this case. If one calls the LOBPCG algorithm for  $5m > n$ , it will most likely break internally, so the code tries to call the standard function instead.

It is not that  $n$  should be large for the LOBPCG to work, but rather the ratio  $n / m$  should be large. If you call LOBPCG with  $m=1$  and  $n=10$ , it works though  $n$  is small. The method is intended for extremely large  $n / m$  [4].

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary  $m$  to make this better.
2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large  $n$ , so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for  $A$ , which is easy to code since  $A$  is tridiagonal.

## References

[1], [2], [3], [4]

## Examples

Solve  $A x = \text{lambda } x$  with constraints and preconditioning.

```
>>> import numpy as np
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = np.arange(1, n + 1)
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1.,  0.,  0., ...,  0.,  0.,  0.],
       [ 0.,  2.,  0., ...,  0.,  0.,  0.],
       [ 0.,  0.,  3., ...,  0.,  0.,  0.],
       ...,
       [ 0.,  0.,  0., ..., 98.,  0.,  0.],
       [ 0.,  0.,  0., ...,  0., 99.,  0.],
       [ 0.,  0.,  0., ...,  0.,  0., 100.]])
```

Constraints:

```
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```
>>> X = np.random.rand(n, 3)
```

Preconditioner in the inverse of A in this example:

```
>>> invA = spdiags([1./vals], 0, n, n)
```

The preconditioner must be defined by a function:

```
>>> def precondition(x):
...     return invA @ x
```

The argument `x` of the preconditioner function is a matrix inside `lobpcg`, thus the use of matrix-matrix product `@`.

The preconditioner function is passed to `lobpcg` as a `LinearOperator`:

```
>>> M = LinearOperator(matvec=precond, matmat=precond,
...                    shape=(n, n), dtype=float)
```

Let us now solve the eigenvalue problem for the matrix A:

```
>>> eigenvalues, _ = lobpcg(A, X, Y=Y, M=M, largest=False)
>>> eigenvalues
array([4., 5., 6.]
```

Note that the vectors passed in `Y` are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

---

<code>svds(A[, k, ncv, tol, which, v0, maxiter, ...])</code>	Compute the largest or smallest $k$ singular values/vectors for a sparse matrix.
--	--

---

## scipy.sparse.linalg.svds

`scipy.sparse.linalg.svds(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True, solver='arpack')`

Compute the largest or smallest  $k$  singular values/vectors for a sparse matrix. The order of the singular values is not guaranteed.

### Parameters

<b>A</b>	[[sparse matrix, LinearOperator]] Array to compute the SVD on, of shape (M, N)
<b>k</b>	[int, optional] Number of singular values and vectors to compute. Must be $1 \leq k < \min(A.shape)$ .
<b>ncv</b>	[int, optional] The number of Lanczos vectors generated <code>ncv</code> must be greater than $k+1$ and smaller than <code>n</code> ; it is recommended that <code>ncv &gt; 2*k</code> Default: <code>min(n, max(2*k + 1, 20))</code>
<b>tol</b>	[float, optional] Tolerance for singular values. Zero (default) means machine precision.
<b>which</b>	[str, ['LM'   'SM'], optional] Which $k$ singular values to find:

- ‘LM’ : largest singular values
  - ‘SM’ : smallest singular values
- New in version 0.12.0.
- v0** [ndarray, optional] Starting vector for iteration, of length  $\min(A.\text{shape})$ . Should be an (approximate) left singular vector if  $N > M$  and a right singular vector otherwise. Default: random
- New in version 0.12.0.
- maxiter** [int, optional] Maximum number of iterations.
- New in version 0.12.0.
- return\_singular\_vectors** [bool or str, optional]
- True: return singular vectors (True) in addition to singular values.
- New in version 0.12.0.
- “u”: only return the u matrix, without computing vh (if  $N > M$ ).
  - “vh”: only return the vh matrix, without computing u (if  $N \leq M$ ).
- New in version 0.16.0.
- solver** [str, optional] Eigenvalue solver to use. Should be ‘arpack’ or ‘lobpcg’. Default: ‘arpack’

**Returns**

- u** [ndarray, shape=(M, k)] Unitary matrix having left singular vectors as columns. If *return\_singular\_vectors* is “vh”, this variable is not computed, and None is returned instead.
- s** [ndarray, shape=(k,)] The singular values.
- vt** [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows. If *return\_singular\_vectors* is “u”, this variable is not computed, and None is returned instead.

**Notes**

This is a naive implementation using ARPACK or LOBPCG as an eigensolver on  $A.H * A$  or  $A * A.H$ , depending on which one is more efficient.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs
>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]], dtype=float)
>>> u, s, vt = svds(A, k=2)
>>> s
array([ 2.75193379,  5.6059665 ])
>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([ 5.6059665 ,  2.75193379])
```

Complete or incomplete LU factorizations

<i>splu</i> (A[, permc_spec, diag_pivot_thresh, ...])	Compute the LU decomposition of a sparse, square matrix.
<i>spilu</i> (A[, drop_tol, fill_factor, drop_rule, ...])	Compute an incomplete LU decomposition for a sparse, square matrix.
<i>SuperLU</i> ()	LU factorization of a sparse matrix.

**scipy.sparse.linalg.splu**

`scipy.sparse.linalg.splu` (*A*, *perm\_spec=None*, *diag\_pivot\_thresh=None*, *relax=None*,  
*panel\_size=None*, *options={}*)

Compute the LU decomposition of a sparse, square matrix.

**Parameters**

- A** [sparse matrix] Sparse matrix to factorize. Should be in CSR or CSC format.
- perm\_spec** [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
- NATURAL: natural ordering.
  - MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
  - MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T + A$ .
  - COLAMD: approximate minimum degree column ordering
- diag\_pivot\_thresh** [float, optional] Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user's guide for details [1]
- relax** [int, optional] Expert option for customizing the degree of relaxing supernodes. See SuperLU user's guide for details [1]
- panel\_size** [int, optional] Expert option for customizing the panel size. See SuperLU user's guide for details [1]
- options** [dict, optional] Dictionary containing additional expert options to SuperLU. See SuperLU user guide [1] (section 2.4 on the 'Options' argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE')` to turn equilibration off and perform a single iterative refinement.

**Returns**

- invA** [scipy.sparse.linalg.SuperLU] Object, which has a `solve` method.

See also:

**spilu**

incomplete LU decomposition

**Notes**

This function uses the SuperLU library.

**References**

[1]

## Examples

```

>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
->dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1.,  2.,  3.])
>>> B.solve(A.dot(x))
array([ 1.,  2.,  3.])

```

**scipy.sparse.linalg.spilu**

`scipy.sparse.linalg.spilu` (*A*, *drop\_tol=None*, *fill\_factor=None*, *drop\_rule=None*, *perm\_spec=None*, *diag\_pivot\_thresh=None*, *relax=None*, *panel\_size=None*, *options=None*)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of *A*.

**Parameters**

- A** [(N, N) array\_like] Sparse matrix to factorize
- drop\_tol** [float, optional] Drop tolerance ( $0 \leq \text{tol} \leq 1$ ) for an incomplete LU decomposition. (default:  $1e-4$ )
- fill\_factor** [float, optional] Specifies the fill ratio upper bound ( $\geq 1.0$ ) for ILU. (default: 10)
- drop\_rule** [str, optional] Comma-separated string of drop rules to use. Available rules: `basic`, `provs`, `column`, `area`, `secondary`, `dynamic`, `interp`. (Default: `basic, area`) See SuperLU documentation for details.

**Remaining other options**

Same as for `splu`

**Returns****invA\_approx**

[`scipy.sparse.linalg.SuperLU`] Object, which has a `solve` method.

See also:

**splu**

complete LU decomposition

## Notes

To improve the better approximation to the inverse, you may need to increase *fill\_factor* AND decrease *drop\_tol*. This function uses the SuperLU library.

## Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
↳dtype=float)
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1.,  2.,  3.])
>>> B.solve(A.dot(x))
array([ 1.,  2.,  3.])
```

## scipy.sparse.linalg.SuperLU

**class** `scipy.sparse.linalg.SuperLU`

LU factorization of a sparse matrix.

Factorization is represented as:

$$P_r * A * P_c = L * U$$

To construct these *SuperLU* objects, call the *splu* and *spilu* functions.

## Notes

New in version 0.14.0.

## Examples

The LU decomposition can be used to solve matrix equations. Consider:

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1, 2, 0, 4], [1, 0, 0, 1], [1, 0, 2, 1], [2, 2, 1, 0.]])
```

This can be solved for a given right-hand side:

```
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([ 1.,  2.,  3.,  4.] )
```

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The L and U factors are sparse matrices in CSC format:

```
>>> lu.L.A
array([[ 1. ,  0. ,  0. ,  0. ],
       [ 0. ,  1. ,  0. ,  0. ],
       [ 0. ,  0. ,  1. ,  0. ],
       [ 1. ,  0.5,  0.5,  1. ]])
>>> lu.U.A
array([[ 2.,  0.,  1.,  4.],
       [ 0.,  2.,  1.,  1.],
       [ 0.,  0.,  1.,  1.],
       [ 0.,  0.,  0., -5.]])
```

The permutation matrices can be constructed:

```
>>> Pr = csc_matrix((np.ones(4), (lu.perm_r, np.arange(4))))
>>> Pc = csc_matrix((np.ones(4), (np.arange(4), lu.perm_c)))
```

We can reassemble the original matrix:

```
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1.,  2.,  0.,  4.],
       [ 1.,  0.,  0.,  1.],
       [ 1.,  0.,  2.,  1.],
       [ 2.,  2.,  1.,  0.]])
```

### Attributes

- shape** Shape of the original matrix as a tuple of ints.
- nnz** Number of nonzero elements in the matrix.
- perm\_c** Permutation Pc represented as an array of indices.
- perm\_r** Permutation Pr represented as an array of indices.
- L** Lower triangular factor with unit diagonal as a *scipy.sparse.csc\_matrix*.
- U** Upper triangular factor as a *scipy.sparse.csc\_matrix*.

### Methods

---

<code>solve(rhs[, trans])</code>	Solves linear system of equations with one or several right-hand sides.
----------------------------------	---

---

**scipy.sparse.linalg.SuperLU.solve**

SuperLU.**solve** (*rhs* [, *trans* ])

Solves linear system of equations with one or several right-hand sides.

**Parameters**

**rhs** [ndarray, shape (n,) or (n, k)] Right hand side(s) of equation  
**trans** [{'N', 'T', 'H'}, optional] Type of system to solve:

'N'	:	A	*	x	==	rhs	(default)
'T'	:	A <sup>T</sup>	*	x	==	rhs	
'H'	:	A <sup>H</sup>	*	x	==	rhs	

i.e., normal, transposed, and hermitian conjugate.

**Returns**

**x** [ndarray, shape *rhs*.shape] Solution vector(s)

**6.24.6 Exceptions**

<i>ArpackNoConvergence</i> (msg, eigenvalues, ...)	ARPACK iteration did not converge
<i>ArpackError</i> (info[, infodict])	ARPACK error

**scipy.sparse.linalg.ArpackNoConvergence**

**exception** `scipy.sparse.linalg.ArpackNoConvergence` (*msg*, *eigenvalues*, *eigenvectors*)

ARPACK iteration did not converge

**Attributes**

**eigenvalues**  
 [ndarray] Partial result. Converged eigenvalues.

**eigenvectors**  
 [ndarray] Partial result. Converged eigenvectors.

**with\_traceback** ()

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

**scipy.sparse.linalg.ArpackError**

**exception** `scipy.sparse.linalg.ArpackError` (*info*, *infodict*={*c*: {- 9999: 'Could not build an Arnoldi factorization. IPARAM(5) returns the size of the current Arnoldi factorization. The user is advised to check that enough workspace and array storage has been allocated.', - 13: "NEV and WHICH = 'BE' are incompatible.", - 12: 'IPARAM(1) must be equal to 0 or 1.', - 11: "IPARAM(7) = 1 and BMAT = 'G' are incompatible.", - 10: 'IPARAM(7) must be 1,2,3.', - 9: 'Starting vector is zero.', - 8: 'Error return from LAPACK eigenvalue calculation;', - 7: 'Length of private work array WORKL is not sufficient.', - 6: "BMAT must be one of 'I' or 'G'.", - 5: " WHICH must be one of 'LM', 'SM', 'LR', 'SR', 'LI', 'SI'", - 4: 'The maximum number of Arnoldi update iterations allowed must be greater than zero.', - 3: 'NCV-NEV >= 2 and less than or equal to N.', - 2: 'NEV must be positive.', - 1: 'N must be positive.', 0: 'Normal exit.', 1: 'Maximum number of iterations taken. `with_traceback()`

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

## 6.25 Compressed sparse graph routines (`scipy.sparse.csgraph`)

Fast graph algorithms based on sparse matrix representations.

### 6.25.1 Contents

<code>connected_components(csgraph[, directed, ...])</code>	Analyze the connected components of a sparse graph
<code>laplacian(csgraph[, normed, return_diag, ...])</code>	Return the Laplacian matrix of a directed graph.
<code>shortest_path(csgraph[, method, directed, ...])</code>	Perform a shortest-path graph search on a positive directed or undirected graph.
<code>dijkstra(csgraph[, directed, indices, ...])</code>	Dijkstra algorithm using Fibonacci Heaps
<code>floyd_warshall(csgraph[, directed, ...])</code>	Compute the shortest path lengths using the Floyd-Warshall algorithm
<code>bellman_ford(csgraph[, directed, indices, ...])</code>	Compute the shortest path lengths using the Bellman-Ford algorithm.
<code>johnson(csgraph[, directed, indices, ...])</code>	Compute the shortest path lengths using Johnson's algorithm.
<code>breadth_first_order(csgraph, i_start[, ...])</code>	Return a breadth-first ordering starting with specified node.
<code>depth_first_order(csgraph, i_start[, ...])</code>	Return a depth-first ordering starting with specified node.
<code>breadth_first_tree(csgraph, i_start[, directed])</code>	Return the tree generated by a breadth-first search
<code>depth_first_tree(csgraph, i_start[, directed])</code>	Return a tree generated by a depth-first search.
<code>minimum_spanning_tree(csgraph[, overwrite])</code>	Return a minimum spanning tree of an undirected graph
<code>reverse_cuthill_mckee(graph[, symmetric_mode])</code>	Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.
<code>maximum_flow(csgraph, source, sink)</code>	Maximize the flow between two vertices in a graph.
<code>maximum_bipartite_matching(graph[, perm_type])</code>	Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph.
<code>min_weight_full_bipartite_matching(...[, ...])</code>	Returns the minimum weight full matching of a bipartite graph.
<code>structural_rank(graph)</code>	Compute the structural rank of a graph (matrix) with a given sparsity pattern.
<code>NegativeCycleError([message])</code>	

### `scipy.sparse.csgraph.connected_components`

`scipy.sparse.csgraph.connected_components` (*csgraph*, *directed=True*, *connection='weak'*, *return\_labels=True*)

Analyze the connected components of a sparse graph

New in version 0.11.0.

#### Parameters

**csgraph** [array\_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.
- connection** [str, optional] ['weak'|'strong']. For directed graphs, the type of connection to use. Nodes *i* and *j* are strongly connected if a path exists both from *i* to *j* and from *j* to *i*. A directed graph is weakly connected if replacing all of its directed edges with undirected edges produces a connected (undirected) graph. If `directed == False`, this keyword is not referenced.
- return\_labels** [bool, optional] If True (default), then return the labels for each of the connected components.

**Returns**

- n\_components: int**  
The number of connected components.
- labels: ndarray**  
The length-N array of labels of the connected components.

**References**

[1]

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import connected_components
```

```
>>> graph = [
... [ 0, 1, 1, 0, 0 ],
... [ 0, 0, 1, 0, 0 ],
... [ 0, 0, 0, 0, 0 ],
... [ 0, 0, 0, 0, 1 ],
... [ 0, 0, 0, 0, 0 ]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 1
(1, 2) 1
(3, 4) 1
```

```
>>> n_components, labels = connected_components(csgraph=graph,
->directed=False, return_labels=True)
>>> n_components
2
>>> labels
array([0, 0, 0, 1, 1], dtype=int32)
```

**scipy.sparse.csgraph.laplacian**

`scipy.sparse.csgraph.laplacian` (*csgraph*, *normed=False*, *return\_diag=False*,  
*use\_out\_degree=False*)

Return the Laplacian matrix of a directed graph.

**Parameters**

- csgraph** [array\_like or sparse matrix, 2 dimensions] compressed-sparse graph, with shape (N, N).
- normed** [bool, optional] If True, then compute symmetric normalized Laplacian.
- return\_diag** [bool, optional] If True, then also return an array related to vertex degrees.
- use\_out\_degree** [bool, optional] If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns**

- lap** [ndarray or sparse matrix] The N x N laplacian matrix of *csgraph*. It will be a NumPy array (dense) if the input was dense, or a sparse matrix otherwise.
- diag** [ndarray, optional] The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

**Notes**

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

**Examples**

```
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```

**scipy.sparse.csgraph.shortest\_path**

`scipy.sparse.csgraph.shortest_path` (*csgraph*, *method='auto'*, *directed=True*, *return\_predecessors=False*, *unweighted=False*, *overwrite=False*, *indices=None*)

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters**

- csgraph** [array, matrix, or sparse matrix, 2 dimensions] The  $N \times N$  array of distances representing the input graph.
- method** [string ['auto'|'FW'|'D'], optional] Algorithm to use for shortest paths. Options are:  
**'auto' – (default) select the best among 'FW', 'D', 'BF', or 'J'**  
 based on the input data.  
**'FW' – Floyd-Warshall algorithm. Computational cost is**  
 approximately  $O[N^3]$ . The input csgraph will be converted to a dense representation.  
**'D' – Dijkstra's algorithm with Fibonacci heaps. Computational**  
 cost is approximately  $O[N(N \cdot k + N \cdot \log(N))]$ , where  $k$  is the average number of connected edges per node. The input csgraph will be converted to a csr representation.  
**'BF' – Bellman-Ford algorithm. This algorithm can be used when**  
 weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately  $O[N(N \cdot 2 \cdot k)]$ , where  $k$  is the average number of connected edges per node. The input csgraph will be converted to a csr representation.  
**'J' – Johnson's algorithm. Like the Bellman-Ford algorithm,**  
 Johnson's algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra's algorithm for faster computation.
- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`
- return\_predecessors** [bool, optional] If True, return the size  $(N, N)$  predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- overwrite** [bool, optional] If True, overwrite `csgraph` with the result. This applies only if `method == 'FW'` and `csgraph` is a dense,  $C$ -ordered array with `dtype=float64`.
- indices** [array\_like or int, optional] If specified, only compute the paths from the points at the given indices. Incompatible with `method == 'FW'`.

**Returns**

- dist\_matrix** [ndarray] The  $N \times N$  matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point  $i$  to point  $j$  along the graph.
- predecessors** [ndarray] Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index

of the previous node in the path from point *i* to point *j*. If no path exists between point *i* and *j*, then `predecessors[i, j] = -9999`

**Raises**

**NegativeCycleError:**

if there are negative cycles in the graph

**Notes**

As currently implemented, Dijkstra's algorithm and Johnson's algorithm do not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are non-equal edges, `method='D'` may yield an incorrect result.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import shortest_path

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3

>>> dist_matrix, predecessors = shortest_path(csgraph=graph,
↳directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0.,  1.,  2.,  2.])
>>> predecessors
array([-9999,  0,  0,  1], dtype=int32)
```

**scipy.sparse.csgraph.dijkstra**

`scipy.sparse.csgraph.dijkstra` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*, *limit=np.inf*, *min\_only=False*)

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

**Parameters**

**csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of non-negative distances representing the input graph.

- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]` and from point *j* to *i* along paths `csgraph[j, i]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* or *j* to *i* along either `csgraph[i, j]` or `csgraph[j, i]`.
- indices** [array\_like or int, optional] if specified, only compute the paths from the points at the given indices.
- return\_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- limit** [float, optional] The maximum distance to calculate, must be  $\geq 0$ . Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance  $> \text{limit}$ . For such pairs, the distance will be equal to `np.inf` (i.e., not connected). New in version 0.14.0.
- min\_only** [bool, optional] If False (default), for every node in the graph, find the shortest path from every node in indices. If True, for every node in the graph, find the shortest path from any of the nodes in indices (which can be substantially faster). New in version 1.3.0.

**Returns**

- dist\_matrix** [ndarray, shape (n\_indices, n\_nodes,)] The matrix of distances between graph nodes. If `min_only=False`, `dist_matrix` has shape (n\_indices, n\_nodes) and `dist_matrix[i, j]` gives the shortest distance from point *i* to point *j* along the graph. If `min_only=True`, `dist_matrix` has shape (n\_nodes,) and contains for a given node the shortest path to that node from any of the nodes in indices.
- predecessors** [ndarray, shape (n\_indices, n\_nodes,)] If `min_only=False`, this has shape (n\_indices, n\_nodes), otherwise it has shape (n\_nodes,). Returned only if `return_predecessors == True`. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row *i* of the predecessor matrix contains information on the shortest paths from point *i*: each entry `predecessors[i, j]` gives the index of the previous node in the path from point *i* to point *j*. If no path exists between point *i* and *j*, then `predecessors[i, j] = -9999`
- sources** [ndarray, shape (n\_nodes,)] Returned only if `min_only=True` and `return_predecessors=True`. Contains the index of the source which had the shortest path to each target. If no path exists within the limit, this will contain -9999. The value at the indices passed will be equal to that index (i.e. the fastest way to reach node *i*, is to start on node *i*).

**Notes**

As currently implemented, Dijkstra's algorithm does not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are not equal and both are nonzero, setting `directed=False` will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford's algorithm or Johnson's algorithm.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import dijkstra
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1)    1
(0, 2)    2
(1, 3)    1
(2, 3)    3
```

```
>>> dist_matrix, predecessors = dijkstra(csgraph=graph, directed=False,
↳ indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0.,  1.,  2.,  2.])
>>> predecessors
array([-9999,    0,    0,    1], dtype=int32)
```

**scipy.sparse.csgraph.floyd\_warshall**

`scipy.sparse.csgraph.floyd_warshall` (*csgraph*, *directed=True*, *return\_predecessors=False*, *unweighted=False*, *overwrite=False*)

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

**Parameters**

- csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`
- return\_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- overwrite** [bool, optional] If True, overwrite `csgraph` with the result. This applies only if `csgraph` is a dense, c-ordered array with `dtype=float64`.

**Returns**

- dist\_matrix** [ndarray] The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.

**predecessors**

[ndarray] Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`

**Raises****NegativeCycleError:**

if there are negative cycles in the graph

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import floyd_warshall
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> dist_matrix, predecessors = floyd_warshall(csgraph=graph,
->directed=False, return_predecessors=True)
>>> dist_matrix
array([[ 0.,  1.,  2.,  2.],
       [ 1.,  0.,  3.,  1.],
       [ 2.,  3.,  0.,  3.],
       [ 2.,  1.,  3.,  0.]])
>>> predecessors
array([[ -9999,    0,    0,    1],
       [    1, -9999,    0,    1],
       [    2,    0, -9999,    2],
       [    1,    3,    3, -9999]], dtype=int32)
```

**scipy.sparse.csgraph.bellman\_ford**

`scipy.sparse.csgraph.bellman_ford` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-Ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, Dijkstra's algorithm may be faster.

New in version 0.11.0.

**Parameters**

- csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`
- indices** [array\_like or int, optional] if specified, only compute the paths from the points at the given indices.
- return\_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns**

- dist\_matrix** [ndarray] The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.
- predecessors** [ndarray] Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

**Raises**

- NegativeCycleError:**  
if there are negative cycles in the graph

**Notes**

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import bellman_ford
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> dist_matrix, predecessors = bellman_ford(csgraph=graph,
->directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

**scipy.sparse.csgraph.johnson**

`scipy.sparse.csgraph.johnson` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using Johnson's algorithm.

Johnson's algorithm combines the Bellman-Ford algorithm and Dijkstra's algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra may be faster.

New in version 0.11.0.

**Parameters**

- csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`
- indices** [array\_like or int, optional] if specified, only compute the paths from the points at the given indices.
- return\_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns****dist\_matrix**

[ndarray] The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.

**predecessors**

[ndarray] Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

**Raises****NegativeCycleError:**

if there are negative cycles in the graph

**Notes**

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import johnson
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1)    1
(0, 2)    2
(1, 3)    1
(2, 0)    2
(2, 3)    3
```

```
>>> dist_matrix, predecessors = johnson(csgraph=graph, directed=False,
->indices=0, return_predecessors=True)
>>> dist_matrix
array([ 0.,  1.,  2.,  2.])
>>> predecessors
array([-9999,    0,    0,    1], dtype=int32)
```

**scipy.sparse.csgraph.breadth\_first\_order**

`scipy.sparse.csgraph.breadth_first_order` (*csgraph*, *i\_start*, *directed=True*, *return\_predecessors=True*)

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

**Parameters**

- csgraph** [array\_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** [int] The index of starting node.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- return\_predecessors** [bool, optional] If True (default), then return the predecessor array (see below).

**Returns**

- node\_array** [ndarray, one dimension] The breadth-first list of nodes, starting with specified node. The length of `node_array` is the number of nodes reachable from the specified node.
- predecessors** [ndarray, one dimension] Returned only if `return_predecessors` is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by `predecessors[i]`. If node i is not in the tree (and for the parent node) then `predecessors[i] = -9999`.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_order
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> breadth_first_order(graph, 0)
(array([0, 1, 2, 3], dtype=int32), array([-9999, 0, 0, 1],
↳dtype=int32))
```

**scipy.sparse.csgraph.depth\_first\_order**

`scipy.sparse.csgraph.depth_first_order` (*csgraph*, *i\_start*, *directed=True*, *return\_predecessors=True*)

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters**

- csgraph** [array\_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** [int] The index of starting node.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- return\_predecessors** [bool, optional] If True (default), then return the predecessor array (see below).

**Returns**

- node\_array** [ndarray, one dimension] The depth-first list of nodes, starting with specified node. The length of `node_array` is the number of nodes reachable from the specified node.
- predecessors** [ndarray, one dimension] Returned only if `return_predecessors` is True. The length-N list of predecessors of each node in a depth-first tree. If node i is in the tree, then its parent is given by `predecessors[i]`. If node i is not in the tree (and for the parent node) then `predecessors[i] = -9999`.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_order
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> depth_first_order(graph, 0)
(array([0, 1, 3, 2], dtype=int32), array([-9999, 0, 0, 1],
↳dtype=int32))
```

**scipy.sparse.csgraph.breadth\_first\_tree**

`scipy.sparse.csgraph.breadth_first_tree(csgraph, i_start, directed=True)`

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

**Parameters**

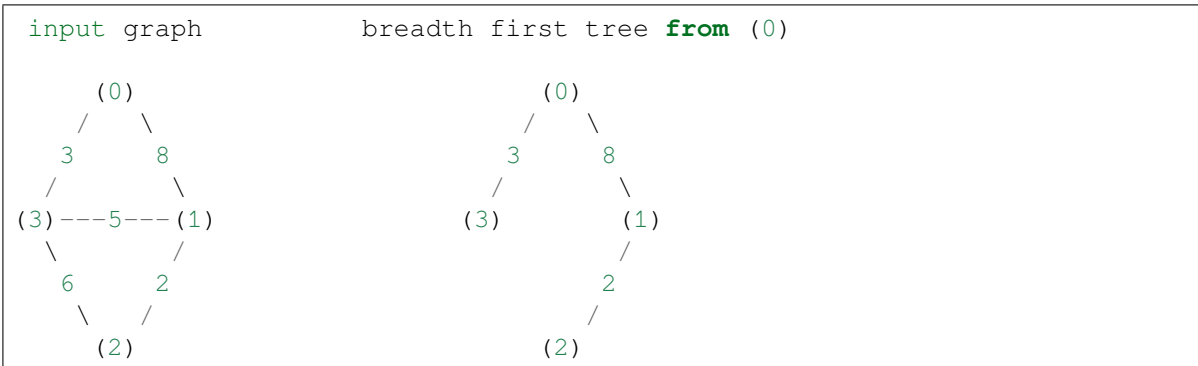

- csgraph** [array\_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** [int] The index of starting node.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.

**Returns**

- cstree** [csr matrix] The N x N directed compressed-sparse representation of the breadth-first tree drawn from csgraph, starting at the specified node.

**Examples**

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])

```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.

## scipy.sparse.csgraph.depth\_first\_tree

`scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)`

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

### Parameters

- csgraph** [array\_like or sparse matrix] The  $N \times N$  matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** [int] The index of starting node.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point  $i$  to point  $j$  along paths  $csgraph[i, j]$ . If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along  $csgraph[i, j]$  or  $csgraph[j, i]$ .

### Returns

- cstree** [csr matrix] The  $N \times N$  directed compressed-sparse representation of the depth-first tree drawn from csgraph, starting at the specified node.

## Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

## scipy.sparse.csgraph.minimum\_spanning\_tree

`scipy.sparse.csgraph.minimum_spanning_tree` (*csgraph*, *overwrite=False*)

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

### Parameters

- csgraph** [array\_like or sparse matrix, 2 dimensions] The N x N matrix representing an undirected graph over N nodes (see notes below).
- overwrite** [bool, optional] if true, then parts of the input graph will be overwritten for efficiency.

### Returns

- span\_tree** [csr matrix] The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

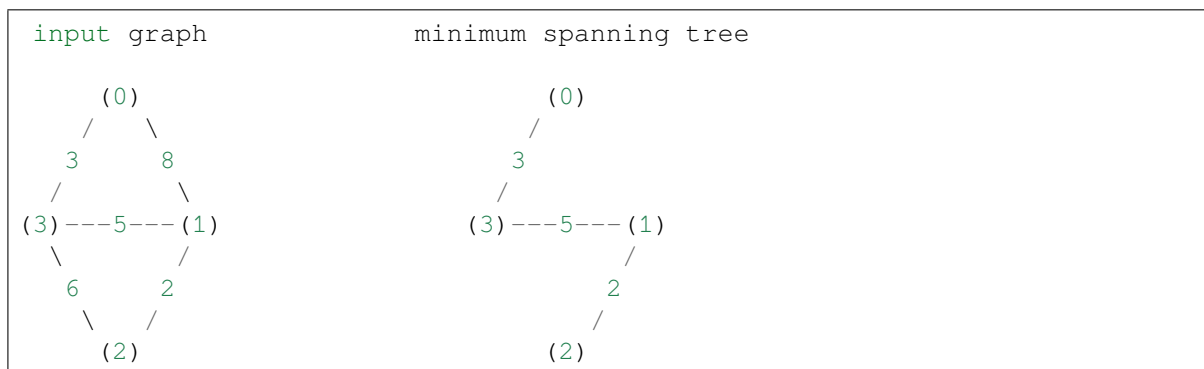

## Notes

This routine uses undirected graphs as input and output. That is, if `graph[i, j]` and `graph[j, i]` are both zero, then nodes `i` and `j` do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

This routine loses precision when users input a dense matrix. Small elements  $< 1E-8$  of the dense matrix are rounded to zero. All users should input sparse matrices if possible to avoid it.

## Examples

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
...                [0, 0, 2, 5],
...                [0, 0, 0, 6],
...                [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])

```

### scipy.sparse.csgraph.reverse\_cuthill\_mckee

`scipy.sparse.csgraph.reverse_cuthill_mckee` (*graph*, *symmetric\_mode=False*)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix  $A+A.T$ . If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

#### Parameters

**graph** [sparse matrix] Input sparse in CSC or CSR sparse matrix format.  
**symmetric\_mode** [bool, optional] Is input matrix guaranteed to be symmetric.

#### Returns

**perm** [ndarray] Array of permuted row and column indices.

#### Notes

New in version 0.15.0.

#### References

#### Examples

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reverse_cuthill_mckee

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]

```

(continues on next page)

(continued from previous page)

```
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> reverse_cuthill_mckee(graph)
array([3, 2, 1, 0], dtype=int32)
```

### scipy.sparse.csgraph.maximum\_flow

`scipy.sparse.csgraph.maximum_flow` (*csgraph*, *source*, *sink*)

Maximize the flow between two vertices in a graph.

New in version 1.4.0.

#### Parameters

<b>csgraph</b>	[csr_matrix] The square matrix representing a directed graph whose (i, j)'th entry is an integer representing the capacity of the edge between vertices i and j.
<b>source</b>	[int] The source vertex from which the flow flows.
<b>sink</b>	[int] The sink vertex to which the flow flows.

#### Returns

<b>res</b>	[MaximumFlowResult] A maximum flow represented by a <code>MaximumFlowResult</code> which includes the value of the flow in <code>flow_value</code> , and the residual graph in <code>residual</code> .
------------	--

#### Raises

**TypeError:**  
if the input graph is not in CSR format.

**ValueError:**  
if the capacity values are not integers, or the source or sink are out of bounds.

### Notes

This solves the maximum flow problem on a given directed weighted graph: A flow associates to every edge a value, also called a flow, less than the capacity of the edge, so that for every vertex (apart from the source and the sink vertices), the total incoming flow is equal to the total outgoing flow. The value of a flow is the sum of the flow of all edges leaving the source vertex, and the maximum flow problem consists of finding a flow whose value is maximal.

By the max-flow min-cut theorem, the maximal value of the flow is also the total weight of the edges in a minimum cut.

To solve the problem, we use the Edmonds–Karp algorithm. [1] This particular implementation strives to exploit sparsity. Its time complexity is  $O(VE^2)$  and its space complexity is  $O(E)$ .

The maximum flow problem is usually defined with real valued capacities, but we require that all capacities are integral to ensure convergence. When dealing with rational capacities, or capacities belonging to  $x\mathbb{Q}$  for some fixed  $x \in \mathbb{R}$ , it is possible to reduce the problem to the integral case by scaling all capacities accordingly.

Solving a maximum-flow problem can be used for example for graph cuts optimization in computer vision [3].

## References

[1], [2], [3]

## Examples

Perhaps the simplest flow problem is that of a graph of only two vertices with an edge from source (0) to sink (1):

```
(0) --5--> (1)
```

Here, the maximum flow is simply the capacity of the edge:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_flow
>>> graph = csr_matrix([[0, 5], [0, 0]])
>>> maximum_flow(graph, 0, 1).flow_value
5
```

If, on the other hand, there is a bottleneck between source and sink, that can reduce the maximum flow:

```
(0) --5--> (1) --3--> (2)
```

```
>>> graph = csr_matrix([[0, 5, 0], [0, 0, 3], [0, 0, 0]])
>>> maximum_flow(graph, 0, 2).flow_value
3
```

A less trivial example is given in [2], Chapter 26.1:

```
>>> graph = csr_matrix([[0, 16, 13, 0, 0, 0],
...                    [0, 10, 0, 12, 0, 0],
...                    [0, 4, 0, 0, 14, 0],
...                    [0, 0, 9, 0, 0, 20],
...                    [0, 0, 0, 7, 0, 4],
...                    [0, 0, 0, 0, 0, 0]])
>>> maximum_flow(graph, 0, 5).flow_value
23
```

It is possible to reduce the problem of finding a maximum matching in a bipartite graph to a maximum flow problem: Let  $G = ((U, V), E)$  be a bipartite graph. Then, add to the graph a source vertex with edges to every vertex in  $U$  and a sink vertex with edges from every vertex in  $V$ . Finally, give every edge in the resulting graph a capacity of 1. Then, a maximum flow in the new graph gives a maximum matching in the original graph consisting of the edges in  $E$  whose flow is positive.

Assume that the edges are represented by a  $|U| \times |V|$  matrix in CSR format whose  $(i, j)$ 'th entry is 1 if there is an edge from  $i \in U$  to  $j \in V$  and 0 otherwise; that is, the input is of the form required by `maximum_bipartite_matching`. Then the CSR representation of the graph constructed above contains this matrix as a block. Here's an example:

```
>>> graph = csr_matrix([[0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 1, 0]])
>>> print(graph.toarray())
[[0 1 0 1]
 [1 0 1 0]
 [0 1 1 0]]
```

(continues on next page)

(continued from previous page)

```

>>> i, j = graph.shape
>>> n = graph.nnz
>>> indptr = np.concatenate([[0],
...                          graph.indptr + i,
...                          np.arange(n + i + 1, n + i + j + 1),
...                          [n + i + j]])
>>> indices = np.concatenate([np.arange(1, i + 1),
...                             graph.indices + i + 1,
...                             np.repeat(i + j + 1, j)])
>>> data = np.ones(n + i + j, dtype=int)
>>>
>>> graph_flow = csr_matrix((data, indices, indptr))
>>> print(graph_flow.toarray())
[[0 1 1 1 0 0 0 0 0]
 [0 0 0 0 0 1 0 1 0]
 [0 0 0 0 1 0 1 0 0]
 [0 0 0 0 0 1 1 0 0]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 0]]

```

At this point, we can find the maximum flow between the added sink and the added source and the desired matching can be obtained by restricting the residual graph to the block corresponding to the original graph:

```

>>> flow = maximum_flow(graph_flow, 0, i+j+1)
>>> matching = flow.residual[1:i+1, i+1:i+j+1]
>>> print(matching.toarray())
[[0 1 0 0]
 [1 0 0 0]
 [0 0 1 0]]

```

This tells us that the first, second, and third vertex in  $U$  are matched with the second, first, and third vertex in  $V$  respectively.

While this solves the maximum bipartite matching problem in general, note that algorithms specialized to that problem, such as *maximum\_bipartite\_matching*, will generally perform better.

This approach can also be used to solve various common generalizations of the maximum bipartite matching problem. If, for instance, some vertices can be matched with more than one other vertex, this may be handled by modifying the capacities of the new graph appropriately.

### scipy.sparse.csgraph.maximum\_bipartite\_matching

`scipy.sparse.csgraph.maximum_bipartite_matching` (*graph*, *perm\_type*='row')

Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph.

#### Parameters

**graph** [sparse matrix] Input sparse in CSR format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix existing in its sparse representation.

**perm\_type**

[str, {'row', 'column'}] Which partition to return the matching in terms of: If 'row', the function produces an array whose length is the number of columns in the input, and whose  $j$ 'th element is the row matched to the  $j$ 'th column. Conversely, if perm\_type is 'column', this returns the columns matched to each row.

**Returns**

**perm** [ndarray] A matching of the vertices in one of the two partitions. Unmatched vertices are represented by a  $-1$  in the result.

**Notes**

This function implements the Hopcroft–Karp algorithm [1]. Its time complexity is  $O(|E|\sqrt{|V|})$ , and its space complexity is linear in the number of rows. In practice, this asymmetry between rows and columns means that it can be more efficient to transpose the input if it contains more columns than rows.

By König's theorem, the cardinality of the matching is also the number of vertices appearing in a minimum vertex cover of the graph.

Note that if the sparse representation contains explicit zeros, these are still counted as edges.

The implementation was changed in SciPy 1.4.0 to allow matching of general bipartite graphs, where previous versions would assume that a perfect matching existed. As such, code written against 1.4.0 will not necessarily work on older versions.

**References**

[1]

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
```

As a simple example, consider a bipartite graph in which the partitions contain 2 and 3 elements respectively. Suppose that one partition contains vertices labelled 0 and 1, and that the other partition contains vertices labelled A, B, and C. Suppose that there are edges connecting 0 and C, 1 and A, and 1 and B. This graph would then be represented by the following sparse matrix:

```
>>> graph = csr_matrix([[0, 0, 1], [1, 1, 0]])
```

Here, the 1s could be anything, as long as they end up being stored as elements in the sparse matrix. We can now calculate maximum matchings as follows:

```
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[ 1 -1 0]
```

The first output tells us that 1 and 2 are matched with C and A respectively, and the second output tells us that A, B, and C are matched with 1, nothing, and 0 respectively.

Note that explicit zeros are still converted to edges. This means that a different way to represent the above graph is by using the CSR structure directly as follows:

```

>>> data = [0, 0, 0]
>>> indices = [2, 0, 1]
>>> indptr = [0, 1, 3]
>>> graph = csr_matrix((data, indices, indptr))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[ 1 -1  0]

```

When one or both of the partitions are empty, the matching is empty as well:

```

>>> graph = csr_matrix((2, 0))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[-1 -1]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[]

```

When the input matrix is square, and the graph is known to admit a perfect matching, i.e. a matching with the property that every vertex in the graph belongs to some edge in the matching, then one can view the output as the permutation of rows (or columns) turning the input matrix into one with the property that all diagonal elements are non-empty:

```

>>> a = [[0, 1, 2, 0], [1, 0, 0, 1], [2, 0, 0, 3], [0, 1, 3, 0]]
>>> graph = csr_matrix(a)
>>> perm = maximum_bipartite_matching(graph, perm_type='row')
>>> print(graph[perm].toarray())
[[1 0 0 1]
 [0 1 2 0]
 [0 1 3 0]
 [2 0 0 3]]

```

### scipy.sparse.csgraph.min\_weight\_full\_bipartite\_matching

`scipy.sparse.csgraph.min_weight_full_bipartite_matching` (*biadjacency\_matrix*, *maximize=False*)

Returns the minimum weight full matching of a bipartite graph.

New in version 1.6.0.

#### Parameters

##### **biadjacency\_matrix**

[sparse matrix] Biadjacency matrix of the bipartite graph: A sparse matrix in CSR, CSC, or COO format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix, and the weight of the edge is given by the value of that entry. This should not be confused with the full adjacency matrix of the graph, as we only need the submatrix defining the bipartite structure.

**maximize** [bool (default: False)] Calculates a maximum weight matching if true.

#### Returns

##### **row\_ind, col\_ind**

[array] An array of row indices and one of corresponding column indices giving the optimal matching. The total weight of the matching can be computed as `graph[row_ind,`

`col_ind].sum()`. The row indices will be sorted; in the case of a square matrix they will be equal to `numpy.arange(graph.shape[0])`.

## Notes

Let  $G = ((U, V), E)$  be a weighted bipartite graph with non-zero weights  $w : E \rightarrow \mathbb{R} \setminus \{0\}$ . This function then produces a matching  $M \subseteq E$  with cardinality

$$|M| = \min(|U|, |V|),$$

which minimizes the sum of the weights of the edges included in the matching,  $\sum_{e \in M} w(e)$ , or raises an error if no such matching exists.

When  $|U| = |V|$ , this is commonly referred to as a perfect matching; here, since we allow  $|U|$  and  $|V|$  to differ, we follow Karp [1] and refer to the matching as *full*.

This function implements the LAPJVsp algorithm [2], short for “Linear assignment problem, Jonker–Volgenant, sparse”.

The problem it solves is equivalent to the rectangular linear assignment problem. [3] As such, this function can be used to solve the same problems as `scipy.optimize.linear_sum_assignment`. That function may perform better when the input is dense, or for certain particular types of inputs, such as those for which the  $(i, j)$ ’th entry is the distance between two points in Euclidean space.

If no full matching exists, this function raises a `ValueError`. For determining the size of the largest matching in the graph, see `maximum_bipartite_matching`.

We require that weights are non-zero only to avoid issues with the handling of explicit zeros when converting between different sparse representations. Zero weights can be handled by adding a constant to all weights, so that the resulting matrix contains no zeros.

## References

[1], [2], [3]

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import min_weight_full_bipartite_matching
```

Let us first consider an example in which all weights are equal:

```
>>> biadjacency_matrix = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
```

Here, all we get is a perfect matching of the graph:

```
>>> print(min_weight_full_bipartite_matching(biadjacency_matrix)[1])
[2 0 1]
```

That is, the first, second, and third rows are matched with the third, first, and second column respectively. Note that in this example, the 0 in the input matrix does *not* correspond to an edge with weight 0, but rather a pair of vertices not paired by an edge.

Note also that in this case, the output matches the result of applying `maximum_bipartite_matching`:

```
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
>>> biadjacency = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
>>> print(maximum_bipartite_matching(biadjacency, perm_type='column'))
[2 0 1]
```

When multiple edges are available, the ones with lowest weights are preferred:

```
>>> biadjacency = csr_matrix([[3, 3, 6], [4, 3, 5], [10, 1, 8]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(col_ind)
[0 2 1]
```

The total weight in this case is  $3 + 5 + 1 = 9$ :

```
>>> print(biadjacency[row_ind, col_ind].sum())
9
```

When the matrix is not square, i.e. when the two partitions have different cardinalities, the matching is as large as the smaller of the two partitions:

```
>>> biadjacency = csr_matrix([[0, 1, 1], [0, 2, 3]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[0 1] [2 1]
>>> biadjacency = csr_matrix([[0, 1], [3, 1], [1, 4]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[0 2] [1 0]
```

When one or both of the partitions are empty, the matching is empty as well:

```
>>> biadjacency = csr_matrix((2, 0))
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[] []
```

In general, we will always reach the same sum of weights as if we had used `scipy.optimize.linear_sum_assignment` but note that for that one, missing edges are represented by a matrix entry of `float('inf')`. Let us generate a random sparse matrix with integer entries between 1 and 10:

```
>>> import numpy as np
>>> from scipy.sparse import random
>>> from scipy.optimize import linear_sum_assignment
>>> sparse = random(10, 10, random_state=42, density=.5, format='coo') * 10
>>> sparse.data = np.ceil(sparse.data)
>>> dense = sparse.toarray()
>>> dense = np.full(sparse.shape, np.inf)
>>> dense[sparse.row, sparse.col] = sparse.data
>>> sparse = sparse.tocsr()
>>> row_ind, col_ind = linear_sum_assignment(dense)
>>> print(dense[row_ind, col_ind].sum())
28.0
>>> row_ind, col_ind = min_weight_full_bipartite_matching(sparse)
```

(continues on next page)

(continued from previous page)

```
>>> print(sparse[row_ind, col_ind].sum())
28.0
```

## scipy.sparse.csgraph.structural\_rank

scipy.sparse.csgraph.**structural\_rank**(*graph*)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

New in version 0.19.0.

### Parameters

**graph** [sparse matrix] Input sparse matrix.

### Returns

**rank** [int] The structural rank of the sparse graph.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import structural_rank
```

```
>>> graph = [
... [0, 1, 2, 0],
... [1, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 1, 3, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 0) 1
(1, 3) 1
(2, 0) 2
(2, 3) 3
(3, 1) 1
(3, 2) 3
```

```
>>> structural_rank(graph)
4
```

**scipy.sparse.csgraph.NegativeCycleError**

**exception** `scipy.sparse.csgraph.NegativeCycleError` (*message=""*)

**with\_traceback()**

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

<code>construct_dist_matrix</code> (graph, predecessors[, ...])	Construct distance matrix from a predecessor matrix
<code>csgraph_from_dense</code> (graph[, null_value, ...])	Construct a CSR-format sparse graph from a dense matrix.
<code>csgraph_from_masked</code> (graph)	Construct a CSR-format graph from a masked array.
<code>csgraph_masked_from_dense</code> (graph[, ...])	Construct a masked array graph representation from a dense matrix.
<code>csgraph_to_dense</code> (csgraph[, null_value])	Convert a sparse graph representation to a dense representation
<code>csgraph_to_masked</code> (csgraph)	Convert a sparse graph representation to a masked array representation
<code>reconstruct_path</code> (csgraph, predecessors[, ...])	Construct a tree from a graph and a predecessor list.

**scipy.sparse.csgraph.construct\_dist\_matrix**

`scipy.sparse.csgraph.construct_dist_matrix` (*graph*, *predecessors*, *directed=True*, *null\_value=np.inf*)

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

**Parameters**

- graph** [array\_like or sparse] The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.
- predecessors** [array\_like] The N x N matrix of predecessors of each node (see Notes below).
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- null\_value** [bool, optional] value to use for distances between unconnected nodes. Default is `np.inf`

**Returns**

- dist\_matrix** [ndarray] The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

## Notes

The predecessor matrix is of the form returned by `shortest_path`. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import construct_dist_matrix
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3
```

```
>>> pred = np.array([[ -9999, 0, 0, 2],
... [1, -9999, 0, 1],
... [2, 0, -9999, 2],
... [1, 3, 3, -9999]]), dtype=np.int32)
```

```
>>> construct_dist_matrix(graph=graph, predecessors=pred, directed=False)
array([[ 0., 1., 2., 5.],
       [ 1., 0., 3., 1.],
       [ 2., 3., 0., 3.],
       [ 2., 1., 3., 0.]])
```

## scipy.sparse.csgraph.csgraph\_from\_dense

`scipy.sparse.csgraph.csgraph_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*)

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

### Parameters

- graph** [array\_like] Input graph. Shape should be (n\_nodes, n\_nodes).
- null\_value** [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.
- infinity\_null** [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.
- nan\_null** [bool] If True (default), then NaN entries are treated as non-edges

### Returns

**csgraph** [csr\_matrix] Compressed sparse representation of graph,

### Examples

```
>>> from scipy.sparse.csgraph import csgraph_from_dense
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
```

```
>>> csgraph_from_dense(graph)
<4x4 sparse matrix of type '<class 'numpy.float64''>'
with 4 stored elements in Compressed Sparse Row format>
```

### scipy.sparse.csgraph.csgraph\_from\_masked

`scipy.sparse.csgraph.csgraph_from_masked`(*graph*)

Construct a CSR-format graph from a masked array.

New in version 0.11.0.

#### Parameters

**graph** [MaskedArray] Input graph. Shape should be (n\_nodes, n\_nodes).

#### Returns

**csgraph** [csr\_matrix] Compressed sparse representation of graph,

### Examples

```
>>> import numpy as np
>>> from scipy.sparse.csgraph import csgraph_from_masked
```

```
>>> graph_masked = np.ma.masked_array(data = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ],
... mask=[[ True, False, False, True],
... [ True, True, True, False],
... [ True, True, True, False],
... [ True, True, True, True]],
... fill_value = 0)
```

```
>>> csgraph_from_masked(graph_masked)
<4x4 sparse matrix of type '<class 'numpy.float64''>'
with 4 stored elements in Compressed Sparse Row format>
```

**scipy.sparse.csgraph.csgraph\_masked\_from\_dense**

`scipy.sparse.csgraph.csgraph_masked_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*, *copy=True*)

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

**Parameters**

- graph** [array\_like] Input graph. Shape should be (n\_nodes, n\_nodes).
- null\_value** [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.
- infinity\_null** [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.
- nan\_null** [bool] If True (default), then NaN entries are treated as non-edges

**Returns**

- csgraph** [MaskedArray] masked array representation of graph

**Examples**

```
>>> from scipy.sparse.csgraph import csgraph_masked_from_dense
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
```

```
>>> csgraph_masked_from_dense(graph)
masked_array(
  data=[[--, 1, 2, --],
        [--, --, --, 1],
        [--, --, --, 3],
        [--, --, --, --]],
  mask=[[ True, False, False,  True],
        [ True,  True,  True, False],
        [ True,  True,  True, False],
        [ True,  True,  True,  True]],
  fill_value=0)
```

**scipy.sparse.csgraph.csgraph\_to\_dense**

`scipy.sparse.csgraph.csgraph_to_dense` (*csgraph*, *null\_value=0*)

Convert a sparse graph representation to a dense representation

New in version 0.11.0.

**Parameters**

- csgraph** [csr\_matrix, csc\_matrix, or lil\_matrix] Sparse representation of a graph.

**null\_value** [float, optional] The value used to indicate null edges in the dense representation. Default is 0.

### Returns

**graph** [ndarray] The dense representation of the sparse graph.

### Notes

For normal sparse graph representations, calling `csgraph_to_dense` with `null_value=0` produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in `scipy.sparse` will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default `scipy.sparse` behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[ inf,  0.],
       [ inf,  inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_dense
```

```
>>> graph = csr_matrix( [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ])
>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64''>'
  with 4 stored elements in Compressed Sparse Row format>
```

```
>>> csgraph_to_dense(graph)
array([[ 0.,  1.,  2.,  0.],
       [ 0.,  0.,  0.,  1.],
       [ 0.,  0.,  0.,  3.],
       [ 0.,  0.,  0.,  0.]])
```

## scipy.sparse.csgraph.csgraph\_to\_masked

`scipy.sparse.csgraph.csgraph_to_masked` (*csgraph*)

Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

### Parameters

**csgraph** [csr\_matrix, csc\_matrix, or lil\_matrix] Sparse representation of a graph.

### Returns

**graph** [MaskedArray] The masked dense representation of the sparse graph.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_masked
```

```
>>> graph = csr_matrix( [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ])
>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64''>'
  with 4 stored elements in Compressed Sparse Row format>
```

```
>>> csgraph_to_masked(graph)
masked_array(
  data=[[--, 1.0, 2.0, --],
        [--, --, --, 1.0],
        [--, --, --, 3.0],
        [--, --, --, --]],
  mask=[[ True, False, False,  True],
        [ True,  True,  True, False],
        [ True,  True,  True, False],
        [ True,  True,  True,  True]],
  fill_value=1e+20)
```

### scipy.sparse.csgraph.reconstruct\_path

`scipy.sparse.csgraph.reconstruct_path` (*csgraph*, *predecessors*, *directed=True*)

Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

#### Parameters

**csgraph** [array\_like or sparse matrix] The N x N matrix representing the directed or undirected graph from which the predecessors are drawn.

**predecessors** [array\_like, one dimension] The length-N array of indices of predecessors for the tree. The index of the parent of node *i* is given by `predecessors[i]`.

**directed** [bool, optional] If True (default), then operate on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`.

#### Returns

**ctree** [csr matrix] The N x N directed compressed-sparse representation of the tree drawn from `csgraph` which is encoded by the predecessor list.

### Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reconstruct_path
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
... ]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1)    1
(0, 2)    2
(1, 3)    1
(2, 3)    3
```

```
>>> pred = np.array([-9999, 0, 0, 1], dtype=np.int32)
```

```
>>> cstree = reconstruct_path(csgraph=graph, predecessors=pred,
↳ directed=False)
>>> cstree.todense()
matrix([[ 0.,  1.,  2.,  0.],
        [ 0.,  0.,  0.,  1.],
        [ 0.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
```

## 6.25.2 Graph Representations

This module uses graphs which are stored in a matrix format. A graph with  $N$  nodes can be represented by an  $(N \times N)$  adjacency matrix  $G$ . If there is a connection from node  $i$  to node  $j$ , then  $G[i, j] = w$ , where  $w$  is the weight of the connection. For nodes  $i$  and  $j$  which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by  $G[i, j] = 0$ , infinity, or NaN.
- for dense masked representations (of type `np.ma.MaskedArray`), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```
>>> G_dense = np.array([[0, 2, 1],
...                    [2, 0, 0],
...                    [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

(continues on next page)

(continued from previous page)

```

/      \
(2)      (1)

```

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```

>>> G2_data = np.array([[np.inf, 2,      0      ],
...                    [2,      np.inf, np.inf],
...                    [0,      np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2.,  0.,  2.,  0.])

```

Here we have used a utility routine from the `csgraph` submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

### Directed vs. undirected

Matrices may represent either directed or undirected graphs. This is specified throughout the `csgraph` module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node  $i$  to node  $j$  can be accomplished over the edge  $G[i, j]$ , but not the edge  $G[j, i]$ . Consider the following dense graph:

```

>>> G_dense = np.array([[0, 1, 0],
...                    [2, 0, 3],
...                    [0, 4, 0]])

```

When `directed=True` we get the graph:

```

---1--> ---3-->
(0)      (1)      (2)
<--2--- <--4---

```

In a non-directed graph, traversal from node  $i$  to node  $j$  can be accomplished over either  $G[i, j]$  or  $G[j, i]$ . If both edges are not null, and the two have unequal weights, then the smaller of the two is used.

So for the same graph, when `directed=False` we get the graph:

```

(0)--1--(1)--2--(2)

```

Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘`directed`’ keyword is set to `True` or `False`. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either `scipy.sparse` representations (`csr`, `csc`, or `lil` format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

## 6.26 Spatial algorithms and data structures (`scipy.spatial`)

### 6.26.1 Spatial transformations

These are contained in the `scipy.spatial.transform` submodule.

### 6.26.2 Nearest-neighbor queries

<code>KDTree</code> (data[, leafsize, compact_nodes, ...])	kd-tree for quick nearest-neighbor lookup
<code>cKDTree</code> (data[, leafsize, compact_nodes, ...])	kd-tree for quick nearest-neighbor lookup
<code>Rectangle</code> (maxes, mins)	Hyperrectangle class.

#### `scipy.spatial.KDTree`

**class** `scipy.spatial.KDTree` (*data*, *leafsize=10*, *compact\_nodes=True*, *copy\_data=False*, *balanced\_tree=True*, *boxsize=None*)  
kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

#### *Parameters*

- data** [array\_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with `copy_data=True`.
- leafsize** [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 10.
- compact\_nodes** [bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.
- copy\_data** [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.
- balanced\_tree** [bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.
- boxsize** [array\_like or scalar, optional] Apply a m-d toroidal topology to the KDTree.. The topology is generated by  $x_i + n_i L_i$  where  $n_i$  are integers and  $L_i$  is the boxsize along i-th dimension. The input data shall be wrapped into  $[0, L_i)$ . A `ValueError` is raised if any of the data is outside of this bound.

## Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the  $r$  closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the  $r$  approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

### Attributes

<b>data</b>	[ndarray, shape (n,m)] The $n$ data points of dimension $m$ to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with <code>copy_data=True</code> .
<b>leafsize</b>	[positive int] The number of points at which the algorithm switches over to brute-force.
<b>m</b>	[int] The dimension of a single data-point.
<b>n</b>	[int] The number of data points.
<b>maxes</b>	[ndarray, shape (m,)] The maximum value in each dimension of the $n$ data points.
<b>mins</b>	[ndarray, shape (m,)] The minimum value in each dimension of the $n$ data points.
<b>size</b>	[int] The number of nodes in the tree.

## Methods

<code>count_neighbors(self, other, r[, p, ...])</code>	Count how many nearby pairs can be formed.
<code>query(self, x[, k, eps, p, ...])</code>	Query the kd-tree for nearest neighbors
<code>query_ball_point(self, x, r[, p, eps, ...])</code>	Find all points within distance $r$ of point(s) $x$ .
<code>query_ball_tree(self, other, r[, p, eps])</code>	Find all pairs of points between <i>self</i> and <i>other</i> whose distance is at most $r$
<code>query_pairs(self, r[, p, eps, output_type])</code>	Find all pairs of points in <i>self</i> whose distance is at most $r$ .
<code>sparse_distance_matrix(self, other, max_distance)</code>	Compute a sparse distance matrix

### scipy.spatial.KDTree.count\_neighbors

`KDTree.count_neighbors(self, other, r, p=2.0, weights=None, cumulative=True)`

Count how many nearby pairs can be formed.

Count the number of pairs  $(x_1, x_2)$  can be formed, with  $x_1$  drawn from *self* and  $x_2$  drawn from *other*, and where  $\text{distance}(x_1, x_2, p) \leq r$ .

Data points on *self* and *other* are optionally weighted by the `weights` argument. (See below)

This is adapted from the “two-point correlation” algorithm described by Gray and Moore [1]. See notes for further discussion.

#### Parameters

**other** [KDTree] The other tree to draw points from, can be the same tree as *self*.

**r** [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative (`cumulative=False`), `r` defines the edges of the bins, and must be non-decreasing.

**p** [float, optional]  $1 \leq p \leq \text{infinity}$ . Which Minkowski  $p$ -norm to use. Default 2.0. A finite large  $p$  may cause a `ValueError` if overflow can occur.

**weights** [tuple, array\_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, `weights[0]` is the weights of points in `self`, and `weights[1]` is the weights of points in `other`; either can be None to indicate the points are unweighted. If given as an array\_like, `weights` is the weights of points in `self` and `other`. For this to make sense, `self` and `other` must be the same tree. If `self` and `other` are two different trees, a `ValueError` is raised. Default: None  
New in version 1.6.0.

**cumulative** [bool, optional] Whether the returned counts are cumulative. When `cumulative` is set to `False` the algorithm is optimized to work with a large number of bins ( $>10$ ) specified by `r`. When `cumulative` is set to `True`, the algorithm is optimized to work with a small number of `r`. Default: `True`  
New in version 1.6.0.

#### Returns

**result** [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If `cumulative` is `False`, `result[i]` contains the counts with  $(-\text{inf} \text{ if } i == 0 \text{ else } r[i-1]) < R \leq r[i]$

#### Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of  $D$  measures the clustering signal in  $D$ . [2]

For example, given the position of two sets of objects,

- objects  $D$  (data) contains the clustering signal, and
- objects  $R$  (random) that contains no signal,

$$\xi(r) = \frac{\langle D, D \rangle - 2f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},$$

where the brackets represents counting pairs between two data sets in a finite bin around  $r$  (distance), corresponding to setting `cumulative=False`, and  $f = \text{float}(\text{len}(D)) / \text{float}(\text{len}(R))$  is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

## Examples

You can count neighbors number between two kd-trees within a distance:

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((5, 2))
>>> points2 = np.random.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
9
```

This number is same as the total pair number calculated by `query_ball_tree`:

```
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
9
```

## scipy.spatial.KDTree.query

`KDTree.query` (*self*, *x*, *k=1*, *eps=0*, *p=2*, *distance\_upper\_bound=inf*, *workers=1*)

Query the kd-tree for nearest neighbors

### Parameters

- x** [array\_like, last dimension self.m] An array of points to query.
- k** [int or Sequence[int], optional] Either the number of nearest neighbors to return, or a list of the k-th nearest neighbors to return, starting from 1.
- eps** [nonnegative float, optional] Return approximate nearest neighbors; the kth returned value is guaranteed to be no further than (1+eps) times the distance to the real kth nearest neighbor.
- p** [float, 1<=p<=infinity, optional] Which Minkowski p-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance A large, finite p may cause a ValueError if overflow can occur.
- distance\_upper\_bound** [nonnegative float, optional] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.
- workers** [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.  
New in version 1.6.0.

### Returns

- d** [float or array of floats] The distances to the nearest neighbors. If *x* has shape `tuple+(self.m, )`, then *d* has shape `tuple+(k, )`. When *k* == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances. Hits are sorted by distance (nearest first).

Deprecated since version 1.6.0: If `k=None`, then `d` is an object array of shape `tuple`, containing lists of distances. This behavior is deprecated and will be removed in SciPy 1.8.0, use `query_ball_point` instead.

`i` [integer or array of integers] The index of each neighbor in `self.data`. `i` is the same shape as `d`. Missing neighbors are indicated with `self.n`.

## Examples

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = KDTree(np.c_[x.ravel(), y.ravel()])
```

To query the nearest neighbours and return squeezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[2.          0.14142136] [ 0 13]
```

To query the nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[2.          ]
 [0.14142136]] [[ 0]
 [13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[2.23606798]
 [0.90553851]] [[ 6]
 [12]]
```

To query the first and second nearest neighbours, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[2.          2.23606798]
 [0.14142136 0.90553851]] [[ 0  6]
 [13 12]]
```

or, be more specific

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[2.          2.23606798]
 [0.14142136 0.90553851]] [[ 0  6]
 [13 12]]
```

**scipy.spatial.KDTree.query\_ball\_point**

`KDTree.query_ball_point` (*self*, *x*, *r*, *p=2.0*, *eps=0*, *workers=1*, *return\_sorted=None*, *return\_length=False*)

Find all points within distance *r* of point(s) *x*.

**Parameters**

- x** [array\_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
- r** [array\_like, float] The radius of points to return, must broadcast to the length of *x*.
- p** [float, optional] Which Minkowski *p*-norm to use. Should be in the range [1, inf]. A finite large *p* may cause a `ValueError` if overflow can occur.
- eps** [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .
- workers** [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.  
New in version 1.6.0.
- return\_sorted** [bool, optional] Sorts returned indices if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added.  
New in version 1.6.0.
- return\_length: bool, optional**  
Return the number of points inside the radius instead of a list of the indices.  
New in version 1.6.0.

**Returns**

- results** [list or array of lists] If *x* is a single point, returns a list of the indices of the neighbors of *x*. If *x* is an array of points, returns an object array of shape tuple containing lists of neighbors.

**Notes**

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a `KDTree` and using `query_ball_tree`.

**Examples**

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.KDTree(points)
>>> sorted(tree.query_ball_point([2, 0], 1))
[5, 10, 11, 15]
```

Query multiple points and plot the results:

```
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point([2, 0], [3, 3], 1):
...     nearby_points = points[results]
```

(continues on next page)

(continued from previous page)

```

...     plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()

```

### scipy.spatial.KDTree.query\_ball\_tree

`KDTree.query_ball_tree` (*self*, *other*, *r*, *p*=2.0, *eps*=0)

Find all pairs of points between *self* and *other* whose distance is at most *r*

#### Parameters

- other** [KDTree instance] The tree containing points to search against.
- r** [float] The maximum distance, has to be positive.
- p** [float, optional] Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ .
- eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

#### Returns

- results** [list of lists] For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

### Examples

You can search all pairs of points between two kd-trees within a distance:

```

>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((15, 2))
>>> points2 = np.random.random((15, 2))

```

(continues on next page)

(continued from previous page)

```

>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
...     for j in indexes[i]:
...         plt.plot([points1[i, 0], points2[j, 0]],
...                 [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()

```

**scipy.spatial.KDTree.query\_pairs**

KDTree.**query\_pairs** (*self*, *r*, *p*=2.0, *eps*=0, *output\_type*='set')

Find all pairs of points in *self* whose distance is at most *r*.

**Parameters**

- r** [positive float] The maximum distance.
- p** [float, optional] Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ .
- eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.
- output\_type** [string, optional] Choose the output container, 'set' or 'ndarray'. Default: 'set'. New in version 1.6.0.

**Returns**

- results** [set or ndarray] Set of pairs (*i*, *j*), with  $i < j$ , for which the corresponding positions are close. If *output\_type* is 'ndarray', an ndarray is returned instead of a set.

**Examples**

You can search all pairs of points in a kd-tree within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> np.random.seed(21701)
>>> points = np.random.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = KDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
...     plt.plot([points[i, 0], points[j, 0]],
...              [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

**scipy.spatial.KDTree.sparse\_distance\_matrix**

KDTree.**sparse\_distance\_matrix** (*self*, *other*, *max\_distance*, *p*=2.0, *output\_type*='dok\_matrix')

Compute a sparse distance matrix

Computes a distance matrix between two KDTrees, leaving as zero any distance greater than *max\_distance*.

**Parameters**

- other** [KDTree]
- max\_distance** [positive float]
- p** [float,  $1 \leq p \leq \text{infinity}$ ] Which Minkowski *p*-norm to use. A finite large *p* may cause a ValueError if overflow can occur.
- output\_type** [string, optional] Which container to use for output data. Options: 'dok\_matrix', 'coo\_matrix', 'dict', or 'ndarray'. Default: 'dok\_matrix'. New in version 1.6.0.

**Returns**

**result** [dok\_matrix, coo\_matrix, dict or ndarray] Sparse matrix representing the results in “dictionary of keys” format. If a dict is returned the keys are (i,j) tuples of indices. If output\_type is ‘ndarray’ a record array with fields ‘i’, ‘j’, and ‘v’ is returned,

**Examples**

You can compute a sparse distance matrix between two kd-trees:

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((5, 2))
>>> points2 = np.random.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> sdm = kd_tree1.sparse_distance_matrix(kd_tree2, 0.3)
>>> sdm.toarray()
array([[0.20220215, 0.14538496, 0.,          0.10257199, 0.          ],
       [0.13491385, 0.27251306, 0.,          0.18793787, 0.          ],
       [0.19262396, 0.,          0.,          0.25795122, 0.          ],
       [0.14859639, 0.07076002, 0.,          0.04065851, 0.          ],
       [0.17308768, 0.,          0.,          0.24823138, 0.          ]])
```

You can check distances above the *max\_distance* are zeros:

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.20220215, 0.14538496, 0.43588092, 0.10257199, 0.4555495 ],
       [0.13491385, 0.27251306, 0.65944131, 0.18793787, 0.68184154],
       [0.19262396, 0.34121593, 0.72176889, 0.25795122, 0.74538858],
       [0.14859639, 0.07076002, 0.48505773, 0.04065851, 0.50043591],
       [0.17308768, 0.32837991, 0.72760803, 0.24823138, 0.75017239]])
```

<b>node</b>	

**scipy.spatial.cKDTree**

**class** `scipy.spatial.cKDTree`(*data*, *leafsize=16*, *compact\_nodes=True*, *copy\_data=False*, *balanced\_tree=True*, *boxsize=None*)  
 kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

**Parameters**

**data** [array\_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with *copy\_data=True*.

<b>leafsize</b>	[positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 16.
<b>compact_nodes</b>	[bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.
<b>copy_data</b>	[bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.
<b>balanced_tree</b>	[bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.
<b>boxsize</b>	[array_like or scalar, optional] Apply a m-d toroidal topology to the KDTree.. The topology is generated by $x_i + n_i L_i$ where $n_i$ are integers and $L_i$ is the boxsize along i-th dimension. The input data shall be wrapped into $[0, L_i)$ . A ValueError is raised if any of the data is outside of this bound.

## Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the  $r$  closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the  $r$  approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

### Attributes

<b>data</b>	[ndarray, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with <i>copy_data=True</i> .
<b>leafsize</b>	[positive int] The number of points at which the algorithm switches over to brute-force.
<b>m</b>	[int] The dimension of a single data-point.
<b>n</b>	[int] The number of data points.
<b>maxes</b>	[ndarray, shape (m,)] The maximum value in each dimension of the n data points.
<b>mins</b>	[ndarray, shape (m,)] The minimum value in each dimension of the n data points.
<b>tree</b>	[object, class cKDTreeNode] This attribute exposes a Python view of the root node in the cKDTree object. A full Python view of the kd-tree is created dynamically on the first access. This attribute allows you to create your own query functions in Python.
<b>size</b>	[int] The number of nodes in the tree.

## Methods

<code>count_neighbors(self, other, r[, p, ...])</code>	Count how many nearby pairs can be formed.
<code>query(self, x[, k, eps, p, ...])</code>	Query the kd-tree for nearest neighbors
<code>query_ball_point(self, x, r[, p, eps, ...])</code>	Find all points within distance <i>r</i> of point(s) <i>x</i> .
<code>query_ball_tree(self, other, r[, p, eps])</code>	Find all pairs of points between <i>self</i> and <i>other</i> whose distance is at most <i>r</i>
<code>query_pairs(self, r[, p, eps])</code>	Find all pairs of points in <i>self</i> whose distance is at most <i>r</i> .
<code>sparse_distance_matrix(self, other, max_distance)</code>	Compute a sparse distance matrix

### scipy.spatial.cKDTree.count\_neighbors

`cKDTree.count_neighbors` (*self*, *other*, *r*, *p*=2.0, *weights*=None, *cumulative*=True)

Count how many nearby pairs can be formed.

Count the number of pairs (*x*<sub>1</sub>, *x*<sub>2</sub>) can be formed, with *x*<sub>1</sub> drawn from *self* and *x*<sub>2</sub> drawn from *other*, and where `distance(x1, x2, p) <= r`.

Data points on *self* and *other* are optionally weighted by the *weights* argument. (See below)

This is adapted from the “two-point correlation” algorithm described by Gray and Moore [1]. See notes for further discussion.

#### Parameters

- other** [cKDTree instance] The other tree to draw points from, can be the same tree as *self*.
- r** [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative (*cumulative*=False), *r* defines the edges of the bins, and must be non-decreasing.
- p** [float, optional] 1<=*p*<=infinity. Which Minkowski *p*-norm to use. Default 2.0. A finite large *p* may cause a `ValueError` if overflow can occur.
- weights** [tuple, array\_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, *weights*[0] is the weights of points in *self*, and *weights*[1] is the weights of points in *other*; either can be None to indicate the points are unweighted. If given as an array\_like, *weights* is the weights of points in *self* and *other*. For this to make sense, *self* and *other* must be the same tree. If *self* and *other* are two different trees, a `ValueError` is raised. Default: None

#### cumulative

[bool, optional] Whether the returned counts are cumulative. When *cumulative* is set to False the algorithm is optimized to work with a large number of bins (>10) specified by *r*. When *cumulative* is set to True, the algorithm is optimized to work with a small number of *r*. Default: True

#### Returns

- result** [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If *cumulative* is False, `result[i]` contains the counts with `(-inf if i == 0 else r[i-1]) < R <= r[i]`

## Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of  $D$  measures the clustering signal in  $D$ . [2]

For example, given the position of two sets of objects,

- objects  $D$  (data) contains the clustering signal, and
- objects  $R$  (random) that contains no signal,

$$\xi(r) = \frac{\langle D, D \rangle - 2f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},$$

where the brackets represents counting pairs between two data sets in a finite bin around  $r$  (distance), corresponding to setting `cumulative=False`, and  $f = \text{float}(\text{len}(D)) / \text{float}(\text{len}(R))$  is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

## Examples

You can count neighbors number between two kd-trees within a distance:

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((5, 2))
>>> points2 = np.random.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
9
```

This number is same as the total pair number calculated by `query_ball_tree`:

```
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
9
```

**scipy.spatial.cKDTree.query**

`cKDTree.query` (*self*, *x*, *k=1*, *eps=0*, *p=2*, *distance\_upper\_bound=np.inf*, *workers=1*)

Query the kd-tree for nearest neighbors

**Parameters**

- x** [array\_like, last dimension *self.m*] An array of points to query.
- k** [list of integer or integer] The list of *k*-th nearest neighbors to return. If *k* is an integer it is treated as a list of [1, ... *k*] (`range(1, k+1)`). Note that the counting starts from 1.
- eps** [non-negative float] Return approximate nearest neighbors; the *k*-th returned value is guaranteed to be no further than  $(1+eps)$  times the distance to the real *k*-th nearest neighbor.
- p** [float,  $1 \leq p \leq \text{infinity}$ ] Which Minkowski *p*-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance A finite large *p* may cause a `ValueError` if overflow can occur.
- distance\_upper\_bound** [nonnegative float] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.
- workers** [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.  
Changed in version 1.6.0: The “`n_jobs`” argument was renamed “`workers`”. The old name “`n_jobs`” is deprecated and will stop working in SciPy 1.8.0.

**Returns**

- d** [array of floats] The distances to the nearest neighbors. If *x* has shape `tuple+(self.m,)`, then *d* has shape `tuple+(k,)`. When *k* == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.
- i** [ndarray of ints] The index of each neighbor in *self.data*. If *x* has shape `tuple+(self.m,)`, then *i* has shape `tuple+(k,)`. When *k* == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with *self.n*.

**Notes**

If the KD-Tree is periodic, the position *x* is wrapped into the box.

When the input *k* is a list, a query for `arange(max(k))` is performed, but only columns that store the requested values of *k* are preserved. This is implemented in a manner that reduces memory usage.

**Examples**

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = cKDTree(np.c_[x.ravel(), y.ravel()])
```

To query the nearest neighbours and return squeezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[2.          0.14142136] [ 0 13]
```

To query the nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[2.          ]
 [0.14142136]] [[ 0]
 [13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[2.23606798]
 [0.90553851]] [[ 6]
 [12]]
```

To query the first and second nearest neighbours, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[2.          2.23606798]
 [0.14142136 0.90553851]] [[ 0  6]
 [13 12]]
```

or, be more specific

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[2.          2.23606798]
 [0.14142136 0.90553851]] [[ 0  6]
 [13 12]]
```

### scipy.spatial.cKDTree.query\_ball\_point

`cKDTree.query_ball_point` (*self*, *x*, *r*, *p=2.0*, *eps=0*, *workers=1*, *return\_sorted=None*, *return\_length=False*)

Find all points within distance *r* of point(s) *x*.

#### Parameters

- x** [array\_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
- r** [array\_like, float] The radius of points to return, shall broadcast to the length of *x*.
- p** [float, optional] Which Minkowski *p*-norm to use. Should be in the range [1, inf]. A finite large *p* may cause a `ValueError` if overflow can occur.
- eps** [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .
- workers** [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.  
Changed in version 1.6.0: The “`n_jobs`” argument was renamed “`workers`”. The old name “`n_jobs`” is deprecated and will stop working in SciPy 1.8.0.
- return\_sorted** [bool, optional] Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added.  
New in version 1.2.0.

**return\_length: bool, optional**

Return the number of points inside the radius instead of a list of the indices. .. version-added:: 1.3.0

**Returns**

**results** [list or array of lists] If  $x$  is a single point, returns a list of the indices of the neighbors of  $x$ . If  $x$  is an array of points, returns an object array of shape tuple containing lists of neighbors.

**Notes**

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a `cKDTree` and using `query_ball_tree`.

**Examples**

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[4, 8, 9, 12]
```

Query multiple points and plot the results:

```
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point([2, 0], [3, 3]), 1):
...     nearby_points = points[results]
...     plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```

**scipy.spatial.cKDTree.query\_ball\_tree**`cKDTree.query_ball_tree` (*self*, *other*, *r*, *p*=2.0, *eps*=0)Find all pairs of points between *self* and *other* whose distance is at most *r***Parameters**

- other** [cKDTree instance] The tree containing points to search against.
- r** [float] The maximum distance, has to be positive.
- p** [float, optional] Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ . A finite large *p* may cause a `ValueError` if overflow can occur.
- eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**Returns**

- results** [list of lists] For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

**Examples**

You can search all pairs of points between two kd-trees within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((15, 2))
>>> points2 = np.random.random((15, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
...     for j in indexes[i]:
...         plt.plot([points1[i, 0], points2[j, 0]],
...                 [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()
```

**scipy.spatial.cKDTree.query\_pairs**`cKDTree.query_pairs` (*self*, *r*, *p*=2.0, *eps*=0)Find all pairs of points in *self* whose distance is at most *r*.**Parameters**

- r** [positive float] The maximum distance.
- p** [float, optional] Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ . A finite large *p* may cause a `ValueError` if overflow can occur.
- eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**output\_type**

[string, optional] Choose the output container, 'set' or 'ndarray'. Default: 'set'

**Returns**

**results** [set or ndarray] Set of pairs  $(i, j)$ , with  $i < j$ , for which the corresponding positions are close. If `output_type` is 'ndarray', an ndarray is returned instead of a set.

**Examples**

You can search all pairs of points in a kd-tree within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> np.random.seed(21701)
>>> points = np.random.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = cKDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
...     plt.plot([points[i, 0], points[j, 0]],
...             [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

**scipy.spatial.cKDTree.sparse\_distance\_matrix**

`cKDTree.sparse_distance_matrix` (*self*, *other*, *max\_distance*, *p=2.0*)

Compute a sparse distance matrix

Computes a distance matrix between two cKDTrees, leaving as zero any distance greater than `max_distance`.

**Parameters**

**other** [cKDTree]

**max\_distance** [positive float]

**p** [float,  $1 \leq p \leq \text{infinity}$ ] Which Minkowski  $p$ -norm to use. A finite large  $p$  may cause a `ValueError` if overflow can occur.

**output\_type** [string, optional] Which container to use for output data. Options: 'dok\_matrix', 'coo\_matrix', 'dict', or 'ndarray'. Default: 'dok\_matrix'.

**Returns**

**result** [dok\_matrix, coo\_matrix, dict or ndarray] Sparse matrix representing the results in "dictionary of keys" format. If a dict is returned the keys are  $(i, j)$  tuples of indices. If `output_type` is 'ndarray' a record array with fields 'i', 'j', and 'v' is returned,

## Examples

You can compute a sparse distance matrix between two kd-trees:

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> np.random.seed(21701)
>>> points1 = np.random.random((5, 2))
>>> points2 = np.random.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> sdm = kd_tree1.sparse_distance_matrix(kd_tree2, 0.3)
>>> sdm.toarray()
array([[0.20220215, 0.14538496, 0.,          0.10257199, 0.          ],
       [0.13491385, 0.27251306, 0.,          0.18793787, 0.          ],
       [0.19262396, 0.,          0.,          0.25795122, 0.          ],
       [0.14859639, 0.07076002, 0.,          0.04065851, 0.          ],
       [0.17308768, 0.,          0.,          0.24823138, 0.          ]])
```

You can check distances above the *max\_distance* are zeros:

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.20220215, 0.14538496, 0.43588092, 0.10257199, 0.4555495 ],
       [0.13491385, 0.27251306, 0.65944131, 0.18793787, 0.68184154],
       [0.19262396, 0.34121593, 0.72176889, 0.25795122, 0.74538858],
       [0.14859639, 0.07076002, 0.48505773, 0.04065851, 0.50043591],
       [0.17308768, 0.32837991, 0.72760803, 0.24823138, 0.75017239]])
```

## scipy.spatial.Rectangle

**class** `scipy.spatial.Rectangle` (*maxes, mins*)

Hyperrectangle class.

Represents a Cartesian product of intervals.

### Methods

<code>max_distance_point</code> (self, x[, p])	Return the maximum distance between input and points in the hyperrectangle.
<code>max_distance_rectangle</code> (self, other[, p])	Compute the maximum distance between points in the two hyperrectangles.
<code>min_distance_point</code> (self, x[, p])	Return the minimum distance between input and points in the hyperrectangle.
<code>min_distance_rectangle</code> (self, other[, p])	Compute the minimum distance between points in the two hyperrectangles.
<code>split</code> (self, d, split)	Produce two hyperrectangles by splitting.
<code>volume</code> (self)	Total volume.

**scipy.spatial.Rectangle.max\_distance\_point**`Rectangle.max_distance_point` (*self*, *x*, *p=2.0*)

Return the maximum distance between input and points in the hyperrectangle.

*Parameters*

**x** [array\_like] Input array.  
**p** [float, optional] Input.

**scipy.spatial.Rectangle.max\_distance\_rectangle**`Rectangle.max_distance_rectangle` (*self*, *other*, *p=2.0*)

Compute the maximum distance between points in the two hyperrectangles.

*Parameters*

**other** [hyperrectangle] Input.  
**p** [float, optional] Input.

**scipy.spatial.Rectangle.min\_distance\_point**`Rectangle.min_distance_point` (*self*, *x*, *p=2.0*)

Return the minimum distance between input and points in the hyperrectangle.

*Parameters*

**x** [array\_like] Input.  
**p** [float, optional] Input.

**scipy.spatial.Rectangle.min\_distance\_rectangle**`Rectangle.min_distance_rectangle` (*self*, *other*, *p=2.0*)

Compute the minimum distance between points in the two hyperrectangles.

*Parameters*

**other** [hyperrectangle] Input.  
**p** [float] Input.

**scipy.spatial.Rectangle.split**`Rectangle.split` (*self*, *d*, *split*)

Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

*Parameters*

**d** [int] Axis to split hyperrectangle along.  
**split** [float] Position along axis *d* to split at.

**scipy.spatial.Rectangle.volume**

`Rectangle.volume` (*self*)  
Total volume.

Distance metrics are contained in the `scipy.spatial.distance` submodule.

**6.26.3 Delaunay triangulation, convex hulls, and Voronoi diagrams**

<code>Delaunay</code> (points[, furthest_site, ...])	Delaunay tessellation in N dimensions.
<code>ConvexHull</code> (points[, incremental, qhull_options])	Convex hulls in N dimensions.
<code>Voronoi</code> (points[, furthest_site, ...])	Voronoi diagrams in N dimensions.
<code>SphericalVoronoi</code> (points[, radius, center, ...])	Voronoi diagrams on the surface of a sphere.
<code>HalfspaceIntersection</code> (halfspaces, interior_point)	Halfspace intersections in N dimensions.

**scipy.spatial.Delaunay**

**class** `scipy.spatial.Delaunay` (*points*, *furthest\_site=False*, *incremental=False*, *qhull\_options=None*)  
Delaunay tessellation in N dimensions.

New in version 0.9.

**Parameters**

**points** [ndarray of floats, shape (npoints, ndim)] Coordinates of points to triangulate

**furthest\_site** [bool, optional] Whether to compute a furthest-site Delaunay triangulation. Default: False  
New in version 0.12.0.

**incremental** [bool, optional] Allow adding new points incrementally. This takes up some additional resources.

**qhull\_options** [str, optional] Additional options to pass to Qhull. See Qhull manual for details. Option “Qt” is always enabled. Default: “Qbb Qc Qz Qx Q12” for `ndim > 4` and “Qbb Qc Qz Q12” otherwise. Incremental mode omits “Qz”.  
New in version 0.12.0.

**Raises**

**QhullError**  
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**ValueError**  
Raised if an incompatible array is given as input.

## Notes

The tessellation is computed using the Qhull library [Qhull library](#).

**Note:** Unless you pass in the Qhull option “QJ”, Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the *coplanar* attribute.

## Examples

Triangulation of a set of points:

```
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices)
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```

Point indices and coordinates for the two triangles forming the triangulation:

```
>>> tri.simplices
array([[2, 3, 0],
       [3, 1, 0]], dtype=int32) # may vary
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```
>>> points[tri.simplices]
array([[1. , 0. ],
       [1. , 1. ]], dtype=float64) # may vary
```

(continues on next page)

(continued from previous page)

```
[ 1. ,  1. ],
 [ 0. ,  0. ]],
 [[ 1. ,  1. ],
 [ 0. ,  1.1],
 [ 0. ,  0. ]]])
```

Triangle 0 is the only neighbor of triangle 1, and it's opposite to vertex 1 of triangle 1:

```
>>> tri.neighbors[1]
array([-1,  0, -1], dtype=int32)
>>> points[tri.simplices[1,1]]
array([ 0. ,  1.1])
```

We can find out which triangle points are in:

```
>>> p = np.array([(0.1, 0.2), (1.5, 0.5), (0.5, 1.05)])
>>> tri.find_simplex(p)
array([ 1, -1,  1], dtype=int32)
```

The returned integers in the array are the indices of the simplex the corresponding point is in. If -1 is returned, the point is in no simplex. Be aware that the shortcut in the following example only works correctly for valid points as invalid points result in -1 which is itself a valid index for the last simplex in the list.

```
>>> p_valids = np.array([(0.1, 0.2), (0.5, 1.05)])
>>> tri.simplices[tri.find_simplex(p_valids)]
array([[3, 1, 0],
       [3, 1, 0]], dtype=int32) # may vary
```

We can also compute barycentric coordinates in triangle 1 for these points:

```
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[ 0.1      ,  0.09090909,  0.80909091],
       [ 1.5      , -0.90909091,  0.40909091],
       [ 0.5      ,  0.5       ,  0.         ]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

#### *Attributes*

- points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- simplices** [ndarray of ints, shape (nsimplex, ndim+1)] Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.
- neighbors** [ndarray of ints, shape (nsimplex, ndim+1)] Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.
- equations** [ndarray of double, shape (nsimplex, ndim+2)] [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see [Qhull documentation](#) for more).
- paraboloid\_scale, paraboloid\_shift** [float] Scale and shift for the extra paraboloid dimension (see [Qhull documentation](#) for more).
- transform** [ndarray of double, shape (nsimplex, ndim+1, ndim)] Affine transform from  $x$  to the barycentric coordinates  $c$ .

- vertex\_to\_simplex**  
[ndarray of int, shape (npoints,)] Lookup array, from a vertex, to some simplex which it is a part of.
- convex\_hull**  
[ndarray of int, shape (nfaces, ndim)] Vertices of facets forming the convex hull of the point set.
- coplanar** [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were *not* included in the triangulation due to numerical precision issues.  
If option “Qc” is not specified, this list is not computed.  
New in version 0.12.0.
- vertices** Same as *simplices*, but deprecated.
- vertex\_neighbor\_vertices**  
[tuple of two ndarrays of int; (indptr, indices)] Neighboring vertices of vertices.
- furthest\_site**  
True if this was a furthest site triangulation and False if not.  
New in version 1.4.0.

## Methods

<code>add_points(points[, restart])</code>	Process a set of additional new points.
<code>close()</code>	Finish incremental processing.
<code>find_simplex(self, xi[, brute-force, tol])</code>	Find the simplices containing the given points.
<code>lift_points(self, x)</code>	Lift points to the Qhull paraboloid.
<code>plane_distance(self, xi)</code>	Compute hyperplane distances to the point <i>xi</i> from all simplices.

## scipy.spatial.Delaunay.add\_points

Delaunay.**add\_points** (*points*, *restart=False*)

Process a set of additional new points.

### Parameters

- points** [ndarray] New points to add. The dimensionality should match that of the initial points.
- restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

### Raises

- QhullError**  
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

`close`

## Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

### `scipy.spatial.Delaunay.close`

`Delaunay.close()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

### `scipy.spatial.Delaunay.find_simplex`

`Delaunay.find_simplex(self, xi, bruteforce=False, tol=None)`

Find the simplices containing the given points.

#### Parameters

<b>tri</b>	[DelaunayInfo] Delaunay triangulation
<b>xi</b>	[ndarray of double, shape (... , ndim)] Points to locate
<b>bruteforce</b>	[bool, optional] Whether to only perform a brute-force search
<b>tol</b>	[float, optional] Tolerance allowed in the inside-triangle check. Default is $100 * \text{eps}$ .

#### Returns

<b>i</b>	[ndarray of int, same shape as <i>xi</i> ] Indices of simplices containing each point. Points outside the triangulation get the value -1.
----------	---

## Notes

This uses an algorithm adapted from Qhull's `qh_findbestfacet`, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in  $N+1$  dimensions, the algorithm falls back to directed search in  $N$  dimensions.

### `scipy.spatial.Delaunay.lift_points`

`Delaunay.lift_points(self, x)`

Lift points to the Qhull paraboloid.

### `scipy.spatial.Delaunay.plane_distance`

`Delaunay.plane_distance(self, xi)`

Compute hyperplane distances to the point *xi* from all simplices.

## `scipy.spatial.ConvexHull`

**class** `scipy.spatial.ConvexHull` (*points, incremental=False, qhull\_options=None*)

Convex hulls in  $N$  dimensions.

New in version 0.12.0.

#### Parameters

<b>points</b>	[ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a convex hull from
---------------	--

**incremental**

[bool, optional] Allow adding new points incrementally. This takes up some additional resources.

**qhull\_options**

[str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qx” for ndim > 4 and “” otherwise) Option “Qt” is always enabled.

*Raises*

**QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**ValueError**

Raised if an incompatible array is given as input.

**Notes**

The convex hull is computed using the [Qhull library](#).

**References**

[Qhull]

**Examples**

Convex hull of a random set of points:

```
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
>>> points = np.random.rand(30, 2) # 30 random points in 2-D
>>> hull = ConvexHull(points)
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> for simplex in hull.simplices:
...     plt.plot(points[simplex, 0], points[simplex, 1], 'k-')
```

We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:

```
>>> plt.plot(points[hull.vertices,0], points[hull.vertices,1], 'r--', lw=2)
>>> plt.plot(points[hull.vertices[0],0], points[hull.vertices[0],1], 'ro')
>>> plt.show()
```

Facets visible from a point:

Create a square and add a point above the square.

```
>>> generators = np.array([[0.2, 0.2],
...                       [0.2, 0.4],
...                       [0.4, 0.4],
```

(continues on next page)

(continued from previous page)

```
...         [0.4, 0.2],
...         [0.3, 0.6]])
```

Call `ConvexHull` with the `QG` option. `QG4` means compute the portions of the hull not including point 4, indicating the facets that are visible from point 4.

```
>>> hull = ConvexHull(points=generators,
...                   qhull_options='QG4')
```

The “good” array indicates which facets are visible from point 4.

```
>>> print(hull.simplices)
[[1 0]
 [1 2]
 [3 0]
 [3 2]]
>>> print(hull.good)
[False True False False]
```

Now plot it, highlighting the visible facets.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1,1,1)
>>> for visible_facet in hull.simplices[hull.good]:
...     ax.plot(hull.points[visible_facet, 0],
...             hull.points[visible_facet, 1],
...             color='violet',
...             lw=6)
>>> convex_hull_plot_2d(hull, ax=ax)
<Figure size 640x480 with 1 Axes> # may vary
>>> plt.show()
```

### Attributes

- points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- vertices** [ndarray of ints, shape (nvertices,)] Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.
- simplices** [ndarray of ints, shape (nfacet, ndim)] Indices of points forming the simplicial facets of the convex hull.
- neighbors** [ndarray of ints, shape (nfacet, ndim)] Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.
- equations** [ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the facet (see [Qhull documentation](#) for more).
- coplanar** [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were *not* included in the triangulation due to numerical precision issues.  
If option “Qc” is not specified, this list is not computed.
- good** [ndarray of bool or None] A one-dimensional Boolean array indicating which facets are good. Used with options that compute good facets, e.g. QGn and QG-n. Good facets are defined as those that are visible (n) or invisible (-n) from point n, where n is the nth point in ‘points’. The ‘good’ attribute may be used as an index into ‘simplices’ to return the good (visible) facets: simplices[good]. A facet is visible from the outside of the hull only, and neither coplanarity nor degeneracy count as cases of visibility.  
If a “QGn” or “QG-n” option is not specified, None is returned.  
New in version 1.3.0.
- area** [float] Surface area of the convex hull when input dimension > 2. When input points are 2-dimensional, this is the perimeter of the convex hull.  
New in version 0.17.0.
- volume** [float] Volume of the convex hull when input dimension > 2. When input points are 2-dimensional, this is the area of the convex hull.  
New in version 0.17.0.

## Methods

<code>add_points(points[, restart])</code>	Process a set of additional new points.
<code>close()</code>	Finish incremental processing.

### `scipy.spatial.ConvexHull.add_points`

`ConvexHull.add_points` (*points*, *restart=False*)

Process a set of additional new points.

#### Parameters

**points** [ndarray] New points to add. The dimensionality should match that of the initial points.  
**restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

#### Raises

##### **QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

#### See also:

`close`

## Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

### `scipy.spatial.ConvexHull.close`

`ConvexHull.close` ()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

## `scipy.spatial.Voronoi`

**class** `scipy.spatial.Voronoi` (*points*, *furthest\_site=False*, *incremental=False*, *qhull\_options=None*)

Voronoi diagrams in N dimensions.

New in version 0.12.0.

#### Parameters

**points** [ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a convex hull from  
**furthest\_site** [bool, optional] Whether to compute a furthest-site Voronoi diagram. Default: False  
**incremental** [bool, optional] Allow adding new points incrementally. This takes up some additional resources.

**qhull\_options**

[str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qbb Qc Qz Qx” for  $\text{ndim} > 4$  and “Qbb Qc QZ” otherwise. Incremental mode omits “QZ”.)

**Raises****QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**ValueError**

Raised if an incompatible array is given as input.

**Notes**

The Voronoi diagram is computed using the [Qhull library](#).

**Examples**

Voronoi diagram for a set of point:

```
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2],
...                    [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> fig = voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:

```
>>> vor.vertices
array([[0.5, 0.5],
       [0.5, 1.5],
       [1.5, 0.5],
       [1.5, 1.5]])
```

There is a single finite Voronoi region, and four finite Voronoi ridges:

```
>>> vor.regions
[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [0, 1, 3,
→ 2], [2, -1, 0], [3, -1, 1]]
>>> vor.ridge_vertices
[[-1, 0], [-1, 0], [-1, 1], [-1, 1], [0, 1], [-1, 3], [-1, 2], [2, 3], [-
→ 1, 3], [-1, 2], [1, 3], [0, 2]]
```

The ridges are perpendicular between lines drawn between the following input points:

```
>>> vor.ridge_points
array([[0, 3],
       [0, 1],
       [2, 5],
       [2, 1],
       [1, 4],
       [7, 8],
       [7, 6],
       [7, 4],
       [8, 5],
       [6, 3],
       [4, 5],
       [4, 3]], dtype=int32)
```

### Attributes

- points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- vertices** [ndarray of double, shape (nvertices, ndim)] Coordinates of the Voronoi vertices.
- ridge\_points** [ndarray of ints, shape (nridges, 2)] Indices of the points between which each Voronoi ridge lies.
- ridge\_vertices** [list of list of ints, shape (nridges, \*)] Indices of the Voronoi vertices forming each Voronoi ridge.
- regions** [list of list of ints, shape (nregions, \*)] Indices of the Voronoi vertices forming each Voronoi region. -1 indicates vertex outside the Voronoi diagram.
- point\_region** [list of ints, shape (npoints)] Index of the Voronoi region for each input point. If qhull option “Qc” was not specified, the list will contain -1 for points that are not associated with a Voronoi region.
- furthest\_site** True if this was a furthest site triangulation and False if not.  
New in version 1.4.0.

## Methods

<code>add_points(points[, restart])</code>	Process a set of additional new points.
<code>close()</code>	Finish incremental processing.

### `scipy.spatial.Voronoi.add_points`

`Voronoi.add_points(points, restart=False)`

Process a set of additional new points.

#### Parameters

**points** [ndarray] New points to add. The dimensionality should match that of the initial points.  
**restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

#### Raises

##### **QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

#### See also:

`close`

## Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

### `scipy.spatial.Voronoi.close`

`Voronoi.close()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

## `scipy.spatial.SphericalVoronoi`

**class** `scipy.spatial.SphericalVoronoi(points, radius=1, center=None, threshold=1e-06)`

Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

#### Parameters

**points** [ndarray of floats, shape (npoints, ndim)] Coordinates of points from which to construct a spherical Voronoi diagram.  
**radius** [float, optional] Radius of the sphere (Default: 1)  
**center** [ndarray of floats, shape (ndim,)] Center of sphere (Default: origin)  
**threshold** [float] Threshold for detecting duplicate points and mismatches between points and sphere parameters. (Default: 1e-06)

#### Raises

**ValueError**

If there are duplicates in *points*. If the provided *radius* is not consistent with *points*.

See also:

**Voronoi**

Conventional Voronoi diagrams in N dimensions.

**Notes**

The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [Caroli]. The Convex Hull neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement).

**References**

[Caroli], [VanOosterom]

**Examples**

Do some imports and take some points on a cube:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import SphericalVoronoi, geometric_slerp
>>> from mpl_toolkits.mplot3d import proj3d
>>> # set input data
>>> points = np.array([[0, 0, 1], [0, 0, -1], [1, 0, 0],
...                   [0, 1, 0], [0, -1, 0], [-1, 0, 0], ])
```

Calculate the spherical Voronoi diagram:

```
>>> radius = 1
>>> center = np.array([0, 0, 0])
>>> sv = SphericalVoronoi(points, radius, center)
```

Generate plot:

```
>>> # sort vertices (optional, helpful for plotting)
>>> sv.sort_vertices_of_regions()
>>> t_vals = np.linspace(0, 1, 2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> # plot the unit sphere for reference (optional)
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
```

(continues on next page)

(continued from previous page)

```
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
>>> # plot generator points
>>> ax.scatter(points[:, 0], points[:, 1], points[:, 2], c='b')
>>> # plot Voronoi vertices
>>> ax.scatter(sv.vertices[:, 0], sv.vertices[:, 1], sv.vertices[:, 2],
...           c='g')
>>> # indicate Voronoi regions (as Euclidean polygons)
>>> for region in sv.regions:
...     n = len(region)
...     for i in range(n):
...         start = sv.vertices[region][i]
...         end = sv.vertices[region][(i + 1) % n]
...         result = geometric_slerp(start, end, t_vals)
...         ax.plot(result[..., 0],
...                 result[..., 1],
...                 result[..., 2],
...                 c='k')
>>> ax.azim = 10
>>> ax.elev = 40
>>> _ = ax.set_xticks([])
>>> _ = ax.set_yticks([])
>>> _ = ax.set_zticks([])
>>> fig.set_size_inches(4, 4)
>>> plt.show()
```

### Attributes

<b>points</b>	[double array of shape (npoints, ndim)] the points in <i>ndim</i> dimensions to generate the Voronoi diagram from
<b>radius</b>	[double] radius of the sphere
<b>center</b>	[double array of shape (ndim,)] center of the sphere
<b>vertices</b>	[double array of shape (nvertices, ndim)] Voronoi vertices corresponding to points
<b>regions</b>	[list of list of integers of shape (npoints, _)] the n-th entry is a list consisting of the indices of the vertices belonging to the n-th point in points

## Methods

---

<code>calculate_areas(self)</code>	Calculates the areas of the Voronoi regions.
------------------------------------	--

---

### `scipy.spatial.SphericalVoronoi.calculate_areas`

`SphericalVoronoi.calculate_areas` (*self*)

Calculates the areas of the Voronoi regions.

For 2D point sets, the regions are circular arcs. The sum of the areas is  $2 * \pi * radius$ .

For 3D point sets, the regions are spherical polygons. The sum of the areas is  $4 * \pi * radius**2$ .

New in version 1.5.0.

#### Returns

**areas** [double array of shape (npoints,)] The areas of the Voronoi regions.

### `scipy.spatial.HalfspaceIntersection`

**class** `scipy.spatial.HalfspaceIntersection` (*halfspaces*, *interior\_point*, *incremental=False*, *qhull\_options=None*)

Halfspace intersections in N dimensions.

New in version 0.19.0.

#### Parameters

**halfspaces** [ndarray of floats, shape (nineq, ndim+1)] Stacked Inequalities of the form  $Ax + b \leq 0$  in format [A; b]

**interior\_point** [ndarray of floats, shape (ndim,)] Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming.

**incremental** [bool, optional] Allow adding new halfspaces incrementally. This takes up some additional resources.

**qhull\_options** [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: "Qx" for  $ndim > 4$  and "" otherwise) Option "H" is always enabled.

#### Raises

**QhullError**  
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**ValueError**  
Raised if an incompatible array is given as input.

## Notes

The intersections are computed using the [Qhull library](#). This reproduces the “qhalf” functionality of Qhull.

## References

[Qhull], [1]

## Examples

Halfspace intersection of planes forming some polygon

```
>>> from scipy.spatial import HalfspaceIntersection
>>> halfspaces = np.array([[ -1,  0.,  0.],
...                       [ 0., -1.,  0.],
...                       [ 2.,  1., -4.],
...                       [-0.5,  1., -2.]])
>>> feasible_point = np.array([0.5, 0.5])
>>> hs = HalfspaceIntersection(halfspaces, feasible_point)
```

Plot halfspaces as filled regions and intersection points:

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1, aspect='equal')
>>> xlim, ylim = (-1, 3), (-1, 3)
>>> ax.set_xlim(xlim)
>>> ax.set_ylim(ylim)
>>> x = np.linspace(-1, 3, 100)
>>> symbols = ['-', '+', 'x', '*']
>>> signs = [0, 0, -1, -1]
>>> fmt = {"color": None, "edgecolor": "b", "alpha": 0.5}
>>> for h, sym, sign in zip(halfspaces, symbols, signs):
...     hlist = h.tolist()
...     fmt["hatch"] = sym
...     if h[1]== 0:
...         ax.axvline(-h[2]/h[0], label='{}x+{}y+{}=0'.format(*hlist))
...         xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
...         ax.fill_between(xi, ylim[0], ylim[1], **fmt)
...     else:
...         ax.plot(x, (-h[2]-h[0]*x)/h[1], label='{}x+{}y+{}=0'.
...             ↪format(*hlist))
...         ax.fill_between(x, (-h[2]-h[0]*x)/h[1], ylim[sign], **fmt)
>>> x, y = zip(*hs.intersections)
>>> ax.plot(x, y, 'o', markersize=8)
```

By default, qhull does not provide with a way to compute an interior point. This can easily be computed using linear programming. Considering halfspaces of the form  $Ax + b \leq 0$ , solving the linear program:

$$\begin{aligned} & \max y \\ & \text{s.t. } Ax + y||A_i|| \leq -b \end{aligned}$$

With  $A_i$  being the rows of A, i.e. the normals to each plane.

Will yield a point  $x$  that is furthest inside the convex polyhedron. To be precise, it is the center of the largest hypersphere of radius  $y$  inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron (see [1] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

```
>>> from scipy.optimize import linprog
>>> from matplotlib.patches import Circle
>>> norm_vector = np.reshape(np.linalg.norm(halfspaces[:, :-1], axis=1),
...                           (halfspaces.shape[0], 1))
>>> c = np.zeros((halfspaces.shape[1],))
>>> c[-1] = -1
>>> A = np.hstack((halfspaces[:, :-1], norm_vector))
>>> b = - halfspaces[:, -1:]
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=(None, None))
>>> x = res.x[:-1]
>>> y = res.x[-1]
>>> circle = Circle(x, radius=y, alpha=0.3)
>>> ax.add_patch(circle)
>>> plt.legend(bbox_to_anchor=(1.6, 1.0))
>>> plt.show()
```

### Attributes

**halfspaces** [ndarray of double, shape (nineq, ndim+1)] Input halfspaces.

**interior\_point** :ndarray of floats, shape (ndim,)

Input interior point.

**intersections**

[ndarray of double, shape (ninter, ndim)] Intersections of all halfspaces.

**dual\_points**

[ndarray of double, shape (nineq, ndim)] Dual points of the input halfspaces.

**dual\_facets**

[list of lists of ints] Indices of points forming the (non necessarily simplicial) facets of the dual convex hull.

**dual\_vertices**

[ndarray of ints, shape (nvertices,)] Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

**dual\_equations**

[ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the dual facet (see [Qhull documentation](#) for more).

**dual\_area** [float] Area of the dual convex hull

**dual\_volume** [float] Volume of the dual convex hull

**Methods**

---

<code>add_halfspaces(halfspaces[, restart])</code>	Process a set of additional new halfspaces.
<code>close()</code>	Finish incremental processing.

---

**scipy.spatial.HalfspaceIntersection.add\_halfspaces**

`HalfspaceIntersection.add_halfspaces(halfspaces, restart=False)`

Process a set of additional new halfspaces.

*Parameters*

**halfspaces** [ndarray] New halfspaces to add. The dimensionality should match that of the initial halfspaces.

**restart** [bool, optional] Whether to restart processing from scratch, rather than adding halfspaces incrementally.

*Raises*

**QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

[close](#)

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after `close` has been called.

**scipy.spatial.HalfspaceIntersection.close**

`HalfspaceIntersection.close()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

## 6.26.4 Plotting helpers

<code>delaunay_plot_2d(tri[, ax])</code>	Plot the given Delaunay triangulation in 2-D
<code>convex_hull_plot_2d(hull[, ax])</code>	Plot the given convex hull diagram in 2-D
<code>voronoi_plot_2d(vor[, ax])</code>	Plot the given Voronoi diagram in 2-D

### `scipy.spatial.delaunay_plot_2d`

`scipy.spatial.delaunay_plot_2d` (*tri*, *ax=None*)

Plot the given Delaunay triangulation in 2-D

#### Parameters

**tri** [scipy.spatial.Delaunay instance] Triangulation to plot  
**ax** [matplotlib.axes.Axes instance, optional] Axes to plot on

#### Returns

**fig** [matplotlib.figure.Figure instance] Figure for the plot

See also:

[Delaunay](#)

`matplotlib.pyplot.triplot`

#### Notes

Requires Matplotlib.

#### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d
```

The Delaunay triangulation of a set of random points:

```
>>> points = np.random.rand(30, 2)
>>> tri = Delaunay(points)
```

Plot it:

```
>>> _ = delaunay_plot_2d(tri)
>>> plt.show()
```

### scipy.spatial.convex\_hull\_plot\_2d

`scipy.spatial.convex_hull_plot_2d(hull, ax=None)`

Plot the given convex hull diagram in 2-D

#### Parameters

**hull** [scipy.spatial.ConvexHull instance] Convex hull to plot  
**ax** [matplotlib.axes.Axes instance, optional] Axes to plot on

#### Returns

**fig** [matplotlib.figure.Figure instance] Figure for the plot

See also:

[ConvexHull](#)

#### Notes

Requires Matplotlib.

#### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
```

The convex hull of a random set of points:

```
>>> points = np.random.rand(30, 2)
>>> hull = ConvexHull(points)
```

Plot it:

```
>>> _ = convex_hull_plot_2d(hull)
>>> plt.show()
```

### scipy.spatial.voronoi\_plot\_2d

`scipy.spatial.voronoi_plot_2d(vor, ax=None, **kw)`  
 Plot the given Voronoi diagram in 2-D

#### Parameters

- vor** [scipy.spatial.Voronoi instance] Diagram to plot
- ax** [matplotlib.axes.Axes instance, optional] Axes to plot on
- show\_points: bool, optional**  
Add the Voronoi points to the plot.
- show\_vertices**  
[bool, optional] Add the Voronoi vertices to the plot.
- line\_colors**  
[string, optional] Specifies the line color for polygon boundaries
- line\_width** [float, optional] Specifies the line width for polygon boundaries
- line\_alpha: float, optional**  
Specifies the line alpha for polygon boundaries
- point\_size: float, optional**  
Specifies the size of points

#### Returns

- fig** [matplotlib.figure.Figure instance] Figure for the plot

See also:

[Voronoi](#)

## Notes

Requires Matplotlib.

## Examples

Set of point:

```
>>> import matplotlib.pyplot as plt
>>> points = np.random.rand(10,2) #random
```

Voronoi diagram of the points:

```
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

using `voronoi_plot_2d` for visualisation:

```
>>> fig = voronoi_plot_2d(vor)
```

using `voronoi_plot_2d` for visualisation with enhancements:

```
>>> fig = voronoi_plot_2d(vor, show_vertices=False, line_colors='orange',
...                       line_width=2, line_alpha=0.6, point_size=2)
>>> plt.show()
```

*Tutorial*

### 6.26.5 Simplex representation

The simplices (triangles, tetrahedra, etc.) appearing in the Delaunay tessellation (N-D simplices), convex hull facets, and Voronoi ridges (N-1-D simplices) are represented in the following scheme:

```
tess = Delaunay(points)
hull = ConvexHull(points)
voro = Voronoi(points)

# coordinates of the jth vertex of the ith simplex
tess.points[tess.simplices[i, j], :]      # tessellation element
hull.points[hull.simplices[i, j], :]      # convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :] # ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition: `tess.neighbors[i, j]` is the neighboring simplex of the `i`th simplex, opposite to the `j`-vertex. It is `-1` in case of no neighbor.

Convex hull facets also define a hyperplane equation:

```
(hull.equations[i, :-1] * coord).sum() + hull.equations[i, -1] == 0
```

Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding N+1-D paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.

## Functions

<code>tsearch(tri, xi)</code>	Find simplices containing the given points.
<code>distance_matrix(x, y[, p, threshold])</code>	Compute the distance matrix.
<code>minkowski_distance(x, y[, p])</code>	Compute the L**p distance between two arrays.
<code>minkowski_distance_p(x, y[, p])</code>	Compute the pth power of the L**p distance between two arrays.
<code>procrustes(data1, data2)</code>	Procrustes analysis, a similarity test for two data sets.
<code>geometric_slerp(start, end, t[, toll])</code>	Geometric spherical linear interpolation.

### scipy.spatial.tsearch

`scipy.spatial.tsearch` (*tri, xi*)

Find simplices containing the given points. This function does the same thing as `Delaunay.find_simplex`.

New in version 0.9.

**See also:**

`Delaunay.find_simplex`

### Examples

```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d, tsearch
```

The Delaunay triangulation of a set of random points:

```
>>> pts = np.random.rand(20, 2)
>>> tri = Delaunay(pts)
>>> _ = delaunay_plot_2d(tri)
```

Find the simplices containing a given set of points:

```
>>> loc = np.random.uniform(0.2, 0.8, (5, 2))
>>> s = tsearch(tri, loc)
>>> plt.triplot(pts[:, 0], pts[:, 1], tri.simplices[s], 'b-', mask=s==1)
>>> plt.scatter(loc[:, 0], loc[:, 1], c='r', marker='x')
>>> plt.show()
```

### scipy.spatial.distance\_matrix

`scipy.spatial.distance_matrix` (*x, y, p=2, threshold=1000000*)

Compute the distance matrix.

Returns the matrix of all pair-wise distances.

#### Parameters

- x** [(M, K) array\_like] Matrix of M vectors in K dimensions.
- y** [(N, K) array\_like] Matrix of N vectors in K dimensions.
- p** [float, 1 <= p <= infinity] Which Minkowski p-norm to use.
- threshold** [positive int] If  $M * N * K > threshold$ , algorithm uses a Python loop instead of large temporary arrays.

**Returns**

**result** [(M, N) ndarray] Matrix containing the distance from every vector in  $x$  to every vector in  $y$ .

**Examples**

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0,0],[0,1]], [[1,0],[1,1]])
array([[ 1.         ,  1.41421356],
       [ 1.41421356,  1.         ]])
```

**scipy.spatial.minkowski\_distance**

`scipy.spatial.minkowski_distance(x, y, p=2)`

Compute the  $L^{**p}$  distance between two arrays.

**Parameters**

**x** [(M, K) array\_like] Input array.  
**y** [(N, K) array\_like] Input array.  
**p** [float, 1 <= p <= infinity] Which Minkowski p-norm to use.

**Examples**

```
>>> from scipy.spatial import minkowski_distance
>>> minkowski_distance([[0,0],[0,0]], [[1,1],[0,1]])
array([ 1.41421356,  1.         ])
```

### scipy.spatial.minkowski\_distance\_p

`scipy.spatial.minkowski_distance_p(x, y, p=2)`

Compute the  $p$ th power of the  $L^{**p}$  distance between two arrays.

For efficiency, this function computes the  $L^{**p}$  distance but does not extract the  $p$ th root. If  $p$  is 1 or infinity, this is equal to the actual  $L^{**p}$  distance.

#### Parameters

<b>x</b>	[(M, K) array_like] Input array.
<b>y</b>	[(N, K) array_like] Input array.
<b>p</b>	[float, 1 <= p <= infinity] Which Minkowski p-norm to use.

#### Examples

```
>>> from scipy.spatial import minkowski_distance_p
>>> minkowski_distance_p([[0, 0], [0, 0]], [[1, 1], [0, 1]])
array([2, 1])
```

### scipy.spatial.procrustes

`scipy.spatial.procrustes(data1, data2)`

Procrustes analysis, a similarity test for two data sets.

Each input matrix is a set of points or vectors (the rows of the matrix). The dimension of the space is the number of columns of each matrix. Given two identically sized matrices, procrustes standardizes both such that:

- $tr(AA^T) = 1$ .
- Both sets of points are centered around the origin.

Procrustes ([1], [2]) then applies the optimal transform to the second matrix (including scaling/dilation, rotations, and reflections) to minimize  $M^2 = \sum (data1 - data2)^2$ , or the sum of the squares of the pointwise differences between the two input datasets.

This function was not designed to handle datasets with different numbers of datapoints (rows). If two data sets have different dimensionality (different number of columns), simply add columns of zeros to the smaller of the two.

#### Parameters

<b>data1</b>	[array_like] Matrix, n rows represent points in k (columns) space <i>data1</i> is the reference data, after it is standardised, the data from <i>data2</i> will be transformed to fit the pattern in <i>data1</i> (must have >1 unique points).
<b>data2</b>	[array_like] n rows of data in k space to be fit to <i>data1</i> . Must be the same shape (numrows, numcols) as <i>data1</i> (must have >1 unique points).

#### Returns

<b>mtx1</b>	[array_like] A standardized version of <i>data1</i> .
<b>mtx2</b>	[array_like] The orientation of <i>data2</i> that best fits <i>data1</i> . Centered, but not necessarily $tr(AA^T) = 1$ .
<b>disparity</b>	[float] $M^2$ as defined above.

#### Raises

##### ValueError

If the input arrays are not two-dimensional. If the shape of the input arrays is different. If the input arrays have zero columns or zero rows.

See also:

`scipy.linalg.orthogonal_procrustes`

`scipy.spatial.distance.directed_hausdorff`

Another similarity test for two data sets

## Notes

- The disparity should not depend on the order of the input matrices, but the output matrices will, as only the first output matrix is guaranteed to be scaled such that  $\text{tr}(AA^T) = 1$ .
- Duplicate data points are generally ok, duplicating a data point will increase its effect on the procrustes fit.
- The disparity scales as the number of points per input matrix.

## References

[1], [2]

## Examples

```
>>> from scipy.spatial import procrustes
```

The matrix `b` is a rotated, shifted, scaled and mirrored version of `a` here:

```
>>> a = np.array([[1, 3], [1, 2], [1, 1], [2, 1]], 'd')
>>> b = np.array([[4, -2], [4, -4], [4, -6], [2, -6]], 'd')
>>> mtx1, mtx2, disparity = procrustes(a, b)
>>> round(disparity)
0.0
```

## `scipy.spatial.geometric_slerp`

`scipy.spatial.geometric_slerp` (*start, end, t, tol=1e-07*)

Geometric spherical linear interpolation.

The interpolation occurs along a unit-radius great circle arc in arbitrary dimensional space.

### Parameters

- start** [(n\_dimensions, ) array-like] Single n-dimensional input coordinate in a 1-D array-like object. *n* must be greater than 1.
- end** [(n\_dimensions, ) array-like] Single n-dimensional input coordinate in a 1-D array-like object. *n* must be greater than 1.
- t: float or (n\_points,) array-like**  
A float or array-like of doubles representing interpolation parameters, with values required in the inclusive interval between 0 and 1. A common approach is to generate the array with `np.linspace(0, 1, n_pts)` for linearly spaced points. Ascending, descending, and scrambled orders are permitted.
- tol: float** The absolute tolerance for determining if the start and end coordinates are antipodes.

### Returns

- result** [(t.size, D)] An array of doubles containing the interpolated spherical path and including start and end when 0 and 1 *t* are used. The interpolated values should correspond to the same sort order provided in the *t* array. The result may be 1-dimensional if *t* is a float.

**Raises****ValueError**

If `start` and `end` are antipodes, not on the unit n-sphere, or for a variety of degenerate conditions.

**See also:**

**`scipy.spatial.transform.Slerp`**

3-D Slerp that works with quaternions

**Notes**

The implementation is based on the mathematical formula provided in [1], and the first known presentation of this algorithm, derived from study of 4-D geometry, is credited to Glenn Davis in a footnote of the original quaternion Slerp publication by Ken Shoemake [2].

New in version 1.5.0.

**References**

[1], [2]

**Examples**

Interpolate four linearly-spaced values on the circumference of a circle spanning 90 degrees:

```
>>> from scipy.spatial import geometric_slerp
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> start = np.array([1, 0])
>>> end = np.array([0, 1])
>>> t_vals = np.linspace(0, 1, 4)
>>> result = geometric_slerp(start,
...                          end,
...                          t_vals)
```

The interpolated results should be at 30 degree intervals recognizable on the unit circle:

```
>>> ax.scatter(result[... ,0], result[... ,1], c='k')
>>> circle = plt.Circle((0, 0), 1, color='grey')
>>> ax.add_artist(circle)
>>> ax.set_aspect('equal')
>>> plt.show()
```

Attempting to interpolate between antipodes on a circle is ambiguous because there are two possible paths, and on a sphere there are infinite possible paths on the geodesic surface. Nonetheless, one of the ambiguous paths is returned along with a warning:

```
>>> opposite_pole = np.array([-1, 0])
>>> with np.testing.suppress_warnings() as sup:
...     sup.filter(UserWarning)
...     geometric_slerp(start,
...                       opposite_pole,
...                       t_vals)
array([[ 1.00000000e+00,  0.00000000e+00],
       [ 5.00000000e-01,  8.66025404e-01],
       [-5.00000000e-01,  8.66025404e-01],
       [-1.00000000e+00,  1.22464680e-16]])
```

Extend the original example to a sphere and plot interpolation points in 3D:

```
>>> from mpl_toolkits.mplot3d import proj3d
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
```

Plot the unit sphere for reference (optional):

```
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
```

Interpolating over a larger number of points may provide the appearance of a smooth curve on the surface of the sphere, which is also useful for discretized integration calculations on a sphere surface:

```
>>> start = np.array([1, 0, 0])
>>> end = np.array([0, 0, 1])
>>> t_vals = np.linspace(0, 1, 200)
>>> result = geometric_slerp(start,
...                           end,
```

(continues on next page)

(continued from previous page)

```

...                               t_vals)
>>> ax.plot(result[... ,0],
...         result[... ,1],
...         result[... ,2],
...         c='k')
>>> plt.show()

```

## 6.27 Distance computations (`scipy.spatial.distance`)

### 6.27.1 Function reference

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

<code>pdist(X[, metric])</code>	Pairwise distances between observations in n-dimensional space.
<code>cdist(XA, XB[, metric])</code>	Compute distance between each pair of the two collections of inputs.
<code>squareform(X[, force, checks])</code>	Convert a vector-form distance vector to a square-form distance matrix, and vice-versa.
<code>directed_hausdorff(u, v[, seed])</code>	Compute the directed Hausdorff distance between two N-D arrays.

**scipy.spatial.distance.pdist**

`scipy.spatial.distance.pdist` (*X*, *metric*='euclidean', \*args, \*\*kwargs)

Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

**Parameters**

<b>X</b>	[ndarray] An m by n array of m original observations in an n-dimensional space.
<b>metric</b>	[str or function, optional] The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.
<b>*args</b>	[tuple. Deprecated.] Additional arguments should be passed as keyword arguments
<b>**kwargs</b>	[dict, optional] Extra arguments to <i>metric</i> : refer to each metric documentation for a list of all possible arguments. Some possible arguments: <i>p</i> : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2. <i>w</i> : ndarray The weight vector for metrics that support weights (e.g., Minkowski). <i>V</i> : ndarray The variance vector for standardized Euclidean. Default: <code>var(X, axis=0, ddof=1)</code> <i>VI</i> : ndarray The inverse of the covariance matrix for Mahalanobis. Default: <code>inv(cov(X.T)).T</code> <i>out</i> : ndarray. The output array If not None, condensed distance matrix Y is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

**Returns**

<b>Y</b>	[ndarray] Returns a condensed distance matrix Y. For each <i>i</i> and <i>j</i> (where $i < j < m$ ), where <i>m</i> is the number of original observations. The metric <code>dist(u=X[i], v=X[j])</code> is computed and stored in entry $m * i + j - ((i + 2) * (i + 1)) // 2$ .
----------	--

See also:

**squareform**

converts between condensed distance matrices and square distance matrices.

**Notes**

See `squareform` for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. `Y = pdist(X, 'euclidean')`

Computes the distance between *m* points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as *m* n-dimensional row vectors in the matrix *X*.

2. `Y = pdist(X, 'minkowski', p=2.)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  (p-norm) where  $p \geq 1$ .

3. `Y = pdist(X, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = pdist(X, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two n-vectors `u` and `v` is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}$$

`V` is the variance vector; `V[i]` is the variance computed over all the `i`'th components of the points. If not passed, it is automatically computed.

5. `Y = pdist(X, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6. `Y = pdist(X, 'cosine')`

Computes the cosine distance between vectors `u` and `v`,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|*\|_2$  is the 2-norm of its argument `*`, and  $u \cdot v$  is the dot product of `u` and `v`.

7. `Y = pdist(X, 'correlation')`

Computes the correlation distance between vectors `u` and `v`. This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector `v`, and  $x \cdot y$  is the dot product of `x` and `y`.

8. `Y = pdist(X, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two n-vectors `u` and `v` which disagree. To save memory, the matrix `X` can be of type boolean.

9. `Y = pdist(X, 'jaccard')`

Computes the Jaccard distance between the points. Given two vectors, `u` and `v`, the Jaccard distance is the proportion of those elements `u[i]` and `v[i]` that disagree.

10. `Y = pdist(X, 'chebyshev')`

Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors `u` and `v` is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|$$

11. `Y = pdist(X, 'canberra')`

Computes the Canberra distance between the points. The Canberra distance between two points `u` and `v` is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

12. `Y = pdist(X, 'braycurtis')`

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points `u` and `v` is

$$d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}$$

13. `Y = pdist(X, 'mahalanobis', VI=None)`

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u-v)(1/V)(u-v)^T}$  where  $(1/V)$  (the `VI` variable) is the inverse covariance. If `VI` is not `None`, `VI` will be used as the inverse covariance matrix.

14. `Y = pdist(X, 'yule')`

Computes the Yule distance between each pair of boolean vectors. (see `yule` function documentation)

15. `Y = pdist(X, 'matching')`

Synonym for 'hamming'.

16. `Y = pdist(X, 'dice')`

Computes the Dice distance between each pair of boolean vectors. (see `dice` function documentation)

17. `Y = pdist(X, 'kulsinski')`

Computes the Kulsinski distance between each pair of boolean vectors. (see `kulsinski` function documentation)

18. `Y = pdist(X, 'rogerstanimoto')`

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see `rogerstanimoto` function documentation)

19. `Y = pdist(X, 'russellrao')`

Computes the Russell-Rao distance between each pair of boolean vectors. (see `russellrao` function documentation)

20. `Y = pdist(X, 'sokalmichener')`

Computes the Sokal-Michener distance between each pair of boolean vectors. (see `sokalmichener` function documentation)

21. `Y = pdist(X, 'sokalsneath')`

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see `sokalsneath` function documentation)

22. `Y = pdist(X, 'wminkowski', p=2, w=w)`

Computes the weighted Minkowski distance between each pair of vectors. (see `wminkowski` function documentation)  
`'wminkowski'` is deprecated and will be removed in SciPy 1.8.0. Use `'minkowski'` instead.

23. `Y = pdist(X, f)`

Computes the distance between all pairs of vectors in `X` using the user supplied 2-arity function `f`. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = pdist(X, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = pdist(X, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function sokalsneath. This would result in sokalsneath being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

```
dm = pdist(X, 'sokalsneath')
```

### scipy.spatial.distance.cdist

`scipy.spatial.distance.cdist(XA, XB, metric='euclidean', *args, **kwargs)`

Compute distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

#### Parameters

- XA** [ndarray] An  $m_A$  by  $n$  array of  $m_A$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.
- XB** [ndarray] An  $m_B$  by  $n$  array of  $m_B$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.
- metric** [str or callable, optional] The distance metric to use. If a string, the distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'wminkowski', 'yule'.
- \*args** [tuple. Deprecated.] Additional arguments should be passed as keyword arguments
- \*\*kwargs** [dict, optional] Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.  
Some possible arguments:  
  - p** : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
  - w** : ndarray The weight vector for metrics that support weights (e.g., Minkowski).
  - V** : ndarray The variance vector for standardized Euclidean. Default: `var(vstack([XA, XB]), axis=0, ddof=1)`
  - VI** : ndarray The inverse of the covariance matrix for Mahalanobis. Default: `inv(cov(vstack([XA, XB].T))).T`
  - out** : ndarray The output array If not None, the distance matrix Y is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

#### Returns

- Y** [ndarray] A  $m_A$  by  $m_B$  distance matrix is returned. For each  $i$  and  $j$ , the metric `dist(u=XA[i], v=XB[j])` is computed and stored in the  $ij$  th entry.

#### Raises

- ValueError**  
An exception is thrown if *XA* and *XB* do not have the same number of columns.

## Notes

The following are common calling conventions:

1. `Y = cdist(XA, XB, 'euclidean')`

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix  $X$ .

2. `Y = cdist(XA, XB, 'minkowski', p=2.)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  ( $p$ -norm) where  $p \geq 1$ .

3. `Y = cdist(XA, XB, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = cdist(XA, XB, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}.$$

$V$  is the variance vector;  $V[i]$  is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5. `Y = cdist(XA, XB, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6. `Y = cdist(XA, XB, 'cosine')`

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|* \|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7. `Y = cdist(XA, XB, 'correlation')`

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8. `Y = cdist(XA, XB, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9. `Y = cdist(XA, XB, 'jaccard')`

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree where at least one of them is non-zero.

10. `Y = cdist(XA, XB, 'chebyshev')`

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|.$$

11. `Y = cdist(XA, XB, 'canberra')`

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

12. `Y = cdist(XA, XB, 'braycurtis')`

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}$$

13. `Y = cdist(XA, XB, 'mahalanobis', VI=None)`

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the `VI` variable) is the inverse covariance. If `VI` is not `None`, `VI` will be used as the inverse covariance matrix.

14. `Y = cdist(XA, XB, 'yule')`

Computes the Yule distance between the boolean vectors. (see [yule](#) function documentation)

15. `Y = cdist(XA, XB, 'matching')`

Synonym for 'hamming'.

16. `Y = cdist(XA, XB, 'dice')`

Computes the Dice distance between the boolean vectors. (see [dice](#) function documentation)

17. `Y = cdist(XA, XB, 'kulsinski')`

Computes the Kulsinski distance between the boolean vectors. (see [kulsinski](#) function documentation)

18. `Y = cdist(XA, XB, 'rogerstanimoto')`

Computes the Rogers-Tanimoto distance between the boolean vectors. (see [rogerstanimoto](#) function documentation)

19. `Y = cdist(XA, XB, 'russellrao')`

Computes the Russell-Rao distance between the boolean vectors. (see [russellrao](#) function documentation)

20. `Y = cdist(XA, XB, 'sokalmichener')`

Computes the Sokal-Michener distance between the boolean vectors. (see [sokalmichener](#) function documentation)

21. `Y = cdist(XA, XB, 'sokalsneath')`

Computes the Sokal-Sneath distance between the vectors. (see `sokalsneath` function documentation)

22. `Y = cdist(XA, XB, 'wminkowski', p=2., w=w)`

Computes the weighted Minkowski distance between the vectors. (see `wminkowski` function documentation)

'wminkowski' is deprecated and will be removed in SciPy 1.8.0. Use 'minkowski' instead.

23. `Y = cdist(XA, XB, f)`

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = cdist(XA, XB, lambda u, v: np.sqrt((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = cdist(XA, XB, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function `sokalsneath`. This would result in `sokalsneath` being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

```
dm = cdist(XA, XB, 'sokalsneath')
```

## Examples

Find the Euclidean distances between four 2-D coordinates:

```
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
...           (35.1174, -89.9711),
...           (35.9728, -83.9422),
...           (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0.         ,  4.7044,  1.6172,  1.8856],
       [ 4.7044,  0.         ,  6.0893,  3.3561],
       [ 1.6172,  6.0893,  0.         ,  2.8477],
       [ 1.8856,  3.3561,  2.8477,  0.         ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```
>>> a = np.array([[0, 0, 0],
...               [0, 0, 1],
...               [0, 1, 0],
...               [0, 1, 1],
...               [1, 0, 0],
...               [1, 0, 1],
...               [1, 1, 0],
...               [1, 1, 1]])
>>> b = np.array([[0.1, 0.2, 0.4]])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
```

(continues on next page)

(continued from previous page)

```
[ 0.9],
 [ 1.3],
 [ 1.5],
 [ 1.5],
 [ 1.7],
 [ 2.1],
 [ 2.3]])
```

**scipy.spatial.distance.squareform**`scipy.spatial.distance.squareform(X, force='no', checks=True)`

Convert a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters**

- X** [ndarray] Either a condensed or redundant distance matrix.
- force** [str, optional] As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.
- checks** [bool, optional] If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that  $X - X.T$  is small and `diag(X)` is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

**Returns**

- Y** [ndarray] If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

**Notes**

1. `v = squareform(X)`

Given a square  $n$ -by- $n$  symmetric distance matrix  $X$ , `v = squareform(X)` returns a  $n * (n-1) / 2$  (i.e. binomial coefficient  $n$  choose 2) sized vector  $v$  where  $v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  is the distance between distinct points  $i$  and  $j$ . If  $X$  is non-square or asymmetric, an error is raised.

2. `X = squareform(v)`

Given a  $n * (n-1) / 2$  sized vector  $v$  for some integer  $n \geq 1$  encoding distances as described, `X = squareform(v)` returns a  $n$ -by- $n$  distance matrix  $X$ . The  $X[i, j]$  and  $X[j, i]$  values are set to  $v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  and all diagonal elements are zero.

In SciPy 0.19.0, `squareform` stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

**scipy.spatial.distance.directed\_hausdorff**

`scipy.spatial.distance.directed_hausdorff(u, v, seed=0)`

Compute the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

**Parameters**

**u** [(M,N) ndarray] Input array.  
**v** [(O,N) ndarray] Input array.  
**seed** [int or None] Local `numpy.random.RandomState` seed. Default is 0, a random shuffling of `u` and `v` that guarantees reproducibility.

**Returns**

**d** [double] The directed Hausdorff distance between arrays `u` and `v`,  
**index\_1** [int] index of point contributing to Hausdorff pair in `u`  
**index\_2** [int] index of point contributing to Hausdorff pair in `v`

**Raises**

**ValueError**  
 An exception is thrown if `u` and `v` do not have the same number of columns.

See also:

**scipy.spatial.procrustes**

Another similarity test for two data sets

**Notes**

Uses the early break technique and the random sampling approach described by [1]. Although worst-case performance is  $O(m * o)$  (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is  $O(m)$ , which is satisfied by selecting an inner loop distance that is less than `cmax` and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to  $O(m)$ .

New in version 0.19.0.

**References**

[1]

**Examples**

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
...              (0.0, 1.0),
...              (-1.0, 0.0),
...              (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
```

(continues on next page)

(continued from previous page)

```
...      (0.0, 2.0),
...      (-2.0, 0.0),
...      (0.0, -4.0)]])
```

```
>>> directed_hausdorff(u, v)[0]
2.23606797749979
>>> directed_hausdorff(v, u)[0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

<code>is_valid_dm(D[, tol, throw, name, warning])</code>	Return True if input array is a valid distance matrix.
<code>is_valid_y(y[, warning, throw, name])</code>	Return True if the input array is a valid condensed distance matrix.
<code>num_obs_dm(d)</code>	Return the number of original observations that correspond to a square, redundant distance matrix.
<code>num_obs_y(Y)</code>	Return the number of original observations that correspond to a condensed distance matrix.

### scipy.spatial.distance.is\_valid\_dm

`scipy.spatial.distance.is_valid_dm(D, tol=0.0, throw=False, name='D', warning=False)`

Return True if input array is a valid distance matrix.

Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

#### Parameters

- D** [ndarray] The candidate object to test for validity.
- tol** [float, optional] The distance matrix should be symmetric. *tol* is the maximum difference between entries *i j* and *j i* for the distance metric to be considered symmetric.
- throw** [bool, optional] An exception is thrown if the distance matrix passed is not valid.
- name** [str, optional] The name of the variable to checked. This is useful if *throw* is set to True so the offending variable can be identified in the exception message when an exception is thrown.
- warning** [bool, optional] Instead of throwing an exception, a warning message is raised.

#### Returns

- valid** [bool] True if the variable *D* passed is a valid distance matrix.

## Notes

Small numerical differences in  $D$  and  $D.T$  and non-zerosness of the diagonal are ignored if they are within the tolerance specified by *tol*.

### scipy.spatial.distance.is\_valid\_y

`scipy.spatial.distance.is_valid_y(y, warning=False, throw=False, name=None)`

Return True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient  $\binom{n}{2}$  for some positive integer  $n$ .

#### Parameters

- y** [ndarray] The condensed distance matrix.
- warning** [bool, optional] Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. *name* is used when referencing the offending variable.
- throw** [bool, optional] Throws an exception if the variable passed is not a valid condensed distance matrix.
- name** [bool, optional] Used when referencing the offending variable in the warning or exception message.

### scipy.spatial.distance.num\_obs\_dm

`scipy.spatial.distance.num_obs_dm(d)`

Return the number of original observations that correspond to a square, redundant distance matrix.

#### Parameters

- d** [ndarray] The target distance matrix.

#### Returns

- num\_obs\_dm** [int] The number of observations in the redundant distance matrix.

### scipy.spatial.distance.num\_obs\_y

`scipy.spatial.distance.num_obs_y(Y)`

Return the number of original observations that correspond to a condensed distance matrix.

#### Parameters

- Y** [ndarray] Condensed distance matrix.

#### Returns

- n** [int] The number of observations in the condensed distance matrix *Y*.

Distance functions between two numeric vectors  $u$  and  $v$ . Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

---

`braycurtis(u, v[, w])`

Compute the Bray-Curtis distance between two 1-D arrays.

continues on next page

Table 215 – continued from previous page

<code>canberra(u, v[, w])</code>	Compute the Canberra distance between two 1-D arrays.
<code>chebyshev(u, v[, w])</code>	Compute the Chebyshev distance.
<code>cityblock(u, v[, w])</code>	Compute the City Block (Manhattan) distance.
<code>correlation(u, v[, w, centered])</code>	Compute the correlation distance between two 1-D arrays.
<code>cosine(u, v[, w])</code>	Compute the Cosine distance between 1-D arrays.
<code>euclidean(u, v[, w])</code>	Computes the Euclidean distance between two 1-D arrays.
<code>jensenshannon(p, q[, base])</code>	Compute the Jensen-Shannon distance (metric) between two 1-D probability arrays.
<code>mahalanobis(u, v, VI)</code>	Compute the Mahalanobis distance between two 1-D arrays.
<code>minkowski(u, v[, p, w])</code>	Compute the Minkowski distance between two 1-D arrays.
<code>seuclidean(u, v, V)</code>	Return the standardized Euclidean distance between two 1-D arrays.
<code>squclidean(u, v[, w])</code>	Compute the squared Euclidean distance between two 1-D arrays.
<code>wminkowski(u, v, p, w)</code>	Compute the weighted Minkowski distance between two 1-D arrays.

### scipy.spatial.distance.braycurtis

`scipy.spatial.distance.braycurtis` (*u*, *v*, *w=None*)

Compute the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

$$\sum |u_i - v_i| / \sum |u_i + v_i|$$

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

#### Parameters

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

#### Returns

- braycurtis** [double] The Bray-Curtis distance between 1-D arrays *u* and *v*.

### Examples

```
>>> from scipy.spatial import distance
>>> distance.braycurtis([1, 0, 0], [0, 1, 0])
1.0
>>> distance.braycurtis([1, 1, 0], [0, 1, 0])
0.33333333333333331
```

**scipy.spatial.distance.canberra**

`scipy.spatial.distance.canberra` ( $u, v, w=None$ )

Compute the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

**Parameters**

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in  $u$  and  $v$ . Default is `None`, which gives each value a weight of 1.0

**Returns**

- canberra** [double] The Canberra distance between vectors  $u$  and  $v$ .

**Notes**

When  $u[i]$  and  $v[i]$  are 0 for given  $i$ , then the fraction  $0/0 = 0$  is used in the calculation.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.canberra([1, 0, 0], [0, 1, 0])
2.0
>>> distance.canberra([1, 1, 0], [0, 1, 0])
1.0
```

**scipy.spatial.distance.chebyshev**

`scipy.spatial.distance.chebyshev` ( $u, v, w=None$ )

Compute the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays  $u$  and  $v$ , which is defined as

$$\max_i |u_i - v_i|.$$

**Parameters**

- u** [(N,) array\_like] Input vector.
- v** [(N,) array\_like] Input vector.
- w** [(N,) array\_like, optional] Unused, as ‘max’ is a weightless operation. Here for API consistency.

**Returns**

- chebyshev** [double] The Chebyshev distance between vectors  $u$  and  $v$ .

## Examples

```
>>> from scipy.spatial import distance
>>> distance.chebyshev([1, 0, 0], [0, 1, 0])
1
>>> distance.chebyshev([1, 1, 0], [0, 1, 0])
1
```

## scipy.spatial.distance.cityblock

`scipy.spatial.distance.cityblock` (*u*, *v*, *w=None*)

Compute the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays *u* and *v*, which is defined as

$$\sum_i |u_i - v_i|.$$

### Parameters

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

### Returns

- cityblock** [double] The City Block (Manhattan) distance between vectors *u* and *v*.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.cityblock([1, 0, 0], [0, 1, 0])
2
>>> distance.cityblock([1, 0, 0], [0, 2, 0])
3
>>> distance.cityblock([1, 0, 0], [1, 1, 0])
1
```

## scipy.spatial.distance.correlation

`scipy.spatial.distance.correlation` (*u*, *v*, *w=None*, *centered=True*)

Compute the correlation distance between two 1-D arrays.

The correlation distance between *u* and *v*, is defined as

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\| (u - \bar{u}) \|_2 \| (v - \bar{v}) \|_2}$$

where  $\bar{u}$  is the mean of the elements of *u* and  $x \cdot y$  is the dot product of *x* and *y*.

### Parameters

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.

**w** [(N,) array\_like, optional] The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**centered** [bool, optional] If True,  $u$  and  $v$  will be centered. Default is True.

**Returns****correlation**

[double] The correlation distance between 1-D array  $u$  and  $v$ .

**scipy.spatial.distance.cosine**

`scipy.spatial.distance.cosine(u, v, w=None)`

Compute the Cosine distance between 1-D arrays.

The Cosine distance between  $u$  and  $v$ , is defined as

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $u \cdot v$  is the dot product of  $u$  and  $v$ .

**Parameters**

**u** [(N,) array\_like] Input array.

**v** [(N,) array\_like] Input array.

**w** [(N,) array\_like, optional] The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns**

**cosine** [double] The Cosine distance between vectors  $u$  and  $v$ .

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.cosine([1, 0, 0], [0, 1, 0])
1.0
>>> distance.cosine([100, 0, 0], [0, 1, 0])
1.0
>>> distance.cosine([1, 1, 0], [0, 1, 0])
0.29289321881345254
```

**scipy.spatial.distance.euclidean**

`scipy.spatial.distance.euclidean(u, v, w=None)`

Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\|u - v\|_2 = \left( \sum (w_i |(u_i - v_i)|^2) \right)^{1/2}$$

**Parameters**

**u** [(N,) array\_like] Input array.

**v** [(N,) array\_like] Input array.

**w** [(N,) array\_like, optional] The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns**

**euclidean** [double] The Euclidean distance between vectors  $u$  and  $v$ .

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.euclidean([1, 0, 0], [0, 1, 0])
1.4142135623730951
>>> distance.euclidean([1, 1, 0], [0, 1, 0])
1.0
```

**scipy.spatial.distance.jensenshannon**

scipy.spatial.distance.**jensenshannon** ( $p, q, base=None$ )

Compute the Jensen-Shannon distance (metric) between two 1-D probability arrays. This is the square root of the Jensen-Shannon divergence.

The Jensen-Shannon distance between two probability vectors  $p$  and  $q$  is defined as,

$$\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}$$

where  $m$  is the pointwise mean of  $p$  and  $q$  and  $D$  is the Kullback-Leibler divergence.

This routine will normalize  $p$  and  $q$  if they don't sum to 1.0.

**Parameters**

**p** [(N,) array\_like] left probability vector  
**q** [(N,) array\_like] right probability vector  
**base** [double, optional] the base of the logarithm used to compute the output if not given, then the routine uses the default base of scipy.stats.entropy.

**Returns**

**js** [double] The Jensen-Shannon distance between  $p$  and  $q$

New in version 1.2.0: ..

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.jensenshannon([1.0, 0.0, 0.0], [0.0, 1.0, 0.0], 2.0)
1.0
>>> distance.jensenshannon([1.0, 0.0], [0.5, 0.5])
0.46450140402245893
>>> distance.jensenshannon([1.0, 0.0, 0.0], [1.0, 0.0, 0.0])
0.0
```

**scipy.spatial.distance.mahalanobis**

`scipy.spatial.distance.mahalanobis` (*u*, *v*, *VI*)

Compute the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays *u* and *v*, is defined as

$$\sqrt{(u - v)V^{-1}(u - v)^T}$$

where *V* is the covariance matrix. Note that the argument *VI* is the inverse of *V*.

**Parameters**

**u** [(N,) array\_like] Input array.  
**v** [(N,) array\_like] Input array.  
**VI** [ndarray] The inverse of the covariance matrix.

**Returns**

**mahalanobis**  
 [double] The Mahalanobis distance between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> iv = [[1, 0.5, 0.5], [0.5, 1, 0.5], [0.5, 0.5, 1]]
>>> distance.mahalanobis([1, 0, 0], [0, 1, 0], iv)
1.0
>>> distance.mahalanobis([0, 2, 0], [0, 1, 0], iv)
1.0
>>> distance.mahalanobis([2, 0, 0], [0, 1, 0], iv)
1.7320508075688772
```

**scipy.spatial.distance.minkowski**

`scipy.spatial.distance.minkowski` (*u*, *v*, *p=2*, *w=None*)

Compute the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays *u* and *v*, is defined as

$$\|u - v\|_p = \left( \sum |u_i - v_i|^p \right)^{1/p}.$$

$$\left( \sum w_i (|u_i - v_i|^p) \right)^{1/p}.$$

**Parameters**

**u** [(N,) array\_like] Input array.  
**v** [(N,) array\_like] Input array.  
**p** [int] The order of the norm of the difference  $\|u - v\|_p$ .  
**w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**minkowski**  
 [double] The Minkowski distance between vectors *u* and *v*.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 1)
2.0
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 2)
1.4142135623730951
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 3)
1.2599210498948732
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 1)
1.0
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 2)
1.0
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 3)
1.0
```

## scipy.spatial.distance.seuclidean

`scipy.spatial.distance.seuclidean` ( $u, v, V$ )

Return the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between  $u$  and  $v$ .

### Parameters

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- V** [(N,) array\_like]  $V$  is an 1-D array of component variances. It is usually computed among a larger collection vectors.

### Returns

- seuclidean** [double] The standardized Euclidean distance between vectors  $u$  and  $v$ .

## Examples

```
>>> from scipy.spatial import distance
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [0.1, 0.1, 0.1])
4.4721359549995796
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [1, 0.1, 0.1])
3.3166247903553998
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [10, 0.1, 0.1])
3.1780497164141406
```

**scipy.spatial.distance.sqeuclidean**

`scipy.spatial.distance.sqeuclidean` (*u*, *v*, *w=None*)

Compute the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between *u* and *v* is defined as

$$\|u - v\|_2^2 \\ \left( \sum (w_i |u_i - v_i|^2) \right)$$

**Parameters**

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- sqeuclidean**  
[double] The squared Euclidean distance between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.sqeuclidean([1, 0, 0], [0, 1, 0])
2.0
>>> distance.sqeuclidean([1, 1, 0], [0, 1, 0])
1.0
```

**scipy.spatial.distance.wminkowski**

`scipy.spatial.distance.wminkowski` (*u*, *v*, *p*, *w*)

Compute the weighted Minkowski distance between two 1-D arrays.

The weighted Minkowski distance between *u* and *v*, defined as

$$\left( \sum (|w_i (u_i - v_i)|^p) \right)^{1/p} .$$

**Parameters**

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- p** [int] The order of the norm of the difference  $\|u - v\|_p$ .
- w** [(N,) array\_like] The weight vector.

**Returns**

- wminkowski**  
[double] The weighted Minkowski distance between vectors *u* and *v*.

## Notes

`wminkowski` is deprecated and will be removed in SciPy 1.8.0. Use `minkowski` with the `w` argument instead.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 1, np.ones(3))
2.0
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 2, np.ones(3))
1.4142135623730951
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 3, np.ones(3))
1.2599210498948732
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 1, np.ones(3))
1.0
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 2, np.ones(3))
1.0
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 3, np.ones(3))
1.0
```

Distance functions between two boolean vectors (representing sets)  $u$  and  $v$ . As in the case of numerical vectors, `pdist` is more efficient for computing the distances between all pairs.

<code>dice(u, v[, w])</code>	Compute the Dice dissimilarity between two boolean 1-D arrays.
<code>hamming(u, v[, w])</code>	Compute the Hamming distance between two 1-D arrays.
<code>jaccard(u, v[, w])</code>	Compute the Jaccard-Needham dissimilarity between two boolean 1-D arrays.
<code>kulsinski(u, v[, w])</code>	Compute the Kulsinski dissimilarity between two boolean 1-D arrays.
<code>rogerstanimoto(u, v[, w])</code>	Compute the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.
<code>russellrao(u, v[, w])</code>	Compute the Russell-Rao dissimilarity between two boolean 1-D arrays.
<code>sokalmichener(u, v[, w])</code>	Compute the Sokal-Michener dissimilarity between two boolean 1-D arrays.
<code>sokalsneath(u, v[, w])</code>	Compute the Sokal-Sneath dissimilarity between two boolean 1-D arrays.
<code>yule(u, v[, w])</code>	Compute the Yule dissimilarity between two boolean 1-D arrays.

## scipy.spatial.distance.dice

`scipy.spatial.distance.dice(u, v, w=None)`

Compute the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between  $u$  and  $v$ , is

$$\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

- u** [(N,) ndarray, bool] Input 1-D array.
- v** [(N,) ndarray, bool] Input 1-D array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- dice** [double] The Dice dissimilarity between 1-D arrays *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.dice([1, 0, 0], [0, 1, 0])
1.0
>>> distance.dice([1, 0, 0], [1, 1, 0])
0.3333333333333333
>>> distance.dice([1, 0, 0], [2, 0, 0])
-0.3333333333333333
```

**scipy.spatial.distance.hamming**

`scipy.spatial.distance.hamming` (*u*, *v*, *w=None*)

Compute the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays *u* and *v*, is simply the proportion of disagreeing components in *u* and *v*. If *u* and *v* are boolean vectors, the Hamming distance is

$$\frac{c_{01} + c_{10}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- hamming** [double] The Hamming distance between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.hamming([1, 0, 0], [0, 1, 0])
0.6666666666666666
>>> distance.hamming([1, 0, 0], [1, 1, 0])
0.3333333333333333
>>> distance.hamming([1, 0, 0], [2, 0, 0])
0.3333333333333333
>>> distance.hamming([1, 0, 0], [3, 0, 0])
0.3333333333333333
```

**scipy.spatial.distance.jaccard**

`scipy.spatial.distance.jaccard(u, v, w=None)`

Compute the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays  $u$  and  $v$ , is defined as

$$\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

**u** [(N,) array\_like, bool] Input array.  
**v** [(N,) array\_like, bool] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns**

**jaccard** [double] The Jaccard distance between vectors  $u$  and  $v$ .

**Notes**

When both  $u$  and  $v$  lead to a  $0/0$  division i.e. there is no overlap between the items in the vectors the returned distance is 0. See the Wikipedia page on the Jaccard index [1], and this paper [2].

Changed in version 1.2.0: Previously, when  $u$  and  $v$  lead to a  $0/0$  division, the function would return NaN. This was changed to return 0 instead.

**References**

[1], [2]

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.jaccard([1, 0, 0], [0, 1, 0])
1.0
>>> distance.jaccard([1, 0, 0], [1, 1, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 2, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 1, 1])
0.66666666666666663
```

**scipy.spatial.distance.kulsinski**

`scipy.spatial.distance.kulsinski` (*u*, *v*, *w=None*)

Compute the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays *u* and *v*, is defined as

$$\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

**u** [(N,) array\_like, bool] Input array.  
**v** [(N,) array\_like, bool] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**kulsinski** [double] The Kulsinski distance between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.kulsinski([1, 0, 0], [0, 1, 0])
1.0
>>> distance.kulsinski([1, 0, 0], [1, 1, 0])
0.75
>>> distance.kulsinski([1, 0, 0], [2, 1, 0])
0.33333333333333331
>>> distance.kulsinski([1, 0, 0], [3, 1, 0])
-0.5
```

**scipy.spatial.distance.rogerstanimoto**

`scipy.spatial.distance.rogerstanimoto` (*u*, *v*, *w=None*)

Compute the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays *u* and *v*, is defined as

$$\frac{R}{c_{TT} + c_{FF} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters**

**u** [(N,) array\_like, bool] Input array.  
**v** [(N,) array\_like, bool] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**rogerstanimoto** [double] The Rogers-Tanimoto dissimilarity between vectors *u* and *v*.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.rogerstanimoto([1, 0, 0], [0, 1, 0])
0.8
>>> distance.rogerstanimoto([1, 0, 0], [1, 1, 0])
0.5
>>> distance.rogerstanimoto([1, 0, 0], [2, 0, 0])
-1.0
```

## scipy.spatial.distance.russellrao

`scipy.spatial.distance.russellrao` (*u*, *v*, *w=None*)

Compute the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays, *u* and *v*, is defined as

$$\frac{n - c_{TT}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

### Parameters

- u** [(N,) array\_like, bool] Input array.
- v** [(N,) array\_like, bool] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

### Returns

- russellrao** [double] The Russell-Rao dissimilarity between vectors *u* and *v*.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.russellrao([1, 0, 0], [0, 1, 0])
1.0
>>> distance.russellrao([1, 0, 0], [1, 1, 0])
0.6666666666666666
>>> distance.russellrao([1, 0, 0], [2, 0, 0])
0.3333333333333333
```

## scipy.spatial.distance.sokalmichener

`scipy.spatial.distance.sokalmichener` (*u*, *v*, *w=None*)

Compute the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays *u* and *v*, is defined as

$$\frac{R}{S + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ ,  $R = 2 * (c_{TF} + c_{FT})$  and  $S = c_{FF} + c_{TT}$ .

**Parameters**

- u** [(N,) array\_like, bool] Input array.
- v** [(N,) array\_like, bool] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns****sokalmichener**

[double] The Sokal-Michener dissimilarity between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.sokalmichener([1, 0, 0], [0, 1, 0])
0.8
>>> distance.sokalmichener([1, 0, 0], [1, 1, 0])
0.5
>>> distance.sokalmichener([1, 0, 0], [2, 0, 0])
-1.0
```

**scipy.spatial.distance.sokalsneath**

`scipy.spatial.distance.sokalsneath(u, v, w=None)`

Compute the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between *u* and *v*,

$$\frac{R}{c_{TT} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters**

- u** [(N,) array\_like, bool] Input array.
- v** [(N,) array\_like, bool] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns****sokalsneath**

[double] The Sokal-Sneath dissimilarity between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.sokalsneath([1, 0, 0], [0, 1, 0])
1.0
>>> distance.sokalsneath([1, 0, 0], [1, 1, 0])
0.6666666666666666
>>> distance.sokalsneath([1, 0, 0], [2, 1, 0])
```

(continues on next page)

(continued from previous page)

```
0.0
>>> distance.sokalsneath([1, 0, 0], [3, 1, 0])
-2.0
```

**scipy.spatial.distance.yule**

`scipy.spatial.distance.yule` (*u*, *v*, *w=None*)

Compute the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

$$\frac{R}{c_{TT} * c_{FF} + \frac{R}{2}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2.0 * c_{TF} * c_{FT}$ .

**Parameters**

- u** [(N,) array\_like, bool] Input array.
- v** [(N,) array\_like, bool] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- yule** [double] The Yule dissimilarity between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.yule([1, 0, 0], [0, 1, 0])
2.0
>>> distance.yule([1, 1, 0], [0, 1, 0])
0.0
```

*hamming* also operates over discrete numerical vectors.

**6.28 Special functions (scipy.special)**

Nearly all of the functions below are universal functions and follow broadcasting and automatic array-looping rules.

**See also:**

`scipy.special.cython_special` – Typed Cython versions of special functions

## 6.28.1 Error handling

Errors are handled by returning NaNs or other appropriate values. Some of the special function routines can emit warnings or raise exceptions when an error occurs. By default this is disabled; to query and control the current error handling state the following functions are provided.

<code>geterr()</code>	Get the current way of handling special-function errors.
<code>seterr()</code>	Set how special-function errors are handled.
<code>errstate(**kwargs)</code>	Context manager for special-function error handling.
<code>SpecialFunctionWarning</code>	Warning that can be emitted by special functions.
<code>SpecialFunctionError</code>	Exception that can be raised by special functions.

### `scipy.special.geterr`

`scipy.special.geterr()`

Get the current way of handling special-function errors.

#### Returns

**err** [dict] A dictionary with keys “singular”, “underflow”, “overflow”, “slow”, “loss”, “no\_result”, “domain”, “arg”, and “other”, whose values are from the strings “ignore”, “warn”, and “raise”. The keys represent possible special-function errors, and the values define how these errors are handled.

#### See also:

##### `seterr`

set how special-function errors are handled

##### `errstate`

context manager for special-function error handling

##### `numpy.geterr`

similar numpy function for floating-point errors

#### Notes

For complete documentation of the types of special-function errors and treatment options, see `seterr`.

#### Examples

By default all errors are ignored.

```
>>> import scipy.special as sc
>>> for key, value in sorted(sc.geterr().items()):
...     print("{}: {}".format(key, value))
...
arg: ignore
domain: ignore
loss: ignore
no_result: ignore
```

(continues on next page)

```

other: ignore
overflow: ignore
singular: ignore
slow: ignore
underflow: ignore

```

## scipy.special.seterr

`scipy.special.seterr()`

Set how special-function errors are handled.

### Parameters

- all** [{"ignore", "warn", "raise"}, optional] Set treatment for all type of special-function errors at once. The options are:
- 'ignore' Take no action when the error occurs
  - 'warn' Print a *SpecialFunctionWarning* when the error occurs (via the Python `warnings` module)
  - 'raise' Raise a *SpecialFunctionError* when the error occurs.
- The default is to not change the current behavior. If behaviors for additional categories of special-function errors are specified, then `all` is applied first, followed by the additional categories.
- singular** [{"ignore", "warn", "raise"}, optional] Treatment for singularities.
- underflow** [{"ignore", "warn", "raise"}, optional] Treatment for underflow.
- overflow** [{"ignore", "warn", "raise"}, optional] Treatment for overflow.
- slow** [{"ignore", "warn", "raise"}, optional] Treatment for slow convergence.
- loss** [{"ignore", "warn", "raise"}, optional] Treatment for loss of accuracy.
- no\_result** [{"ignore", "warn", "raise"}, optional] Treatment for failing to find a result.
- domain** [{"ignore", "warn", "raise"}, optional] Treatment for an invalid argument to a function.
- arg** [{"ignore", "warn", "raise"}, optional] Treatment for an invalid parameter to a function.
- other** [{"ignore", "warn", "raise"}, optional] Treatment for an unknown error.

### Returns

- olderr** [dict] Dictionary containing the old settings.

See also:

[`geterr`](#)

get the current way of handling special-function errors

[`errstate`](#)

context manager for special-function error handling

[`numpy.seterr`](#)

similar numpy function for floating-point errors

## Examples

```
>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> olderr = sc.seterr(singular='raise')
>>> with raises(sc.SpecialFunctionError):
...     sc.gammaln(0)
...
>>> _ = sc.seterr(**olderr)
```

We can also raise for every category except one.

```
>>> olderr = sc.seterr(all='raise', singular='ignore')
>>> sc.gammaln(0)
inf
>>> with raises(sc.SpecialFunctionError):
...     sc.spence(-1)
...
>>> _ = sc.seterr(**olderr)
```

## scipy.special.errstate

**class** `scipy.special.errstate` (*\*\*kwargs*)

Context manager for special-function error handling.

Using an instance of `errstate` as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with `seterr`, and upon exiting it is restored to what it was before.

### Parameters

**kwargs** [{all, singular, underflow, overflow, slow, loss, no\_result, domain, arg, other}] Keyword arguments. The valid keywords are possible special-function errors. Each keyword should have a string value that defines the treatment for the particular type of error. Values must be 'ignore', 'warn', or 'other'. See `seterr` for details.

**See also:**

### `geterr`

get the current way of handling special-function errors

### `seterr`

set how special-function errors are handled

### `numpy.errstate`

similar numpy function for floating-point errors

## Examples

```
>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> with sc.errstate(singular='raise'):
...     with raises(sc.SpecialFunctionError):
...         sc.gammaln(0)
...
>>> sc.gammaln(0)
inf
```

We can also raise on every category except one.

```
>>> with sc.errstate(all='raise', singular='ignore'):
...     sc.gammaln(0)
...     with raises(sc.SpecialFunctionError):
...         sc.spence(-1)
...
inf
```

### scipy.special.SpecialFunctionWarning

**exception** `scipy.special.SpecialFunctionWarning`

Warning that can be emitted by special functions.

**with\_traceback()**

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### scipy.special.SpecialFunctionError

**exception** `scipy.special.SpecialFunctionError`

Exception that can be raised by special functions.

**with\_traceback()**

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

## 6.28.2 Available functions

### Airy functions

<code>airy(z)</code>	Airy functions and their derivatives.
<code>airye(z)</code>	Exponentially scaled Airy functions and their derivatives.
<code>ai_zeros(nt)</code>	Compute $nt$ zeros and values of the Airy function $Ai$ and its derivative.
<code>bi_zeros(nt)</code>	Compute $nt$ zeros and values of the Airy function $Bi$ and its derivative.
<code>itairy(x)</code>	Integrals of Airy functions

**scipy.special.airy**

`scipy.special.airy(z) = <ufunc 'airy'>`

Airy functions and their derivatives.

**Parameters**

**z** [array\_like] Real or complex argument.

**Returns**

**Ai, Aip, Bi, Bip**

[ndarrays] Airy functions Ai and Bi, and their derivatives Aip and Bip.

**See also:****airye**

exponentially scaled Airy functions.

**Notes**

The Airy functions Ai and Bi are two independent solutions of

$$y''(x) = xy(x).$$

For real  $z$  in  $[-10, 10]$ , the computation is carried out by calling the Cephes [1] `airy` routine, which uses power series summation for small  $z$  and rational minimax approximations for large  $z$ .

Outside this range, the AMOS [2] `zairy` and `zbiry` routines are employed. They are computed using power series for  $|z| < 1$  and the following relations to modified Bessel functions for larger  $z$  (where  $t \equiv 2z^{3/2}/3$ ):

$$\begin{aligned} Ai(z) &= \frac{1}{\pi\sqrt{3}} K_{1/3}(t) \\ Ai'(z) &= -\frac{z}{\pi\sqrt{3}} K_{2/3}(t) \\ Bi(z) &= \sqrt{\frac{z}{3}} (I_{-1/3}(t) + I_{1/3}(t)) \\ Bi'(z) &= \frac{z}{\sqrt{3}} (I_{-2/3}(t) + I_{2/3}(t)) \end{aligned}$$

**References**

[1], [2]

**Examples**

Compute the Airy functions on the interval  $[-15, 5]$ .

```
>>> from scipy import special
>>> x = np.linspace(-15, 5, 201)
>>> ai, aip, bi, bip = special.airy(x)
```

Plot Ai(x) and Bi(x).

```

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, ai, 'r', label='Ai(x)')
>>> plt.plot(x, bi, 'b--', label='Bi(x)')
>>> plt.ylim(-0.5, 1.0)
>>> plt.grid()
>>> plt.legend(loc='upper left')
>>> plt.show()

```

### scipy.special.airye

`scipy.special.airye(z) = <ufunc 'airye'>`

Exponentially scaled Airy functions and their derivatives.

Scaling:

```

eAi = Ai * exp(2.0/3.0*z*sqrt(z))
eAip = Aip * exp(2.0/3.0*z*sqrt(z))
eBi = Bi * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
eBip = Bip * exp(-abs(2.0/3.0*(z*sqrt(z)).real))

```

#### Parameters

**z** [array\_like] Real or complex argument.

#### Returns

**eAi, eAip, eBi, eBip**

[array\_like] Exponentially scaled Airy functions eAi and eBi, and their derivatives eAip and eBip

See also:

[airy](#)

## Notes

Wrapper for the AMOS [1] routines *zairy* and *zbiry*.

## References

[1]

## Examples

We can compute exponentially scaled Airy functions and their derivatives:

```
>>> from scipy.special import airy
>>> import matplotlib.pyplot as plt
>>> z = np.linspace(0, 50, 500)
>>> eAi, eAip, eBi, eBip = airy(z)
>>> f, ax = plt.subplots(2, 1, sharex=True)
>>> for ind, data in enumerate([[eAi, eAip, ["eAi", "eAip"]],
...                             [eBi, eBip, ["eBi", "eBip"]]]):
...     ax[ind].plot(z, data[0], "-r", z, data[1], "-b")
...     ax[ind].legend(data[2])
...     ax[ind].grid(True)
>>> plt.show()
```

We can compute these using usual non-scaled Airy functions by:

```
>>> from scipy.special import airy
>>> Ai, Aip, Bi, Bip = airy(z)
>>> np.allclose(eAi, Ai * np.exp(2.0 / 3.0 * z * np.sqrt(z)))
True
>>> np.allclose(eAip, Aip * np.exp(2.0 / 3.0 * z * np.sqrt(z)))
True
```

(continues on next page)

(continued from previous page)

```

>>> np.allclose(eBi, Bi * np.exp(-abs(np.real(2.0 / 3.0 * z * np.
  ↳sqrt(z))))))
True
>>> np.allclose(eBip, Bip * np.exp(-abs(np.real(2.0 / 3.0 * z * np.
  ↳sqrt(z))))))
True

```

Comparing non-scaled and exponentially scaled ones, the usual non-scaled function quickly underflows for large values, whereas the exponentially scaled function does not.

```

>>> airy(200)
(0.0, 0.0, nan, nan)
>>> airye(200)
(0.07501041684381093, -1.0609012305109042, 0.15003188417418148, 2.
  ↳1215836725571093)

```

## scipy.special.ai\_zeros

`scipy.special.ai_zeros` (*nt*)

Compute *nt* zeros and values of the Airy function  $Ai$  and its derivative.

Computes the first *nt* zeros, *a*, of the Airy function  $Ai(x)$ ; first *nt* zeros, *ap*, of the derivative of the Airy function  $Ai'(x)$ ; the corresponding values  $Ai(a')$ ; and the corresponding values  $Ai'(a)$ .

### Parameters

**nt** [int] Number of zeros to compute

### Returns

**a** [ndarray] First *nt* zeros of  $Ai(x)$   
**ap** [ndarray] First *nt* zeros of  $Ai'(x)$   
**ai** [ndarray] Values of  $Ai(x)$  evaluated at first *nt* zeros of  $Ai'(x)$   
**aip** [ndarray] Values of  $Ai'(x)$  evaluated at first *nt* zeros of  $Ai(x)$

## References

```

**scipy.special.itairy**`scipy.special.itairy(x) = <ufunc 'itairy'>`

Integrals of Airy functions

Calculates the integrals of Airy functions from 0 to  $x$ .**Parameters****x: array\_like**  
Upper limit of integration (float).**Returns**

**Apt** Integral of  $Ai(t)$  from 0 to  $x$ .  
**Bpt** Integral of  $Bi(t)$  from 0 to  $x$ .  
**Ant** Integral of  $Ai(-t)$  from 0 to  $x$ .  
**Bnt** Integral of  $Bi(-t)$  from 0 to  $x$ .

## Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

## Elliptic functions and integrals

<code>ellipj(u, m)</code>	Jacobian elliptic functions
<code>ellipk(m)</code>	Complete elliptic integral of the first kind.
<code>ellipkm1(p)</code>	Complete elliptic integral of the first kind around $m = 1$
<code>ellipkinc(phi, m)</code>	Incomplete elliptic integral of the first kind
<code>ellipe(m)</code>	Complete elliptic integral of the second kind
<code>ellipeinc(phi, m)</code>	Incomplete elliptic integral of the second kind

### scipy.special.ellipj

`scipy.special.ellipj(u, m) = <ufunc 'ellipj'>`  
 Jacobian elliptic functions

Calculates the Jacobian elliptic functions of parameter  $m$  between 0 and 1, and real argument  $u$ .

#### Parameters

**m** [array\_like] Parameter.  
**u** [array\_like] Argument.

#### Returns

**sn, cn, dn, ph**  
 [ndarrays] The returned functions:

$sn(u|m), cn(u|m), dn(u|m)$

The value  $ph$  is such that if  $u = ellipkinc(ph, m)$ , then  $sn(u|m) = sin(ph)$  and  $cn(u|m) = cos(ph)$ .

#### See also:

#### `ellipk`

Complete elliptic integral of the first kind

#### `ellipkinc`

Incomplete elliptic integral of the first kind

## Notes

Wrapper for the Cephes [1] routine *ellpj*.

These functions are periodic, with quarter-period on the real axis equal to the complete elliptic integral *ellipk(m)*.

Relation to incomplete elliptic integral: If  $u = \text{ellipkinc}(\phi, m)$ , then  $\text{sn}(u|m) = \sin(\phi)$ , and  $\text{cn}(u|m) = \cos(\phi)$ . The  $\phi$  is called the amplitude of  $u$ .

Computation is by means of the arithmetic-geometric mean algorithm, except when  $m$  is within  $1e-9$  of 0 or 1. In the latter case with  $m$  close to 1, the approximation applies only for  $\phi < \pi/2$ .

## References

[1]

### scipy.special.ellipk

`scipy.special.ellipk(m) = <ufunc 'ellipk'>`  
Complete elliptic integral of the first kind.

This function is defined as

$$K(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

#### Parameters

**m** [array\_like] The parameter of the elliptic integral.

#### Returns

**K** [array\_like] Value of the elliptic integral.

See also:

#### `ellipkm1`

Complete elliptic integral of the first kind around  $m = 1$

#### `ellipkinc`

Incomplete elliptic integral of the first kind

#### `ellipe`

Complete elliptic integral of the second kind

#### `ellipeinc`

Incomplete elliptic integral of the second kind

## Notes

For more precision around point  $m = 1$ , use `ellipkm1`, which this function calls.

The parameterization in terms of  $m$  follows that of section 17.2 in [1]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

## References

[1]

### scipy.special.ellipkm1

`scipy.special.ellipkm1(p) = <ufunc 'ellipkm1'>`

Complete elliptic integral of the first kind around  $m = 1$

This function is defined as

$$K(p) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

where  $m = 1 - p$ .

#### Parameters

**p** [array\_like] Defines the parameter of the elliptic integral as  $m = 1 - p$ .

#### Returns

**K** [ndarray] Value of the elliptic integral.

See also:

#### `ellipk`

Complete elliptic integral of the first kind

#### `ellipkinc`

Incomplete elliptic integral of the first kind

#### `ellipe`

Complete elliptic integral of the second kind

#### `ellipeinc`

Incomplete elliptic integral of the second kind

## Notes

Wrapper for the Cephes [1] routine `ellpk`.

For  $p \leq 1$ , computation uses the approximation,

$$K(p) \approx P(p) - \log(p)Q(p),$$

where  $P$  and  $Q$  are tenth-order polynomials. The argument  $p$  is used internally rather than  $m$  so that the logarithmic singularity at  $m = 1$  will be shifted to the origin; this preserves maximum accuracy. For  $p > 1$ , the identity

$$K(p) = K(1/p) / \sqrt{p}$$

is used.

## References

[1]

### scipy.special.ellipkinc

`scipy.special.ellipkinc(phi, m) = <ufunc 'ellipkinc'>`

Incomplete elliptic integral of the first kind

This function is defined as

$$K(\phi, m) = \int_0^\phi [1 - m \sin(t)^2]^{-1/2} dt$$

This function is also called  $F(\phi, m)$ .

#### Parameters

**phi** [array\_like] amplitude of the elliptic integral  
**m** [array\_like] parameter of the elliptic integral

#### Returns

**K** [ndarray] Value of the elliptic integral

**See also:**

#### `ellipkm1`

Complete elliptic integral of the first kind, near  $m = 1$

#### `ellipk`

Complete elliptic integral of the first kind

#### `ellipe`

Complete elliptic integral of the second kind

#### `ellipeinc`

Incomplete elliptic integral of the second kind

## Notes

Wrapper for the Cephes [1] routine *ellik*. The computation is carried out using the arithmetic-geometric mean algorithm.

The parameterization in terms of  $m$  follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

## References

[1], [2]

### scipy.special.ellipe

`scipy.special.ellipe(m) = <ufunc 'ellipe'>`

Complete elliptic integral of the second kind

This function is defined as

$$E(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{1/2} dt$$

#### Parameters

**m** [array\_like] Defines the parameter of the elliptic integral.

#### Returns

**E** [ndarray] Value of the elliptic integral.

See also:

#### [ellipkm1](#)

Complete elliptic integral of the first kind, near  $m = 1$

#### [ellipk](#)

Complete elliptic integral of the first kind

#### [ellipkinc](#)

Incomplete elliptic integral of the first kind

#### [ellipeinc](#)

Incomplete elliptic integral of the second kind

## Notes

Wrapper for the Cephes [1] routine *ellpe*.

For  $m > 0$  the computation uses the approximation,

$$E(m) \approx P(1 - m) - (1 - m) \log(1 - m)Q(1 - m),$$

where  $P$  and  $Q$  are tenth-order polynomials. For  $m < 0$ , the relation

$$E(m) = E(m/(m - 1))\sqrt{1 - m}$$

is used.

The parameterization in terms of  $m$  follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

## References

[1], [2]

## Examples

This function is used in finding the circumference of an ellipse with semi-major axis  $a$  and semi-minor axis  $b$ .

```
>>> from scipy import special
```

```
>>> a = 3.5
>>> b = 2.1
>>> e_sq = 1.0 - b**2/a**2 # eccentricity squared
```

Then the circumference is found using the following:

```
>>> C = 4*a*special.ellipe(e_sq) # circumference formula
>>> C
17.868899204378693
```

When  $a$  and  $b$  are the same (meaning eccentricity is 0), this reduces to the circumference of a circle.

```
>>> 4*a*special.ellipe(0.0) # formula for ellipse with a = b
21.991148575128552
>>> 2*np.pi*a # formula for circle of radius a
21.991148575128552
```

## scipy.special.ellipeinc

`scipy.special.ellipeinc(phi, m) = <ufunc 'ellipeinc'>`

Incomplete elliptic integral of the second kind

This function is defined as

$$E(\phi, m) = \int_0^{\phi} [1 - m \sin(t)^2]^{1/2} dt$$

### Parameters

**phi** [array\_like] amplitude of the elliptic integral.  
**m** [array\_like] parameter of the elliptic integral.

### Returns

**E** [ndarray] Value of the elliptic integral.

See also:

### ellipkm1

Complete elliptic integral of the first kind, near  $m = 1$

### ellipk

Complete elliptic integral of the first kind

### ellipkinc

Incomplete elliptic integral of the first kind

**ellipe**

Complete elliptic integral of the second kind

**Notes**

Wrapper for the Cephes [1] routine *ellie*.

Computation uses arithmetic-geometric means algorithm.

The parameterization in terms of  $m$  follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

**scipy.special.jv**

`scipy.special.jv(v, z) = <ufunc 'jv'>`

Bessel function of the first kind of real order and complex argument.

**Parameters**

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

**Returns**

**J** [ndarray] Value of the Bessel function,  $J_v(z)$ .

**See also:**

**jve**

$J_v$  with leading exponential behavior stripped off.

**spherical\_jn**

spherical Bessel functions.

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [1] *zbesj* routine, which exploits the connection to the modified Bessel function  $I_\nu$ ,

$$\begin{aligned} J_\nu(z) &= \exp(v\pi i/2) I_\nu(-iz) & (\Im z > 0) \\ J_\nu(z) &= \exp(-v\pi i/2) I_\nu(iz) & (\Im z < 0) \end{aligned}$$

For negative  $\nu$  values the formula,

$$J_{-\nu}(z) = J_\nu(z) \cos(\pi\nu) - Y_\nu(z) \sin(\pi\nu)$$

is used, where  $Y_\nu(z)$  is the Bessel function of the second kind, computed using the AMOS routine *zbesy*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

Not to be confused with the spherical Bessel functions (see [spherical\\_jn](#)).

**References**

[1]

**scipy.special.jve**

`scipy.special.jve(v, z) = <ufunc 'jve'>`

Exponentially scaled Bessel function of order  $\nu$ .

Defined as:

```
jve(v, z) = jv(v, z) * exp(-abs(z.imag))
```

**Parameters**

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

**Returns**

**J** [ndarray] Value of the exponentially scaled Bessel function.

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [1] *zbesj* routine, which exploits the connection to the modified Bessel function  $I_\nu$ ,

$$J_\nu(z) = \exp(\nu\pi i/2)I_\nu(-iz) \quad (\Im z > 0)$$

$$J_\nu(z) = \exp(-\nu\pi i/2)I_\nu(iz) \quad (\Im z < 0)$$

For negative  $\nu$  values the formula,

$$J_{-\nu}(z) = J_\nu(z) \cos(\pi\nu) - Y_\nu(z) \sin(\pi\nu)$$

is used, where  $Y_\nu(z)$  is the Bessel function of the second kind, computed using the AMOS routine *zbesy*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

**References**

[1]

**scipy.special.yn**

`scipy.special.yn(n, x) = <ufunc 'yn'>`

Bessel function of the second kind of integer order and real argument.

**Parameters**

**n** [array\_like] Order (integer).  
**z** [array\_like] Argument (float).

**Returns**

**Y** [ndarray] Value of the Bessel function,  $Y_n(x)$ .

**See also:**

**yv**

For real order and real or complex argument.

**Notes**

Wrapper for the Cephes [1] routine *yn*.

The function is evaluated by forward recurrence on  $n$ , starting with values computed by the Cephes routines *y0* and *y1*. If  $n = 0$  or 1, the routine for *y0* or *y1* is called directly.

## References

[1]

### scipy.special.yv

`scipy.special.yv(v, z) = <ufunc 'yv'>`

Bessel function of the second kind of real order and complex argument.

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**Y** [ndarray] Value of the Bessel function of the second kind,  $Y_\nu(x)$ .

See also:

#### yve

$Y_\nu$  with leading exponential behavior stripped off.

## Notes

For positive  $\nu$  values, the computation is carried out using the AMOS [1] `zbesy` routine, which exploits the connection to the Hankel Bessel functions  $H_\nu^{(1)}$  and  $H_\nu^{(2)}$ ,

$$Y_\nu(z) = \frac{1}{2i}(H_\nu^{(1)} - H_\nu^{(2)}).$$

For negative  $\nu$  values the formula,

$$Y_{-\nu}(z) = Y_\nu(z) \cos(\pi\nu) + J_\nu(z) \sin(\pi\nu)$$

is used, where  $J_\nu(z)$  is the Bessel function of the first kind, computed using the AMOS routine `zbesj`. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

## References

[1]

### scipy.special.yve

`scipy.special.yve(v, z) = <ufunc 'yve'>`

Exponentially scaled Bessel function of the second kind of real order.

Returns the exponentially scaled Bessel function of the second kind of real order  $\nu$  at complex  $z$ :

$$\text{yve}(v, z) = \text{yv}(v, z) * \exp(-\text{abs}(z.\text{imag}))$$

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**Y** [ndarray] Value of the exponentially scaled Bessel function.

## Notes

For positive  $\nu$  values, the computation is carried out using the AMOS [1] *zbesy* routine, which exploits the connection to the Hankel Bessel functions  $H_\nu^{(1)}$  and  $H_\nu^{(2)}$ ,

$$Y_\nu(z) = \frac{1}{2i}(H_\nu^{(1)} - H_\nu^{(2)}).$$

For negative  $\nu$  values the formula,

$$Y_{-\nu}(z) = Y_\nu(z) \cos(\pi\nu) + J_\nu(z) \sin(\pi\nu)$$

is used, where  $J_\nu(z)$  is the Bessel function of the first kind, computed using the AMOS routine *zbesj*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

## References

[1]

### scipy.special.kn

`scipy.special.kn(n, x) = <ufunc 'kn'>`

Modified Bessel function of the second kind of integer order  $n$

Returns the modified Bessel function of the second kind for integer order  $n$  at real  $z$ .

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions.

#### Parameters

**n** [array\_like of int] Order of Bessel functions (floats will truncate with a warning)  
**z** [array\_like of float] Argument at which to evaluate the Bessel functions

#### Returns

**out** [ndarray] The results

See also:

#### kv

Same function, but accepts real order and complex argument

#### kvp

Derivative of this function

## Notes

Wrapper for AMOS [1] routine *zbesk*. For a discussion of the algorithm used, see [2] and the references therein.

## References

[1], [2]

## Examples

Plot the function of several orders for real input:

```
>>> from scipy.special import kn
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in range(6):
...     plt.plot(x, kn(N, x), label='$K_{%d}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_n(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:

```
>>> kn([4, 5, 6], 1)
array([ 44.23241585, 360.9605896 , 3653.83831186])
```

## scipy.special.kv

`scipy.special.kv(v, z) = <ufunc 'kv'>`

Modified Bessel function of the second kind of real order  $\nu$

Returns the modified Bessel function of the second kind for real order  $\nu$  at complex  $z$ .

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions. They are defined as those solutions of the modified Bessel equation for which,

$$K_\nu(x) \sim \sqrt{\pi/(2x)} \exp(-x)$$

as  $x \rightarrow \infty$  [3].

**Parameters**

- v** [array\_like of float] Order of Bessel functions  
**z** [array\_like of complex] Argument at which to evaluate the Bessel functions

**Returns**

- out** [ndarray] The results. Note that input must be of complex type to get complex output, e.g. `kv(3, -2+0j)` instead of `kv(3, -2)`.

**See also:****kve**

This function with leading exponential behavior stripped off.

**kvp**

Derivative of this function

**Notes**

Wrapper for AMOS [1] routine *zbesk*. For a discussion of the algorithm used, see [2] and the references therein.

**References**

[1], [2], [3]

**Examples**

Plot the function of several orders for real input:

```
>>> from scipy.special import kv
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in np.linspace(0, 6, 5):
...     plt.plot(x, kv(N, x), label='$K_{\{\}\}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_{\nu}(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:

```
>>> kv([4, 4.5, 5], 1+2j)
array([ 0.1992+2.3892j,  2.3493+3.6j      ,  7.2827+3.8104j])
```

### scipy.special.kve

`scipy.special.kve(v, z) = <ufunc 'kve'>`

Exponentially scaled modified Bessel function of the second kind.

Returns the exponentially scaled, modified Bessel function of the second kind (sometimes called the third kind) for real order  $\nu$  at complex  $z$ :

$$\text{kve}(v, z) = \text{kv}(v, z) * \exp(z)$$

#### Parameters

- v** [array\_like of float] Order of Bessel functions
- z** [array\_like of complex] Argument at which to evaluate the Bessel functions

#### Returns

- out** [ndarray] The exponentially scaled modified Bessel function of the second kind.

#### Notes

Wrapper for AMOS [1] routine *zbesk*. For a discussion of the algorithm used, see [2] and the references therein.

#### References

[1], [2]

**scipy.special.iv**

```
scipy.special.iv(v, z) = <ufunc 'iv'>
```

Modified Bessel function of the first kind of real order.

**Parameters**

**v** [array\_like] Order. If  $z$  is of real type and negative,  $v$  must be integer valued.  
**z** [array\_like of float or complex] Argument.

**Returns**

**out** [ndarray] Values of the modified Bessel function.

**See also:****kve**

This function with leading exponential behavior stripped off.

**Notes**

For real  $z$  and  $v \in [-50, 50]$ , the evaluation is carried out using Temme's method [1]. For larger orders, uniform asymptotic expansions are applied.

For complex  $z$  and positive  $v$ , the AMOS [2] *zbesi* routine is called. It uses a power series for small  $z$ , the asymptotic expansion for large  $abs(z)$ , the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for  $I_v(z)$  and  $J_v(z)$  for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of  $z$  is positive). For negative  $v$ , the formula

$$I_{-v}(z) = I_v(z) + \frac{2}{\pi} \sin(\pi v) K_v(z)$$

is used, where  $K_v(z)$  is the modified Bessel function of the second kind, evaluated using the AMOS routine *zbesk*.

**References**

[1], [2]

**scipy.special.ive**

```
scipy.special.ive(v, z) = <ufunc 'ive'>
```

Exponentially scaled modified Bessel function of the first kind

Defined as:

```
ive(v, z) = iv(v, z) * exp(-abs(z.real))
```

**Parameters**

**v** [array\_like of float] Order.  
**z** [array\_like of float or complex] Argument.

**Returns**

**out** [ndarray] Values of the exponentially scaled modified Bessel function.

## Notes

For positive  $\nu$ , the AMOS [1] `zbesi` routine is called. It uses a power series for small  $z$ , the asymptotic expansion for large  $abs(z)$ , the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for  $I_\nu(z)$  and  $J_\nu(z)$  for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_\nu(z \exp(\pm i\pi)) = \exp(\pm \pi\nu) I_\nu(z)$$

(valid when the real part of  $z$  is positive). For negative  $\nu$ , the formula

$$I_{-\nu}(z) = I_\nu(z) + \frac{2}{\pi} \sin(\pi\nu) K_\nu(z)$$

is used, where  $K_\nu(z)$  is the modified Bessel function of the second kind, evaluated using the AMOS routine `zbesk`.

### scipy.special.hankel1

`scipy.special.hankel1`( $\nu, z$ ) = <ufunc 'hankel1'>  
Hankel function of the first kind

#### Parameters

**$\nu$**  [array\_like] Order (float).  
 **$z$**  [array\_like] Argument (float or complex).

#### Returns

**out** [Values of the Hankel function of the first kind.]

See also:

### [hankelle](#)

this function with leading exponential behavior stripped off.

## Notes

A wrapper for the AMOS [1] routine `zbesh`, which carries out the computation using the relation,

$$H_\nu^{(1)}(z) = \frac{2}{i\pi} \exp(-i\pi\nu/2) K_\nu(z \exp(-i\pi/2))$$

where  $K_\nu$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-\nu}^{(1)}(z) = H_\nu^{(1)}(z) \exp(i\pi\nu)$$

is used.

## References

[1]

### scipy.special.hankel1e

`scipy.special.hankel1e(v, z) = <ufunc 'hankel1e'>`

Exponentially scaled Hankel function of the first kind

Defined as:

$$\text{hankel1e}(v, z) = \text{hankel1}(v, z) * \exp(-1j * z)$$

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**out** [Values of the exponentially scaled Hankel function.]

## Notes

A wrapper for the AMOS [1] routine *zbesj*, which carries out the computation using the relation,

$$H_v^{(1)}(z) = \frac{2}{i\pi} \exp(-i\pi v/2) K_v(z \exp(-i\pi/2))$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(1)}(z) = H_v^{(1)}(z) \exp(i\pi v)$$

is used.

## References

[1]

### scipy.special.hankel2

`scipy.special.hankel2(v, z) = <ufunc 'hankel2'>`

Hankel function of the second kind

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**out** [Values of the Hankel function of the second kind.]

See also:

#### [hankel1e](#)

this function with leading exponential behavior stripped off.

## Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(2)}(z) = -\frac{2}{i\pi} \exp(i\pi v/2) K_v(z \exp(i\pi/2))$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(2)}(z) = H_v^{(2)}(z) \exp(-i\pi v)$$

is used.

## References

[1]

### scipy.special.hankel2e

`scipy.special.hankel2e(v, z) = <ufunc 'hankel2e'>`

Exponentially scaled Hankel function of the second kind

Defined as:

```
hankel2e(v, z) = hankel2(v, z) * exp(1j * z)
```

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**out** [Values of the exponentially scaled Hankel function of the second kind.]

## Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(2)}(z) = -\frac{2}{i\pi} \exp\left(\frac{i\pi v}{2}\right) K_v\left(z \exp\left(\frac{i\pi}{2}\right)\right)$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(2)}(z) = H_v^{(2)}(z) \exp(-i\pi v)$$

is used.

`lmbda(v, x)`

Jahnke-Emden Lambda function, `Lambdav(x)`.

---

### scipy.special.lmbda

`scipy.special.lmbda(v, x)`

Jahnke-Emden Lambda function, `Lambdav(x)`.

This function is defined as [2],

$$\Lambda_v(x) = \Gamma(v + 1) \frac{J_v(x)}{(x/2)^v},$$

where  $\Gamma$  is the gamma function and  $J_v$  is the Bessel function of the first kind.

#### Parameters

- v** [float] Order of the Lambda function
- x** [float] Value at which to evaluate the function and derivatives

#### Returns

- vl** [ndarray] Values of `Lambda_vi(x)`, for  $v_i=v-\text{int}(v)$ ,  $v_i=1+v-\text{int}(v)$ , ...,  $v_i=v$ .
- dl** [ndarray] Derivatives `Lambda_vi'(x)`, for  $v_i=v-\text{int}(v)$ ,  $v_i=1+v-\text{int}(v)$ , ...,  $v_i=v$ .

```

## scipy.special.y0\_zeros

`scipy.special.y0_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel function  $Y_0(z)$ , and derivative at each zero.

The derivatives are given by  $Y_0'(z_0) = -Y_1(z_0)$  at each zero  $z_0$ .

### Parameters

**nt** [int] Number of zeros to return  
**complex** [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

### Returns

**z0n** [ndarray] Location of *n*th zero of  $Y_0(z)$   
**y0pz0n** [ndarray] Value of derivative  $Y_0'(z_0)$  for *n*th zero

## References

[1]

## scipy.special.y1\_zeros

`scipy.special.y1_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel function  $Y_1(z)$ , and derivative at each zero.

The derivatives are given by  $Y_1'(z_1) = Y_0(z_1)$  at each zero  $z_1$ .

### Parameters

**nt** [int] Number of zeros to return  
**complex** [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

### Returns

**z1n** [ndarray] Location of *n*th zero of  $Y_1(z)$   
**y1pz1n** [ndarray] Value of derivative  $Y_1'(z_1)$  for *n*th zero

## References

[1]

### scipy.special.y1p\_zeros

`scipy.special.y1p_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel derivative  $Y_1'(z)$ , and value at each zero.

The values are given by  $Y_1(z_1)$  at each  $z_1$  where  $Y_1'(z_1)=0$ .

#### Parameters

**nt** [int] Number of zeros to return  
**complex** [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

#### Returns

**z1pn** [ndarray] Location of *n*th zero of  $Y_1'(z)$   
**y1z1pn** [ndarray] Value of derivative  $Y_1(z_1)$  for *n*th zero

## References

### Faster versions of common Bessel functions

$j_0(x)$	Bessel function of the first kind of order 0.
$j_1(x)$	Bessel function of the first kind of order 1.
$y_0(x)$	Bessel function of the second kind of order 0.
$y_1(x)$	Bessel function of the second kind of order 1.
$i_0(x)$	Modified Bessel function of order 0.
$i_0e(x)$	Exponentially scaled modified Bessel function of order 0.
$i_1(x)$	Modified Bessel function of order 1.
$i_1e(x)$	Exponentially scaled modified Bessel function of order 1.
$k_0(x)$	Modified Bessel function of the second kind of order 0, $K_0$ .
$k_0e(x)$	Exponentially scaled modified Bessel function K of order 0
$k_1(x)$	Modified Bessel function of the second kind of order 1, $K_1(x)$ .
$k_1e(x)$	Exponentially scaled modified Bessel function K of order 1

**scipy.special.j0**

`scipy.special.j0(x) = <ufunc 'j0'>`

Bessel function of the first kind of order 0.

**Parameters**

**x** [array\_like] Argument (float).

**Returns**

**J** [ndarray] Value of the Bessel function of the first kind of order 0 at  $x$ .

**See also:**

[jv](#)

Bessel function of real order and complex argument.

[spherical\\_jn](#)

spherical Bessel functions.

**Notes**

The domain is divided into the intervals  $[0, 5]$  and  $(5, \text{infinity})$ . In the first interval the following rational approximation is used:

$$J_0(x) \approx (w - r_1^2)(w - r_2^2) \frac{P_3(w)}{Q_8(w)},$$

where  $w = x^2$  and  $r_1, r_2$  are the zeros of  $J_0$ , and  $P_3$  and  $Q_8$  are polynomials of degrees 3 and 8, respectively.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine `j0`. It should not be confused with the spherical Bessel functions (see [spherical\\_jn](#)).

**References**

[1]

**scipy.special.j1**

`scipy.special.j1(x) = <ufunc 'j1'>`

Bessel function of the first kind of order 1.

**Parameters**

**x** [array\_like] Argument (float).

**Returns**

**J** [ndarray] Value of the Bessel function of the first kind of order 1 at  $x$ .

**See also:**

[jv](#)

### spherical\_jn

spherical Bessel functions.

#### Notes

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 24 term Chebyshev expansion is used. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine *j1*. It should not be confused with the spherical Bessel functions (see *spherical\_jn*).

#### References

[1]

### scipy.special.y0

`scipy.special.y0(x) = <ufunc 'y0'>`  
Bessel function of the second kind of order 0.

#### Parameters

**x** [array\_like] Argument (float).

#### Returns

**Y** [ndarray] Value of the Bessel function of the second kind of order 0 at *x*.

See also:

[j0](#)

[yv](#)

#### Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval a rational approximation  $R(x)$  is employed to compute,

$$Y_0(x) = R(x) + \frac{2 \log(x) J_0(x)}{\pi},$$

where  $J_0$  is the Bessel function of the first kind of order 0.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine *y0*.

## References

[1]

### scipy.special.y1

`scipy.special.y1(x) = <ufunc 'y1'>`  
Bessel function of the second kind of order 1.

#### Parameters

**x** [array\_like] Argument (float).

#### Returns

**Y** [ndarray] Value of the Bessel function of the second kind of order 1 at  $x$ .

See also:

[j1](#)

[yn](#)

[yv](#)

## Notes

The domain is divided into the intervals  $[0, 8]$  and  $(8, \infty)$ . In the first interval a 25 term Chebyshev expansion is used, and computing  $J_1$  (the Bessel function of the first kind) is required. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine `y1`.

### scipy.special.i0

`scipy.special.i0(x) = <ufunc 'i0'>`  
Modified Bessel function of order 0.

Defined as,

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(ix),$$

where  $J_0$  is the Bessel function of the first kind of order 0.

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**I** [ndarray] Value of the modified Bessel function of order 0 at  $x$ .

**See also:**

[iv](#)

[i0e](#)

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *i0*.

**References**

[1]

**scipy.special.i0e**

`scipy.special.i0e(x) = <ufunc 'i0e'>`  
 Exponentially scaled modified Bessel function of order 0.

Defined as:

$$i0e(x) = \exp(-\text{abs}(x)) * i0(x) .$$

**Parameters**

**x** [array\_like] Argument (float)

**Returns**

**I** [ndarray] Value of the exponentially scaled modified Bessel function of order 0 at *x*.

**See also:**

[iv](#)

[i0](#)

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in *i0*, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine *i0e*.

## References

[1]

### scipy.special.i1

`scipy.special.i1(x) = <ufunc 'i1'>`

Modified Bessel function of order 1.

Defined as,

$$I_1(x) = \frac{1}{2}x \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k+1)!} = -iJ_1(ix),$$

where  $J_1$  is the Bessel function of the first kind of order 1.

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**I** [ndarray] Value of the modified Bessel function of order 1 at  $x$ .

See also:

[iv](#)

[i1e](#)

## Notes

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine `i1`.

## References

[1]

### scipy.special.i1e

`scipy.special.i1e(x) = <ufunc 'i1e'>`

Exponentially scaled modified Bessel function of order 1.

Defined as:

$$i1e(x) = \exp(-\text{abs}(x)) * i1(x)$$

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**I** [ndarray] Value of the exponentially scaled modified Bessel function of order 1 at  $x$ .

**See also:**

[iv](#)

[i1](#)

### Notes

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in [i1](#), but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine [i1e](#).

## scipy.special.k0

`scipy.special.k0(x) = <ufunc 'k0'>`

Modified Bessel function of the second kind of order 0,  $K_0$ .

This function is also sometimes referred to as the modified Bessel function of the third kind of order 0.

#### *Parameters*

**x** [array\_like] Argument (float).

#### *Returns*

**K** [ndarray] Value of the modified Bessel function  $K_0$  at  $x$ .

**See also:**

[kv](#)

[k0e](#)

### Notes

The range is partitioned into the two intervals  $[0, 2]$  and  $(2, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine [k0](#).

## References

[1]

### scipy.special.k0e

`scipy.special.k0e(x) = <ufunc 'k0e'>`  
 Exponentially scaled modified Bessel function K of order 0

Defined as:

$$k0e(x) = \exp(x) * k0(x).$$

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**K** [ndarray] Value of the exponentially scaled modified Bessel function K of order 0 at  $x$ .

See also:

[kv](#)

[k0](#)

#### Notes

The range is partitioned into the two intervals  $[0, 2]$  and  $(2, \infty)$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine `k0e`.

## References

[1]

### scipy.special.k1

`scipy.special.k1(x) = <ufunc 'k1'>`  
 Modified Bessel function of the second kind of order 1,  $K_1(x)$ .

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**K** [ndarray] Value of the modified Bessel function K of order 1 at  $x$ .

See also:

[kv](#)

[k1e](#)

## Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *k1*.

## Integrals of Bessel functions

<code>itj0y0(x[, out])</code>	Integrals of Bessel functions of the first kind of order 0.
<code>it2j0y0(x[, out])</code>	Integrals related to Bessel functions of the first kind of order 0.
<code>iti0k0(x[, out])</code>	Integrals of modified Bessel functions of order 0.
<code>it2i0k0(x[, out])</code>	Integrals related to modified Bessel functions of order 0.
<code>besselpoly(a, lmb, nu[, out])</code>	Weighted integral of the Bessel function of the first kind.

### scipy.special.itj0y0

`scipy.special.itj0y0(x, out=None) = <ufunc 'itj0y0'>`  
Integrals of Bessel functions of the first kind of order 0.

Computes the integrals

$$\int_0^x J_0(t) dt$$

$$\int_0^x Y_0(t) dt.$$

For more on  $J_0$  and  $Y_0$  see [j0](#) and [y0](#).

#### Parameters

**x** [array\_like] Values at which to evaluate the integrals.  
**out** [tuple of ndarrays, optional] Optional output arrays for the function results.

#### Returns

**ij0** [scalar or ndarray] The integral of [j0](#)  
**iy0** [scalar or ndarray] The integral of [y0](#)

### scipy.special.it2j0y0

`scipy.special.it2j0y0(x, out=None) = <ufunc 'it2j0y0'>`  
Integrals related to Bessel functions of the first kind of order 0.

Computes the integrals

$$\int_0^x \frac{1 - J_0(t)}{t} dt$$

$$\int_x^\infty \frac{Y_0(t)}{t} dt.$$

For more on  $J_0$  and  $Y_0$  see [j0](#) and [y0](#).

#### Parameters

**x** [array\_like] Values at which to evaluate the integrals.  
**out** [tuple of ndarrays, optional] Optional output arrays for the function results.

#### Returns

**ij0** [scalar or ndarray] The integral for [j0](#)  
**iy0** [scalar or ndarray] The integral for [y0](#)

**scipy.special.iti0k0**`scipy.special.iti0k0(x, out=None) = <ufunc 'iti0k0'>`

Integrals of modified Bessel functions of order 0.

Computes the integrals

$$\int_0^x I_0(t) dt$$
$$\int_0^x K_0(t) dt.$$

For more on  $I_0$  and  $K_0$  see [i0](#) and [k0](#).**Parameters**

**x** [array\_like] Values at which to evaluate the integrals.  
**out** [tuple of ndarrays, optional] Optional output arrays for the function results.

**Returns**

**ii0** [scalar or ndarray] The integral for [i0](#)  
**ik0** [scalar or ndarray] The integral for [k0](#)

**scipy.special.it2i0k0**`scipy.special.it2i0k0(x, out=None) = <ufunc 'it2i0k0'>`

Integrals related to modified Bessel functions of order 0.

Computes the integrals

$$\int_0^x \frac{I_0(t) - 1}{t} dt$$
$$\int_x^\infty \frac{K_0(t)}{t} dt.$$

**Parameters**

**x** [array\_like] Values at which to evaluate the integrals.  
**out** [tuple of ndarrays, optional] Optional output arrays for the function results.

**Returns**

**ii0** [scalar or ndarray] The integral for [i0](#)  
**ik0** [scalar or ndarray] The integral for [k0](#)

**scipy.special.besselpoly**`scipy.special.besselpoly(a, lmb, nu, out=None) = <ufunc 'besselpoly'>`

Weighted integral of the Bessel function of the first kind.

Computes

$$\int_0^1 x^\lambda J_\nu(2ax) dx$$

where  $J_\nu$  is a Bessel function and  $\lambda = lmb, \nu = nu$ .

**Parameters**

<b>a</b>	[array_like] Scale factor inside the Bessel function.
<b>lmb</b>	[array_like] Power of $x$
<b>nu</b>	[array_like] Order of the Bessel function.
<b>out</b>	[ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
Value of the integral.

**Derivatives of Bessel functions**

$jvp(v, z[, n])$	Compute derivatives of Bessel functions of the first kind.
$yvp(v, z[, n])$	Compute derivatives of Bessel functions of the second kind.
$kvp(v, z[, n])$	Compute nth derivative of real-order modified Bessel function $Kv(z)$
$ivp(v, z[, n])$	Compute derivatives of modified Bessel functions of the first kind.
$h1vp(v, z[, n])$	Compute nth derivative of Hankel function $H1v(z)$ with respect to $z$ .
$h2vp(v, z[, n])$	Compute nth derivative of Hankel function $H2v(z)$ with respect to $z$ .

**scipy.special.jvp**

`scipy.special.jvp(v, z, n=1)`

Compute derivatives of Bessel functions of the first kind.

Compute the nth derivative of the Bessel function  $J_\nu$  with respect to  $z$ .

**Parameters**

<b>v</b>	[float] Order of Bessel function
<b>z</b>	[complex] Argument at which to evaluate the derivative; can be real or complex.
<b>n</b>	[int, default 1] Order of derivative

**Returns**

**scalar or ndarray**  
Values of the derivative of the Bessel function.

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [2].

## References

[1], [2]

### scipy.special.yvp

`scipy.special.yvp` ( $v, z, n=1$ )

Compute derivatives of Bessel functions of the second kind.

Compute the  $n$ th derivative of the Bessel function  $Y_\nu$  with respect to  $z$ .

#### Parameters

<b>v</b>	[float] Order of Bessel function
<b>z</b>	[complex] Argument at which to evaluate the derivative
<b>n</b>	[int, default 1] Order of derivative

#### Returns

**scalar or ndarray**  
nth derivative of the Bessel function.

## Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

## References

[1], [2]

### scipy.special.kvp

`scipy.special.kvp` ( $v, z, n=1$ )

Compute  $n$ th derivative of real-order modified Bessel function  $K_\nu(z)$

$K_\nu(z)$  is the modified Bessel function of the second kind. Derivative is calculated with respect to  $z$ .

#### Parameters

<b>v</b>	[array_like of float] Order of Bessel function
<b>z</b>	[array_like of complex] Argument at which to evaluate the derivative
<b>n</b>	[int] Order of derivative. Default is first derivative.

#### Returns

**out** [ndarray] The results

## Notes

The derivative is computed using the relation DLFM 10.29.5 [2].

## References

[1], [2]

## Examples

Calculate multiple values at order 5:

```
>>> from scipy.special import kvp
>>> kvp(5, (1, 2, 3+5j))
array([-1.84903536e+03+0.j          , -2.57735387e+01+0.j          ,
       -3.06627741e-02+0.08750845j])
```

Calculate for a single value at multiple orders:

```
>>> kvp((4, 4.5, 5), 1)
array([-184.0309, -568.9585, -1849.0354])
```

## scipy.special.ivp

`scipy.special.ivp(v, z, n=1)`

Compute derivatives of modified Bessel functions of the first kind.

Compute the  $n$ th derivative of the modified Bessel function  $I_v$  with respect to  $z$ .

### Parameters

<b>v</b>	[array_like] Order of Bessel function
<b>z</b>	[array_like] Argument at which to evaluate the derivative; can be real or complex.
<b>n</b>	[int, default 1] Order of derivative

### Returns

**scalar or ndarray**  
 $n$ th derivative of the modified Bessel function.

See also:

`iv`

## Notes

The derivative is computed using the relation DLFM 10.29.5 [2].

## References

[1], [2]

### scipy.special.h1vp

`scipy.special.h1vp` ( $v, z, n=1$ )

Compute nth derivative of Hankel function  $H_1v(z)$  with respect to  $z$ .

#### Parameters

**v** [array\_like] Order of Hankel function  
**z** [array\_like] Argument at which to evaluate the derivative. Can be real or complex.  
**n** [int, default 1] Order of derivative

#### Returns

**scalar or ndarray**  
Values of the derivative of the Hankel function.

## Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

## References

[1], [2]

### scipy.special.h2vp

`scipy.special.h2vp` ( $v, z, n=1$ )

Compute nth derivative of Hankel function  $H_2v(z)$  with respect to  $z$ .

#### Parameters

**v** [array\_like] Order of Hankel function  
**z** [array\_like] Argument at which to evaluate the derivative. Can be real or complex.  
**n** [int, default 1] Order of derivative

#### Returns

**scalar or ndarray**  
Values of the derivative of the Hankel function.

## Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

## References

[1], [2]

## Spherical Bessel functions

<code>spherical_jn(n, z[, derivative])</code>	Spherical Bessel function of the first kind or its derivative.
<code>spherical_yn(n, z[, derivative])</code>	Spherical Bessel function of the second kind or its derivative.
<code>spherical_in(n, z[, derivative])</code>	Modified spherical Bessel function of the first kind or its derivative.
<code>spherical_kn(n, z[, derivative])</code>	Modified spherical Bessel function of the second kind or its derivative.

## scipy.special.spherical\_jn

`scipy.special.spherical_jn(n, z, derivative=False)`

Spherical Bessel function of the first kind or its derivative.

Defined as [1],

$$j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z),$$

where  $J_n$  is the Bessel function of the first kind.

### Parameters

- n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).
- z** [complex or float, array\_like] Argument of the Bessel function.
- derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

### Returns

- jn** [ndarray]

## Notes

For real arguments greater than the order, the function is computed using the ascending recurrence [2]. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations [3],

$$j'_n(z) = j_{n-1}(z) - \frac{n+1}{z} j_n(z).$$

$$j'_0(z) = -j_1(z)$$

New in version 0.18.0.

## References

[1], [2], [3]

### scipy.special.spherical\_yn

`scipy.special.spherical_yn` ( $n, z, \text{derivative}=\text{False}$ )  
Spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z),$$

where  $Y_n$  is the Bessel function of the second kind.

#### Parameters

- n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).  
**z** [complex or float, array\_like] Argument of the Bessel function.  
**derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

#### Returns

**yn** [ndarray]

## Notes

For real arguments, the function is computed using the ascending recurrence [2]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [3],

$$y'_n = y_{n-1} - \frac{n+1}{z} y_n.$$
$$y'_0 = -y_1$$

New in version 0.18.0.

## References

[1], [2], [3]

### scipy.special.spherical\_in

`scipy.special.spherical_in` ( $n, z, \text{derivative}=\text{False}$ )  
Modified spherical Bessel function of the first kind or its derivative.

Defined as [1],

$$i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z),$$

where  $I_n$  is the modified Bessel function of the first kind.

#### Parameters

**n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).  
**z** [complex or float, array\_like] Argument of the Bessel function.  
**derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

**in** [ndarray]

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind.

The derivative is computed using the relations [2],

$$i'_n = i_{n-1} - \frac{n+1}{z} i_n.$$

$$i'_1 = i_0$$

New in version 0.18.0.

**References**

[1], [2]

**scipy.special.spherical\_kn**

`scipy.special.spherical_kn` ( $n, z, derivative=False$ )

Modified spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$k_n(z) = \sqrt{\frac{\pi}{2z}} K_{n+1/2}(z),$$

where  $K_n$  is the modified Bessel function of the second kind.

**Parameters**

**n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).  
**z** [complex or float, array\_like] Argument of the Bessel function.  
**derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

**kn** [ndarray]

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations [2],

$$k'_n = -k_{n-1} - \frac{n+1}{z} k_n.$$

$$k'_0 = -k_1$$

New in version 0.18.0.

## Riccati-Bessel functions

These are not universal functions:

---

<code>riccati_jn(n, x)</code>	Compute Riccati-Bessel function of the first kind and its derivative.
<code>riccati_yn(n, x)</code>	Compute Riccati-Bessel function of the second kind and its derivative.

---

## scipy.special.riccati\_jn

`scipy.special.riccati_jn(n, x)`

Compute Riccati-Bessel function of the first kind and its derivative.

The Riccati-Bessel function of the first kind is defined as  $xj_n(x)$ , where  $j_n$  is the spherical Bessel function of the first kind of order  $n$ .

This function computes the value and first derivative of the Riccati-Bessel function for all orders up to and including  $n$ .

### Parameters

**n** [int] Maximum order of function to compute  
**x** [float] Argument at which to evaluate

### Returns

**jn** [ndarray] Value of  $j_0(x), \dots, j_n(x)$   
**jnp** [ndarray] First derivative  $j_0'(x), \dots, j_n'(x)$

## Notes

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

## References

[1], [2]

## scipy.special.riccati\_yn

`scipy.special.riccati_yn(n, x)`

Compute Riccati-Bessel function of the second kind and its derivative.

The Riccati-Bessel function of the second kind is defined as  $xy_n(x)$ , where  $y_n$  is the spherical Bessel function of the second kind of order  $n$ .

This function computes the value and first derivative of the function for all orders up to and including  $n$ .

### Parameters

**n** [int] Maximum order of function to compute  
**x** [float] Argument at which to evaluate

**Returns**

**yn** [ndarray] Value of  $y_0(x), \dots, y_n(x)$   
**ynp** [ndarray] First derivative  $y_0'(x), \dots, y_n'(x)$

**Notes**

The computation is carried out via ascending recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**References**

[1], [2]

**Struve functions**

<code>struve(v, x)</code>	Struve function.
<code>modstruve(v, x)</code>	Modified Struve function.
<code>itstruve0(x)</code>	Integral of the Struve function of order 0.
<code>it2struve0(x)</code>	Integral related to the Struve function of order 0.
<code>itmodstruve0(x)</code>	Integral of the modified Struve function of order 0.

**scipy.special.struve**

`scipy.special.struve(v, x) = <ufunc 'struve'>`

Struve function.

Return the value of the Struve function of order  $\nu$  at  $x$ . The Struve function is defined as,

$$H_\nu(x) = (x/2)^{\nu+1} \sum_{n=0}^{\infty} \frac{(-1)^n (x/2)^{2n}}{\Gamma(n + \frac{3}{2})\Gamma(n + \nu + \frac{3}{2})},$$

where  $\Gamma$  is the gamma function.

**Parameters**

**v** [array\_like] Order of the Struve function (float).  
**x** [array\_like] Argument of the Struve function (float; must be positive unless  $\nu$  is an integer).

**Returns**

**H** [ndarray] Value of the Struve function of order  $\nu$  at  $x$ .

See also:

`modstruve`

## Notes

Three methods discussed in [1] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if  $|z| < |v| + 20$ )
- asymptotic large- $z$  expansion (if  $z \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

## References

[1]

### scipy.special.modstruve

`scipy.special.modstruve(v, x) = <ufunc 'modstruve'>`  
Modified Struve function.

Return the value of the modified Struve function of order  $\nu$  at  $x$ . The modified Struve function is defined as,

$$L_\nu(x) = -i \exp(-\pi\nu/2) H_\nu(ix),$$

where  $H_\nu$  is the Struve function.

#### Parameters

- |          |  |
|----------|--|
| <b>v</b> | [array_like] Order of the modified Struve function (float).  |
| <b>x</b> | [array_like] Argument of the Struve function (float; must be positive unless $\nu$ is an integer). |

#### Returns

- |          |   |
|----------|---|
| <b>L</b> | [ndarray] Value of the modified Struve function of order $\nu$ at $x$ . |
|----------|---|

**See also:**

[struve](#)

## Notes

Three methods discussed in [1] are used to evaluate the function:

- power series
- expansion in Bessel functions (if  $|x| < |v| + 20$ )
- asymptotic large- $x$  expansion (if  $x \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

<i>gdtrib</i> (a, p, x[, out])	Inverse of <i>gdttr</i> vs b.
<i>gdtrix</i> (a, b, p[, out])	Inverse of <i>gdttr</i> vs x.
<i>nbdtr</i> (k, n, p)	Negative binomial cumulative distribution function.
<i>nbdtrc</i> (k, n, p)	Negative binomial survival function.
<i>nbdtri</i> (k, n, y)	Inverse of <i>nbdtr</i> vs p.
<i>nbdtrik</i> (y, n, p)	Inverse of <i>nbdtr</i> vs k.
<i>nbdtrin</i> (k, y, p)	Inverse of <i>nbdtr</i> vs n.
<i>ncfdtr</i> (dfn, dfd, nc, f)	Cumulative distribution function of the non-central F distribution.
<i>ncfdtridfd</i> (dfn, p, nc, f)	Calculate degrees of freedom (denominator) for the non-central F-distribution.
<i>ncfdtridfn</i> (p, dfd, nc, f)	Calculate degrees of freedom (numerator) for the non-central F-distribution.
<i>ncfdtri</i> (dfn, dfd, nc, p)	Inverse with respect to <i>f</i> of the CDF of the non-central F distribution.
<i>ncfdtrinc</i> (dfn, dfd, p, f)	Calculate non-centrality parameter for non-central F distribution.
<i>nctdtr</i> (df, nc, t)	Cumulative distribution function of the non-central <i>t</i> distribution.
<i>nctdtridf</i> (p, nc, t)	Calculate degrees of freedom for non-central <i>t</i> distribution.
<i>nctdtrit</i> (df, nc, p)	Inverse cumulative distribution function of the non-central <i>t</i> distribution.
<i>nctdtrinc</i> (df, p, t)	Calculate non-centrality parameter for non-central <i>t</i> distribution.
<i>nrtrimn</i> (p, x, std)	Calculate mean of normal distribution given other params.
<i>nrtrisd</i> (p, x, mn)	Calculate standard deviation of normal distribution given other params.
<i>pdtr</i> (k, m[, out])	Poisson cumulative distribution function.
<i>pdtrc</i> (k, m)	Poisson survival function
<i>pdtri</i> (k, y)	Inverse to <i>pdtr</i> vs m
<i>pdtrik</i> (p, m)	Inverse to <i>pdtr</i> vs k
<i>stdtr</i> (df, t)	Student <i>t</i> distribution cumulative distribution function
<i>stdtridf</i> (p, t)	Inverse of <i>stdtr</i> vs df
<i>stdtrit</i> (df, p)	Inverse of <i>stdtr</i> vs <i>t</i>
<i>chdtr</i> (v, x[, out])	Chi square cumulative distribution function.
<i>chdtrc</i> (v, x[, out])	Chi square survival function.
<i>chdtri</i> (v, p[, out])	Inverse to <i>chdtrc</i> with respect to <i>x</i> .
<i>chdtriv</i> (p, x[, out])	Inverse to <i>chdtr</i> with respect to <i>v</i> .
<i>ndtr</i> (x)	Gaussian cumulative distribution function.
<i>log_ndtr</i> (x)	Logarithm of Gaussian cumulative distribution function.
<i>ndtri</i> (y)	Inverse of <i>ndtr</i> vs <i>x</i>
<i>chndtr</i> (x, df, nc)	Non-central chi square cumulative distribution function
<i>chndtridf</i> (x, p, nc)	Inverse to <i>chndtr</i> vs <i>df</i>
<i>chndtrinc</i> (x, df, p)	Inverse to <i>chndtr</i> vs <i>nc</i>
<i>chndtrix</i> (p, df, nc)	Inverse to <i>chndtr</i> vs <i>x</i>
<i>smirnov</i> (n, d)	Kolmogorov-Smirnov complementary cumulative distribution function

continues on next page

Table 229 – continued from previous page

<code>smirnovi(n, p)</code>	Inverse to <code>smirnov</code>
<code>kolmogorov(y)</code>	Complementary cumulative distribution (Survival Function) function of Kolmogorov distribution.
<code>kolmogi(p)</code>	Inverse Survival Function of Kolmogorov distribution
<code>tklmbda(x, lmbda)</code>	Tukey-Lambda cumulative distribution function
<code>logit(x)</code>	Logit ufunc for ndarrays.
<code>expit(x)</code>	Expit (a.k.a.
<code>boxcox(x, lmbda)</code>	Compute the Box-Cox transformation.
<code>boxcox1p(x, lmbda)</code>	Compute the Box-Cox transformation of $1 + x$ .
<code>inv_boxcox(y, lmbda)</code>	Compute the inverse of the Box-Cox transformation.
<code>inv_boxcox1p(y, lmbda)</code>	Compute the inverse of the Box-Cox transformation.
<code>owens_t(h, a)</code>	Owen's T Function.

### scipy.special.bdtr

`scipy.special.bdtr(k, n, p) = <ufunc 'bdtr'>`

Binomial distribution cumulative distribution function.

Sum of the terms 0 through  $\text{floor}(k)$  of the Binomial probability density.

$$\text{bdtr}(k, n, p) = \sum_{j=0}^{\lfloor k \rfloor} \binom{n}{j} p^j (1-p)^{n-j}$$

#### Parameters

- k** [array\_like] Number of successes (double), rounded down to the nearest integer.
- n** [array\_like] Number of events (int).
- p** [array\_like] Probability of success in a single event (float).

#### Returns

- y** [ndarray] Probability of  $\text{floor}(k)$  or fewer successes in  $n$  independent events with success probabilities of  $p$ .

#### Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtr}(k, n, p) = I_{1-p}(n - \lfloor k \rfloor, \lfloor k \rfloor + 1).$$

Wrapper for the Cephes [1] routine `bdtr`.

#### References

- [1]

**scipy.special.bdtrc**

`scipy.special.bdtrc(k, n, p) = <ufunc 'bdtrc'>`

Binomial distribution survival function.

Sum of the terms  $\text{floor}(k) + 1$  through  $n$  of the binomial probability density,

$$\text{bdtrc}(k, n, p) = \sum_{j=\lfloor k \rfloor + 1}^n \binom{n}{j} p^j (1-p)^{n-j}$$

**Parameters**

- k** [array\_like] Number of successes (double), rounded down to nearest integer.
- n** [array\_like] Number of events (int)
- p** [array\_like] Probability of success in a single event.

**Returns**

- y** [ndarray] Probability of  $\text{floor}(k) + 1$  or more successes in  $n$  independent events with success probabilities of  $p$ .

See also:

[bdtr](#)

[betainc](#)

**Notes**

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtrc}(k, n, p) = I_p(\lfloor k \rfloor + 1, n - \lfloor k \rfloor).$$

Wrapper for the Cephes [1] routine *bdtrc*.

**References**

[1]

**scipy.special.bdtri**

`scipy.special.bdtri(k, n, y) = <ufunc 'bdtri'>`

Inverse function to *bdtr* with respect to  $p$ .

Finds the event probability  $p$  such that the sum of the terms 0 through  $k$  of the binomial probability density is equal to the given cumulative probability  $y$ .

**Parameters**

- k** [array\_like] Number of successes (float), rounded down to the nearest integer.
- n** [array\_like] Number of events (float)
- y** [array\_like] Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).

**Returns**

- p** [ndarray] The event probability such that  $\text{bdtr}(\text{floor } k \text{ rfloor}, n, p) = y$ .

See also:

`bdtr`  
`betaincinv`

## Notes

The computation is carried out using the inverse beta integral function and the relation,:

$$1 - p = \text{betaincinv}(n - k, k + 1, y).$$

Wrapper for the Cephes [1] routine `bdtri`.

## References

[1]

## `scipy.special.bdtrik`

`scipy.special.bdtrik(y, n, p) = <ufunc 'bdtrik'>`

Inverse function to `bdtr` with respect to  $k$ .

Finds the number of successes  $k$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for  $n$  events with probability  $p$  is equal to the given cumulative probability  $y$ .

### Parameters

**y** [array\_like] Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).  
**n** [array\_like] Number of events (float).  
**p** [array\_like] Success probability (float).

### Returns

**k** [ndarray] The number of successes  $k$  such that  $\text{bdtr}(k, n, p) = y$ .

**See also:**

`bdtr`

## Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

Wrapper for the CDFLIB [2] Fortran routine `cdfbin`.

## References

[1], [2]

### scipy.special.bdtrn

`scipy.special.bdtrn(k, y, p) = <ufunc 'bdtrn'>`

Inverse function to `bdtr` with respect to  $n$ .

Finds the number of events  $n$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for events with probability  $p$  is equal to the given cumulative probability  $y$ .

#### Parameters

**k** [array\_like] Number of successes (float).  
**y** [array\_like] Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).  
**p** [array\_like] Success probability (float).

#### Returns

**n** [ndarray] The number of events  $n$  such that  $bdtr(k, n, p) = y$ .

See also:

[bdtr](#)

## Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

Wrapper for the CDFLIB [2] Fortran routine `cdfbin`.

## References

[1], [2]

### scipy.special.btdtr

`scipy.special.btdtr(a, b, x) = <ufunc 'btdtr'>`

Cumulative distribution function of the beta distribution.

Returns the integral from zero to  $x$  of the beta probability density function,

$$I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

where  $\Gamma$  is the gamma function.

#### Parameters

**a** [array\_like] Shape parameter ( $a > 0$ ).  
**b** [array\_like] Shape parameter ( $b > 0$ ).  
**x** [array\_like] Upper limit of integration, in  $[0, 1]$ .

#### Returns

**I** [ndarray] Cumulative distribution function of the beta distribution with parameters  $a$  and  $b$  at  $x$ .

See also:

[betainc](#)

## Notes

This function is identical to the incomplete beta integral function [betainc](#).

Wrapper for the Cephes [1] routine [btdtr](#).

## References

[1]

### `scipy.special.btdtri`

`scipy.special.btdtri(a, b, p) = <ufunc 'btdtri'>`

The  $p$ -th quantile of the beta distribution.

This function is the inverse of the beta cumulative distribution function, [btdtr](#), returning the value of  $x$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

#### *Parameters*

- a** [array\_like] Shape parameter ( $a > 0$ ).
- b** [array\_like] Shape parameter ( $b > 0$ ).
- p** [array\_like] Cumulative probability, in  $[0, 1]$ .

#### *Returns*

- x** [ndarray] The quantile corresponding to  $p$ .

See also:

[betaincinv](#)

[btdtr](#)

## Notes

The value of  $x$  is found by interval halving or Newton iterations.

Wrapper for the Cephes [1] routine [incbi](#), which solves the equivalent problem of finding the inverse of the incomplete beta integral.

## References

[1]

### scipy.special.btdtria

`scipy.special.btdtria(p, b, x) = <ufunc 'btdtria'>`

Inverse of `btdtr` with respect to  $a$ .

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of  $a$ , returning the value of  $a$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

#### Parameters

**p** [array\_like] Cumulative probability, in [0, 1].  
**b** [array\_like] Shape parameter ( $b > 0$ ).  
**x** [array\_like] The quantile, in [0, 1].

#### Returns

**a** [ndarray] The value of the shape parameter  $a$  such that  $btdtr(a, b, x) = p$ .

See also:

`btdtr`

Cumulative distribution function of the beta distribution.

`btdtri`

Inverse with respect to  $x$ .

`btdtrib`

Inverse with respect to  $b$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine `cdfbet`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

## References

[1], [2]

**scipy.special.btdtrib**`scipy.special.btdtrib(a, p, x) = <ufunc 'btdtrib'>`Inverse of `btdtr` with respect to  $b$ .

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of  $b$ , returning the value of  $b$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**

- a** [array\_like] Shape parameter ( $a > 0$ ).
- p** [array\_like] Cumulative probability, in  $[0, 1]$ .
- x** [array\_like] The quantile, in  $[0, 1]$ .

**Returns**

- b** [ndarray] The value of the shape parameter  $b$  such that  $btdtr(a, b, x) = p$ .

**See also:****btdtr**

Cumulative distribution function of the beta distribution.

**btdtri**Inverse with respect to  $x$ .**btdtria**Inverse with respect to  $a$ .**Notes**Wrapper for the CDFLIB [1] Fortran routine `cdfbet`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $b$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $b$ .

**References**

[1], [2]

**scipy.special.fdtr**`scipy.special.fdtr(dfn, dfd, x) = <ufunc 'fdtr'>`

F cumulative distribution function.

Returns the value of the cumulative distribution function of the F-distribution, also known as Snedecor's F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters  $d_n$  and  $d_d$  is the distribution of the random variable,

$$X = \frac{U_n/d_n}{U_d/d_d},$$

where  $U_n$  and  $U_d$  are random variables distributed  $\chi^2$ , with  $d_n$  and  $d_d$  degrees of freedom, respectively.

**Parameters**

<b>dfn</b>	[array_like] First parameter (positive float).
<b>dfd</b>	[array_like] Second parameter (positive float).
<b>x</b>	[array_like] Argument (nonnegative float).

**Returns**

<b>y</b>	[ndarray] The CDF of the F-distribution with parameters <i>dfn</i> and <i>dfd</i> at <i>x</i> .
----------	---

**Notes**

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{x d_n / (d_d + x d_n)}(d_n/2, d_d/2).$$

Wrapper for the Cephes [1] routine *fdtr*.

**References**

[1]

**scipy.special.fdtc**

`scipy.special.fdtc(dfn, dfd, x) = <ufunc 'fdtrc'>`  
F survival function.

Returns the complemented F-distribution function (the integral of the density from *x* to infinity).

**Parameters**

<b>dfn</b>	[array_like] First parameter (positive float).
<b>dfd</b>	[array_like] Second parameter (positive float).
<b>x</b>	[array_like] Argument (nonnegative float).

**Returns**

<b>y</b>	[ndarray] The complemented F-distribution function with parameters <i>dfn</i> and <i>dfd</i> at <i>x</i> .
----------	--

**See also:**

[`fdtr`](#)

**Notes**

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{d_d / (d_d + x d_n)}(d_d/2, d_n/2).$$

Wrapper for the Cephes [1] routine *fdtrc*.

## References

[1]

### scipy.special.fdtri

`scipy.special.fdtri(dfn, dfd, p) = <ufunc 'fdtri'>`

The  $p$ -th quantile of the F-distribution.

This function is the inverse of the F-distribution CDF, `fdtr`, returning the  $x$  such that  $fdtr(dfn, dfd, x) = p$ .

#### Parameters

**dfn** [array\_like] First parameter (positive float).  
**dfd** [array\_like] Second parameter (positive float).  
**p** [array\_like] Cumulative probability, in [0, 1].

#### Returns

**x** [ndarray] The quantile corresponding to  $p$ .

## Notes

The computation is carried out using the relation to the inverse regularized beta function,  $I_x^{-1}(a, b)$ . Let  $z = I_p^{-1}(d_d/2, d_n/2)$ . Then,

$$x = \frac{d_d(1-z)}{d_n z}.$$

If  $p$  is such that  $x < 0.5$ , the following relation is used instead for improved stability: let  $z' = I_{1-p}^{-1}(d_n/2, d_d/2)$ . Then,

$$x = \frac{d_d z'}{d_n(1-z')}.$$

Wrapper for the Cephes [1] routine `fdtri`.

## References

[1]

### scipy.special.fdtridfd

`scipy.special.fdtridfd(dfn, p, x) = <ufunc 'fdtridfd'>`

Inverse to `fdtr` vs `dfd`

Finds the F density argument `dfd` such that `fdtr(dfn, dfd, x) == p`.

### scipy.special.gdtr

`scipy.special.gdtr(a, b, x) = <ufunc 'gdtr'>`

Gamma distribution cumulative distribution function.

Returns the integral from zero to  $x$  of the gamma probability density function,

$$F = \int_0^x \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

**Parameters**

- a** [array\_like] The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .
- b** [array\_like] The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).
- x** [array\_like] The quantile (upper limit of integration; float).

**Returns**

- F** [ndarray] The CDF of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

See also:

[gdt rc](#)

1 - CDF of the gamma distribution.

**Notes**

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [1] routine *gdt r*.

**References**

[1]

**scipy.special.gdt rc**

`scipy.special.gdt rc(a, b, x) = <ufunc 'gdt rc'>`

Gamma distribution survival function.

Integral from  $x$  to infinity of the gamma probability density function,

$$F = \int_x^{\infty} \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

**Parameters**

- a** [array\_like] The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .
- b** [array\_like] The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).
- x** [array\_like] The quantile (lower limit of integration; float).

**Returns**

- F** [ndarray] The survival function of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

See also:

[gdt r](#), [gdt rix](#)

## Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).  
Wrapper for the Cephes [1] routine *gdtrc*.

## References

[1]

### scipy.special.gdtria

`scipy.special.gdtria(p, b, x, out=None) = <ufunc 'gdtria'>`

Inverse of *gdtr* vs *a*.

Returns the inverse with respect to the parameter *a* of  $p = \text{gdtr}(a, b, x)$ , the cumulative distribution function of the gamma distribution.

#### Parameters

- |            |   |
|------------|---|
| <b>p</b>   | [array_like] Probability values.  |
| <b>b</b>   | [array_like] <i>b</i> parameter values of <i>gdtr(a, b, x)</i> . <i>b</i> is the “shape” parameter of the gamma distribution.   |
| <b>x</b>   | [array_like] Nonnegative real values, from the domain of the gamma distribution.  |
| <b>out</b> | [ndarray, optional] If a fourth argument is given, it must be a <code>numpy.ndarray</code> whose size matches the broadcast result of <i>a</i> , <i>b</i> and <i>x</i> . <i>out</i> is then the array returned by the function. |

#### Returns

- |          |   |
|----------|---|
| <b>a</b> | [ndarray] Values of the <i>a</i> parameter such that $p = \text{gdtr}(a, b, x)$ . $1/a$ is the “scale” parameter of the gamma distribution. |
|----------|---|

#### See also:

##### `gdtr`

CDF of the gamma distribution.

##### `gdtrib`

Inverse with respect to *b* of *gdtr(a, b, x)*.

##### `gdtrix`

Inverse with respect to *x* of *gdtr(a, b, x)*.

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfgam*.

The cumulative distribution function *p* is computed using a routine by DiDinato and Morris [2]. Computation of *a* involves a search for a value that produces the desired value of *p*. The search relies on the monotonicity of *p* with *a*.

## References

[1], [2]

## Examples

First evaluate `gdtr`.

```
>>> from scipy.special import gdtr, gdtria
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtria(p, 3.4, 5.6)
1.2
```

## scipy.special.gdtrib

`scipy.special.gdtrib(a, p, x, out=None) = <ufunc 'gdtrib'>`

Inverse of `gdtr` vs `b`.

Returns the inverse with respect to the parameter `b` of `p = gdtr(a, b, x)`, the cumulative distribution function of the gamma distribution.

### Parameters

- a** [array\_like] `a` parameter values of `gdtr(a, b, x)`.  $1/a$  is the “scale” parameter of the gamma distribution.
- p** [array\_like] Probability values.
- x** [array\_like] Nonnegative real values, from the domain of the gamma distribution.
- out** [ndarray, optional] If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of `a`, `b` and `x`. `out` is then the array returned by the function.

### Returns

- b** [ndarray] Values of the `b` parameter such that `p = gdtr(a, b, x)`. `b` is the “shape” parameter of the gamma distribution.

See also:

### `gdtr`

CDF of the gamma distribution.

### `gdtria`

Inverse with respect to `a` of `gdtr(a, b, x)`.

### `gdtrix`

Inverse with respect to `x` of `gdtr(a, b, x)`.

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfgam*.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $b$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $b$ .

3.3999999999723882
```

## scipy.special.gdftrix

`scipy.special.gdftrix(a, b, p, out=None) = <ufunc 'gdftrix'>`

Inverse of *gdftr* vs  $x$ .

Returns the inverse with respect to the parameter  $x$  of  $p = \text{gdftr}(a, b, x)$ , the cumulative distribution function of the gamma distribution. This is also known as the  $p$ th quantile of the distribution.

### Parameters

- a** [array\_like]  $a$  parameter values of  $\text{gdftr}(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.
- b** [array\_like]  $b$  parameter values of  $\text{gdftr}(a, b, x)$ .  $b$  is the “shape” parameter of the gamma distribution.
- p** [array\_like] Probability values.
- out** [ndarray, optional] If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of  $a$ ,  $b$  and  $x$ . *out* is then the array returned by the function.

### Returns

- x** [ndarray] Values of the  $x$  parameter such that  $p = \text{gdftr}(a, b, x)$ .

**See also:**

### [gdftr](#)

CDF of the gamma distribution.

### [gdftria](#)

Inverse with respect to  $a$  of  $\text{gdftr}(a, b, x)$ .

**gdtrib**

**scipy.special.nbdtr**

`scipy.special.nbdtr(k, n, p) = <ufunc 'nbdtr'>`

Negative binomial cumulative distribution function.

Returns the sum of the terms 0 through  $k$  of the negative binomial distribution probability mass function,

$$F = \sum_{j=0}^k \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that  $k$  or fewer failures precede the  $n$ th success.

**Parameters**

**k** [array\_like] The maximum number of allowed failures (nonnegative int).  
**n** [array\_like] The target number of successes (positive int).  
**p** [array\_like] Probability of success in a single event (float).

**Returns**

**F** [ndarray] The probability of  $k$  or fewer failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

See also:

`nbdtrc`

## Notes

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdttr}(k, n, p) = I_p(n, k + 1).$$

Wrapper for the Cephes [1] routine `nbdttr`.

## References

[1]

### `scipy.special.nbdtrc`

`scipy.special.nbdtrc(k, n, p) = <ufunc 'nbdtrc'>`

Negative binomial survival function.

Returns the sum of the terms  $k + 1$  to infinity of the negative binomial distribution probability mass function,

$$F = \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that more than  $k$  failures precede the  $n$ th success.

#### *Parameters*

- k** [array\_like] The maximum number of allowed failures (nonnegative int).
- n** [array\_like] The target number of successes (positive int).
- p** [array\_like] Probability of success in a single event (float).

#### *Returns*

- F** [ndarray] The probability of  $k + 1$  or more failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

## Notes

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdtrc}(k, n, p) = I_{1-p}(k + 1, n).$$

Wrapper for the Cephes [1] routine `nbdtrc`.

## References

[1]

### scipy.special.nbdtri

`scipy.special.nbdtri(k, n, y) = <ufunc 'nbdtri'>`

Inverse of `nbdtr` vs  $p$ .

Returns the inverse with respect to the parameter  $p$  of  $y = nbdtr(k, n, p)$ , the negative binomial cumulative distribution function.

#### Parameters

**k** [array\_like] The maximum number of allowed failures (nonnegative int).  
**n** [array\_like] The target number of successes (positive int).  
**y** [array\_like] The probability of  $k$  or fewer failures before  $n$  successes (float).

#### Returns

**p** [ndarray] Probability of success in a single event (float) such that  $nbdtr(k, n, p) = y$ .

See also:

#### `nbdtr`

Cumulative distribution function of the negative binomial.

#### `nbdtrik`

Inverse with respect to  $k$  of  $nbdtr(k, n, p)$ .

#### `nbdtrin`

Inverse with respect to  $n$  of  $nbdtr(k, n, p)$ .

## Notes

Wrapper for the Cephes [1] routine `nbdtri`.

## References

[1]

### scipy.special.nbdtrik

`scipy.special.nbdtrik(y, n, p) = <ufunc 'nbdtrik'>`

Inverse of `nbdtr` vs  $k$ .

Returns the inverse with respect to the parameter  $k$  of  $y = nbdtr(k, n, p)$ , the negative binomial cumulative distribution function.

#### Parameters

**y** [array\_like] The probability of  $k$  or fewer failures before  $n$  successes (float).  
**n** [array\_like] The target number of successes (positive int).  
**p** [array\_like] Probability of success in a single event (float).

#### Returns

**k** [ndarray] The maximum number of allowed failures such that  $nbdtr(k, n, p) = y$ .

See also:

`nbdt r`

Cumulative distribution function of the negative binomial.

`nbdt ri`

Inverse with respect to  $p$  of  $nbdt r(k, n, p)$ .

`nbdt rin`

Inverse with respect to  $n$  of  $nbdt r(k, n, p)$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

## References

[1], [2]

### `scipy.special.nbdtrin`

`scipy.special.nbdtrin(k, y, p) = <ufunc 'nbdtrin'>`

Inverse of `nbdt r` vs  $n$ .

Returns the inverse with respect to the parameter  $n$  of  $y = nbdt r(k, n, p)$ , the negative binomial cumulative distribution function.

#### *Parameters*

**k** [array\_like] The maximum number of allowed failures (nonnegative int).  
**y** [array\_like] The probability of  $k$  or fewer failures before  $n$  successes (float).  
**p** [array\_like] Probability of success in a single event (float).

#### *Returns*

**n** [ndarray] The number of successes  $n$  such that  $nbdt r(k, n, p) = y$ .

See also:

`nbdt r`

Cumulative distribution function of the negative binomial.

`nbdt ri`

Inverse with respect to  $p$  of  $nbdt r(k, n, p)$ .

`nbdt rik`

Inverse with respect to  $k$  of  $nbdt r(k, n, p)$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

### scipy.special.ncfdtr

`scipy.special.ncfdtr` (*dfn, dfd, nc, f*) = `<ufunc 'ncfdtr'>`  
Cumulative distribution function of the non-central F distribution.

The non-central F describes the distribution of,

$$Z = \frac{X/d_n}{Y/d_d}$$

where  $X$  and  $Y$  are independently distributed, with  $X$  distributed non-central  $\chi^2$  with noncentrality parameter  $nc$  and  $d_n$  degrees of freedom, and  $Y$  distributed  $\chi^2$  with  $d_d$  degrees of freedom.

#### Parameters

<b>dfn</b>	[array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
<b>dfd</b>	[array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
<b>nc</b>	[array_like] Noncentrality parameter. Should be in range (0, 1e4).
<b>f</b>	[array_like] Quantiles, i.e. the upper limit of integration.

#### Returns

<b>cdf</b>	[float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.
------------	---

See also:

#### `ncfdtri`

Quantile function; inverse of `ncfdtr` with respect to  $f$ .

#### `ncfdtridf`

Inverse of `ncfdtr` with respect to  $dfd$ .

#### `ncfdtridfn`

Inverse of `ncfdtr` with respect to  $dfn$ .

#### `ncfdtrinc`

Inverse of `ncfdtr` with respect to  $nc$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdffnc*.

The cumulative distribution function is computed using Formula 26.6.20 of [2]:

$$F(d_n, d_d, n_c, f) = \sum_{j=0}^{\infty} e^{-n_c/2} \frac{(n_c/2)^j}{j!} I_x\left(\frac{d_n}{2} + j, \frac{d_d}{2}\right),$$

where  $I$  is the regularized incomplete beta function, and  $x = fd_n/(fd_n + d_d)$ .

The computation time required for this routine is proportional to the noncentrality parameter  $nc$ . Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.

## References

[1], [2]

## Examples

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central F distribution, for  $nc=0$ . Compare with the F-distribution from `scipy.stats`:

```
>>> x = np.linspace(-1, 8, num=500)
>>> dfn = 3
>>> dfd = 2
>>> ncf_stats = stats.f.cdf(x, dfn, dfd)
>>> ncf_special = special.ncfdtr(dfn, dfd, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()
```

## scipy.special.ncfdtridfd

`scipy.special.ncfdtridfd(dfn, p, nc, f) = <ufunc 'ncfdtridfd'>`

Calculate degrees of freedom (denominator) for the noncentral F-distribution.

This is the inverse with respect to  $dfd$  of `ncfdtr`. See `ncfdtr` for more details.

### Parameters

<b>dfn</b>	[array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
<b>p</b>	[array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
<b>nc</b>	[array_like] Noncentrality parameter. Should be in range (0, 1e4).
<b>f</b>	[array_like] Quantiles, i.e., the upper limit of integration.

### Returns

<b>dfd</b>	[float] Degrees of freedom of the denominator sum of squares.
------------	---

See also:

`ncfdtr`

CDF of the non-central F distribution.

`ncfdtri`

Quantile function; inverse of `ncfdtr` with respect to  $f$ .

`ncfdtridfn`

Inverse of `ncfdtr` with respect to  $dfn$ .

`ncfdtrinc`

Inverse of `ncfdtr` with respect to  $nc$ .

## Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

## Examples

```
>>> from scipy.special import ncfdtr, ncfdtridfd
```

Compute the CDF for several values of  $dfd$ :

```
>>> dfd = [1, 2, 3]
>>> p = ncfdtr(2, dfd, 0.25, 15)
>>> p
array([ 0.8097138 ,  0.93020416,  0.96787852])
```

Compute the inverse. We recover the values of  $dfd$ , as expected:

```
>>> ncfidtridf(2, p, 0.25, 15)
array([ 1.,  2.,  3.]
```

### scipy.special.ncfdtridf

`scipy.special.ncfdtridf(p, dfd, nc, f) = <ufunc 'ncfdtridf'>`

Calculate degrees of freedom (numerator) for the noncentral F-distribution.

This is the inverse with respect to *dfn* of *ncfdtr*. See *ncfdtr* for more details.

#### Parameters

**p** [array\_like] Value of the cumulative distribution function. Must be in the range [0, 1].  
**dfd** [array\_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (0, 1e4).  
**f** [float] Quantiles, i.e., the upper limit of integration.

#### Returns

**dfn** [float] Degrees of freedom of the numerator sum of squares.

See also:

#### [ncfdtr](#)

CDF of the non-central F distribution.

#### [ncfdtri](#)

Quantile function; inverse of *ncfdtr* with respect to *f*.

#### [ncfdtridf](#)

Inverse of *ncfdtr* with respect to *dfd*.

#### [ncfdtrinc](#)

Inverse of *ncfdtr* with respect to *nc*.

### Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

### Examples

```
>>> from scipy.special import ncfidtr, ncfidtridf
```

Compute the CDF for several values of *dfn*:

```
>>> dfn = [1, 2, 3]
>>> p = ncfidtr(dfn, 2, 0.25, 15)
>>> p
array([ 0.92562363,  0.93020416,  0.93188394])
```

Compute the inverse. We recover the values of *dfn*, as expected:

```
>>> ncfidtridf(p, 2, 0.25, 15)
array([ 1.,  2.,  3.]
```

### scipy.special.ncfdtri

`scipy.special.ncfdtri(dfn, dfd, nc, p) = <ufunc 'ncfdtri'>`

Inverse with respect to  $f$  of the CDF of the non-central F distribution.

See `ncfdtr` for more details.

#### Parameters

**dfn** [array\_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).  
**dfd** [array\_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (0, 1e4).  
**p** [array\_like] Value of the cumulative distribution function. Must be in the range [0, 1].

#### Returns

**f** [float] Quantiles, i.e., the upper limit of integration.

See also:

#### `ncfdtr`

CDF of the non-central F distribution.

#### `ncfdtridf`

Inverse of `ncfdtr` with respect to  $dfd$ .

#### `ncfdtridfn`

Inverse of `ncfdtr` with respect to  $dfn$ .

#### `ncfdtrinc`

Inverse of `ncfdtr` with respect to  $nc$ .

### Examples

```
>>> from scipy.special import ncfidtr, ncfidtri
```

Compute the CDF for several values of  $f$ :

```
>>> f = [0.5, 1, 1.5]
>>> p = ncfidtr(2, 3, 1.5, f)
>>> p
array([ 0.20782291,  0.36107392,  0.47345752])
```

Compute the inverse. We recover the values of  $f$ , as expected:

```
>>> ncfidtri(2, 3, 1.5, p)
array([ 0.5,  1. ,  1.5])
```

**scipy.special.ncfdtrinc**

`scipy.special.ncfdtrinc(dfn, dfd, p, f) = <ufunc 'ncfdtrinc'>`  
Calculate non-centrality parameter for non-central F distribution.

This is the inverse with respect to *nc* of `ncfdtr`. See `ncfdtr` for more details.

**Parameters**

**dfn** [array\_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).  
**dfd** [array\_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).  
**p** [array\_like] Value of the cumulative distribution function. Must be in the range [0, 1].  
**f** [array\_like] Quantiles, i.e., the upper limit of integration.

**Returns**

**nc** [float] Noncentrality parameter.

**See also:****ncfdtr**

CDF of the non-central F distribution.

**ncfdtri**

Quantile function; inverse of `ncfdtr` with respect to *f*.

**ncfdtridfd**

Inverse of `ncfdtr` with respect to *dfd*.

**ncfdtridfn**

Inverse of `ncfdtr` with respect to *dfn*.

**Examples**

```
>>> from scipy.special import ncfdtr, ncfdtrinc
```

Compute the CDF for several values of *nc*:

```
>>> nc = [0.5, 1.5, 2.0]
>>> p = ncfdtr(2, 3, nc, 15)
>>> p
array([ 0.96309246,  0.94327955,  0.93304098])
```

Compute the inverse. We recover the values of *nc*, as expected:

```
>>> ncfdtrinc(2, 3, p, 15)
array([ 0.5,  1.5,  2. ])
```

**scipy.special.nctdtr**

`scipy.special.nctdtr(df, nc, t) = <ufunc 'nctdtr'>`  
 Cumulative distribution function of the non-central  $t$  distribution.

**Parameters**

**df** [array\_like] Degrees of freedom of the distribution. Should be in range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (-1e6, 1e6).  
**t** [array\_like] Quantiles, i.e., the upper limit of integration.

**Returns**

**cdf** [float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise, it will be an array.

**See also:****nctdtrit**

Inverse CDF (iCDF) of the non-central  $t$  distribution.

**nctdtridf**

Calculate degrees of freedom, given CDF and iCDF values.

**nctdtrinc**

Calculate non-centrality parameter, given CDF iCDF values.

**Examples**

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central  $t$  distribution, for  $nc=0$ . Compare with the  $t$ -distribution from `scipy.stats`:

```
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.nctdtr(df, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-')
>>> plt.show()
```

### scipy.special.ncdtridf

`scipy.special.ncdtridf(p, nc, t) = <ufunc 'ncdtridf'>`  
 Calculate degrees of freedom for non-central t distribution.

See [ncdtr](#) for more details.

#### Parameters

- p** [array\_like] CDF values, in range (0, 1].
- nc** [array\_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
- t** [array\_like] Quantiles, i.e., the upper limit of integration.

### scipy.special.ncdtrit

`scipy.special.ncdtrit(df, nc, p) = <ufunc 'ncdtrit'>`  
 Inverse cumulative distribution function of the non-central t distribution.

See [ncdtr](#) for more details.

#### Parameters

- df** [array\_like] Degrees of freedom of the distribution. Should be in range (0, inf).
- nc** [array\_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
- p** [array\_like] CDF values, in range (0, 1].

### scipy.special.ncdtrinc

`scipy.special.ncdtrinc(df, p, t) = <ufunc 'ncdtrinc'>`  
 Calculate non-centrality parameter for non-central t distribution.

See [ncdtr](#) for more details.

#### Parameters

- df** [array\_like] Degrees of freedom of the distribution. Should be in range (0, inf).
- p** [array\_like] CDF values, in range (0, 1].
- t** [array\_like] Quantiles, i.e., the upper limit of integration.

**scipy.special.nrdtrimn**

`scipy.special.nrdtrimn(p, x, std) = <ufunc 'nrdtrimn'>`

Calculate mean of normal distribution given other params.

**Parameters**

**p** [array\_like] CDF values, in range (0, 1].  
**x** [array\_like] Quantiles, i.e. the upper limit of integration.  
**std** [array\_like] Standard deviation.

**Returns**

**mn** [float or ndarray] The mean of the normal distribution.

See also:

[nrdtrimn](#), [ndtr](#)

**scipy.special.nrdtrisd**

`scipy.special.nrdtrisd(p, x, mn) = <ufunc 'nrdtrisd'>`

Calculate standard deviation of normal distribution given other params.

**Parameters**

**p** [array\_like] CDF values, in range (0, 1].  
**x** [array\_like] Quantiles, i.e. the upper limit of integration.  
**mn** [float or ndarray] The mean of the normal distribution.

**Returns**

**std** [array\_like] Standard deviation.

See also:

[ndtr](#)

**scipy.special.pdtr**

`scipy.special.pdtr(k, m, out=None) = <ufunc 'pdtr'>`

Poisson cumulative distribution function.

Defined as the probability that a Poisson-distributed random variable with event rate  $m$  is less than or equal to  $k$ . More concretely, this works out to be [1]

$$\exp(-m) \sum_{j=0}^{\lfloor k \rfloor} \frac{m^j}{j!}.$$

**Parameters**

**k** [array\_like] Nonnegative real argument  
**m** [array\_like] Nonnegative real shape parameter  
**out** [ndarray] Optional output array for the function results

**Returns**

**scalar or ndarray**  
 Values of the Poisson cumulative distribution function

See also:

**pdtrc**

Poisson survival function

**pdtrik**

inverse of *pdtr* with respect to *k*

**pdtri**

inverse of *pdtr* with respect to *m*

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

It is a cumulative distribution function, so it converges to 1 monotonically as *k* goes to infinity.

```
>>> sc.pdtr([1, 10, 100, np.inf], 1)
array([0.73575888, 0.99999999, 1.          , 1.          ])
```

It is discontinuous at integers and constant between integers.

```
>>> sc.pdtr([1, 1.5, 1.9, 2], 1)
array([0.73575888, 0.73575888, 0.73575888, 0.9196986 ])
```

**scipy.special.pdtrc**

`scipy.special.pdtrc(k, m) = <ufunc 'pdtrc'>`  
 Poisson survival function

Returns the sum of the terms from *k*+1 to infinity of the Poisson distribution:  $\sum(\exp(-m) * m^{**j} / j!, j=k+1..inf)$   
 = `gammainc(k+1, m)`. Arguments must both be non-negative doubles.

**scipy.special.pdtri**

`scipy.special.pdtri(k, y) = <ufunc 'pdtri'>`  
 Inverse to *pdtr* vs *m*

Returns the Poisson variable *m* such that the sum from 0 to *k* of the Poisson density is equal to the given probability *y*: calculated by `gammaincinv(k+1, y)`. *k* must be a nonnegative integer and *y* between 0 and 1.

**scipy.special.pdtrik**

`scipy.special.pdtrik(p, m) = <ufunc 'pdtrik'>`  
 Inverse to *pdtr* vs *k*

Returns the quantile *k* such that `pdtr(k, m) = p`

**scipy.special.stdtr**

`scipy.special.stdtr(df, t) = <ufunc 'stdtr'>`  
 Student t distribution cumulative distribution function

Returns the integral from minus infinity to  $t$  of the Student t distribution with  $df > 0$  degrees of freedom:

```
gamma((df+1)/2)/(sqrt(df*pi)*gamma(df/2)) *
integral((1+x**2/df)**(-df/2-1/2), x=-inf..t)
```

**scipy.special.stdtridf**

`scipy.special.stdtridf(p, t) = <ufunc 'stdtridf'>`  
 Inverse of `stdtr` vs  $df$

Returns the argument  $df$  such that `stdtr(df, t)` is equal to  $p$ .

**scipy.special.stdtrit**

`scipy.special.stdtrit(df, p) = <ufunc 'stdtrit'>`  
 Inverse of `stdtr` vs  $t$

Returns the argument  $t$  such that `stdtr(df, t)` is equal to  $p$ .

**scipy.special.chdtr**

`scipy.special.chdtr(v, x, out=None) = <ufunc 'chdtr'>`  
 Chi square cumulative distribution function.

Returns the area under the left tail (from 0 to  $x$ ) of the Chi square probability density function with  $v$  degrees of freedom:

$$\frac{1}{2^{v/2}\Gamma(v/2)} \int_0^x t^{v/2-1} e^{-t/2} dt$$

Here  $\Gamma$  is the Gamma function; see [gamma](#). This integral can be expressed in terms of the regularized lower incomplete gamma function [gammainc](#) as `gammainc(v / 2, x / 2)`. [1]

**Parameters**

- v** [array\_like] Degrees of freedom.
- x** [array\_like] Upper bound of the integral.
- out** [ndarray, optional] Optional output array for the function results.

**Returns**

- scalar or ndarray**  
 Values of the cumulative distribution function.

See also:

[chdtrc](#), [chdtri](#), [chdtriv](#), [gammainc](#)

## References

[1]

## Examples

```
>>> import scipy.special as sc
```

It can be expressed in terms of the regularized lower incomplete gamma function.

```
>>> v = 1
>>> x = np.arange(4)
>>> sc.chdtr(v, x)
array([0.          , 0.68268949, 0.84270079, 0.91673548])
>>> sc.gammainc(v / 2, x / 2)
array([0.          , 0.68268949, 0.84270079, 0.91673548])
```

## scipy.special.chdtrc

`scipy.special.chdtrc(v, x, out=None)` = <ufunc 'chdtrc'>

Chi square survival function.

Returns the area under the right hand tail (from  $x$  to infinity) of the Chi square probability density function with  $v$  degrees of freedom:

$$\frac{1}{2^{v/2}\Gamma(v/2)} \int_x^\infty t^{v/2-1} e^{-t/2} dt$$

Here  $\Gamma$  is the Gamma function; see [gamma](#). This integral can be expressed in terms of the regularized upper incomplete gamma function [gammaincc](#) as `gammaincc(v / 2, x / 2)`. [1]

### Parameters

**v** [array\_like] Degrees of freedom.  
**x** [array\_like] Lower bound of the integral.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
Values of the survival function.

See also:

[chdtr](#), [chdtri](#), [chdtriv](#), [gammaincc](#)

## References

[1]

## Examples

```
>>> import scipy.special as sc
```

It can be expressed in terms of the regularized upper incomplete gamma function.

```
>>> v = 1
>>> x = np.arange(4)
>>> sc.chdtrc(v, x)
array([1.          , 0.31731051, 0.15729921, 0.08326452])
>>> sc.gammaincc(v / 2, x / 2)
array([1.          , 0.31731051, 0.15729921, 0.08326452])
```

## scipy.special.chdtri

`scipy.special.chdtri(v, p, out=None) = <ufunc 'chdtri'>`

Inverse to `chdtrc` with respect to  $x$ .

Returns  $x$  such that `chdtrc(v, x) == p`.

### Parameters

**v** [array\_like] Degrees of freedom.  
**p** [array\_like] Probability.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**x** [scalar or ndarray] Value so that the probability a Chi square random variable with  $v$  degrees of freedom is greater than  $x$  equals  $p$ .

See also:

`chdtrc`, `chdtr`, `chdtriv`

## References

[1]

## Examples

```
>>> import scipy.special as sc
```

It inverts `chdtrc`.

```
>>> v, p = 1, 0.3
>>> sc.chdtrc(v, sc.chdtri(v, p))
0.3
>>> x = 1
>>> sc.chdtri(v, sc.chdtrc(v, x))
1.0
```

### scipy.special.chdtriv

`scipy.special.chdtriv(p, x, out=None) = <ufunc 'chdtriv'>`

Inverse to `chdtr` with respect to  $v$ .

Returns  $v$  such that `chdtr(v, x) == p`.

#### Parameters

**p** [array\_like] Probability that the Chi square random variable is less than or equal to  $x$ .  
**x** [array\_like] Nonnegative input.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
 Degrees of freedom.

See also:

`chdtr`, `chdtrc`, `chdtri`

### References

[1]

### Examples

```
>>> import scipy.special as sc
```

It inverts `chdtr`.

```
>>> p, x = 0.5, 1
>>> sc.chdtr(sc.chdtriv(p, x), x)
0.50000000000202172
>>> v = 1
>>> sc.chdtriv(sc.chdtr(v, x), v)
1.00000000000000013
```

### scipy.special.ndtr

`scipy.special.ndtr(x) = <ufunc 'ndtr'>`

Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to  $x$

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-t^2/2) dt$$

#### Parameters

**x** [array\_like, real or complex] Argument

#### Returns

**ndarray** The value of the normal CDF evaluated at  $x$

See also:

[erf](#)  
[erfc](#)  
[scipy.stats.norm](#)  
[log\\_ndtr](#)

### scipy.special.log\_ndtr

`scipy.special.log_ndtr(x) = <ufunc 'log_ndtr'>`  
 Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to  $x$ :

$$\log(1/\sqrt{2\pi}) * \text{integral}(\exp(-t^2 / 2), t=-\text{inf}..x)$$

#### Parameters

**x** [array\_like, real or complex] Argument

#### Returns

**ndarray** The value of the log of the normal CDF evaluated at  $x$

See also:

[erf](#)  
[erfc](#)  
[scipy.stats.norm](#)  
[ndtr](#)

### scipy.special.ndtri

`scipy.special.ndtri(y) = <ufunc 'ndtri'>`  
 Inverse of `ndtr` vs  $x$

Returns the argument  $x$  for which the area under the Gaussian probability density function (integrated from minus infinity to  $x$ ) is equal to  $y$ .

### scipy.special.chndtr

`scipy.special.chndtr(x, df, nc) = <ufunc 'chndtr'>`  
 Non-central chi square cumulative distribution function

### scipy.special.chndtridf

`scipy.special.chndtridf(x, p, nc) = <ufunc 'chndtridf'>`  
 Inverse to `chndtr` vs  $df$

**scipy.special.chndtrinc**

`scipy.special.chndtrinc(x, df, p) = <ufunc 'chndtrinc'>`  
Inverse to `chndtr` vs `nc`

**scipy.special.chndtrix**

`scipy.special.chndtrix(p, df, nc) = <ufunc 'chndtrix'>`  
Inverse to `chndtr` vs `x`

**scipy.special.smirnov**

`scipy.special.smirnov(n, d) = <ufunc 'smirnov'>`  
Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function, (aka the Survival Function) of  $D_n^+$  (or  $D_n^-$ ) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on  $n$  samples is greater than  $d$ .

**Parameters**

**n** [int] Number of samples  
**d** [float array\_like] Deviation between the Empirical CDF (ECDF) and the target CDF.

**Returns**

**float** The value(s) of `smirnov(n, d)`,  $\text{Prob}(D_n^+ \geq d)$  (Also  $\text{Prob}(D_n^- \geq d)$ )

**See also:****smirnovi**

The Inverse Survival Function for the distribution

**scipy.stats.kstest**

Provides the functionality as a continuous distribution

**kolmogorov, kolmogi**

Functions for the two-sided distribution

**Notes**

`smirnov` is used by `stats.kstest` in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in `scipy.special`, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the `stats.kstest` distribution.

**Examples**

```
>>> from scipy.special import smirnov
```

Show the probability of a gap at least as big as 0, 0.5 and 1.0 for a sample of size 5

```
>>> smirnov(5, [0, 0.5, 1.0])  
array([ 1.    ,  0.056 ,  0.    ])
```

Compare a sample of size 5 drawn from a source  $N(0.5, 1)$  distribution against a target  $N(0, 1)$  CDF.

```

>>> from scipy.stats import norm
>>> n = 5
>>> gendist = norm(0.5, 1)      # Normal distribution, mean 0.5, stddev 1
>>> np.random.seed(seed=233423) # Set the seed for reproducibility
>>> x = np.sort(gendist.rvs(size=n))
>>> x
array([-0.20946287,  0.71688765,  0.95164151,  1.44590852,  3.08880533])
>>> target = norm(0, 1)
>>> cdfs = target.cdf(x)
>>> cdfs
array([ 0.41704346,  0.76327829,  0.82936059,  0.92589857,  0.99899518])
# Construct the Empirical CDF and the K-S statistics (Dn+, Dn-, Dn)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> cols = np.column_stack([x, ecdfs[1:], cdfs, cdfs - ecdfs[:n],
→ecdfs[1:] - cdfs])
>>> np.set_printoptions(precision=3)
>>> cols
array([[ -2.095e-01,  2.000e-01,  4.170e-01,  4.170e-01,  -2.170e-01],
       [  7.169e-01,  4.000e-01,  7.633e-01,  5.633e-01,  -3.633e-01],
       [  9.516e-01,  6.000e-01,  8.294e-01,  4.294e-01,  -2.294e-01],
       [  1.446e+00,  8.000e-01,  9.259e-01,  3.259e-01,  -1.259e-01],
       [  3.089e+00,  1.000e+00,  9.990e-01,  1.990e-01,  1.005e-03]])
>>> gaps = cols[:, -2:]
>>> Dnpm = np.max(gaps, axis=0)
>>> print('Dn-=%f, Dn+=%f' % (Dnpm[0], Dnpm[1]))
Dn-=0.563278, Dn+=0.001005
>>> probs = smirnov(n, Dnpm)
>>> print(chr(10).join(['For a sample of size %d drawn from a N(0, 1)
→distribution:' % n,
...   ' Smirnov n=%d: Prob(Dn- >= %f) = %.4f' % (n, Dnpm[0],
→probs[0]),
...   ' Smirnov n=%d: Prob(Dn+ >= %f) = %.4f' % (n, Dnpm[1],
→probs[1])]))
For a sample of size 5 drawn from a N(0, 1) distribution:
Smirnov n=5: Prob(Dn- >= 0.563278) = 0.0250
Smirnov n=5: Prob(Dn+ >= 0.001005) = 0.9990

```

Plot the Empirical CDF against the target N(0, 1) CDF

```

>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[ -3], x]), ecdfs, where='post', label=
→'Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
# Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r',
→linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='m',
→linestyle='dashed', lw=4)
>>> plt.show()

```

### scipy.special.smirnovi

`scipy.special.smirnovi(n, p) = <ufunc 'smirnovi'>`

Inverse to `smirnov`

Returns  $d$  such that `smirnov(n, d) == p`, the critical value corresponding to  $p$ .

#### Parameters

**n** [int] Number of samples  
**p** [float array\_like] Probability

#### Returns

**float** The value(s) of `smirnovi(n, p)`, the critical values.

See also:

#### `smirnov`

The Survival Function (SF) for the distribution

#### `scipy.stats.kstest`

Provides the functionality as a continuous distribution

#### `kolmogorov`, `kolmogi`, `scipy.stats.kstwobign`

Functions for the two-sided distribution

## Notes

*smirnov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstest* distribution.

## scipy.special.kolmogorov

`scipy.special.kolmogorov(y) = <ufunc 'kolmogorov'>`

Complementary cumulative distribution (Survival Function) function of Kolmogorov distribution.

Returns the complementary cumulative distribution function of Kolmogorov's limiting distribution ( $D_n \sqrt{n}$  as  $n$  goes to infinity) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as  $n \rightarrow \infty$  of the) probability that  $\sqrt{n} \cdot \max \text{ absolute deviation} > y$ .

### Parameters

**y** [float array\_like] Absolute deviation between the Empirical CDF (ECDF) and the target CDF, multiplied by  $\sqrt{n}$ .

### Returns

**float** The value(s) of `kolmogorov(y)`

See also:

### kolmogi

The Inverse Survival Function for the distribution

### scipy.stats.kstwobign

Provides the functionality as a continuous distribution

### smirnov, smirnovi

Functions for the one-sided distribution

## Notes

*kolmogorov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstwobign* distribution.

## Examples

Show the probability of a gap at least as big as 0, 0.5 and 1.0.

```
>>> from scipy.special import kolmogorov
>>> from scipy.stats import kstwobign
>>> kolmogorov([0, 0.5, 1.0])
array([ 1.          ,  0.96394524,  0.26999967])
```

Compare a sample of size 1000 drawn from a Laplace(0, 1) distribution against the target distribution, a Normal(0, 1) distribution.

```

>>> from scipy.stats import norm, laplace
>>> n = 1000
>>> np.random.seed(seed=233423)
>>> lap01 = laplace(0, 1)
>>> x = np.sort(lap01.rvs(n))
>>> np.mean(x), np.std(x)
(-0.083073685397609842, 1.3676426568399822)

```

Construct the Empirical CDF and the K-S statistic  $D_n$ .

```

>>> target = norm(0,1) # Normal mean 0, stddev 1
>>> cdfs = target.cdf(x)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> gaps = np.column_stack([cdfs - ecdfs[:n], ecdfs[1:] - cdfs])
>>> Dn = np.max(gaps)
>>> Kn = np.sqrt(n) * Dn
>>> print('Dn=%f, sqrt(n)*Dn=%f' % (Dn, Kn))
Dn=0.058286, sqrt(n)*Dn=1.843153
>>> print(chr(10).join(['For a sample of size n drawn from a N(0, 1) ↵
↵distribution:',
... ' the approximate Kolmogorov probability that sqrt(n)*Dn>=%f is %f
↵' % (Kn, kolmogorov(Kn)),
... ' the approximate Kolmogorov probability that sqrt(n)*Dn<=%f is %f
↵' % (Kn, kstwobign.cdf(Kn))]))
For a sample of size n drawn from a N(0, 1) distribution:
the approximate Kolmogorov probability that sqrt(n)*Dn>=1.843153 is 0.
↵002240
the approximate Kolmogorov probability that sqrt(n)*Dn<=1.843153 is 0.
↵997760

```

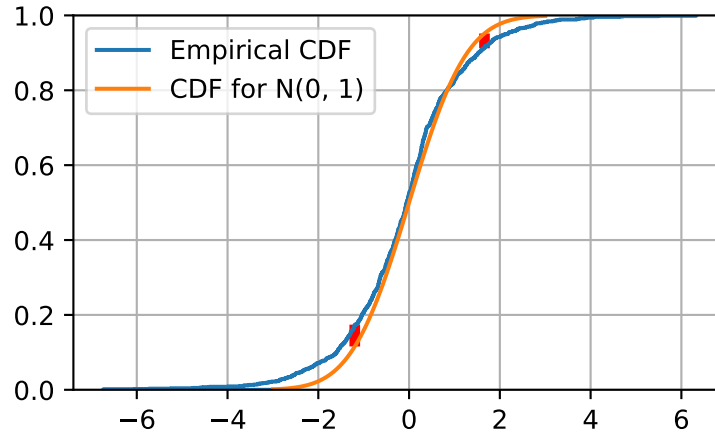

Plot the Empirical CDF against the target  $N(0, 1)$  CDF.

```

>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[ -3], x]), ecdfs, where='post', label=
↵'Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
>>> # Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r', ↵
↵linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='r', ↵
↵linestyle='dashed', lw=4)
>>> plt.show()

```

### scipy.special.kolmogi

`scipy.special.kolmogi(p) = <ufunc 'kolmogi'>`  
Inverse Survival Function of Kolmogorov distribution

It is the inverse function to *kolmogorov*. Returns  $y$  such that  $\text{kolmogorov}(y) == p$ .

#### Parameters

**p** [float array\_like] Probability

#### Returns

**float** The value(s) of  $\text{kolmogi}(p)$

See also:

#### `kolmogorov`

The Survival Function for the distribution

#### `scipy.stats.kstwobign`

Provides the functionality as a continuous distribution

#### `smirnov`, `smirnovi`

Functions for the one-sided distribution

### Notes

*kolmogorov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstwobign* distribution.

## Examples

```
>>> from scipy.special import kolmogi
>>> kolmogi([0, 0.1, 0.25, 0.5, 0.75, 0.9, 1.0])
array([          inf,  1.22384787,  1.01918472,  0.82757356,  0.67644769,
        0.57117327,  0.          ])
```

### scipy.special.tklmbda

`scipy.special.tklmbda(x, lambda) = <ufunc 'tklmbda'>`  
 Tukey-Lambda cumulative distribution function

### scipy.special.logit

`scipy.special.logit(x) = <ufunc 'logit'>`  
 Logit ufunc for ndarrays.

The logit function is defined as  $\text{logit}(p) = \log(p/(1-p))$ . Note that  $\text{logit}(0) = -\text{inf}$ ,  $\text{logit}(1) = \text{inf}$ , and  $\text{logit}(p)$  for  $p < 0$  or  $p > 1$  yields nan.

#### Parameters

**x** [ndarray] The ndarray to apply logit to element-wise.

#### Returns

**out** [ndarray] An ndarray of the same shape as x. Its entries are logit of the corresponding entry of x.

#### See also:

[expit](#)

#### Notes

As a ufunc logit takes a number of optional keyword arguments. For more information see [ufuncs](#)

New in version 0.10.0.

## Examples

```
>>> from scipy.special import logit, expit
```

```
>>> logit([0, 0.25, 0.5, 0.75, 1])
array([          -inf, -1.09861229,  0.          ,  1.09861229,           inf])
```

`expit` is the inverse of `logit`:

```
>>> expit(logit([0.1, 0.75, 0.999]))
array([ 0.1 ,  0.75 ,  0.999])
```

Plot  $\text{logit}(x)$  for  $x$  in  $[0, 1]$ :

```

>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 1, 501)
>>> y = logit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.ylim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('logit(x)')
>>> plt.show()

```

### scipy.special.expit

`scipy.special.expit(x)` = <ufunc 'expit'>

Expit (a.k.a. logistic sigmoid) ufunc for ndarrays.

The expit function, also known as the logistic sigmoid function, is defined as  $\text{expit}(x) = 1 / (1 + \exp(-x))$ . It is the inverse of the logit function.

#### Parameters

**x** [ndarray] The ndarray to apply expit to element-wise.

#### Returns

**out** [ndarray] An ndarray of the same shape as x. Its entries are `expit` of the corresponding entry of x.

See also:

[logit](#)

## Notes

As a ufunc `expit` takes a number of optional keyword arguments. For more information see [ufuncs](#)

New in version 0.10.0.

## Examples

```
>>> from scipy.special import expit, logit
```

```
>>> expit([-np.inf, -1.5, 0, 1.5, np.inf])
array([ 0.          ,  0.18242552,  0.5          ,  0.81757448,  1.          ])
```

`logit` is the inverse of `expit`:

```
>>> logit(expit([-2.5, 0, 3.1, 5.0]))
array([-2.5,  0. ,  3.1,  5. ])
```

Plot `expit(x)` for `x` in `[-6, 6]`:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-6, 6, 121)
>>> y = expit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.xlim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('expit(x)')
>>> plt.show()
```

**scipy.special.boxcox**

`scipy.special.boxcox(x, lambda) = <ufunc 'boxcox'>`  
 Compute the Box-Cox transformation.

The Box-Cox transformation is:

```
y = (x**lambda - 1) / lambda  if lambda != 0
    log(x)                    if lambda == 0
```

Returns *nan* if  $x < 0$ . Returns *-inf* if  $x == 0$  and  $lambda < 0$ .

**Parameters**

**x** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**y** [array] Transformed data.

**Notes**

New in version 0.14.0.

**Examples**

```
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([ 0.          , 12.4          , 126.09110641])
>>> boxcox(2, [0, 1, 2])
array([ 0.69314718, 1.          , 1.5          ])
```

**scipy.special.boxcox1p**

`scipy.special.boxcox1p(x, lambda) = <ufunc 'boxcox1p'>`  
 Compute the Box-Cox transformation of  $1 + x$ .

The Box-Cox transformation computed by `boxcox1p` is:

```
y = ((1+x)**lambda - 1) / lambda  if lambda != 0
    log(1+x)                      if lambda == 0
```

Returns *nan* if  $x < -1$ . Returns *-inf* if  $x == -1$  and  $lambda < 0$ .

**Parameters**

**x** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**y** [array] Transformed data.

## Notes

New in version 0.14.0.

## Examples

```
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([ 9.99950003e-05,  9.99975001e-05,  1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([ 0.00996272,  0.09645476])
```

## scipy.special.inv\_boxcox

`scipy.special.inv_boxcox(y, lambda) = <ufunc 'inv_boxcox'>`

Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

```
y = (x**lambda - 1) / lambda  if lambda != 0
    log(x)                    if lambda == 0
```

### Parameters

**y** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

### Returns

**x** [array] Transformed data.

## Notes

New in version 0.16.0.

## Examples

```
>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.])
```

## scipy.special.inv\_boxcox1p

`scipy.special.inv_boxcox1p(y, lambda) = <ufunc 'inv_boxcox1p'>`

Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

```
y = ((1+x)**lambda - 1) / lambda  if lambda != 0
    log(1+x)                       if lambda == 0
```

### Parameters

**y** [array\_like] Data to be transformed.  
**lmbda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**x** [array] Transformed data.

**Notes**

New in version 0.16.0.

**Examples**

```
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.]
```

**scipy.special.owens\_t**

`scipy.special.owens_t(h, a) = <ufunc 'owens_t'>`

Owen's T Function.

The function  $T(h, a)$  gives the probability of the event  $(X > h \text{ and } 0 < Y < a * X)$  where  $X$  and  $Y$  are independent standard normal random variables.

**Parameters**

**h: array\_like**  
Input value.  
**a: array\_like**  
Input value.

**Returns**

**t: scalar or ndarray**  
Probability of the event  $(X > h \text{ and } 0 < Y < a * X)$ , where  $X$  and  $Y$  are independent standard normal random variables.

**References**

[1]

**Examples**

```
>>> from scipy import special
>>> a = 3.5
>>> h = 0.78
>>> special.owens_t(h, a)
0.10877216734852274
```

## Information Theory functions

<code>entr(x)</code>	Elementwise function for computing entropy.
<code>rel_entr(x, y[, out])</code>	Elementwise function for computing relative entropy.
<code>kl_div(x, y[, out])</code>	Elementwise function for computing Kullback-Leibler divergence.
<code>huber(delta, r)</code>	Huber loss function.
<code>pseudo_huber(delta, r)</code>	Pseudo-Huber loss function.

### scipy.special.entr

`scipy.special.entr(x) = <ufunc 'entr'>`

Elementwise function for computing entropy.

$$\text{entr}(x) = \begin{cases} -x \log(x) & x > 0 \\ 0 & x = 0 \\ -\infty & \text{otherwise} \end{cases}$$

#### Parameters

**x** [ndarray] Input array.

#### Returns

**res** [ndarray] The value of the elementwise entropy function at the given points  $x$ .

See also:

`kl_div`, `rel_entr`

#### Notes

This function is concave.

New in version 0.15.0.

### scipy.special.rel\_entr

`scipy.special.rel_entr(x, y, out=None) = <ufunc 'rel_entr'>`

Elementwise function for computing relative entropy.

$$\text{rel_entr}(x, y) = \begin{cases} x \log(x/y) & x > 0, y > 0 \\ 0 & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

#### Parameters

**x, y** [array\_like] Input arrays

**out** [ndarray, optional] Optional output array for the function results

#### Returns

**scalar or ndarray**  
Relative entropy of the inputs

See also:

`entr`, `kl_div`

## Notes

New in version 0.15.0.

This function is jointly convex in  $x$  and  $y$ .

The origin of this function is in convex programming; see [1]. Given two discrete probability distributions  $p_1, \dots, p_n$  and  $q_1, \dots, q_n$ , to get the relative entropy of statistics compute the sum

$$\sum_{i=1}^n \text{rel\_entr}(p_i, q_i).$$

See [2] for details.

## References

[1], [2]

### scipy.special.kl\_div

`scipy.special.kl_div(x, y, out=None)` = `<ufunc 'kl_div'>`  
Elementwise function for computing Kullback-Leibler divergence.

$$\text{kl\_div}(x, y) = \begin{cases} x \log(x/y) - x + y & x > 0, y > 0 \\ y & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

#### Parameters

**x, y** [array\_like] Real arguments  
**out** [ndarray, optional] Optional output array for the function results

#### Returns

**scalar or ndarray**  
Values of the Kullback-Liebler divergence.

See also:

[entr](#), [rel\\_entr](#)

## Notes

New in version 0.15.0.

This function is non-negative and is jointly convex in  $x$  and  $y$ .

The origin of this function is in convex programming; see [1] for details. This is why the the function contains the extra  $-x + y$  terms over what might be expected from the Kullback-Leibler divergence. For a version of the function without the extra terms, see [rel\\_entr](#).

## References

[1]

### scipy.special.huber

`scipy.special.huber(delta, r) = <ufunc 'huber'>`  
Huber loss function.

$$\text{huber}(\delta, r) = \begin{cases} \infty & \delta < 0 \\ \frac{1}{2}r^2 & 0 \leq \delta, |r| \leq \delta \\ \delta(|r| - \frac{1}{2}\delta) & \text{otherwise} \end{cases}$$

#### Parameters

**delta** [ndarray] Input array, indicating the quadratic vs. linear loss changepoint.  
**r** [ndarray] Input array, possibly representing residuals.

#### Returns

**res** [ndarray] The computed Huber loss function values.

## Notes

This function is convex in  $r$ .

New in version 0.15.0.

### scipy.special.pseudo\_huber

`scipy.special.pseudo_huber(delta, r) = <ufunc 'pseudo_huber'>`  
Pseudo-Huber loss function.

$$\text{pseudo\_huber}(\delta, r) = \delta^2 \left( \sqrt{1 + \left(\frac{r}{\delta}\right)^2} - 1 \right)$$

#### Parameters

**delta** [ndarray] Input array, indicating the soft quadratic vs. linear loss changepoint.  
**r** [ndarray] Input array, possibly representing residuals.

#### Returns

**res** [ndarray] The computed Pseudo-Huber loss function values.

## Notes

This function is convex in  $r$ .

New in version 0.15.0.

## Gamma and related functions

<code>gamma(z)</code>	gamma function.
<code>gammaaln(x[, out])</code>	Logarithm of the absolute value of the gamma function.
<code>loggamma(z[, out])</code>	Principal branch of the logarithm of the gamma function.
<code>gamma<sub>sgn</sub>(x)</code>	Sign of the gamma function.
<code>gamma<sub>inc</sub>(a, x)</code>	Regularized lower incomplete gamma function.
<code>gamma<sub>incinv</sub>(a, y)</code>	Inverse to the lower incomplete gamma function with respect to $x$ .
<code>gamma<sub>inc</sub>cc(a, x)</code>	Regularized upper incomplete gamma function.
<code>gamma<sub>inc</sub>ccinv(a, y)</code>	Inverse of the upper incomplete gamma function with respect to $x$ .
<code>beta(a, b[, out])</code>	Beta function.
<code>betaln(a, b)</code>	Natural logarithm of absolute value of beta function.
<code>beta<sub>inc</sub>(a, b, x[, out])</code>	Incomplete beta function.
<code>beta<sub>inc</sub>inv(a, b, y[, out])</code>	Inverse of the incomplete beta function.
<code>psi(z[, out])</code>	The digamma function.
<code>rgamma(z[, out])</code>	Reciprocal of the gamma function.
<code>polygamma(n, x)</code>	Polygamma functions.
<code>multigammaln(a, d)</code>	Returns the log of multivariate gamma, also sometimes called the generalized gamma.
<code>digamma(z[, out])</code>	The digamma function.
<code>poch(z, m)</code>	Pochhammer symbol.

### scipy.special.gamma

`scipy.special.gamma(z) = <ufunc 'gamma'>`  
gamma function.

The gamma function is defined as

$$\Gamma(z) = \int_0^{\infty} t^{z-1} e^{-t} dt$$

for  $\Re(z) > 0$  and is extended to the rest of the complex plane by analytic continuation. See [dlmf] for more details.

#### Parameters

**z** [array\_like] Real or complex valued argument

#### Returns

**scalar or ndarray**  
Values of the gamma function

#### Notes

The gamma function is often referred to as the generalized factorial since  $\Gamma(n + 1) = n!$  for natural numbers  $n$ . More generally it satisfies the recurrence relation  $\Gamma(z + 1) = z \cdot \Gamma(z)$  for complex  $z$ , which, combined with the fact that  $\Gamma(1) = 1$ , implies the above identity for  $z = n$ .

## References

[dlmf]

## Examples

```
>>> from scipy.special import gamma, factorial
```

```
>>> gamma([0, 0.5, 1, 5])
array([          inf,    1.77245385,    1.          ,   24.          ])
```

```
>>> z = 2.5 + 1j
>>> gamma(z)
(0.77476210455108352+0.70763120437959293j)
>>> gamma(z+1), z*gamma(z) # Recurrence property
((1.2292740569981171+2.5438401155000685j),
 (1.2292740569981158+2.5438401155000658j))
```

```
>>> gamma(0.5)**2 # gamma(0.5) = sqrt(pi)
3.1415926535897927
```

Plot  $\gamma(x)$  for real  $x$

```
>>> x = np.linspace(-3.5, 5.5, 2251)
>>> y = gamma(x)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'b', alpha=0.6, label='gamma(x)')
>>> k = np.arange(1, 7)
>>> plt.plot(k, factorial(k-1), 'k*', alpha=0.6,
...         label='(x-1)!, x = 1, 2, ...')
>>> plt.xlim(-3.5, 5.5)
>>> plt.ylim(-10, 25)
>>> plt.grid()
>>> plt.xlabel('x')
>>> plt.legend(loc='lower right')
>>> plt.show()
```

## scipy.special.gammaln

`scipy.special.gammaln(x, out=None) = <ufunc 'gammaln'>`

Logarithm of the absolute value of the gamma function.

Defined as

$$\ln(|\Gamma(x)|)$$

where  $\Gamma$  is the gamma function. For more details on the gamma function, see [dlmf].

### Parameters

<b>x</b>	[array_like] Real argument
<b>out</b>	[ndarray, optional] Optional output array for the function results

**Returns**

scalar or ndarray

Values of the log of the absolute value of gamma

**See also:**

[`gamma.sgn`](#)

sign of the gamma function

[`loggamma`](#)

principal branch of the logarithm of the gamma function

**Notes**

It is the same function as the Python standard library function `math.lgamma`.

When used in conjunction with [`gamma.sgn`](#), this function is useful for working in logspace on the real axis without having to deal with complex numbers via the relation  $\exp(\text{gamma.ln}(x)) = \text{gamma.sgn}(x) * \text{gamma}(x)$ .

For complex-valued log-gamma, use [`loggamma`](#) instead of [`gamma.ln`](#).

**References**

[dlmf]

## Examples

```
>>> import scipy.special as sc
```

It has two positive zeros.

```
>>> sc.gammaln([1, 2])
array([0., 0.]
```

It has poles at nonpositive integers.

```
>>> sc.gammaln([0, -1, -2, -3, -4])
array([inf, inf, inf, inf, inf])
```

It asymptotically approaches  $x * \log(x)$  (Stirling's formula).

```
>>> x = np.array([1e10, 1e20, 1e40, 1e80])
>>> sc.gammaln(x)
array([2.20258509e+11, 4.50517019e+21, 9.11034037e+41, 1.83206807e+82])
>>> x * np.log(x)
array([2.30258509e+11, 4.60517019e+21, 9.21034037e+41, 1.84206807e+82])
```

## scipy.special.loggamma

`scipy.special.loggamma(z, out=None) = <ufunc 'loggamma'>`

Principal branch of the logarithm of the gamma function.

Defined to be  $\log(\Gamma(x))$  for  $x > 0$  and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

### Parameters

**z** [array-like] Values in the complex plain at which to compute `loggamma`  
**out** [ndarray, optional] Output array for computed values of `loggamma`

### Returns

**loggamma** [ndarray] Values of `loggamma` at `z`.

See also:

`gammaln`

logarithm of the absolute value of the gamma function

`gamma_sgn`

sign of the gamma function

## Notes

It is not generally true that  $\log \Gamma(z) = \log(\Gamma(z))$ , though the real parts of the functions do agree. The benefit of not defining `loggamma` as  $\log(\Gamma(z))$  is that the latter function has a complicated branch cut structure whereas `loggamma` is analytic except for on the negative real axis.

The identities

$$\begin{aligned}\exp(\log \Gamma(z)) &= \Gamma(z) \\ \log \Gamma(z + 1) &= \log(z) + \log \Gamma(z)\end{aligned}$$

make `loggamma` useful for working in complex logspace.

On the real line `loggamma` is related to `gammaaln` via  $\exp(\loggamma(x + 0j)) = \text{gamma} - \text{masgn}(x) * \exp(\text{gammaaln}(x))$ , up to rounding error.

The implementation here is based on [hare1997].

## References

[hare1997]

### scipy.special.gammasgn

`scipy.special.gammasgn(x) = <ufunc 'gammasgn'>`

Sign of the gamma function.

It is defined as

$$\text{gammasgn}(x) = \begin{cases} +1 & \Gamma(x) > 0 \\ -1 & \Gamma(x) < 0 \end{cases}$$

where  $\Gamma$  is the gamma function; see `gamma`. This definition is complete since the gamma function is never zero; see the discussion after [dlmf].

#### Parameters

**x** [array\_like] Real argument

#### Returns

**scalar or ndarray**  
Sign of the gamma function

#### See also:

##### `gamma`

the gamma function

##### `gammaaln`

log of the absolute value of the gamma function

##### `loggamma`

analytic continuation of the log of the gamma function

## Notes

The gamma function can be computed as `gammasgn(x) * np.exp(gammaln(x))`.

## References

[dlmf]

## Examples

```
>>> import scipy.special as sc
```

It is 1 for  $x > 0$ .

```
>>> sc.gammasgn([1, 2, 3, 4])
array([1., 1., 1., 1.])
```

It alternates between -1 and 1 for negative integers.

```
>>> sc.gammasgn([-0.5, -1.5, -2.5, -3.5])
array([-1., 1., -1., 1.])
```

It can be used to compute the gamma function.

```
>>> x = [1.5, 0.5, -0.5, -1.5]
>>> sc.gammasgn(x) * np.exp(sc.gammaln(x))
array([ 0.88622693,  1.77245385, -3.5449077 ,  2.3632718 ])
>>> sc.gamma(x)
array([ 0.88622693,  1.77245385, -3.5449077 ,  2.3632718 ])
```

## scipy.special.gammainc

`scipy.special.gammainc(a, x) = <ufunc 'gammainc'>`

Regularized lower incomplete gamma function.

It is defined as

$$P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . See [dlmf] for details.

### Parameters

**a** [array\_like] Positive parameter  
**x** [array\_like] Nonnegative argument

### Returns

**scalar or ndarray**

Values of the lower incomplete gamma function

See also:

[gammaincc](#)

regularized upper incomplete gamma function

**gammaincinv**

inverse of the regularized lower incomplete gamma function with respect to  $x$

**gammainccinv**

inverse of the regularized upper incomplete gamma function with respect to  $x$

**Notes**

The function satisfies the relation  $\text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1$  where *gammaincc* is the regularized upper incomplete gamma function.

The implementation largely follows that of [boost].

**References**

[dlmf], [boost]

**Examples**

```
>>> import scipy.special as sc
```

It is the CDF of the gamma distribution, so it starts at 0 and monotonically increases to 1.

```
>>> sc.gammainc(0.5, [0, 1, 10, 100])
array([0.          , 0.84270079, 0.99999226, 1.          ])
```

It is equal to one minus the upper incomplete gamma function.

```
>>> a, x = 0.5, 0.4
>>> sc.gammainc(a, x)
0.6289066304773024
>>> 1 - sc.gammaincc(a, x)
0.6289066304773024
```

**scipy.special.gammaincinv**

`scipy.special.gammaincinv(a, y) = <ufunc 'gammaincinv'>`

Inverse to the lower incomplete gamma function with respect to  $x$ .

Given an input  $y$  between 0 and 1, returns  $x$  such that  $y = P(a, x)$ . Here  $P$  is the regularized lower incomplete gamma function; see *gammainc*. This is well-defined because the lower incomplete gamma function is monotonic as can be seen from its definition in [dlmf].

**Parameters**

**a** [array\_like] Positive parameter  
**y** [array\_like] Parameter between 0 and 1, inclusive

**Returns**

**scalar or ndarray**  
 Values of the inverse of the lower incomplete gamma function

See also:

**gammainc**

regularized lower incomplete gamma function

**gammaincc**

regularized upper incomplete gamma function

**gammainccinv**inverse of the regularized upper incomplete gamma function with respect to  $x$ **References**[\[dlmf\]](#)**Examples**

```
>>> import scipy.special as sc
```

It starts at 0 and monotonically increases to infinity.

```
>>> sc.gammaincinv(0.5, [0, 0.1, 0.5, 1])
array([0.          , 0.00789539, 0.22746821,          inf])
```

It inverts the lower incomplete gamma function.

```
>>> a, x = 0.5, [0, 0.1, 0.5, 1]
>>> sc.gammainc(a, sc.gammaincinv(a, x))
array([0. , 0.1, 0.5, 1. ])
```

```
>>> a, x = 0.5, [0, 10, 25]
>>> sc.gammaincinv(a, sc.gammainc(a, x))
array([ 0.          , 10.          , 25.00001465])
```

**scipy.special.gammaincc**`scipy.special.gammaincc(a, x) = <ufunc 'gammaincc'>`

Regularized upper incomplete gamma function.

It is defined as

$$Q(a, x) = \frac{1}{\Gamma(a)} \int_x^\infty t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . See [\[dlmf\]](#) for details.**Parameters**

**a** [array\_like] Positive parameter  
**x** [array\_like] Nonnegative argument

**Returns**

**scalar or ndarray**  
Values of the upper incomplete gamma function

**See also:**

**gammainc**

regularized lower incomplete gamma function

**gammaincinv**

inverse of the regularized lower incomplete gamma function with respect to  $x$

**gammainccinv**

inverse to of the regularized upper incomplete gamma function with respect to  $x$

**Notes**

The function satisfies the relation  $\text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1$  where *gammainc* is the regularized lower incomplete gamma function.

The implementation largely follows that of [boost].

**References**

[dlmf], [boost]

**Examples**

```
>>> import scipy.special as sc
```

It is the survival function of the gamma distribution, so it starts at 1 and monotonically decreases to 0.

```
>>> sc.gammaincc(0.5, [0, 1, 10, 100, 1000])
array([1.00000000e+00, 1.57299207e-01, 7.74421643e-06, 2.08848758e-45,
       0.00000000e+00])
```

It is equal to one minus the lower incomplete gamma function.

```
>>> a, x = 0.5, 0.4
>>> sc.gammaincc(a, x)
0.37109336952269756
>>> 1 - sc.gammainc(a, x)
0.37109336952269756
```

**scipy.special.gammainccinv**

`scipy.special.gammainccinv(a, y) = <ufunc 'gammainccinv'>`

Inverse of the upper incomplete gamma function with respect to  $x$

Given an input  $y$  between 0 and 1, returns  $x$  such that  $y = Q(a, x)$ . Here  $Q$  is the upper incomplete gamma function; see *gammaincc*. This is well-defined because the upper incomplete gamma function is monotonic as can be seen from its definition in [dlmf].

**Parameters**

**a** [array\_like] Positive parameter  
**y** [array\_like] Argument between 0 and 1, inclusive

**Returns**

**scalar or ndarray**

Values of the inverse of the upper incomplete gamma function

See also:

`gammaincc`

regularized upper incomplete gamma function

`gammainc`

regularized lower incomplete gamma function

`gammaincinv`

inverse of the regularized lower incomplete gamma function with respect to  $x$

## References

[dlmf]

## Examples

```
>>> import scipy.special as sc
```

It starts at infinity and monotonically decreases to 0.

```
>>> sc.gammainccinv(0.5, [0, 0.1, 0.5, 1])
array([          inf, 1.35277173, 0.22746821, 0.          ])
```

It inverts the upper incomplete gamma function.

```
>>> a, x = 0.5, [0, 0.1, 0.5, 1]
>>> sc.gammaincc(a, sc.gammainccinv(a, x))
array([0. , 0.1, 0.5, 1. ])
```

```
>>> a, x = 0.5, [0, 10, 50]
>>> sc.gammainccinv(a, sc.gammaincc(a, x))
array([ 0., 10., 50.] )
```

## scipy.special.beta

`scipy.special.beta(a, b, out=None) = <ufunc 'beta'>`

Beta function.

This function is defined in [1] as

$$B(a, b) = \int_0^1 t^{a-1} (1-t)^{b-1} dt = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)},$$

where  $\Gamma$  is the gamma function.

### Parameters

**a, b** [array-like] Real-valued arguments  
**out** [ndarray, optional] Optional output array for the function result

### Returns

**scalar or ndarray**

Value of the beta function

**See also:****gamma**

the gamma function

**betainc**

the incomplete beta function

**betaln**

the natural logarithm of the absolute value of the beta function

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

The beta function relates to the gamma function by the definition given above:

```
>>> sc.beta(2, 3)
0.08333333333333333
>>> sc.gamma(2)*sc.gamma(3)/sc.gamma(2 + 3)
0.08333333333333333
```

As this relationship demonstrates, the beta function is symmetric:

```
>>> sc.beta(1.7, 2.4)
0.16567527689031739
>>> sc.beta(2.4, 1.7)
0.16567527689031739
```

This function satisfies  $B(1, b) = 1/b$ :

```
>>> sc.beta(1, 4)
0.25
```

**scipy.special.betaln**

`scipy.special.betaln(a, b) = <ufunc 'betaln'>`

Natural logarithm of absolute value of beta function.

Computes  $\ln(\text{abs}(\text{beta}(a, b)))$ .

**scipy.special.betainc**

`scipy.special.betainc(a, b, x, out=None) = <ufunc 'betainc'>`

Incomplete beta function.

Computes the incomplete beta function, defined as [1]:

$$I_x(a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1}(1-t)^{b-1} dt,$$

for  $0 \leq x \leq 1$ .

**Parameters**

**a, b** [array-like] Positive, real-valued parameters  
**x** [array-like] Real-valued such that  $0 \leq x \leq 1$ , the upper limit of integration  
**out** [ndarray, optional] Optional output array for the function values

**Returns**

**array-like** Value of the incomplete beta function

**See also:**

**beta**

beta function

**betaincinv**

inverse of the incomplete beta function

**Notes**

The incomplete beta function is also sometimes defined without the *gamma* terms, in which case the above definition is the so-called regularized incomplete beta function. Under this definition, you can get the incomplete beta function by multiplying the result of the SciPy function by *beta*.

**References**

[1]

**Examples**

Let  $B(a, b)$  be the *beta* function.

```
>>> import scipy.special as sc
```

The coefficient in terms of *gamma* is equal to  $1/B(a, b)$ . Also, when  $x = 1$  the integral is equal to  $B(a, b)$ . Therefore,  $I_{x=1}(a, b) = 1$  for any  $a, b$ .

```
>>> sc.betainc(0.2, 3.5, 1.0)
1.0
```

It satisfies  $I_x(a, b) = x^a F(a, 1-b, a+1, x)/(aB(a, b))$ , where  $F$  is the hypergeometric function *hyp2f1*:

```
>>> a, b, x = 1.4, 3.1, 0.5
>>> x**a * sc.hyp2f1(a, 1 - b, a + 1, x) / (a * sc.beta(a, b))
0.8148904036225295
>>> sc.betainc(a, b, x)
0.8148904036225296
```

This function satisfies the relationship  $I_x(a, b) = 1 - I_{1-x}(b, a)$ :

```
>>> sc.betainc(2.2, 3.1, 0.4)
0.49339638807619446
>>> 1 - sc.betainc(3.1, 2.2, 1 - 0.4)
0.49339638807619446
```

### scipy.special.betaincinv

`scipy.special.betaincinv(a, b, y, out=None)` = <ufunc 'betaincinv'>  
Inverse of the incomplete beta function.

Computes  $x$  such that:

$$y = I_x(a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1}(1-t)^{b-1} dt,$$

where  $I_x$  is the normalized incomplete beta function `betainc` and  $\Gamma$  is the `gamma` function [1].

#### Parameters

**a, b** [array-like] Positive, real-valued parameters  
**y** [array-like] Real-valued input  
**out** [ndarray, optional] Optional output array for function values

#### Returns

**array-like** Value of the inverse of the incomplete beta function

See also:

#### `betainc`

incomplete beta function

#### `gamma`

gamma function

### References

[1]

## Examples

```
>>> import scipy.special as sc
```

This function is the inverse of `betainc` for fixed values of  $a$  and  $b$ .

```
>>> a, b = 1.2, 3.1
>>> y = sc.betainc(a, b, 0.2)
>>> sc.betaincinv(a, b, y)
0.2
>>>
>>> a, b = 7.5, 0.4
>>> x = sc.betaincinv(a, b, 0.5)
>>> sc.betainc(a, b, x)
0.5
```

## scipy.special.psi

`scipy.special.psi(z, out=None) = <ufunc 'psi'>`

The digamma function.

The logarithmic derivative of the gamma function evaluated at  $z$ .

### Parameters

**z** [array\_like] Real or complex argument.  
**out** [ndarray, optional] Array for the computed values of `psi`.

### Returns

**digamma** [ndarray] Computed values of `psi`.

## Notes

For large values not close to the negative real axis, `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis, the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis, the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

## References

[1], [2]

**scipy.special.rgamma**

`scipy.special.rgamma(z, out=None) = <ufunc 'rgamma'>`

Reciprocal of the gamma function.

Defined as  $1/\Gamma(z)$ , where  $\Gamma$  is the gamma function. For more on the gamma function see [gamma](#).

**Parameters**

**z** [array\_like] Real or complex valued input  
**out** [ndarray, optional] Optional output array for the function results

**Returns**

**scalar or ndarray**  
 Function results

See also:

[gamma](#), [gammaaln](#), [loggamma](#)

**Notes**

The gamma function has no zeros and has simple poles at nonpositive integers, so *rgamma* is an entire function with zeros at the nonpositive integers. See the discussion in [dlmf] for more details.

**References**

[dlmf]

**Examples**

```
>>> import scipy.special as sc
```

It is the reciprocal of the gamma function.

```
>>> sc.rgamma([1, 2, 3, 4])
array([1.         , 1.         , 0.5         , 0.16666667])
>>> 1 / sc.gamma([1, 2, 3, 4])
array([1.         , 1.         , 0.5         , 0.16666667])
```

It is zero at nonpositive integers.

```
>>> sc.rgamma([0, -1, -2, -3])
array([0., 0., 0., 0.])
```

It rapidly underflows to zero along the positive real axis.

```
>>> sc.rgamma([10, 100, 179])
array([2.75573192e-006, 1.07151029e-156, 0.00000000e+000])
```

**scipy.special.polygamma**`scipy.special.polygamma` (*n*, *x*)

Polygamma functions.

Defined as  $\psi^{(n)}(x)$  where  $\psi$  is the *digamma* function. See [dlmf] for details.**Parameters**

**n** [array\_like] The order of the derivative of the digamma function; must be integral  
**x** [array\_like] Real valued input

**Returns**

**ndarray** Function results

See also:

[digamma](#)**References**[\[dlmf\]](#)**Examples**

```
>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([ 0.64493407,  0.39493407,  0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([ True,  True,  True], dtype=bool)
```

**scipy.special.multigammaln**`scipy.special.multigammaln` (*a*, *d*)

Returns the log of multivariate gamma, also sometimes called the generalized gamma.

**Parameters**

**a** [ndarray] The multivariate gamma is computed for each item of *a*.  
**d** [int] The dimension of the space of integration.

**Returns**

**res** [ndarray] The values of the log multivariate gamma at the given points *a*.

**Notes**The formal definition of the multivariate gamma of dimension *d* for a real *a* is

$$\Gamma_d(a) = \int_{A>0} e^{-tr(A)} |A|^{a-(d+1)/2} dA$$

with the condition  $a > (d - 1)/2$ , and  $A > 0$  being the set of all the positive definite matrices of dimension *d*. Note that *a* is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

$$\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^d \Gamma(a - (i - 1)/2).$$

## References

R. J. Muirhead, Aspects of multivariate statistical theory (Wiley Series in probability and mathematical statistics).

## scipy.special.digamma

`scipy.special.digamma(z, out=None) = <ufunc 'psi'>`

The digamma function.

The logarithmic derivative of the gamma function evaluated at `z`.

### Parameters

**z** [array\_like] Real or complex argument.  
**out** [ndarray, optional] Array for the computed values of `psi`.

### Returns

**digamma** [ndarray] Computed values of `psi`.

## Notes

For large values not close to the negative real axis, `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis, the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis, the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

## scipy.special.poch

`scipy.special.poch(z, m) = <ufunc 'poch'>`

Pochhammer symbol.

The Pochhammer symbol (rising factorial) is defined as

$$(z)_m = \frac{\Gamma(z + m)}{\Gamma(z)}$$

For positive integer `m` it reads

$$(z)_m = z(z + 1)\dots(z + m - 1)$$

See [dlmf] for more details.

### Parameters

**z, m** [array\_like] Real-valued arguments.

**Returns**

**scalar or ndarray**  
The value of the function.

**References**

[dlmf]

**Examples**

```
>>> import scipy.special as sc
```

It is 1 when m is 0.

```
>>> sc.poch([1, 2, 3, 4], 0)
array([1., 1., 1., 1.])
```

For z equal to 1 it reduces to the factorial function.

```
>>> sc.poch(1, 5)
120.0
>>> 1 * 2 * 3 * 4 * 5
120
```

It can be expressed in terms of the gamma function.

```
>>> z, m = 3.7, 2.1
>>> sc.poch(z, m)
20.529581933776953
>>> sc.gamma(z + m) / sc.gamma(z)
20.52958193377696
```

**Error function and Fresnel integrals**

<i>erf</i> (z)	Returns the error function of complex argument.
<i>erfc</i> (x[, out])	Complementary error function, $1 - \text{erf}(x)$ .
<i>erfcx</i> (x[, out])	Scaled complementary error function, $\exp(x^2) * \text{erfc}(x)$ .
<i>erfi</i> (z[, out])	Imaginary error function, $-i \text{erf}(i z)$ .
<i>erfinv</i> (x, /[, out, where, casting, order, ...])	Inverse of the error function.
<i>erfcinv</i> (x, /[, out, where, casting, order, ...])	Inverse of the complementary error function.
<i>wofz</i> (z)	Faddeeva function
<i>dawson</i> (x)	Dawson's integral.
<i>fresnel</i> (z[, out])	Fresnel integrals.
<i>fresnel_zeros</i> (nt)	Compute nt complex zeros of sine and cosine Fresnel integrals S(z) and C(z).
<i>modfresnelp</i> (x)	Modified Fresnel positive integrals

continues on next page

Table 232 – continued from previous page

<code>modfresnelm(x)</code>	Modified Fresnel negative integrals
<code>voigt_profile(x, sigma, gamma[, out])</code>	Voigt profile.

**scipy.special.erf**

`scipy.special.erf(z) = <ufunc 'erf'>`

Returns the error function of complex argument.

It is defined as  $2/\sqrt{\pi} \int_0^z \exp(-t^2) dt$ .

**Parameters**

**x** [ndarray] Input array.

**Returns**

**res** [ndarray] The values of the error function at the given points *x*.

See also:

[erfc](#), [erfcinv](#), [erfcinv](#), [wofz](#), [erfcx](#), [erfi](#)

**Notes**

The cumulative of the unit normal distribution is given by  $\Phi(z) = 1/2[1 + \text{erf}(z/\sqrt{2})]$ .

**References**

[1], [2], [3]

**Examples**

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erf(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$\text{erf}(x)$')
>>> plt.show()
```

**scipy.special.erfc**

`scipy.special.erfc(x, out=None) = <ufunc 'erfc'>`

Complementary error function,  $1 - \text{erf}(x)$ .

**Parameters**

**x** [array\_like] Real or complex valued argument

**out** [ndarray, optional] Optional output array for the function results

**Returns**

**scalar or ndarray**

Values of the complementary error function

See also:

`erf`, `erfi`, `erfcx`, `dawsn`, `wofz`

## References

[1]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfc(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erfc(x)$')
>>> plt.show()
```

## scipy.special.erfcx

`scipy.special.erfcx(x, out=None) = <ufunc 'erfcx'>`  
 Scaled complementary error function,  $\exp(x^2) * \text{erfc}(x)$ .

### Parameters

**x** [array\_like] Real or complex valued argument  
**out** [ndarray, optional] Optional output array for the function results

### Returns

**scalar or ndarray**  
 Values of the scaled complementary error function

See also:

`erf`, `erfc`, `erfi`, `dawsn`, `wofz`

### Notes

New in version 0.12.0.

### References

[1]

### Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfcx(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erfcx(x)$')
>>> plt.show()
```

### scipy.special.erfi

scipy.special.**erfi**(z, out=None) = <ufunc 'erfi'>

Imaginary error function,  $-i \operatorname{erf}(i z)$ .

#### Parameters

**z** [array\_like] Real or complex valued argument  
**out** [ndarray, optional] Optional output array for the function results

#### Returns

**scalar or ndarray**  
 Values of the imaginary error function

See also:

`erf`, `erfc`, `erfcx`, `dawsn`, `wofz`

### Notes

New in version 0.12.0.

### References

[1]

### Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfi(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erfi(x)$')
>>> plt.show()
```

### `scipy.special.erfinv`

`scipy.special.erfinv`(*x*, /, *out=None*, \*, *where=True*, *casting='same\_kind'*, *order='K'*, *dtype=None*, *subok=True*[, *signature*, *extobj*]) = <ufunc 'erfinv'>

Inverse of the error function.

Computes the inverse of the error function.

In the complex domain, there is no unique complex number  $w$  satisfying  $\text{erf}(w)=z$ . This indicates a true inverse function would have multi-value. When the domain restricts to the real,  $-1 < x < 1$ , there is a unique real number satisfying  $\text{erf}(\text{erfinv}(x)) = x$ .

#### *Parameters*

**y** [ndarray] Argument at which to evaluate. Domain: [-1, 1]

#### Returns

**erfinv** [ndarray] The inverse of erf of y, element-wise)

#### See also:

##### erf

Error function of a complex argument

##### erfc

Complementary error function,  $1 - \text{erf}(x)$

##### erfcinv

Inverse of the complementary error function

#### Examples

- 1) evaluating a float number

```
>>> from scipy import special
>>> special.erfinv(0.5)
0.4769362762044698
```

- 2) evaluating an ndarray

```
>>> from scipy import special
>>> y = np.linspace(-1.0, 1.0, num=10)
>>> special.erfinv(y)
array([-inf, -0.86312307, -0.5407314 , -0.30457019, -0.0987901 ,
        0.0987901 , 0.30457019, 0.5407314 , 0.86312307,  inf])
```

**scipy.special.erfcinv**

`scipy.special.erfcinv(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature, extobj]) = <ufunc 'erfcinv'>`

Inverse of the complementary error function.

Computes the inverse of the complementary error function.

In the complex domain, there is no unique complex number  $w$  satisfying  $\operatorname{erfc}(w)=z$ . This indicates a true inverse function would have multi-value. When the domain restricts to the real,  $0 < x < 2$ , there is a unique real number satisfying  $\operatorname{erfc}(\operatorname{erfcinv}(x)) = \operatorname{erfcinv}(\operatorname{erfc}(x))$ .

It is related to inverse of the error function by  $\operatorname{erfcinv}(1-x) = \operatorname{erfinv}(x)$

**Parameters**

**y** [ndarray] Argument at which to evaluate. Domain: [0, 2]

**Returns**

**erfcinv** [ndarray] The inverse of  $\operatorname{erfc}$  of  $y$ , element-wise

**See also:****erf**

Error function of a complex argument

**erfc**

Complementary error function,  $1 - \operatorname{erf}(x)$

**erfinv**

Inverse of the error function

**Examples**

- 1) evaluating a float number

```
>>> from scipy import special
>>> special.erfcinv(0.5)
0.4769362762044698
```

- 2) evaluating an ndarray

```
>>> from scipy import special
>>> y = np.linspace(0.0, 2.0, num=11)
>>> special.erfcinv(y)
array([          inf,  0.9061938 ,  0.59511608,  0.37080716,  0.17914345,
        -0.          , -0.17914345, -0.37080716, -0.59511608, -0.9061938 ,
        -inf])
```

**scipy.special.wofz**

`scipy.special.wofz(z)` = <ufunc 'wofz'>

Faddeeva function

Returns the value of the Faddeeva function for complex argument:

```
exp(-z**2) * erfc(-i*z)
```

See also:

[dawsn](#), [erf](#), [erfc](#), [erfcx](#), [erfi](#)

**References**

[1]

**Examples**

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-3, 3)
>>> z = special.wofz(x)
```

```
>>> plt.plot(x, z.real, label='wofz(x).real')
>>> plt.plot(x, z.imag, label='wofz(x).imag')
>>> plt.xlabel('$x$')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```

**scipy.special.dawsn**

`scipy.special.dawsn(x)` = <ufunc 'dawsn'>  
Dawson's integral.

Computes:

```
exp(-x**2) * integral(exp(t**2), t=0..x).
```

See also:

[wofz](#), [erf](#), [erfc](#), [erfcx](#), [erfi](#)

**References**

[1]

**Examples**

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-15, 15, num=1000)
>>> plt.plot(x, special.dawsn(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$dawsn(x)$')
>>> plt.show()
```

**scipy.special.fresnel**

`scipy.special.fresnel(z, out=None) = <ufunc 'fresnel'>`  
 Fresnel integrals.

The Fresnel integrals are defined as

$$S(z) = \int_0^z \sin(\pi t^2/2) dt$$

$$C(z) = \int_0^z \cos(\pi t^2/2) dt.$$

See [dlmf] for details.

**Parameters**

**z** [array\_like] Real or complex valued argument  
**out** [2-tuple of ndarrays, optional] Optional output arrays for the function results

**Returns**

**S, C** [2-tuple of scalar or ndarray] Values of the Fresnel integrals

See also:

**fresnel\_zeros**

zeros of the Fresnel integrals

**References**

[dlmf]

**Examples**

```
>>> import scipy.special as sc
```

As  $z$  goes to infinity along the real axis,  $S$  and  $C$  converge to 0.5.

```
>>> S, C = sc.fresnel([0.1, 1, 10, 100, np.inf])
>>> S
array([0.00052359, 0.43825915, 0.46816998, 0.4968169 , 0.5       ])
>>> C
array([0.09999753, 0.7798934 , 0.49989869, 0.4999999 , 0.5       ])
```

They are related to the error function *erf*.

```
>>> z = np.array([1, 2, 3, 4])
>>> zeta = 0.5 * np.sqrt(np.pi) * (1 - 1j) * z
>>> S, C = sc.fresnel(z)
>>> C + 1j*S
array([0.7798934 +0.43825915j, 0.48825341+0.34341568j,
       0.60572079+0.496313j , 0.49842603+0.42051575j])
>>> 0.5 * (1 + 1j) * sc.erf(zeta)
array([0.7798934 +0.43825915j, 0.48825341+0.34341568j,
       0.60572079+0.496313j , 0.49842603+0.42051575j])
```

### scipy.special.fresnel\_zeros

`scipy.special.fresnel_zeros` (*nt*)

Compute *nt* complex zeros of sine and cosine Fresnel integrals  $S(z)$  and  $C(z)$ .

#### References

[1]

### scipy.special.modfresnelp

`scipy.special.modfresnelp` (*x*) = `<ufunc 'modfresnelp'>`

Modified Fresnel positive integrals

#### Returns

**fp**      Integral  $F_+(x)$ :  $\text{integral}(\exp(1j*t*t), t=x..\text{inf})$   
**kp**      Integral  $K_+(x)$ :  $1/\text{sqrt}(\text{pi}) * \exp(-1j*(x*x+\text{pi}/4)) * \text{fp}$

### scipy.special.modfresnelm

`scipy.special.modfresnelm` (*x*) = `<ufunc 'modfresnelm'>`

Modified Fresnel negative integrals

#### Returns

**fm**      Integral  $F_-(x)$ :  $\text{integral}(\exp(-1j*t*t), t=x..\text{inf})$   
**km**      Integral  $K_-(x)$ :  $1/\text{sqrt}(\text{pi}) * \exp(1j*(x*x+\text{pi}/4)) * \text{fp}$

### scipy.special.voigt\_profile

`scipy.special.voigt_profile` (*x, sigma, gamma, out=None*) = `<ufunc 'voigt_profile'>`

Voigt profile.

The Voigt profile is a convolution of a 1-D Normal distribution with standard deviation *sigma* and a 1-D Cauchy distribution with half-width at half-maximum *gamma*.

If *sigma* = 0, PDF of Cauchy distribution is returned. Conversely, if *gamma* = 0, PDF of Normal distribution is returned. If *sigma* = *gamma* = 0, the return value is `Inf` for *x* = 0, and 0 for all other *x*.

#### Parameters

**x**            [array\_like] Real argument  
**sigma**       [array\_like] The standard deviation of the Normal distribution part  
**gamma**       [array\_like] The half-width at half-maximum of the Cauchy distribution part  
**out**         [ndarray, optional] Optional output array for the function values

#### Returns

**scalar or ndarray**  
 The Voigt profile at the given arguments

See also:

[wofz](#)

Faddeeva function

## Notes

It can be expressed in terms of Faddeeva function

$$V(x; \sigma, \gamma) = \frac{\operatorname{Re}[w(z)]}{\sigma\sqrt{2\pi}},$$

$$z = \frac{x + i\gamma}{\sqrt{2}\sigma}$$

where  $w(z)$  is the Faddeeva function.

## References

[1]

These are not universal functions:

<code>erf_zeros(nt)</code>	Compute the first <code>nt</code> zero in the first quadrant, ordered by absolute value.
<code>fresnelc_zeros(nt)</code>	Compute <code>nt</code> complex zeros of cosine Fresnel integral $C(z)$ .
<code>fresnels_zeros(nt)</code>	Compute <code>nt</code> complex zeros of sine Fresnel integral $S(z)$ .

## scipy.special.erf\_zeros

`scipy.special.erf_zeros(nt)`

Compute the first `nt` zero in the first quadrant, ordered by absolute value.

Zeros in the other quadrants can be obtained by using the symmetries  $\operatorname{erf}(-z) = -\operatorname{erf}(z)$  and  $\operatorname{erf}(\operatorname{conj}(z)) = \operatorname{conj}(\operatorname{erf}(z))$ .

### Parameters

**nt** [int] The number of zeros to compute

### Returns

#### The locations of the zeros of erf

[ndarray (complex)] Complex values at which zeros of  $\operatorname{erf}(z)$

## References

[1]

## Examples

```
>>> from scipy import special
>>> special.erf_zeros(1)
array([1.45061616+1.880943j])
```

Check that erf is (close to) zero for the value returned by `erf_zeros`

```
>>> special.erf(special.erf_zeros(1))
array([4.95159469e-14-1.16407394e-16j])
```

### scipy.special.fresnelc\_zeros

`scipy.special.fresnelc_zeros` (*nt*)  
 Compute *nt* complex zeros of cosine Fresnel integral C(z).

#### References

[1]

### scipy.special.fresnels\_zeros

`scipy.special.fresnels_zeros` (*nt*)  
 Compute *nt* complex zeros of sine Fresnel integral S(z).

#### References

[1]

## Legendre functions

<code>lpmv</code> ( <i>m</i> , <i>v</i> , <i>x</i> )	Associated Legendre function of integer order and real degree.
<code>sph_harm</code> ( <i>m</i> , <i>n</i> , <i>theta</i> , <i>phi</i> )	Compute spherical harmonics.

### scipy.special.lpmv

`scipy.special.lpmv` (*m*, *v*, *x*) = `<ufunc 'lpmv'>`  
 Associated Legendre function of integer order and real degree.

Defined as

$$P_v^m = (-1)^m (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_v(x)$$

where

$$P_v = \sum_{k=0}^{\infty} \frac{(-v)_k (v+1)_k}{(k!)^2} \left(\frac{1-x}{2}\right)^k$$

is the Legendre function of the first kind. Here  $(\cdot)_k$  is the Pochhammer symbol; see [poch](#).

#### Parameters

- m** [array\_like] Order (int or float). If passed a float not equal to an integer the function returns NaN.
- v** [array\_like] Degree (float).
- x** [array\_like] Argument (float). Must have  $|x| \leq 1$ .

#### Returns

- pmv** [ndarray] Value of the associated Legendre function.

See also:

#### `lpmn`

Compute the associated Legendre function for all orders  $0, \dots, m$  and degrees  $0, \dots, n$ .

**clpmn**

Compute the associated Legendre function at complex arguments.

**Notes**

Note that this implementation includes the Condon-Shortley phase.

**References**

[1]

**scipy.special.sph\_harm**

`scipy.special.sph_harm(m, n, theta, phi) = <ufunc 'sph_harm'>`

Compute spherical harmonics.

The spherical harmonics are defined as

$$Y_n^m(\theta, \phi) = \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} e^{im\theta} P_n^m(\cos(\phi))$$

where  $P_n^m$  are the associated Legendre functions; see [lpmv](#).

**Parameters**

- m** [array\_like] Order of the harmonic (int); must have  $|m| \leq n$ .
- n** [array\_like] Degree of the harmonic (int); must have  $n \geq 0$ . This is often denoted by  $l$  (lower case L) in descriptions of spherical harmonics.
- theta** [array\_like] Azimuthal (longitudinal) coordinate; must be in  $[0, 2\pi]$ .
- phi** [array\_like] Polar (colatitudinal) coordinate; must be in  $[0, \pi]$ .

**Returns**

- y\_mn** [complex float] The harmonic  $Y_n^m$  sampled at `theta` and `phi`.

**Notes**

There are different conventions for the meanings of the input arguments `theta` and `phi`. In SciPy `theta` is the azimuthal angle and `phi` is the polar angle. It is common to see the opposite convention, that is, `theta` as the polar angle and `phi` as the azimuthal angle.

Note that SciPy's spherical harmonics include the Condon-Shortley phase [2] because it is part of [lpmv](#).

With SciPy's conventions, the first several spherical harmonics are

$$\begin{aligned} Y_0^0(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{1}{\pi}} \\ Y_1^{-1}(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{-i\theta} \sin(\phi) \\ Y_1^0(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos(\phi) \\ Y_1^1(\theta, \phi) &= -\frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{i\theta} \sin(\phi). \end{aligned}$$

## scipy.special.clpmn

`scipy.special.clpmn(m, n, z, type=3)`

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order  $m$  and degree  $n$ ,  $P_{mn}(z) = P_n^m(z)$ , and its derivative,  $P_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $P_{mn}(z)$  and  $P_{mn}'(z)$  for all orders from  $0 \dots m$  and degrees from  $0 \dots n$ .

### Parameters

- m** [int]  $|m| \leq n$ ; the order of the Legendre function.
- n** [int] where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function
- z** [float or complex] Input value.
- type** [int, optional] takes values 2 or 3 2: cut on the real axis  $|x| > 1$  3: cut on the real axis  $-1 < x < 1$  (default)

### Returns

- Pmn\_z** [(m+1, n+1) array] Values for all orders  $0 \dots m$  and degrees  $0 \dots n$
- Pmn\_d\_z** [(m+1, n+1) array] Derivatives for all orders  $0 \dots m$  and degrees  $0 \dots n$

See also:

[lpmn](#)

associated Legendre functions of the first kind for real  $z$

## Notes

By default, i.e. for `type=3`, phase conventions are chosen according to [1] such that the function is analytic. The cut lies on the interval  $(-1, 1)$ . Approaching the cut from above or below in general yields a phase factor with respect to Ferrer's function of the first kind (cf. [lpmn](#)).

For `type=2` a cut at  $|x| > 1$  is chosen. Approaching the real values on the interval  $(-1, 1)$  in the complex plane yields Ferrer's function of the first kind.

## References

[1], [2]

### scipy.special.lpn

`scipy.special.lpn` ( $n, z$ )

Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials),  $P_n(z)$  and derivatives for all degrees from 0 to  $n$  (inclusive).

See also `special.legendre` for polynomial class.

## References

[1]

### scipy.special.lqn

`scipy.special.lqn` ( $n, z$ )

Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind,  $Q_n(z)$  and derivatives for all degrees from 0 to  $n$  (inclusive).

## References

[1]

### scipy.special.lpmn

`scipy.special.lpmn` ( $m, n, z$ )

Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order  $m$  and degree  $n$ ,  $P_{nm}(z) = P_n^m(z)$ , and its derivative,  $P_{nm}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $P_{nm}(z)$  and  $P_{nm}'(z)$  for all orders from  $0..m$  and degrees from  $0..n$ .

This function takes a real argument  $z$ . For complex arguments  $z$  use `clpmn` instead.

#### Parameters

<b>m</b>	[int] $ m  \leq n$ ; the order of the Legendre function.
<b>n</b>	[int] where $n \geq 0$ ; the degree of the Legendre function. Often called $l$ (lower case L) in descriptions of the associated Legendre function
<b>z</b>	[float] Input value.

#### Returns

<b>Pmn_z</b>	[( $m+1, n+1$ ) array] Values for all orders $0..m$ and degrees $0..n$
<b>Pmn_d_z</b>	[( $m+1, n+1$ ) array] Derivatives for all orders $0..m$ and degrees $0..n$

See also:

#### `clpmn`

associated Legendre functions of the first kind for complex  $z$

## Notes

In the interval  $(-1, 1)$ , Ferrer's function of the first kind is returned. The phase convention used for the intervals  $(1, \infty)$  and  $(-\infty, -1)$  is such that the result is always real.

## References

[1], [2]

### scipy.special.lqmn

`scipy.special.lqmn(m, n, z)`

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order  $m$  and degree  $n$ ,  $Q_{mn}(z) = Q_n^m(z)$ , and its derivative,  $Q_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $Q_{mn}(z)$  and  $Q_{mn}'(z)$  for all orders from  $0..m$  and degrees from  $0..n$ .

#### Parameters

- m** [int]  $|m| \leq n$ ; the order of the Legendre function.
- n** [int] where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function
- z** [complex] Input value.

#### Returns

- Qmn\_z** [(m+1, n+1) array] Values for all orders  $0..m$  and degrees  $0..n$
- Qmn\_d\_z** [(m+1, n+1) array] Derivatives for all orders  $0..m$  and degrees  $0..n$

### Ellipsoidal harmonics

<code>ellip_harm(h2, k2, n, p, s, signm, signn)</code>	Ellipsoidal harmonic functions $E^p_n(l)$
<code>ellip_harm_2(h2, k2, n, p, s)</code>	Ellipsoidal harmonic functions $F^p_n(l)$
<code>ellip_normal(h2, k2, n, p)</code>	Ellipsoidal harmonic normalization constants $\gamma^p_n$

### scipy.special.ellip\_harm

`scipy.special.ellip_harm(h2, k2, n, p, s, signm=1, signn=1)`

Ellipsoidal harmonic functions  $E^p_n(l)$

These are also known as Lamé functions of the first kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

#### Parameters

- h2** [float]  $h^2$
- k2** [float]  $k^2$ ; should be larger than  $h^2$

**n** [int] Degree  
**s** [float] Coordinate  
**p** [int] Order, can range between  $[1, 2n+1]$   
**signm** [{1, -1}, optional] Sign of prefactor of functions. Can be +/-1. See Notes.  
**signn** [{1, -1}, optional] Sign of prefactor of functions. Can be +/-1. See Notes.

**Returns**

**E** [float] the harmonic  $E_n^p(s)$

See also:

`ellip_harm_2`, `ellip_normal`

**Notes**

The geometric interpretation of the ellipsoidal functions is explained in [2], [3], [4]. The *signm* and *signn* arguments control the sign of prefactors for functions according to their type:

```
K : +1
L : signm
M : signn
N : signm*signn
```

New in version 0.15.0.

**References**

[1], [2], [3], [4]

**Examples**

```
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5, 8, 1, 1, 2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lamé equation:

```
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
...     r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 -
...     ↪ k**2)*df - n*(n+1)*s**2*f)/f
...     return -r.mean(), r.std()
>>> s = np.linspace(0.1, 10, 200)
>>> k, h, n, p = 8.0, 2.2, 3, 2
>>> E = ellip_harm(h**2, k**2, n, p, s)
>>> E_spl = UnivariateSpline(s, E)
>>> a, a_err = eigenvalue(E_spl(s), E_spl(s, 1), E_spl(s, 2))
>>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

## scipy.special.ellip\_harm\_2

`scipy.special.ellip_harm_2` (*h2, k2, n, p, s*)

Ellipsoidal harmonic functions  $F^p_n(l)$

These are also known as Lamé functions of the second kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

### Parameters

<b>h2</b>	[float] $h^{**2}$
<b>k2</b>	[float] $k^{**2}$ ; should be larger than $h^{**2}$
<b>n</b>	[int] Degree.
<b>p</b>	[int] Order, can range between $[1, 2n+1]$ .
<b>s</b>	[float] Coordinate

### Returns

<b>F</b>	[float] The harmonic $F^p_n(s)$
----------	---------------------------------

See also:

[ellip\\_harm](#), [ellip\\_normal](#)

## Notes

Lamé functions of the second kind are related to the functions of the first kind:

$$F^p_n(s) = (2n + 1)E^p_n(s) \int_0^{1/s} \frac{du}{(E^p_n(1/u))^2 \sqrt{(1 - u^2k^2)(1 - u^2h^2)}}$$

New in version 0.15.0.

## Examples

```
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5, 8, 2, 1, 10)
>>> w
0.00108056853382
```

## scipy.special.ellip\_normal

`scipy.special.ellip_normal` (*h2, k2, n, p*)

Ellipsoidal harmonic normalization constants  $\gamma^p_n$

The normalization constant is defined as

$$\gamma^p_n = 8 \int_0^h dx \int_h^k dy \frac{(y^2 - x^2)(E^p_n(y)E^p_n(x))^2}{\sqrt{(k^2 - y^2)(y^2 - h^2)(h^2 - x^2)(k^2 - x^2)}}$$

### Parameters

<b>h2</b>	[float] $h^{**2}$
<b>k2</b>	[float] $k^{**2}$ ; should be larger than $h^{**2}$
<b>n</b>	[int] Degree.

**p** [int] Order, can range between  $[1, 2n+1]$ .

**Returns**

**gamma** [float] The normalization constant  $\gamma_n^p$

See also:

`ellip_harm`, `ellip_harm_2`

**Notes**

New in version 0.15.0.

**Examples**

```
>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5, 8, 3, 7)
>>> w
1723.38796997
```

**Orthogonal polynomials**

The following functions evaluate values of orthogonal polynomials:

<code>assoc_laguerre(x, n[, k])</code>	Compute the generalized (associated) Laguerre polynomial of degree $n$ and order $k$ .
<code>eval_legendre(n, x[, out])</code>	Evaluate Legendre polynomial at a point.
<code>eval_chebyt(n, x[, out])</code>	Evaluate Chebyshev polynomial of the first kind at a point.
<code>eval_chebyu(n, x[, out])</code>	Evaluate Chebyshev polynomial of the second kind at a point.
<code>eval_chebyc(n, x[, out])</code>	Evaluate Chebyshev polynomial of the first kind on $[-2, 2]$ at a point.
<code>eval_chebys(n, x[, out])</code>	Evaluate Chebyshev polynomial of the second kind on $[-2, 2]$ at a point.
<code>eval_jacobi(n, alpha, beta, x[, out])</code>	Evaluate Jacobi polynomial at a point.
<code>eval_laguerre(n, x[, out])</code>	Evaluate Laguerre polynomial at a point.
<code>eval_genlaguerre(n, alpha, x[, out])</code>	Evaluate generalized Laguerre polynomial at a point.
<code>eval_hermite(n, x[, out])</code>	Evaluate physicist's Hermite polynomial at a point.
<code>eval_hermitenorm(n, x[, out])</code>	Evaluate probabilist's (normalized) Hermite polynomial at a point.
<code>eval_gegenbauer(n, alpha, x[, out])</code>	Evaluate Gegenbauer polynomial at a point.
<code>eval_sh_legendre(n, x[, out])</code>	Evaluate shifted Legendre polynomial at a point.
<code>eval_sh_chebyt(n, x[, out])</code>	Evaluate shifted Chebyshev polynomial of the first kind at a point.
<code>eval_sh_chebyu(n, x[, out])</code>	Evaluate shifted Chebyshev polynomial of the second kind at a point.
<code>eval_sh_jacobi(n, p, q, x[, out])</code>	Evaluate shifted Jacobi polynomial at a point.

**scipy.special.assoc\_laguerre**`scipy.special.assoc_laguerre(x, n, k=0.0)`Compute the generalized (associated) Laguerre polynomial of degree  $n$  and order  $k$ .The polynomial  $L_n^{(k)}(x)$  is orthogonal over  $[0, \infty)$ , with weighting function  $\exp(-x) * x^{**k}$  with  $k > -1$ .**Notes***assoc\_laguerre* is a simple wrapper around *eval\_genlaguerre*, with reversed argument order ( $x, n, k=0.0$ )  $\rightarrow$  ( $n, k, x$ ).**scipy.special.eval\_legendre**`scipy.special.eval_legendre(n, x, out=None) = <ufunc 'eval_legendre'>`

Evaluate Legendre polynomial at a point.

The Legendre polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$P_n(x) = {}_2F_1(-n, n + 1; 1; (1 - x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.49 in [AS] for details.**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Legendre polynomial

**Returns**

- P** [ndarray] Values of the Legendre polynomial

**See also:****roots\_legendre**

roots and quadrature weights of Legendre polynomials

**legendre**

Legendre polynomial object

**hyp2f1**

Gauss hypergeometric function

**numpy.polynomial.legendre.Legendre**

## Examples

```
>>> from scipy.special import eval_legendre
```

Evaluate the zero-order Legendre polynomial at  $x = 0$

```
>>> eval_legendre(0, 0)
1.0
```

Evaluate the first-order Legendre polynomial between -1 and 1

```
>>> import numpy as np
>>> X = np.linspace(-1, 1, 5) # Domain of Legendre polynomials
>>> eval_legendre(1, X)
array([-1. , -0.5,  0. ,  0.5,  1. ])
```

Evaluate Legendre polynomials of order 0 through 4 at  $x = 0$

```
>>> N = range(0, 5)
>>> eval_legendre(N, 0)
array([ 1. ,  0. , -0.5 ,  0. ,  0.375])
```

Plot Legendre polynomials of order 0 through 4

```
>>> X = np.linspace(-1, 1)
```

```
>>> import matplotlib.pyplot as plt
>>> for n in range(0, 5):
...     y = eval_legendre(n, X)
...     plt.plot(X, y, label=r'$P_{%d}(x)$'.format(n))
```

```
>>> plt.title("Legendre Polynomials")
>>> plt.xlabel("x")
>>> plt.ylabel(r'$P_n(x)$')
>>> plt.legend(loc='lower right')
>>> plt.show()
```

## scipy.special.eval\_chebyt

`scipy.special.eval_chebyt(n, x, out=None)` = <ufunc 'eval\_chebyt'>

Evaluate Chebyshev polynomial of the first kind at a point.

The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$T_n(x) = {}_2F_1(n, -n; 1/2; (1-x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.47 in [AS] for details.

### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

**Returns**

- T** [ndarray] Values of the Chebyshev polynomial

**See also:**

**roots\_chebyt**

roots and quadrature weights of Chebyshev polynomials of the first kind

**chebyu**

Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

**hyp2f1**

Gauss hypergeometric function

**numpy.polynomial.chebyshev.Chebyshev**

Chebyshev series

## Notes

This routine is numerically stable for  $x$  in  $[-1, 1]$  at least up to order 10000.

## References

[AS]

### scipy.special.eval\_chebyu

`scipy.special.eval_chebyu(n, x, out=None) = <ufunc 'eval_chebyu'>`

Evaluate Chebyshev polynomial of the second kind at a point.

The Chebyshev polynomials of the second kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$U_n(x) = (n + 1) {}_2F_1(-n, n + 2; 3/2; (1 - x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.48 in [AS] for details.

#### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

#### Returns

- U** [ndarray] Values of the Chebyshev polynomial

See also:

#### roots\_chebyu

roots and quadrature weights of Chebyshev polynomials of the second kind

#### chebyu

Chebyshev polynomial object

#### eval\_chebyt

Evaluate probabilist's (normalized) Hermite polynomial at a point.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$  is a polynomial of degree  $n$ . See 22.11.8 in [AS] for details.

#### Parameters

**n** [array\_like] Degree of the polynomial  
**x** [array\_like] Points at which to evaluate the Hermite polynomial

#### Returns

**He** [ndarray] Values of the Hermite polynomial

**See also:**

`roots_hermitenorm`

roots and quadrature weights of probabilist's Hermite polynomials

`hermitenorm`

probabilist's Hermite polynomial object

`numpy.polynomial.hermite_e.HermiteE`

Probabilist's Hermite series

`eval_hermite`

evaluate physicist's Hermite polynomials

## `scipy.special.eval_gegenbauer`

`scipy.special.eval_gegenbauer` (*n*, *alpha*, *x*, *out=None*) = <ufunc 'eval\_gegenbauer'>

Evaluate Gegenbauer polynomial at a point.

The Gegenbauer polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$C_n^{(\alpha)} = \frac{(2\alpha)_n}{\Gamma(n+1)} {}_2F_1(-n, 2\alpha+n; \alpha+1/2; (1-z)/2).$$

When *n* is an integer the result is a polynomial of degree *n*. See 22.5.46 in [AS] for details.

### Parameters

**n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**alpha** [array\_like] Parameter

**x** [array\_like] Points at which to evaluate the Gegenbauer polynomial

### Returns

**C** [ndarray] Values of the Gegenbauer polynomial

**See also:**

`roots_gegenbauer`

roots and quadrature weights of Gegenbauer polynomials

`gegenbauer`

Gegenbauer polynomial object

`hyp2f1`

Gauss hypergeometric function

### scipy.special.eval\_sh\_legendre

`scipy.special.eval_sh_legendre(n, x, out=None) = <ufunc 'eval_sh_legendre'>`

Evaluate shifted Legendre polynomial at a point.

These polynomials are defined as

$$P_n^*(x) = P_n(2x - 1)$$

where  $P_n$  is a Legendre polynomial. See 2.2.11 in [AS] for details.

#### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer, the value is determined via the relation to `eval_legendre`.
- x** [array\_like] Points at which to evaluate the shifted Legendre polynomial

#### Returns

- P** [ndarray] Values of the shifted Legendre polynomial

See also:

### scipy.special.eval\_sh\_chebyt

`scipy.special.eval_sh_chebyt(n, x, out=None) = <ufunc 'eval_sh_chebyt'>`

Evaluate shifted Chebyshev polynomial of the first kind at a point.

These polynomials are defined as

$$T_n^*(x) = T_n(2x - 1)$$

where  $T_n$  is a Chebyshev polynomial of the first kind. See 22.5.14 in [AS] for details.

#### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.
- x** [array\_like] Points at which to evaluate the shifted Chebyshev polynomial

**Returns**

**T** [ndarray] Values of the shifted Chebyshev polynomial

**See also:****roots\_sh\_chebyt**

roots and quadrature weights of shifted Chebyshev polynomials of the first kind

**sh\_chebyt**

shifted Chebyshev polynomial object

**eval\_chebyt**

evaluate Chebyshev polynomials of the first kind

**numpy.polynomial.chebyshev.Chebyshev**

Chebyshev series

**References**

[AS]

**scipy.special.eval\_sh\_chebyu**

`scipy.special.eval_sh_chebyu(n, x, out=None) = <ufunc 'eval_sh_chebyu'>`

Evaluate shifted Chebyshev polynomial of the second kind at a point.

These polynomials are defined as

$$U_n^*(x) = U_n(2x - 1)$$

where  $U_n$  is a Chebyshev polynomial of the first kind. See 22.5.15 in [AS] for details.

**Parameters**

**n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyu`.

**x** [array\_like] Points at which to evaluate the shifted Chebyshev polynomial

**Returns**

**U** [ndarray] Values of the shifted Chebyshev polynomial

**See also:****roots\_sh\_chebyu**

roots and quadrature weights of shifted Chebyshev polynomials of the second kind

**sh\_chebyu**

shifted Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

### scipy.special.eval\_sh\_jacobi

`scipy.special.eval_sh_jacobi(n, p, q, x, out=None) = <ufunc 'eval_sh_jacobi'>`  
 Evaluate shifted Jacobi polynomial at a point.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the n-th Jacobi polynomial. See 22.5.2 in [AS] for details.

#### Parameters

**n** [int] Degree of the polynomial. If not an integer, the result is determined via the relation to *binom* and *eval\_jacobi*.  
**p** [float] Parameter  
**q** [float] Parameter

#### Returns

**G** [ndarray] Values of the shifted Jacobi polynomial.

See also:

**scipy.special.roots\_legendre**

`scipy.special.roots_legendre` (*n*, *mu=False*)

Gauss-Legendre quadrature.

Compute the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the *n*th degree Legendre polynomial  $P_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $w(x) = 1.0$ . See 2.2.10 in [AS] for more details.

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

### `scipy.special.roots_jacobi`

`scipy.special.roots_jacobi` (*n*, *alpha*, *beta*, *mu=False*)

Gauss-Jacobi quadrature.

Compute the sample points and weights for Gauss-Jacobi quadrature. The sample points are the roots of the *n*th degree Jacobi polynomial,  $P_n^{\alpha,\beta}(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $w(x) = (1 - x)^\alpha(1 + x)^\beta$ . See 22.2.1 in [AS] for details.

#### Parameters

**n** [int] quadrature order  
**alpha** [float] alpha must be  $> -1$   
**beta** [float] beta must be  $> -1$   
**mu** [bool, optional] If True, return the sum of the weights, optional.

#### Returns

<b>x</b>	[ndarray] Sample points
<b>w</b>	[ndarray] Weights
<b>mu</b>	[float] Sum of the weights

**scipy.special.roots\_hermite**

`scipy.special.roots_hermite` (*n*, *mu=False*)

Gauss-Hermite (physicist's) quadrature.

Compute the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the *n*th degree Hermite polynomial,  $H_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-\infty, \infty]$  with weight function  $w(x) = e^{-x^2}$ . See 22.2.14 in [AS] for details.

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

See also:

`scipy.integrate.quadrature`

`scipy.integrate.fixed_quad`

`numpy.polynomial.hermite.hermgauss`

`roots_hermitenorm`

**Notes**

For small *n* up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For *n* larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large *n* (several thousand or more) feasible.

The functions below, in turn, return the polynomial coefficients in `orthopoly1d` objects, which function similarly as `numpy.poly1d`. The `orthopoly1d` class also has an attribute `weights`, which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an  $n \times 3$  array with roots in the first column, weights in the second column, and total weights in the final column. Note that `orthopoly1d` objects are converted to `poly1d` when doing arithmetic, and lose information of the original orthogonal polynomial.

<code>legendre</code> ( <i>n</i> [, <i>monic</i> ])	Legendre polynomial.
<code>chebyt</code> ( <i>n</i> [, <i>monic</i> ])	Chebyshev polynomial of the first kind.
<code>chebyu</code> ( <i>n</i> [, <i>monic</i> ])	Chebyshev polynomial of the second kind.
<code>chebyc</code> ( <i>n</i> [, <i>monic</i> ])	Chebyshev polynomial of the first kind on $[-2, 2]$ .

<code>sh_chebyu(n[, monic])</code>	Shifted Chebyshev polynomial of the second kind.
<code>sh_jacobi(n, p, q[, monic])</code>	Shifted Jacobi polynomial.

### scipy.special.legendre

`scipy.special.legendre` (*n*, *monic=False*)

Legendre polynomial.

Defined to be the solution of

$$\frac{d}{dx} \left[ (1 - x^2) \frac{d}{dx} P_n(x) \right] + n(n + 1)P_n(x) = 0;$$

$P_n(x)$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- P** [orthopoly1d] Legendre polynomial.

### Notes

The polynomials  $P_n$  are orthogonal over  $[-1, 1]$  with weight function 1.

### Examples

Generate the 3rd-order Legendre polynomial  $1/2*(5x^3 + 0x^2 - 3x + 0)$ :

```
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([ 2.5,  0. , -1.5,  0. ])
```

### scipy.special.chebyt

`scipy.special.chebyt` (*n*, *monic=False*)

Chebyshev polynomial of the first kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} T_n - x \frac{d}{dx} T_n + n^2 T_n = 0;$$

$T_n$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- T** [orthopoly1d] Chebyshev polynomial of the first kind.

See also:

**chebyu**

Chebyshev polynomial of the second kind.

**Notes**

The polynomials  $T_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{-1/2}$ .

**scipy.special.chebyu**

`scipy.special.chebyu` (*n*, *monic=False*)

Chebyshev polynomial of the second kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} U_n - 3x \frac{d}{dx} U_n + n(n + 2) U_n = 0;$$

$U_n$  is a polynomial of degree  $n$ .

**Parameters**

- n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

- U** [orthopoly1d] Chebyshev polynomial of the second kind.

**See also:**

**chebyt**

Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $U_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{1/2}$ .

**scipy.special.chebyc**

`scipy.special.chebyc` (*n*, *monic=False*)

Chebyshev polynomial of the first kind on  $[-2, 2]$ .

Defined as  $C_n(x) = 2T_n(x/2)$ , where  $T_n$  is the  $n$ th Chebychev polynomial of the first kind.

**Parameters**

- n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

- C** [orthopoly1d] Chebyshev polynomial of the first kind on  $[-2, 2]$ .

**See also:**

**chebyt**

Chebyshev polynomial of the first kind.

## Notes

The polynomials  $C_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $1/\sqrt{1 - (x/2)^2}$ .

## References

[1]

### scipy.special.chebys

`scipy.special.chebys` (*n*, *monic=False*)

Chebyshev polynomial of the second kind on  $[-2, 2]$ .

Defined as  $S_n(x) = U_n(x/2)$  where  $U_n$  is the *n*th Chebychev polynomial of the second kind.

#### Parameters

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

**S** [orthopoly1d] Chebyshev polynomial of the second kind on  $[-2, 2]$ .

See also:

#### chebyu

Chebyshev polynomial of the second kind

## Notes

The polynomials  $S_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $\sqrt{1 - (x/2)^2}$ .

## References

[1]

### scipy.special.jacobi

`scipy.special.jacobi` (*n*, *alpha*, *beta*, *monic=False*)

Jacobi polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} P_n^{(\alpha, \beta)} + (\beta - \alpha - (\alpha + \beta + 2)x) \frac{d}{dx} P_n^{(\alpha, \beta)} + n(n + \alpha + \beta + 1) P_n^{(\alpha, \beta)} = 0$$

for  $\alpha, \beta > -1$ ;  $P_n^{(\alpha, \beta)}$  is a polynomial of degree *n*.

#### Parameters

**n** [int] Degree of the polynomial.  
**alpha** [float] Parameter, must be greater than -1.  
**beta** [float] Parameter, must be greater than -1.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

**P** [orthopoly1d] Jacobi polynomial.

## Notes

For fixed  $\alpha, \beta$ , the polynomials  $P_n^{(\alpha, \beta)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1-x)^\alpha(1+x)^\beta$ .

### scipy.special.laguerre

`scipy.special.laguerre` ( $n$ , *monic=False*)

Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n + (1-x) \frac{d}{dx} L_n + n L_n = 0;$$

$L_n$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- L** [orthopoly1d] Laguerre Polynomial.

## Notes

The polynomials  $L_n$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}$ .

### scipy.special.genlaguerre

`scipy.special.genlaguerre` ( $n$ , *alpha*, *monic=False*)

Generalized (associated) Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n^{(\alpha)} + (\alpha + 1 - x) \frac{d}{dx} L_n^{(\alpha)} + n L_n^{(\alpha)} = 0,$$

where  $\alpha > -1$ ;  $L_n^{(\alpha)}$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.  
**alpha** [float] Parameter, must be greater than -1.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- L** [orthopoly1d] Generalized Laguerre polynomial.

See also:

#### laguerre

Laguerre polynomial.

## Notes

For fixed  $\alpha$ , the polynomials  $L_n^{(\alpha)}$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}x^\alpha$ .

The Laguerre polynomials are the special case where  $\alpha = 0$ .

## scipy.special.hermite

`scipy.special.hermite` ( $n$ , *monic=False*)

Physicist's Hermite polynomial.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$  is a polynomial of degree  $n$ .

### Parameters

- n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

### Returns

- H** [orthopoly1d] Hermite polynomial.

## Notes

The polynomials  $H_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2}$ .

## scipy.special.hermite norm

`scipy.special.hermite norm` ( $n$ , *monic=False*)

Normalized (probabilist's) Hermite polynomial.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$  is a polynomial of degree  $n$ .

### Parameters

- n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

### Returns

- He** [orthopoly1d] Hermite polynomial.

## Notes

The polynomials  $He_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2/2}$ .

### scipy.special.gegenbauer

`scipy.special.gegenbauer` ( $n$ ,  $alpha$ ,  $monic=False$ )

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} C_n^{(\alpha)} - (2\alpha + 1)x \frac{d}{dx} C_n^{(\alpha)} + n(n + 2\alpha) C_n^{(\alpha)} = 0$$

for  $\alpha > -1/2$ ;  $C_n^{(\alpha)}$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- C** [orthopoly1d] Gegenbauer polynomial.

## Notes

The polynomials  $C_n^{(\alpha)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{(\alpha-1/2)}$ .

### scipy.special.sh\_legendre

`scipy.special.sh_legendre` ( $n$ ,  $monic=False$ )

Shifted Legendre polynomial.

Defined as  $P_n^*(x) = P_n(2x - 1)$  for  $P_n$  the  $n$ th Legendre polynomial.

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- P** [orthopoly1d] Shifted Legendre polynomial.

## Notes

The polynomials  $P_n^*$  are orthogonal over  $[0, 1]$  with weight function 1.

### scipy.special.sh\_chebyt

`scipy.special.sh_chebyt` ( $n$ ,  $monic=False$ )

Shifted Chebyshev polynomial of the first kind.

Defined as  $T_n^*(x) = T_n(2x - 1)$  for  $T_n$  the  $n$ th Chebyshev polynomial of the first kind.

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**T** [orthopoly1d] Shifted Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $T_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{-1/2}$ .

**scipy.special.sh\_chebyu**

`scipy.special.sh_chebyu` (*n*, *monic=False*)

Shifted Chebyshev polynomial of the second kind.

Defined as  $U_n^*(x) = U_n(2x - 1)$  for  $U_n$  the *n*th Chebyshev polynomial of the second kind.

**Parameters**

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**U** [orthopoly1d] Shifted Chebyshev polynomial of the second kind.

**Notes**

The polynomials  $U_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{1/2}$ .

**scipy.special.sh\_jacobi**

`scipy.special.sh_jacobi` (*n*, *p*, *q*, *monic=False*)

Shifted Jacobi polynomial.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the *n*th Jacobi polynomial.

**Parameters**

**n** [int] Degree of the polynomial.  
**p** [float] Parameter, must have  $p > q - 1$ .  
**q** [float] Parameter, must be greater than 0.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**G** [orthopoly1d] Shifted Jacobi polynomial.

## Notes

For fixed  $p, q$ , the polynomials  $G_n^{(p,q)}$  are orthogonal over  $[0, 1]$  with weight function  $(1 - x)^{p-q}x^{q-1}$ .

**Warning:** Computing values of high-order polynomials (around `order > 20`) using polynomial coefficients is numerically unstable. To evaluate polynomial values, the `eval_*` functions should be used instead.

## Hypergeometric functions

<code>hyp2f1(a, b, c, z)</code>	Gauss hypergeometric function $2F1(a, b; c; z)$
<code>hyp1f1(a, b, x[, out])</code>	Confluent hypergeometric function $1F1$ .
<code>hyperu(a, b, x[, out])</code>	Confluent hypergeometric function $U$
<code>hyp0f1(v, z[, out])</code>	Confluent hypergeometric limit function $0F1$ .

### scipy.special.hyp2f1

`scipy.special.hyp2f1(a, b, c, z) = <ufunc 'hyp2f1'>`  
Gauss hypergeometric function  $2F1(a, b; c; z)$

#### Parameters

**a, b, c** [array\_like] Arguments, should be real-valued.  
**z** [array\_like] Argument, real or complex.

#### Returns

**hyp2f1** [scalar or ndarray] The values of the gaussian hypergeometric function.

#### See also:

##### `hyp0f1`

confluent hypergeometric limit function.

##### `hyp1f1`

Kummer's (confluent hypergeometric) function.

## Notes

This function is defined for  $|z| < 1$  as

$$\text{hyp2f1}(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n} \frac{z^n}{n!},$$

and defined on the rest of the complex  $z$ -plane by analytic continuation [1]. Here  $(\cdot)_n$  is the Pochhammer symbol; see *poch*. When  $n$  is an integer the result is a polynomial of degree  $n$ .

The implementation for complex values of  $z$  is described in [2].

## References

[1], [2], [3]

## Examples

```
>>> import scipy.special as sc
```

It has poles when  $c$  is a negative integer.

```
>>> sc.hyp2f1(1, 1, -2, 1)
inf
```

It is a polynomial when  $a$  or  $b$  is a negative integer.

```
>>> a, b, c = -1, 1, 1.5
>>> z = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, c, z)
array([1.          , 0.83333333, 0.66666667, 0.5          , 0.33333333])
>>> 1 + a * b * z / c
array([1.          , 0.83333333, 0.66666667, 0.5          , 0.33333333])
```

It is symmetric in  $a$  and  $b$ .

```
>>> a = np.linspace(0, 1, 5)
>>> b = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, 1, 0.5)
array([1.          , 1.03997334, 1.1803406 , 1.47074441, 2.          ])
>>> sc.hyp2f1(b, a, 1, 0.5)
array([1.          , 1.03997334, 1.1803406 , 1.47074441, 2.          ])
```

It contains many other functions as special cases.

```
>>> z = 0.5
>>> sc.hyp2f1(1, 1, 2, z)
1.3862943611198901
>>> -np.log(1 - z) / z
1.3862943611198906
```

```
>>> sc.hyp2f1(0.5, 1, 1.5, z**2)
1.098612288668109
>>> np.log((1 + z) / (1 - z)) / (2 * z)
1.0986122886681098
```

```
>>> sc.hyp2f1(0.5, 1, 1.5, -z**2)
0.9272952180016117
>>> np.arctan(z) / z
0.9272952180016123
```

**scipy.special.hyp1f1**

`scipy.special.hyp1f1(a, b, x, out=None)` = `<ufunc 'hyp1f1'>`  
 Confluent hypergeometric function 1F1.

The confluent hypergeometric function is defined by the series

$${}_1F_1(a; b; x) = \sum_{k=0}^{\infty} \frac{(a)_k}{(b)_k k!} x^k.$$

See [dlmf] for more details. Here  $(\cdot)_k$  is the Pochhammer symbol; see *poch*.

**Parameters**

**a, b** [array\_like] Real parameters  
**x** [array\_like] Real or complex argument  
**out** [ndarray, optional] Optional output array for the function results

**Returns**

**scalar or ndarray**  
 Values of the confluent hypergeometric function

**See also:**

[hyperu](#)

another confluent hypergeometric function

[hyp0f1](#)

confluent hypergeometric limit function

[hyp2f1](#)

Gaussian hypergeometric function

**References**

[dlmf]

**Examples**

```
>>> import scipy.special as sc
```

It is one when  $x$  is zero:

```
>>> sc.hyp1f1(0.5, 0.5, 0)
1.0
```

It is singular when  $b$  is a nonpositive integer.

```
>>> sc.hyp1f1(0.5, -1, 0)
inf
```

It is a polynomial when  $a$  is a nonpositive integer.

```
>>> a, b, x = -1, 0.5, np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.hyp1f1(a, b, x)
array([-1., -3., -5., -7.])
>>> 1 + (a / b) * x
array([-1., -3., -5., -7.])
```

It reduces to the exponential function when  $a = b$ .

```
>>> sc.hyp1f1(2, 2, [1, 2, 3, 4])
array([ 2.71828183,  7.3890561 , 20.08553692, 54.59815003])
>>> np.exp([1, 2, 3, 4])
array([ 2.71828183,  7.3890561 , 20.08553692, 54.59815003])
```

## scipy.special.hyperu

`scipy.special.hyperu(a, b, x, out=None)` = <ufunc 'hyperu'>  
Confluent hypergeometric function U

It is defined as the solution to the equation

$$x \frac{d^2 w}{dx^2} + (b - x) \frac{dw}{dx} - aw = 0$$

which satisfies the property

$$U(a, b, x) \sim x^{-a}$$

as  $x \rightarrow \infty$ . See [dlmf] for more details.

### Parameters

**a, b** [array\_like] Real-valued parameters  
**x** [array\_like] Real-valued argument  
**out** [ndarray] Optional output array for the function values

### Returns

**scalar or ndarray**  
 Values of  $U$

## References

[dlmf]

## Examples

```
>>> import scipy.special as sc
```

It has a branch cut along the negative  $x$  axis.

```
>>> x = np.linspace(-0.1, -10, 5)
>>> sc.hyperu(1, 1, x)
array([nan, nan, nan, nan, nan])
```

It approaches zero as  $x$  goes to infinity.

```
>>> x = np.array([1, 10, 100])
>>> sc.hyperu(1, 1, x)
array([0.59634736, 0.09156333, 0.00990194])
```

It satisfies Kummer's transformation.

```
>>> a, b, x = 2, 1, 1
>>> sc.hyperu(a, b, x)
0.1926947246463881
>>> x**(1 - b) * sc.hyperu(a - b + 1, 2 - b, x)
0.1926947246463881
```

### scipy.special.hyp0f1

`scipy.special.hyp0f1(v, z, out=None) = <ufunc 'hyp0f1'>`  
 Confluent hypergeometric limit function 0F1.

#### Parameters

**v** [array\_like] Real-valued parameter  
**z** [array\_like] Real- or complex-valued argument  
**out** [ndarray, optional] Optional output array for the function results

#### Returns

**scalar or ndarray**  
 The confluent hypergeometric limit function

#### Notes

This function is defined as:

$${}_0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.$$

It's also the limit as  $q \rightarrow \infty$  of  ${}_1F_1(q; v; z/q)$ , and satisfies the differential equation  $f''(z) + v f'(z) = f(z)$ . See [1] for more information.

#### References

[1]

#### Examples

```
>>> import scipy.special as sc
```

It is one when  $z$  is zero.

```
>>> sc.hyp0f1(1, 0)
1.0
```

It is the limit of the confluent hypergeometric function as  $q$  goes to infinity.

```
>>> q = np.array([1, 10, 100, 1000])
>>> v = 1
>>> z = 1
>>> sc.hyp1f1(q, v, z / q)
array([2.71828183, 2.31481985, 2.28303778, 2.27992985])
>>> sc.hyp0f1(v, z)
2.2795853023360673
```

It is related to Bessel functions.

```
>>> n = 1
>>> x = np.linspace(0, 1, 5)
>>> sc.jv(n, x)
array([0.          , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
>>> (0.5 * x)**n / sc.factorial(n) * sc.hyp0f1(n + 1, -0.25 * x**2)
array([0.          , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
```

## Parabolic cylinder functions

<code>pbdv(v, x)</code>	Parabolic cylinder function D
<code>pbvv(v, x)</code>	Parabolic cylinder function V
<code>pbwa(a, x)</code>	Parabolic cylinder function W.

### scipy.special.pbdv

`scipy.special.pbdv(v, x) = <ufunc 'pbdv'>`  
 Parabolic cylinder function D

Returns (d, dp) the parabolic cylinder function  $Dv(x)$  in d and the derivative,  $Dv'(x)$  in dp.

#### Returns

**d** Value of the function  
**dp** Value of the derivative vs x

### scipy.special.pbvv

`scipy.special.pbvv(v, x) = <ufunc 'pbvv'>`  
 Parabolic cylinder function V

Returns the parabolic cylinder function  $Vv(x)$  in v and the derivative,  $Vv'(x)$  in vp.

#### Returns

**v** Value of the function  
**vp** Value of the derivative vs x

**scipy.special.pbwa**

`scipy.special.pbwa(a, x) = <ufunc 'pbwa'>`  
 Parabolic cylinder function W.

The function is a particular solution to the differential equation

$$y'' + \left(\frac{1}{4}x^2 - a\right)y = 0,$$

for a full definition see section 12.14 in [1].

**Parameters**

**a** [array\_like] Real parameter  
**x** [array\_like] Real argument

**Returns**

**w** [scalar or ndarray] Value of the function  
**wp** [scalar or ndarray] Value of the derivative in x

**Notes**

The function is a wrapper for a Fortran routine by Zhang and Jin [2]. The implementation is accurate only for  $|a|, |x| < 5$  and returns NaN outside that range.

**References**

[1], [2]

These are not universal functions:

<a href="#"><code>pbdv_seq(v, x)</code></a>	Parabolic cylinder functions $Dv(x)$ and derivatives.
<a href="#"><code>pbvv_seq(v, x)</code></a>	Parabolic cylinder functions $Vv(x)$ and derivatives.
<a href="#"><code>pbdn_seq(n, z)</code></a>	Parabolic cylinder functions $Dn(z)$ and derivatives.

**scipy.special.pbdv\_seq**

`scipy.special.pbdv_seq(v, x)`  
 Parabolic cylinder functions  $Dv(x)$  and derivatives.

**Parameters**

**v** [float] Order of the parabolic cylinder function  
**x** [float] Value at which to evaluate the function and derivatives

**Returns**

**dv** [ndarray] Values of  $D_{vi}(x)$ , for  $vi=v-int(v), vi=1+v-int(v), \dots, vi=v$ .  
**dp** [ndarray] Derivatives  $D_{vi}'(x)$ , for  $vi=v-int(v), vi=1+v-int(v), \dots, vi=v$ .

## References

[1]

### scipy.special.pbvv\_seq

`scipy.special.pbvv_seq(v, x)`

Parabolic cylinder functions  $V_v(x)$  and derivatives.

#### Parameters

**v** [float] Order of the parabolic cylinder function  
**x** [float] Value at which to evaluate the function and derivatives

#### Returns

**dv** [ndarray] Values of  $V_{v_i}(x)$ , for  $v_i=v-\text{int}(v)$ ,  $v_i=1+v-\text{int}(v)$ , ...,  $v_i=v$ .  
**dp** [ndarray] Derivatives  $V'_{v_i}(x)$ , for  $v_i=v-\text{int}(v)$ ,  $v_i=1+v-\text{int}(v)$ , ...,  $v_i=v$ .

## References

[1]

### scipy.special.pbdn\_seq

`scipy.special.pbdn_seq(n, z)`

Parabolic cylinder functions  $D_n(z)$  and derivatives.

#### Parameters

**n** [int] Order of the parabolic cylinder function  
**z** [complex] Value at which to evaluate the function and derivatives

#### Returns

**dv** [ndarray] Values of  $D_i(z)$ , for  $i=0, \dots, i=n$ .  
**dp** [ndarray] Derivatives  $D'_i(z)$ , for  $i=0, \dots, i=n$ .

## Mathieu and related functions

---

<code>mathieu_a(m, q)</code>	Characteristic value of even Mathieu functions
<code>mathieu_b(m, q)</code>	Characteristic value of odd Mathieu functions

---

**scipy.special.mathieu\_a**

`scipy.special.mathieu_a(m, q)` = <ufunc 'mathieu\_a'>  
 Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution,  $ce_m(z, q)$ , of Mathieu's equation.

**scipy.special.mathieu\_b**

`scipy.special.mathieu_b(m, q)` = <ufunc 'mathieu\_b'>  
 Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution,  $se_m(z, q)$ , of Mathieu's equation.

These are not universal functions:

<code>mathieu_even_coef(m, q)</code>	Fourier coefficients for even Mathieu and modified Mathieu functions.
<code>mathieu_odd_coef(m, q)</code>	Fourier coefficients for odd Mathieu and modified Mathieu functions.

**scipy.special.mathieu\_even\_coef**

`scipy.special.mathieu_even_coef(m, q)`  
 Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

$$ce_{2n}(z, q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz$$

$$ce_{2n+1}(z, q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k+1)z$$

This function returns the coefficients  $A_{(2n)}^{(2k)}$  for even input  $m=2n$ , and the coefficients  $A_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

**Parameters**

- m** [int] Order of Mathieu functions. Must be non-negative.  
**q** [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

**Returns**

- Ak** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd  $m$ .

**References**

[1], [2]

### scipy.special.mathieu\_odd\_coef

`scipy.special.mathieu_odd_coef(m, q)`

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

$$se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k+1)z$$

$$se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k+2)z$$

This function returns the coefficients  $B_{(2n+2)}^{(2k+2)}$  for even input  $m=2n+2$ , and the coefficients  $B_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

#### Parameters

- m** [int] Order of Mathieu functions. Must be non-negative.
- q** [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

#### Returns

- Bk** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd m.

### References

[1]

The following return both function and first derivative:

<code>mathieu_cem(m, q, x)</code>	Even Mathieu function and its derivative
<code>mathieu_sem(m, q, x)</code>	Odd Mathieu function and its derivative
<code>mathieu_modcem1(m, q, x)</code>	Even modified Mathieu function of the first kind and its derivative
<code>mathieu_modcem2(m, q, x)</code>	Even modified Mathieu function of the second kind and its derivative
<code>mathieu_modsem1(m, q, x)</code>	Odd modified Mathieu function of the first kind and its derivative
<code>mathieu_modsem2(m, q, x)</code>	Odd modified Mathieu function of the second kind and its derivative

### scipy.special.mathieu\_cem

`scipy.special.mathieu_cem(m, q, x) = <ufunc 'mathieu_cem'>`

Even Mathieu function and its derivative

Returns the even Mathieu function,  $ce_m(x, q)$ , of order  $m$  and parameter  $q$  evaluated at  $x$  (given in degrees). Also returns the derivative with respect to  $x$  of  $ce_m(x, q)$

#### Parameters

- m** Order of the function
- q** Parameter of the function
- x** Argument of the function, *given in degrees, not radians*

#### Returns

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs x

**scipy.special.mathieu\_sem**

```
scipy.special.mathieu_sem(m, q, x) = <ufunc 'mathieu_sem'>
```

Odd Mathieu function and its derivative

Returns the odd Mathieu function,  $se_m(x, q)$ , of order  $m$  and parameter  $q$  evaluated at  $x$  (given in degrees). Also returns the derivative with respect to  $x$  of  $se_m(x, q)$ .

**Parameters**

<b>m</b>	Order of the function
<b>q</b>	Parameter of the function
<b>x</b>	Argument of the function, <i>given in degrees, not radians.</i>

**Returns**

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs x

**scipy.special.mathieu\_modcem1**

```
scipy.special.mathieu_modcem1(m, q, x) = <ufunc 'mathieu_modcem1'>
```

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind,  $Mc1m(x, q)$ , and its derivative at  $x$  for order  $m$  and parameter  $q$ .

**Returns**

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs x

**scipy.special.mathieu\_modcem2**

```
scipy.special.mathieu_modcem2(m, q, x) = <ufunc 'mathieu_modcem2'>
```

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind,  $Mc2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs x

**scipy.special.mathieu\_modsem1**

```
scipy.special.mathieu_modsem1(m, q, x) = <ufunc 'mathieu_modsem1'>
```

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind,  $Ms1m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs x

### scipy.special.mathieu\_modsem2

`scipy.special.mathieu_modsem2(m, q, x) = <ufunc 'mathieu_modsem2'>`

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind,  $Ms_{2m}(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

**y**            Value of the function  
**yp**           Value of the derivative vs  $x$

### Spheroidal wave functions

<code>pro_ang1(m, n, c, x)</code>	Prolate spheroidal angular function of the first kind and its derivative
<code>pro_rad1(m, n, c, x)</code>	Prolate spheroidal radial function of the first kind and its derivative
<code>pro_rad2(m, n, c, x)</code>	Prolate spheroidal radial function of the second kind and its derivative
<code>obl_ang1(m, n, c, x)</code>	Oblate spheroidal angular function of the first kind and its derivative
<code>obl_rad1(m, n, c, x)</code>	Oblate spheroidal radial function of the first kind and its derivative
<code>obl_rad2(m, n, c, x)</code>	Oblate spheroidal radial function of the second kind and its derivative.
<code>pro_cv(m, n, c)</code>	Characteristic value of prolate spheroidal function
<code>obl_cv(m, n, c)</code>	Characteristic value of oblate spheroidal function
<code>pro_cv_seq(m, n, c)</code>	Characteristic values for prolate spheroidal wave functions.
<code>obl_cv_seq(m, n, c)</code>	Characteristic values for oblate spheroidal wave functions.

### scipy.special.pro\_ang1

`scipy.special.pro_ang1(m, n, c, x) = <ufunc 'pro_ang1'>`

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s**            Value of the function  
**sp**           Value of the derivative vs  $x$

### scipy.special.pro\_rad1

`scipy.special.pro_rad1(m, n, c, x) = <ufunc 'pro_rad1'>`

Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s**            Value of the function  
**sp**           Value of the derivative vs  $x$

**scipy.special.pro\_rad2**

`scipy.special.pro_rad2(m, n, c, x) = <ufunc 'pro_rad2'>`

Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.obl\_ang1**

`scipy.special.obl_ang1(m, n, c, x) = <ufunc 'obl_ang1'>`

Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.obl\_rad1**

`scipy.special.obl_rad1(m, n, c, x) = <ufunc 'obl_rad1'>`

Oblate spheroidal radial function of the first kind and its derivative

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.obl\_rad2**

`scipy.special.obl_rad2(m, n, c, x) = <ufunc 'obl_rad2'>`

Oblate spheroidal radial function of the second kind and its derivative.

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.pro\_cv**

`scipy.special.pro_cv(m, n, c) = <ufunc 'pro_cv'>`

Characteristic value of prolate spheroidal function

Computes the characteristic value of prolate spheroidal wave functions of order  $m, n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

### scipy.special.obl\_cv

`scipy.special.obl_cv(m, n, c) = <ufunc 'obl_cv'>`

Characteristic value of oblate spheroidal function

Computes the characteristic value of oblate spheroidal wave functions of order  $m, n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

### scipy.special.pro\_cv\_seq

`scipy.special.pro_cv_seq(m, n, c)`

Characteristic values for prolate spheroidal wave functions.

Compute a sequence of characteristic values for the prolate spheroidal wave functions for mode  $m$  and  $n'=m..n$  and spheroidal parameter  $c$ .

### References

[1]

### scipy.special.obl\_cv\_seq

`scipy.special.obl_cv_seq(m, n, c)`

Characteristic values for oblate spheroidal wave functions.

Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode  $m$  and  $n'=m..n$  and spheroidal parameter  $c$ .

### References

[1]

The following functions require pre-computed characteristic value:

<code>pro_ang1_cv(m, n, c, cv, x)</code>	Prolate spheroidal angular function <code>pro_ang1</code> for pre-computed characteristic value
<code>pro_rad1_cv(m, n, c, cv, x)</code>	Prolate spheroidal radial function <code>pro_rad1</code> for pre-computed characteristic value
<code>pro_rad2_cv(m, n, c, cv, x)</code>	Prolate spheroidal radial function <code>pro_rad2</code> for pre-computed characteristic value
<code>obl_ang1_cv(m, n, c, cv, x)</code>	Oblate spheroidal angular function <code>obl_ang1</code> for pre-computed characteristic value
<code>obl_rad1_cv(m, n, c, cv, x)</code>	Oblate spheroidal radial function <code>obl_rad1</code> for pre-computed characteristic value
<code>obl_rad2_cv(m, n, c, cv, x)</code>	Oblate spheroidal radial function <code>obl_rad2</code> for pre-computed characteristic value

**scipy.special.pro\_ang1\_cv**

`scipy.special.pro_ang1_cv(m, n, c, cv, x) = <ufunc 'pro_ang1_cv'>`

Prolate spheroidal angular function `pro_ang1` for precomputed characteristic value

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.pro\_rad1\_cv**

`scipy.special.pro_rad1_cv(m, n, c, cv, x) = <ufunc 'pro_rad1_cv'>`

Prolate spheroidal radial function `pro_rad1` for precomputed characteristic value

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.pro\_rad2\_cv**

`scipy.special.pro_rad2_cv(m, n, c, cv, x) = <ufunc 'pro_rad2_cv'>`

Prolate spheroidal radial function `pro_rad2` for precomputed characteristic value

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.obl\_ang1\_cv**

`scipy.special.obl_ang1_cv(m, n, c, cv, x) = <ufunc 'obl_ang1_cv'>`

Oblate spheroidal angular function `obl_ang1` for precomputed characteristic value

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

### scipy.special.obl\_rad1\_cv

`scipy.special.obl_rad1_cv(m, n, c, cv, x) = <ufunc 'obl_rad1_cv'>`

Oblate spheroidal radial function `obl_rad1` for precomputed characteristic value

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

### scipy.special.obl\_rad2\_cv

`scipy.special.obl_rad2_cv(m, n, c, cv, x) = <ufunc 'obl_rad2_cv'>`

Oblate spheroidal radial function `obl_rad2` for precomputed characteristic value

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

## Kelvin functions

<code>kelvin(x)</code>	Kelvin functions as complex numbers
<code>kelvin_zeros(nt)</code>	Compute $nt$ zeros of all Kelvin functions.
<code>ber(x[, out])</code>	Kelvin function <code>ber</code> .
<code>bei(x[, out])</code>	Kelvin function <code>bei</code> .
<code>berp(x[, out])</code>	Derivative of the Kelvin function <code>ber</code> .
<code>beip(x[, out])</code>	Derivative of the Kelvin function <code>bei</code> .
<code>ker(x[, out])</code>	Kelvin function <code>ker</code> .
<code>kei(x[, out])</code>	Kelvin function <code>kei</code> .
<code>kerp(x[, out])</code>	Derivative of the Kelvin function <code>ker</code> .
<code>keip(x[, out])</code>	Derivative of the Kelvin function <code>kei</code> .

### scipy.special.kelvin

`scipy.special.kelvin(x) = <ufunc 'kelvin'>`

Kelvin functions as complex numbers

**Returns**

**Be, Ke, Bep, Kep**

The tuple (Be, Ke, Bep, Kep) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at  $x$ . For example, `kelvin(x)[0].real = ber x` and `kelvin(x)[0].imag = bei x` with similar relationships for `ker` and `kei`.

**scipy.special.kelvin\_zeros**

`scipy.special.kelvin_zeros` (*nt*)

Compute *nt* zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length *nt*. The tuple contains the arrays of zeros of (ber, bei, ker, kei, ber', bei', ker', kei').

**References**

[1]

**scipy.special.ber**

`scipy.special.ber` (*x*, *out=None*) = <ufunc 'ber'>

Kelvin function ber.

Defined as

$$\text{ber}(x) = \Re[J_0(xe^{3\pi i/4})]$$

where  $J_0$  is the Bessel function of the first kind of order zero (see [jv](#)). See [dlmf](#) for more details.

**Parameters**

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
 Values of the Kelvin function.

**See also:****bei**

the corresponding real part

**berp**

the derivative of bei

**jv**

Bessel function of the first kind

**References**

[dlmf]

## Examples

It can be expressed using Bessel functions.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).real
array([ 0.98438178,  0.75173418, -0.22138025, -2.56341656])
>>> sc.ber(x)
array([ 0.98438178,  0.75173418, -0.22138025, -2.56341656])
```

## scipy.special.ber

`scipy.special.ber(x, out=None) = <ufunc 'ber'>`  
Kelvin function ber.

Defined as

$$\text{ber}(x) = \Im[J_0(xe^{3\pi i/4})]$$

where  $J_0$  is the Bessel function of the first kind of order zero (see [jv](#)). See [dlmf](#) for more details.

### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
Values of the Kelvin function.

See also:

[ber](#)

the corresponding real part

[beip](#)

the derivative of ber

[jv](#)

Bessel function of the first kind

## References

[\[dlmf\]](#)

## Examples

It can be expressed using Bessel functions.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).imag
array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
>>> sc.bei(x)
array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
```

## scipy.special.berp

`scipy.special.berp(x, out=None) = <ufunc 'berp'>`

Derivative of the Kelvin function ber.

### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
 The values of the derivative of ber.

See also:

[ber](#)

## References

[dlmf]

## scipy.special.beip

`scipy.special.beip(x, out=None) = <ufunc 'beip'>`

Derivative of the Kelvin function bei.

### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
 The values of the derivative of bei.

See also:

[bei](#)

## References

[dlmf]

### scipy.special.ker

`scipy.special.ker(x, out=None) = <ufunc 'ker'>`

Kelvin function `ker`.

Defined as

$$\text{ker}(x) = \Re[K_0(xe^{\pi i/4})]$$

Where  $K_0$  is the modified Bessel function of the second kind (see [kv](#)). See [dlmf] for more details.

#### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
Values of the Kelvin function.

**See also:**

[kei](#)

the corresponding imaginary part

[kerp](#)

the derivative of `ker`

[kv](#)

modified Bessel function of the second kind

## References

[dlmf]

## Examples

It can be expressed using the modified Bessel function of the second kind.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.kv(0, x * np.exp(np.pi * 1j / 4)).real
array([ 0.28670621, -0.04166451, -0.06702923, -0.03617885])
>>> sc.ker(x)
array([ 0.28670621, -0.04166451, -0.06702923, -0.03617885])
```

**scipy.special.kei**

`scipy.special.kei(x, out=None) = <ufunc 'kei'>`  
Kelvin function kei.

Defined as

$$\text{kei}(x) = \Im[K_0(xe^{\pi i/4})]$$

where  $K_0$  is the modified Bessel function of the second kind (see [kv](#)). See [dlmf](#) for more details.

**Parameters**

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
Values of the Kelvin function.

**See also:**

[ker](#)

the corresponding real part

[keip](#)

the derivative of kei

[kv](#)

modified Bessel function of the second kind

**References**

[dlmf](#)

**Examples**

It can be expressed using the modified Bessel function of the second kind.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.kv(0, x * np.exp(np.pi * 1j / 4)).imag
array([-0.49499464, -0.20240007, -0.05112188,  0.0021984 ])
>>> sc.kei(x)
array([-0.49499464, -0.20240007, -0.05112188,  0.0021984 ])
```

### scipy.special.kerp

`scipy.special.kerp(x, out=None) = <ufunc 'kerp'>`

Derivative of the Kelvin function ker.

#### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
 Values of the derivative of ker.

See also:

[ker](#)

### References

[dlmf]

### scipy.special.keip

`scipy.special.keip(x, out=None) = <ufunc 'keip'>`

Derivative of the Kelvin function kei.

#### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
 The values of the derivative of kei.

See also:

[kei](#)

## Combinatorics

---

<code>comb(N, k[, exact, repetition])</code>	The number of combinations of N things taken k at a time.
<code>perm(N, k[, exact])</code>	Permutations of N things taken k at a time, i.e., k-permutations of N.

---

### scipy.special.comb

`scipy.special.comb(N, k, exact=False, repetition=False)`

The number of combinations of N things taken k at a time.

This is often expressed as “N choose k”.

#### Parameters

- N** [int, ndarray] Number of things.
- k** [int, ndarray] Number of elements taken.
- exact** [bool, optional] If *exact* is False, then floating point precision is used, otherwise exact long integer is computed.
- repetition** [bool, optional] If *repetition* is True, then the number of combinations with repetition is computed.

#### Returns

- val** [int, float, ndarray] The total number of combinations.

See also:

#### [binom](#)

Binomial coefficient ufunc

## Notes

- Array arguments accepted only for `exact=False` case.
- If  $N < 0$ , or  $k < 0$ , then 0 is returned.
- If  $k > N$  and `repetition=False`, then 0 is returned.

## Examples

```
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([ 120.,  210.])
>>> comb(10, 3, exact=True)
120
>>> comb(10, 3, exact=True, repetition=True)
220
```

## scipy.special.perm

`scipy.special.perm(N, k, exact=False)`

Permutations of  $N$  things taken  $k$  at a time, i.e.,  $k$ -permutations of  $N$ .

It's also known as “partial permutations”.

### Parameters

<b>N</b>	[int, ndarray] Number of things.
<b>k</b>	[int, ndarray] Number of elements taken.
<b>exact</b>	[bool, optional] If <i>exact</i> is False, then floating point precision is used, otherwise exact long integer is computed.

### Returns

<b>val</b>	[int, ndarray] The number of $k$ -permutations of $N$ .
------------	---

## Notes

- Array arguments accepted only for `exact=False` case.
- If  $k > N$ ,  $N < 0$ , or  $k < 0$ , then a 0 is returned.

## Examples

```
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([ 720., 5040.])
>>> perm(10, 3, exact=True)
720
```

## Lambert W and related functions

<code>lambertw(z[, k, tol])</code>	Lambert W function.
<code>wrightomega(z[, out])</code>	Wright Omega function.

## scipy.special.lambertw

`scipy.special.lambertw(z, k=0, tol=1e-08)`

Lambert W function.

The Lambert W function  $W(z)$  is defined as the inverse function of  $w * \exp(w)$ . In other words, the value of  $W(z)$  is such that  $z = W(z) * \exp(W(z))$  for any complex number  $z$ .

The Lambert W function is a multivalued function with infinitely many branches. Each branch gives a separate solution of the equation  $z = w * \exp(w)$ . Here, the branches are indexed by the integer  $k$ .

### Parameters

<b>z</b>	[array_like] Input argument.
<b>k</b>	[int, optional] Branch index.
<b>tol</b>	[float, optional] Evaluation tolerance.

**Returns**

`w` [array] `w` will have the same shape as `z`.

See also:

**wrightomega**

the Wright Omega function

**Notes**

All branches are supported by `lambertw`:

- `lambertw(z)` gives the principal solution (branch 0)
- `lambertw(z, k)` gives the solution on branch `k`

The Lambert W function has two partially real branches: the principal branch ( $k = 0$ ) is real for real  $z > -1/e$ , and the  $k = -1$  branch is real for  $-1/e < z < 0$ . All branches except  $k = 0$  have a logarithmic singularity at  $z = 0$ .

**Possible issues**

The evaluation can become inaccurate very close to the branch point at  $-1/e$ . In some corner cases, `lambertw` might currently fail to converge, or can end up on the wrong branch.

**Algorithm**

Halley's iteration is used to invert  $w * \exp(w)$ , using a first-order asymptotic approximation ( $O(\log(w))$  or  $O(w)$ ) as the initial estimate.

The definition, implementation and choice of branches is based on [2].

**References**

[1], [2]

**Examples**

The Lambert W function is the inverse of  $w \exp(w)$ :

```
>>> from scipy.special import lambertw
>>> w = lambertw(1)
>>> w
(0.56714329040978384+0j)
>>> w * np.exp(w)
(1.0+0j)
```

Any branch gives a valid inverse:

```
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090377+17.113535539412148j)
>>> w*np.exp(w)
(1.0000000000000002+1.609823385706477e-15j)
```

### Applications to equation-solving

The Lambert W function may be used to solve various kinds of equations, such as finding the value of the infinite power tower  $z^{z^{z^{\dots}}}$ :

```
>>> def tower(z, n):
...     if n == 0:
...         return z
...     return z ** tower(z, n-1)
...
>>> tower(0.5, 100)
0.641185744504986
>>> -lambertw(-np.log(0.5)) / np.log(0.5)
(0.64118574450498589+0j)
```

### scipy.special.wrightomega

`scipy.special.wrightomega(z, out=None) = <ufunc 'wrightomega'>`  
Wright Omega function.

Defined as the solution to

$$\omega + \log(\omega) = z$$

where  $\log$  is the principal branch of the complex logarithm.

#### Parameters

**z** [array\_like] Points at which to evaluate the Wright Omega function

#### Returns

**omega** [ndarray] Values of the Wright Omega function

See also:

#### [lambertw](#)

The Lambert W function

#### Notes

New in version 0.19.0.

The function can also be defined as

$$\omega(z) = W_{K(z)}(e^z)$$

where  $K(z) = \lceil (\Im(z) - \pi)/(2\pi) \rceil$  is the unwinding number and  $W$  is the Lambert W function.

The implementation here is taken from [1].

<code>zetac(x)</code>	Riemann zeta function minus 1.

## scipy.special.agm

`scipy.special.agm(a, b) = <ufunc 'agm'>`

Compute the arithmetic-geometric mean of  $a$  and  $b$ .

Start with  $a_0 = a$  and  $b_0 = b$  and iteratively compute:

$$\begin{aligned} a_{n+1} &= (a_n + b_n) / 2 \\ b_{n+1} &= \text{sqrt}(a_n * b_n) \end{aligned}$$

$a_n$  and  $b_n$  converge to the same limit as  $n$  increases; their common limit is  $\text{agm}(a, b)$ .

### Parameters

**a, b** [array\_like] Real values only. If the values are both negative, the result is negative. If one value is negative and the other is positive, *nan* is returned.

### Returns

**float** The arithmetic-geometric mean of  $a$  and  $b$ .

## Examples

```
>>> from scipy.special import agm
>>> a, b = 24.0, 6.0
>>> agm(a, b)
13.458171481725614
```

Compare that result to the iteration:

```
>>> while a != b:
...     a, b = (a + b)/2, np.sqrt(a*b)
...     print("a = %19.16f  b=%19.16f" % (a, b))
...
a = 15.000000000000000000  b=12.000000000000000000
a = 13.500000000000000000  b=13.4164078649987388
a = 13.4582039324993694  b=13.4581390309909850
a = 13.4581714817451772  b=13.4581714817060547
a = 13.4581714817256159  b=13.4581714817256159
```

When array-like arguments are given, broadcasting applies:

```
>>> a = np.array([[1.5], [3], [6]]) # a has shape (3, 1).
>>> b = np.array([6, 12, 24, 48]) # b has shape (4,).
>>> agm(a, b)
array([[ 3.36454287,  5.42363427,  9.05798751, 15.53650756],
       [ 4.37037309,  6.72908574, 10.84726853, 18.11597502],
       [ 6.          ,  8.74074619, 13.45817148, 21.69453707]])
```

## scipy.special.bernoulli

`scipy.special.bernoulli` ( $n$ )  
Bernoulli numbers  $B_0..B_n$  (inclusive).

## References

[1]

## scipy.special.binom

`scipy.special.binom` ( $n, k$ ) = <ufunc 'binom'>  
Binomial coefficient

**See also:**

### `comb`

The number of combinations of  $N$  things taken  $k$  at a time.

**scipy.special.diric**`scipy.special.diric(x, n)`

Periodic sinc function, also called the Dirichlet function.

The Dirichlet function is defined as:

$$\text{diric}(x, n) = \frac{\sin(x * n/2)}{(n * \sin(x / 2))},$$
where  $n$  is a positive integer.**Parameters**

**x** [array\_like] Input data  
**n** [int] Integer defining the periodicity.

**Returns****diric** [ndarray]**Examples**

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-8*np.pi, 8*np.pi, num=201)
>>> plt.figure(figsize=(8, 8));
>>> for idx, n in enumerate([2, 3, 4, 9]):
...     plt.subplot(2, 2, idx+1)
...     plt.plot(x, special.diric(x, n))
...     plt.title('diric, n={}'.format(n))
>>> plt.show()
```

The following example demonstrates that `diric` gives the magnitudes (modulo the sign and scaling) of the Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```
>>> np.set_printoptions(suppress=True)
```

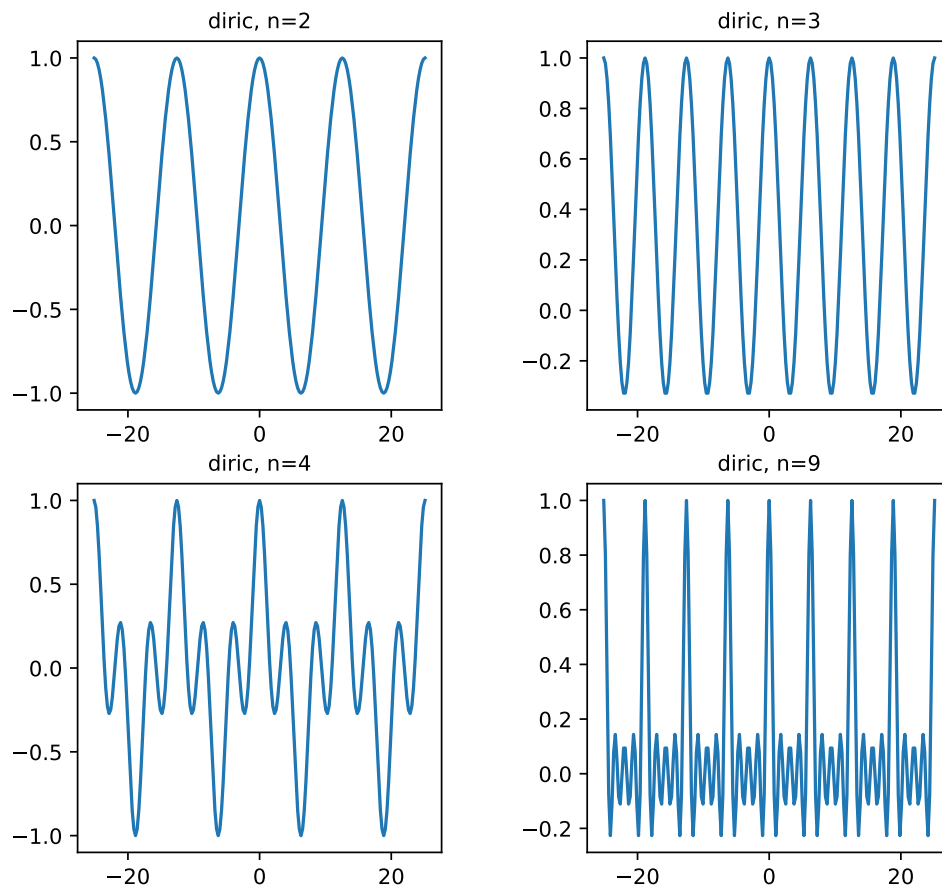

Create a signal  $x$  of length  $m$  with  $k$  ones:

```
>>> m = 8
>>> k = 3
>>> x = np.zeros(m)
>>> x[:k] = 1
```

Use the FFT to compute the Fourier transform of  $x$ , and inspect the magnitudes of the coefficients:

```
>>> np.abs(np.fft.fft(x))
array([ 3.          ,  2.41421356,  1.          ,  0.41421356,  1.          ,
        0.41421356,  1.          ,  2.41421356])
```

Now find the same values (up to sign) using `diric`. We multiply by  $k$  to account for the different scaling conventions of `numpy.fft.fft` and `diric`:

```
>>> theta = np.linspace(0, 2*np.pi, m, endpoint=False)
>>> k * special.diric(theta, k)
array([ 3.          ,  2.41421356,  1.          , -0.41421356, -1.          ,
        -0.41421356,  1.          ,  2.41421356])
```

### scipy.special.euler

scipy.special.euler(*n*)

Euler numbers  $E(0), E(1), \dots, E(n)$ .

The Euler numbers [1] are also known as the secant numbers.

Because `euler(n)` returns floating point values, it does not give exact values for large  $n$ . The first inexact value is  $E(22)$ .

#### Parameters

**n** [int] The highest index of the Euler number to be returned.

#### Returns

**ndarray** The Euler numbers  $[E(0), E(1), \dots, E(n)]$ . The odd Euler numbers, which are all zero, are included.

### References

[1], [2]

### Examples

```
>>> from scipy.special import euler
>>> euler(6)
array([ 1.,  0., -1.,  0.,  5.,  0., -61.])
```

```
>>> euler(13).astype(np.int64)
array([  1,  0, -1,  0,  5,  0, -61,
        0, 1385,  0, -50521,  0, 2702765,  0])
```

```
>>> euler(22)[-1] # Exact value of E(22) is -69348874393137901.
-69348874393137976.0
```

### scipy.special.expn

scipy.special.expn(*n, x, out=None*) = <ufunc 'expn'>

Generalized exponential integral  $E_n$ .

For integer  $n \geq 0$  and real  $x \geq 0$  the generalized exponential integral is defined as [dlmf]

$$E_n(x) = x^{n-1} \int_x^\infty \frac{e^{-t}}{t^n} dt.$$

#### Parameters

**n: array\_like**  
Non-negative integers

**x: array\_like**  
Real argument

**out: ndarray, optional**  
Optional output array for the function results

**Returns**

**scalar or ndarray**  
Values of the generalized exponential integral

**See also:****exp1**

special case of  $E_n$  for  $n = 1$

**exp1**

related to  $E_n$  when  $n = 1$

**References**

[dlmf]

**Examples**

```
>>> import scipy.special as sc
```

Its domain is nonnegative  $n$  and  $x$ .

```
>>> sc.expn(-1, 1.0), sc.expn(1, -1.0)
(nan, nan)
```

It has a pole at  $x = 0$  for  $n = 1, 2$ ; for larger  $n$  it is equal to  $1 / (n - 1)$ .

```
>>> sc.expn([0, 1, 2, 3, 4], 0)
array([          inf,          inf, 1.          , 0.5          , 0.33333333])
```

For  $n$  equal to 0 it reduces to  $\exp(-x) / x$ .

```
>>> x = np.array([1, 2, 3, 4])
>>> sc.expn(0, x)
array([0.36787944, 0.06766764, 0.01659569, 0.00457891])
>>> np.exp(-x) / x
array([0.36787944, 0.06766764, 0.01659569, 0.00457891])
```

For  $n$  equal to 1 it reduces to  $\exp1$ .

```
>>> sc.expn(1, x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

**scipy.special.exp1**

`scipy.special.exp1(z, out=None)` = <ufunc 'exp1'>  
Exponential integral E1.

For complex  $z \neq 0$  the exponential integral can be defined as [1]

$$E_1(z) = \int_z^\infty \frac{e^{-t}}{t} dt,$$

where the path of the integral does not cross the negative real axis or pass through the origin.

**Parameters**

**z:** array\_like  
Real or complex argument.  
**out:** ndarray, optional  
Optional output array for the function results

**Returns**

scalar or ndarray  
Values of the exponential integral E1

**See also:****exp1**

exponential integral  $Ei$

**expn**

generalization of  $E_1$

**Notes**

For  $x > 0$  it is related to the exponential integral  $Ei$  (see `exp1`) via the relation

$$E_1(x) = -Ei(-x).$$

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

It has a pole at 0.

```
>>> sc.exp1(0)
inf
```

It has a branch cut on the negative real axis.

```
>>> sc.exp1(-1)
nan
>>> sc.exp1(complex(-1, 0))
(-1.8951178163559368-3.141592653589793j)
>>> sc.exp1(complex(-1, -0.0))
(-1.8951178163559368+3.141592653589793j)
```

It approaches 0 along the positive real axis.

```
>>> sc.exp1([1, 10, 100, 1000])
array([2.19383934e-01, 4.15696893e-06, 3.68359776e-46, 0.00000000e+00])
```

It is related to `exp1`.

```
>>> x = np.array([1, 2, 3, 4])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> -sc.exp1(-x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

## scipy.special.exp1

`scipy.special.exp1(x, out=None) = <ufunc 'exp1'>`  
Exponential integral  $E_1$ .

For real  $x$ , the exponential integral is defined as [1]

$$E_1(x) = \int_{-\infty}^x \frac{e^t}{t} dt.$$

For  $x > 0$  the integral is understood as a Cauchy principle value.

It is extended to the complex plane by analytic continuation of the function on the interval  $(0, \infty)$ . The complex variant has a branch cut on the negative real axis.

### Parameters

- x: array\_like**  
Real or complex valued argument
- out: ndarray, optional**  
Optional output array for the function results

### Returns

- scalar or ndarray**  
Values of the exponential integral

See also:

### exp1

Exponential integral  $E_1$

### expn

Generalized exponential integral  $E_n$

## Notes

The exponential integrals  $E_1$  and  $Ei$  satisfy the relation

$$E_1(x) = -Ei(-x)$$

for  $x > 0$ .

## References

[1]

## Examples

```
>>> import scipy.special as sc
```

It is related to `exp1`.

```
>>> x = np.array([1, 2, 3, 4])
>>> -sc.expi(-x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

The complex variant has a branch cut on the negative real axis.

```
>>> import scipy.special as sc
>>> sc.expi(-1 + 1e-12j)
(-0.21938393439552062+3.1415926535894254j)
>>> sc.expi(-1 - 1e-12j)
(-0.21938393439552062-3.1415926535894254j)
```

As the complex variant approaches the branch cut, the real parts approach the value of the real variant.

```
>>> sc.expi(-1)
-0.21938393439552062
```

The SciPy implementation returns the real variant for complex values on the branch cut.

```
>>> sc.expi(complex(-1, 0.0))
(-0.21938393439552062-0j)
>>> sc.expi(complex(-1, -0.0))
(-0.21938393439552062-0j)
```

**scipy.special.factorial**`scipy.special.factorial` (*n*, *exact=False*)

The factorial of a number or array of numbers.

The factorial of non-negative integer *n* is the product of all positive integers less than or equal to *n*:

$$n! = n * (n - 1) * (n - 2) * \dots * 1$$

**Parameters**

- n** [int or array\_like of ints] Input values. If  $n < 0$ , the return value is 0.
- exact** [bool, optional] If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the `gamma` function. Default is False.

**Returns**

- nf** [float or int or ndarray] Factorial of *n*, as integer or float depending on *exact*.

**Notes**

For arrays with `exact=True`, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to `int64` or `object` if necessary.

With `exact=False` the factorial is approximated using the gamma function:

$$n! = \Gamma(n + 1)$$

**Examples**

```
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([ 6., 24., 120.])
>>> factorial(arr, exact=True)
array([ 6, 24, 120])
>>> factorial(5, exact=True)
120
```

**scipy.special.factorial2**`scipy.special.factorial2` (*n*, *exact=False*)

Double factorial.

This is the factorial with every second value skipped. E.g.,  $7!! = 7 * 5 * 3 * 1$ . It can be approximated numerically as:

$$\begin{aligned} n!! &= \text{special.gamma}(n/2+1) * 2^{**((m+1)/2)} / \text{sqrt}(\text{pi}) & n \text{ odd} \\ &= 2^{** (n/2)} * (n/2)! & n \text{ even} \end{aligned}$$

**Parameters**

- n** [int or array\_like] Calculate  $n!!$ . Arrays are only supported with *exact* set to False. If  $n < 0$ , the return value is 0.
- exact** [bool, optional] The result can be approximated rapidly using the gamma-formula above (default). If *exact* is set to True, calculate the answer exactly using integer arithmetic.

**Returns**

**nff** [float or int] Double factorial of  $n$ , as an int or a float depending on *exact*.

**Examples**

```
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105
```

**scipy.special.factorialk**

`scipy.special.factorialk` ( $n, k, exact=True$ )

Multifactorial of  $n$  of order  $k$ ,  $n(!!\dots!)$ .

This is the multifactorial of  $n$  skipping  $k$  values. For example,

$$\text{factorialk}(17, 4) = 17!!!! = 17 * 13 * 9 * 5 * 1$$

In particular, for any integer  $n$ , we have

$$\text{factorialk}(n, 1) = \text{factorial}(n)$$

$$\text{factorialk}(n, 2) = \text{factorial2}(n)$$

**Parameters**

**n** [int] Calculate multifactorial. If  $n < 0$ , the return value is 0.  
**k** [int] Order of multifactorial.  
**exact** [bool, optional] If *exact* is set to `True`, calculate the answer exactly using integer arithmetic.

**Returns**

**val** [int] Multifactorial of  $n$ .

**Raises**

**NotImplementedError**  
Raises when *exact* is `False`

**Examples**

```
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120
>>> factorialk(5, 3, exact=True)
10
```

**scipy.special.shichi**

`scipy.special.shichi(x, out=None) = <ufunc 'shichi'>`  
 Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

$$\int_0^x \frac{\sinh t}{t} dt$$

and the hyperbolic cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and  $\log$  is the principle branch of the logarithm.

**Parameters**

**x** [array\_like] Real or complex points at which to compute the hyperbolic sine and cosine integrals.

**Returns**

**si** [ndarray] Hyperbolic sine integral at  $x$   
**ci** [ndarray] Hyperbolic cosine integral at  $x$

**Notes**

For real arguments with  $x < 0$ , `chi` is the real part of the hyperbolic cosine integral. For such points `chi(x)` and `chi(x + 0j)` differ by a factor of  $1j\pi$ .

For real arguments the function is computed by calling Cephes' [1] *shichi* routine. For complex arguments the algorithm is based on Mpmath's [2] *shi* and *chi* routines.

**References**

[1], [2]

**scipy.special.sici**

`scipy.special.sici(x, out=None) = <ufunc 'sici'>`  
 Sine and cosine integrals.

The sine integral is

$$\int_0^x \frac{\sin t}{t} dt$$

and the cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and  $\log$  is the principle branch of the logarithm.

**Parameters**

**x** [array\_like] Real or complex points at which to compute the sine and cosine integrals.

**Returns**

**si** [ndarray] Sine integral at  $x$   
**ci** [ndarray] Cosine integral at  $x$

```
>>> m = softmax(x)
>>> m
array([[ 4.48309e-06,  2.71913e-06,  2.01438e-06,  3.31258e-05],
       [ 4.48309e-06,  6.06720e-07,  1.80861e-03,  3.31258e-05],
       [ 1.21863e-05,  2.68421e-01,  7.29644e-01,  3.31258e-05]])
```

```
>>> m.sum()
1.00000000000000002
```

Compute the softmax transformation along the first axis (i.e., the columns).

```
>>> m = softmax(x, axis=0)
```

```
>>> m
array([[ 2.11942e-01,  1.01300e-05,  2.75394e-06,  3.33333e-01],
       [ 2.11942e-01,  2.26030e-06,  2.47262e-03,  3.33333e-01],
       [ 5.76117e-01,  9.99988e-01,  9.97525e-01,  3.33333e-01]])
```

```
>>> m.sum(axis=0)
array([ 1.,  1.,  1.,  1.])
```

Compute the softmax transformation along the second axis (i.e., the rows).

```
>>> m = softmax(x, axis=1)
>>> m
array([[ 1.05877e-01,  6.42177e-02,  4.75736e-02,  7.82332e-01],
       [ 2.42746e-03,  3.28521e-04,  9.79307e-01,  1.79366e-02],
       [ 1.22094e-05,  2.68929e-01,  7.31025e-01,  3.31885e-05]])
```

```
>>> m.sum(axis=1)
array([ 1.,  1.,  1.])
```

### scipy.special.log\_softmax

`scipy.special.log_softmax(x, axis=None)`

Logarithm of softmax function:

```
log_softmax(x) = log(softmax(x))
```

#### Parameters

- x** [array\_like] Input array.
- axis** [int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array *x*.

#### Returns

- s** [ndarray or scalar] An array with the same shape as *x*. Exponential of the result will sum to 1 along the specified axis. If *x* is a scalar, a scalar is returned.

## Notes

`log_softmax` is more accurate than `np.log(softmax(x))` with inputs that make `softmax` saturate (see examples below).

New in version 1.5.0.

## Examples

```
>>> from scipy.special import log_softmax
>>> from scipy.special import softmax
>>> np.set_printoptions(precision=5)
```

```
>>> x = np.array([1000.0, 1.0])
```

```
>>> y = log_softmax(x)
>>> y
array([ 0., -999.] )
```

```
>>> with np.errstate(divide='ignore') :
...     y = np.log(softmax(x))
...
>>> y
array([ 0., -inf])
```

## scipy.special.spence

`scipy.special.spence(z, out=None) = <ufunc 'spence'>`

Spence's function, also known as the dilogarithm.

It is defined to be

$$\int_0^z \frac{\log(t)}{1-t} dt$$

for complex  $z$ , where the contour of integration is taken to avoid the branch cut of the logarithm. Spence's function is analytic everywhere except the negative real axis where it has a branch cut.

### Parameters

**z** [array\_like] Points at which to evaluate Spence's function

### Returns

**s** [ndarray] Computed values of Spence's function

## Notes

There is a different convention which defines Spence's function by the integral

$$-\int_0^z \frac{\log(1-t)}{t} dt;$$

this is our `spence(1 - z)`.

**scipy.special.zeta**

`scipy.special.zeta` ( $x$ ,  $q=None$ ,  $out=None$ )

Riemann or Hurwitz zeta function.

**Parameters**

**x** [array\_like of float] Input data, must be real  
**q** [array\_like of float, optional] Input data, must be real. Defaults to Riemann zeta.  
**out** [ndarray, optional] Output array for the computed values.

**Returns**

**out** [array\_like] Values of  $\zeta(x)$ .

See also:

[zetac](#)

**Notes**

The two-argument version is the Hurwitz zeta function

$$\zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x};$$

see [\[dlmf\]](#) for details. The Riemann zeta function corresponds to the case when  $q = 1$ .

**References**

[\[dlmf\]](#)

**Examples**

```
>>> from scipy.special import zeta, polygamma, factorial
```

Some specific values:

```
>>> zeta(2), np.pi**2/6
(1.6449340668482266, 1.6449340668482264)
```

```
>>> zeta(4), np.pi**4/90
(1.0823232337111381, 1.082323233711138)
```

Relation to the *polygamma* function:

```
>>> m = 3
>>> x = 1.25
>>> polygamma(m, x)
array(2.782144009188397)
>>> (-1)**(m+1) * factorial(m) * zeta(m+1, x)
2.7821440091883969
```

**scipy.special.zetac**

`scipy.special.zetac(x)` = <ufunc 'zetac'>  
Riemann zeta function minus 1.

This function is defined as

$$\zeta(x) = \sum_{k=2}^{\infty} 1/k^x,$$

where  $x > 1$ . For  $x < 1$  the analytic continuation is computed. For more information on the Riemann zeta function, see [dlmf].

**Parameters**

**x** [array\_like of float] Values at which to compute  $\zeta(x) - 1$  (must be real).

**Returns**

**out** [array\_like] Values of  $\zeta(x) - 1$ .

See also:

[zeta](#)

**References**

[dlmf]

**Examples**

```
>>> from scipy.special import zetac, zeta
```

Some special values:

```
>>> zetac(2), np.pi**2/6 - 1
(0.64493406684822641, 0.6449340668482264)
```

```
>>> zetac(-1), -1.0/12 - 1
(-1.0833333333333333, -1.0833333333333333)
```

Compare `zetac(x)` to `zeta(x) - 1` for large  $x$ :

```
>>> zetac(60), zeta(60) - 1
(8.673617380119933e-19, 0.0)
```

## Convenience functions

<code>cbrt(x)</code>	Element-wise cube root of $x$ .
<code>exp10(x)</code>	Compute $10^{**x}$ element-wise.
<code>exp2(x)</code>	Compute $2^{**x}$ element-wise.
<code>radian(d, m, s[, out])</code>	Convert from degrees to radians.
<code>cosdg(x[, out])</code>	Cosine of the angle $x$ given in degrees.
<code>sindg(x[, out])</code>	Sine of the angle $x$ given in degrees.
<code>tandg(x[, out])</code>	Tangent of angle $x$ given in degrees.
<code>cotdg(x[, out])</code>	Cotangent of the angle $x$ given in degrees.
<code>log1p(x[, out])</code>	Calculates $\log(1 + x)$ for use when $x$ is near zero.
<code>expm1(x)</code>	Compute $\exp(x) - 1$ .
<code>cosm1(x[, out])</code>	$\cos(x) - 1$ for use when $x$ is near zero.
<code>round(x[, out])</code>	Round to the nearest integer.
<code>xlogy(x, y)</code>	Compute $x \cdot \log(y)$ so that the result is 0 if $x = 0$ .
<code>xlog1py(x, y)</code>	Compute $x \cdot \log_{1p}(y)$ so that the result is 0 if $x = 0$ .
<code>logsumexp(a[, axis, b, keepdims, return_sign])</code>	Compute the log of the sum of exponentials of input elements.
<code>exprel(x)</code>	Relative error exponential, $(\exp(x) - 1) / x$ .
<code>sinc(x)</code>	Return the normalized sinc function.

### scipy.special.cbirt

`scipy.special.cbirt(x) = <ufunc 'cbirt'>`  
Element-wise cube root of  $x$ .

#### Parameters

**x** [array\_like]  $x$  must contain real numbers.

#### Returns

**float** The cube root of each value in  $x$ .

### Examples

```
>>> from scipy.special import cbirt
```

```
>>> cbirt(8)
2.0
>>> cbirt([-8, -3, 0.125, 1.331])
array([-2.          , -1.44224957,  0.5          ,  1.1          ])
```

### scipy.special.exp10

`scipy.special.exp10(x) = <ufunc 'exp10'>`  
Compute  $10^{**x}$  element-wise.

#### Parameters

**x** [array\_like]  $x$  must contain real numbers.

#### Returns

**float**  $10^{**x}$ , computed element-wise.

## Examples

```
>>> from scipy.special import exp10
```

```
>>> exp10(3)
1000.0
>>> x = np.array([[ -1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp10(x)
array([[ 0.1          ,  0.31622777,  1.          ],
       [ 3.16227766, 10.          , 31.6227766 ]])
```

## scipy.special.exp2

`scipy.special.exp2(x) = <ufunc 'exp2'>`

Compute  $2^{**x}$  element-wise.

### Parameters

**x** [array\_like] x must contain real numbers.

### Returns

**float**  $2^{**x}$ , computed element-wise.

## Examples

```
>>> from scipy.special import exp2
```

```
>>> exp2(3)
8.0
>>> x = np.array([[ -1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp2(x)
array([[ 0.5          ,  0.70710678,  1.          ],
       [ 1.41421356,  2.          ,  2.82842712 ]])
```

## scipy.special.radians

`scipy.special.radians(d, m, s, out=None) = <ufunc 'radians'>`

Convert from degrees to radians.

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.

### Parameters

**d** [array\_like] Degrees, can be real-valued.

**m** [array\_like] Minutes, can be real-valued.

**s** [array\_like] Seconds, can be real-valued.

**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**

Values of the inputs in radians.

## Examples

```
>>> import scipy.special as sc
```

There are many ways to specify an angle.

```
>>> sc.radian(90, 0, 0)
1.5707963267948966
>>> sc.radian(0, 60 * 90, 0)
1.5707963267948966
>>> sc.radian(0, 0, 60**2 * 90)
1.5707963267948966
```

The inputs can be real-valued.

```
>>> sc.radian(1.5, 0, 0)
0.02617993877991494
>>> sc.radian(1, 30, 0)
0.02617993877991494
```

## scipy.special.cosdg

`scipy.special.cosdg(x, out=None) = <ufunc 'cosdg'>`

Cosine of the angle  $x$  given in degrees.

### Parameters

**x** [array\_like] Angle, given in degrees.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
 Cosine of the input.

See also:

[sindg](#), [tandg](#), [cotdg](#)

## Examples

```
>>> import scipy.special as sc
```

It is more accurate than using cosine directly.

```
>>> x = 90 + 180 * np.arange(3)
>>> sc.cosdg(x)
array([-0.,  0., -0.])
>>> np.cos(x * np.pi / 180)
array([ 6.1232340e-17, -1.8369702e-16,  3.0616170e-16])
```

**scipy.special.sindg**

`scipy.special.sindg(x, out=None) = <ufunc 'sindg'>`  
Sine of the angle  $x$  given in degrees.

**Parameters**

**x** [array\_like] Angle, given in degrees.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
Sine at the input.

See also:

[cosdg](#), [tandg](#), [cotdg](#)

**Examples**

```
>>> import scipy.special as sc
```

It is more accurate than using sine directly.

```
>>> x = 180 * np.arange(3)
>>> sc.sindg(x)
array([ 0., -0.,  0.])
>>> np.sin(x * np.pi / 180)
array([ 0.0000000e+00,  1.2246468e-16, -2.4492936e-16])
```

**scipy.special.tandg**

`scipy.special.tandg(x, out=None) = <ufunc 'tandg'>`  
Tangent of angle  $x$  given in degrees.

**Parameters**

**x** [array\_like] Angle, given in degrees.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
Tangent at the input.

See also:

[sindg](#), [cosdg](#), [cotdg](#)

## Examples

```
>>> import scipy.special as sc
```

It is more accurate than using tangent directly.

```
>>> x = 180 * np.arange(3)
>>> sc.tandg(x)
array([0., 0., 0.])
>>> np.tan(x * np.pi / 180)
array([ 0.0000000e+00, -1.2246468e-16, -2.4492936e-16])
```

## scipy.special.cotdg

`scipy.special.cotdg(x, out=None) = <ufunc 'cotdg'>`

Cotangent of the angle  $x$  given in degrees.

### Parameters

**x** [array\_like] Angle, given in degrees.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
 Cotangent at the input.

See also:

[sindg](#), [cosdg](#), [tandg](#)

## Examples

```
>>> import scipy.special as sc
```

It is more accurate than using cotangent directly.

```
>>> x = 90 + 180 * np.arange(3)
>>> sc.cotdg(x)
array([0., 0., 0.])
>>> 1 / np.tan(x * np.pi / 180)
array([6.1232340e-17, 1.8369702e-16, 3.0616170e-16])
```

## scipy.special.log1p

`scipy.special.log1p(x, out=None) = <ufunc 'log1p'>`

Calculates  $\log(1 + x)$  for use when  $x$  is near zero.

### Parameters

**x** [array\_like] Real or complex valued input.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
 Values of  $\log(1 + x)$ .

See also:

`expm1`, `cosm1`

## Examples

```
>>> import scipy.special as sc
```

It is more accurate than using  $\log(1 + x)$  directly for  $x$  near 0. Note that in the below example  $1 + 1e-17 == 1$  to double precision.

```
>>> sc.log1p(1e-17)
1e-17
>>> np.log(1 + 1e-17)
0.0
```

## `scipy.special.expm1`

`scipy.special.expm1(x) = <ufunc 'expm1'>`  
 Compute  $\exp(x) - 1$ .

When  $x$  is near zero,  $\exp(x)$  is near 1, so the numerical calculation of  $\exp(x) - 1$  can suffer from catastrophic loss of precision. `expm1(x)` is implemented to avoid the loss of precision that occurs when  $x$  is near zero.

### Parameters

**x** [array\_like]  $x$  must contain real numbers.

### Returns

**float**  $\exp(x) - 1$  computed element-wise.

## Examples

```
>>> from scipy.special import expm1
```

```
>>> expm1(1.0)
1.7182818284590451
>>> expm1([-0.2, -0.1, 0, 0.1, 0.2])
array([-0.18126925, -0.09516258, 0.          , 0.10517092, 0.22140276])
```

The exact value of  $\exp(7.5e-13) - 1$  is:

```
7.5000000000028125000000007031250000001318...*10**-13.
```

Here is what `expm1(7.5e-13)` gives:

```
>>> expm1(7.5e-13)
7.5000000000028135e-13
```

Compare that to  $\exp(7.5e-13) - 1$ , where the subtraction results in a “catastrophic” loss of precision:

```
>>> np.exp(7.5e-13) - 1
7.5006667543675576e-13
```

**scipy.special.cosm1**

`scipy.special.cosm1(x, out=None) = <ufunc 'cosm1'>`  
`cos(x) - 1` for use when  $x$  is near zero.

**Parameters**

**x** [array\_like] Real valued argument.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
 Values of  $\cos(x) - 1$ .

See also:

[expm1](#), [log1p](#)

**Examples**

```
>>> import scipy.special as sc
```

It is more accurate than computing  $\cos(x) - 1$  directly for  $x$  around 0.

```
>>> x = 1e-30
>>> np.cos(x) - 1
0.0
>>> sc.cosm1(x)
-5.0000000000000005e-61
```

**scipy.special.round**

`scipy.special.round(x, out=None) = <ufunc 'round'>`  
 Round to the nearest integer.

Returns the nearest integer to  $x$ . If  $x$  ends in 0.5 exactly, the nearest even integer is chosen.

**Parameters**

**x** [array\_like] Real valued input.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
 The nearest integers to the elements of  $x$ . The result is of floating type, not integer type.

**Examples**

```
>>> import scipy.special as sc
```

It rounds to even.

```
>>> sc.round([0.5, 1.5])
array([0., 2.])
```

### scipy.special.xlogy

`scipy.special.xlogy(x, y) = <ufunc 'xlogy'>`  
 Compute  $x \cdot \log(y)$  so that the result is 0 if  $x = 0$ .

#### Parameters

**x** [array\_like] Multiplier  
**y** [array\_like] Argument

#### Returns

**z** [array\_like] Computed  $x \cdot \log(y)$

#### Notes

New in version 0.13.0.

### scipy.special.xlog1py

`scipy.special.xlog1py(x, y) = <ufunc 'xlog1py'>`  
 Compute  $x \cdot \log_1p(y)$  so that the result is 0 if  $x = 0$ .

#### Parameters

**x** [array\_like] Multiplier  
**y** [array\_like] Argument

#### Returns

**z** [array\_like] Computed  $x \cdot \log_1p(y)$

#### Notes

New in version 0.13.0.

### scipy.special.logsumexp

`scipy.special.logsumexp(a, axis=None, b=None, keepdims=False, return_sign=False)`  
 Compute the log of the sum of exponentials of input elements.

#### Parameters

**a** [array\_like] Input array.  
**axis** [None or int or tuple of ints, optional] Axis or axes over which the sum is taken. By default *axis* is None, and all elements are summed.  
 New in version 0.11.0.  
**keepdims** [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.  
 New in version 0.15.0.  
**b** [array-like, optional] Scaling factor for  $\exp(a)$  must be of the same shape as *a* or broadcastable to *a*. These values may be negative in order to implement subtraction.  
 New in version 0.12.0.  
**return\_sign** [bool, optional] If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).  
 New in version 0.16.0.

#### Returns

**res** [ndarray] The result, `np.log(np.sum(np.exp(a)))` calculated in a numerically more stable way. If *b* is given then `np.log(np.sum(b*np.exp(a)))` is returned.

**sgn** [ndarray] If `return_sign` is `True`, this will be an array of floating-point numbers matching `res` and `+1`, `0`, or `-1` depending on the sign of the result. If `False`, only one result is returned.

See also:

`numpy.logaddexp`, `numpy.logaddexp2`

## Notes

NumPy has a `logaddexp` function which is very similar to `logsumexp`, but only handles two arguments. `logaddexp.reduce` is similar to this function, but may be less stable.

## Examples

```
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.4586297444267107
>>> logsumexp(a)
9.4586297444267107
```

With weights

```
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
9.9170178533034665
>>> np.log(np.sum(b*np.exp(a)))
9.9170178533034647
```

Returning a sign flag

```
>>> logsumexp([1, 2], b=[1, -1], return_sign=True)
(1.5413248546129181, -1.0)
```

Notice that `logsumexp` does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
...                 mask=[False, True, False])
>>> b = (~a.mask).astype(int)
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005
```

### scipy.special.exprel

`scipy.special.exprel(x)` = <ufunc 'exprel'>

Relative error exponential,  $(\exp(x) - 1)/x$ .

When  $x$  is near zero,  $\exp(x)$  is near 1, so the numerical calculation of  $\exp(x) - 1$  can suffer from catastrophic loss of precision. `exprel(x)` is implemented to avoid the loss of precision that occurs when  $x$  is near zero.

#### Parameters

**x** [ndarray] Input array.  $x$  must contain real numbers.

#### Returns

**float**  $(\exp(x) - 1)/x$ , computed element-wise.

See also:

[expm1](#)

#### Notes

New in version 0.17.0.

#### Examples

```
>>> from scipy.special import exprel
```

```
>>> exprel(0.01)
1.0050167084168056
>>> exprel([-0.25, -0.1, 0, 0.1, 0.25])
array([ 0.88479687,  0.95162582,  1.          ,  1.05170918,  1.13610167])
```

Compare `exprel(5e-9)` to the naive calculation. The exact value is `1.000000002500000000416...`

```
>>> exprel(5e-9)
1.0000000025
```

```
>>> (np.exp(5e-9) - 1)/5e-9
0.99999999392252903
```

### scipy.special.sinc

`scipy.special.sinc(x)`

Return the normalized sinc function.

The sinc function is  $\sin(\pi x)/(\pi x)$ .

---

**Note:** Note the normalization factor of `pi` used in the definition. This is the most commonly used definition in signal processing. Use `sinc(x / np.pi)` to obtain the unnormalized sinc function  $\sin(x)/x$  that is more common in mathematics.

---

#### Parameters

**x** [ndarray] Array (possibly multi-dimensional) of values for which to calculate `sinc(x)`.

**Returns**

**out** [ndarray] `sinc(x)`, which has the same shape as the input.

**Notes**

`sinc(0)` is the limit value 1.

The name `sinc` is short for “sine cardinal” or “sinus cardinalis”.

The `sinc` function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the `sinc` function.

```

## 6.29 Statistical functions (`scipy.stats`)

This module contains a large number of probability distributions as well as a growing library of statistical functions.

Each univariate distribution is an instance of a subclass of `rv_continuous` (`rv_discrete` for discrete distributions):

<code>rv_continuous</code> ([momtype, a, b, xtol, ...])	A generic continuous random variable class meant for subclassing.
<code>rv_discrete</code> ([a, b, name, badvalue, ...])	A generic discrete random variable class meant for subclassing.
<code>rv_histogram</code> (histogram, *args, **kwargs)	Generates a distribution given by a histogram.

### 6.29.1 `scipy.stats.rv_continuous`

**class** `scipy.stats.rv_continuous` (*momtype=1, a=None, b=None, xtol=1e-14, badvalue=None, name=None, longname=None, shapes=None, extradoc=None, seed=None*)

A generic continuous random variable class meant for subclassing.

`rv_continuous` is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

#### Parameters

<b>momtype</b>	[int, optional] The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.
<b>a</b>	[float, optional] Lower bound of the support of the distribution, default is minus infinity.
<b>b</b>	[float, optional] Upper bound of the support of the distribution, default is plus infinity.
<b>xtol</b>	[float, optional] The tolerance for fixed point calculation for generic ppf.
<b>badvalue</b>	[float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is <code>np.nan</code> .
<b>name</b>	[str, optional] The name of the instance. This string is used to construct the default example for distributions.
<b>longname</b>	[str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: <code>longname</code> exists for backwards compatibility, do not use for new subclasses.
<b>shapes</b>	[str, optional] The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, <code>_pdf</code> and <code>_cdf</code> of the instance.
<b>extradoc</b>	[str, optional, deprecated] This string is used as the last part of the docstring returned when

## Notes

Public methods of an instance of a distribution class (e.g., `pdf`, `cdf`) check their arguments and pass valid arguments to private, computational methods (`_pdf`, `_cdf`). For `pdf(x)`, `x` is valid if it is within the support of the distribution. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.)

## Subclassing

New random variables can be defined by subclassing the `rv_continuous` class and re-defining at least the `_pdf` or the `_cdf` method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the `_argcheck` method.

For most of the `scipy.stats` distributions, the support interval doesn't depend on the shape parameters. `x` being in the support interval is equivalent to `self.a <= x <= self.b`. If either of the endpoints of the support do depend on the shape parameters, then i) the distribution must implement the `_get_support` method; and ii) those dependent endpoints must be omitted from the distribution's call to the `rv_continuous` initializer.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can override:

```
_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf
```

The default method `_rvs` relies on the inverse of the cdf, `_ppf`, applied to a uniform random variate. In order to generate random variates efficiently, either the default `_ppf` needs to be overwritten (e.g. if the inverse cdf can be expressed in an explicit form) or a sampling method needs to be implemented in a custom `_rvs` method.

If possible, you should override `_isf`, `_sf` or `_logsf`. The main reason would be to improve numerical accuracy: for example, the survival function `_sf` is computed as `1 - _cdf` which can result in loss of precision if `_cdf(x)` is close to one.

## Methods that can be overwritten by subclasses

```
_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
_get_support
```

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.

A note on `shapes`: subclasses need not specify them explicitly. In this case, `shapes` will be automatically deduced from the signatures of the overridden methods (`pdf`, `cdf` etc). If, for some reason, you prefer to avoid relying on introspection, you can specify `shapes` explicitly as an argument to the instance constructor.

## Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters to each call of a method of a distribution.

Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a “frozen” continuous RV object:

`rv = generic(<shape(s)>, loc=0, scale=1)`

`rv_frozen` object with the same methods but holding the given shape, location, and scale fixed

### Statistics

Statistics are computed using numerical integration by default. For speed you can redefine this using `_stats`:

- take shape parameters and return `mu, mu2, g1, g2`
- If you can’t compute one of these, return it as `None`
- Can also be defined with a keyword argument `moments`, which is a string composed of “m”, “v”, “s”, and/or “k”. Only the components appearing in string should be computed and returned in the order “m”, “v”, “s”, or “k” with missing values returned as `None`.

Alternatively, you can override `_munp`, which takes `n` and shape parameters and returns the `n`-th non-central moment of the distribution.

### Examples

To create a new Gaussian distribution, we would do the following:

```
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
...     "Gaussian distribution"
...     def _pdf(self, x):
...         return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

`scipy.stats` distributions are *instances*, so here we subclass `rv_continuous` and create an instance. With this, we now have a fully functional distribution with all relevant methods automatically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using `loc` and `scale` parameters: `gaussian.pdf(x, loc, scale)` essentially computes  $y = (x - loc) / scale$  and `gaussian._pdf(y) / scale`.

#### Attributes

##### `random_state`

Get or set the `RandomState` object for generating random variates.

### Methods

<code>rvs(self, *args, **kwargs)</code>	Random variates of given type.
<code>pdf(self, x, *args, **kwargs)</code>	Probability density function at <code>x</code> of the given RV.
<code>logpdf(self, x, *args, **kwargs)</code>	Log of the probability density function at <code>x</code> of the given RV.
<code>cdf(self, x, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>logcdf(self, x, *args, **kwargs)</code>	Log of the cumulative distribution function at <code>x</code> of the given RV.
<code>sf(self, x, *args, **kwargs)</code>	Survival function ( $1 - cdf$ ) at <code>x</code> of the given RV.
<code>logsf(self, x, *args, **kwargs)</code>	Log of the survival function of the given RV.

continues on next page

Table 255 – continued from previous page

<code>ppf(self, q, *args, **kwargs)</code>	Percent point function (inverse of <code>cdf</code> ) at <code>q</code> of the given RV.
<code>isf(self, q, *args, **kwargs)</code>	Inverse survival function (inverse of <code>sf</code> ) at <code>q</code> of the given RV.
<code>moment(self, n, *args, **kwargs)</code>	<code>n</code> -th order non-central moment of distribution.
<code>stats(self, *args, **kwargs)</code>	Some statistics of the given RV.
<code>entropy(self, *args, **kwargs)</code>	Differential entropy of the RV.
<code>expect(self[, func, args, loc, scale, lb, ...])</code>	Calculate expected value of a function with respect to the distribution by numerical integration.
<code>median(self, *args, **kwargs)</code>	Median of the distribution.
<code>mean(self, *args, **kwargs)</code>	Mean of the distribution.
<code>std(self, *args, **kwargs)</code>	Standard deviation of the distribution.
<code>var(self, *args, **kwargs)</code>	Variance of the distribution.
<code>interval(self, alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>__call__(self, *args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>fit(self, data, *args, **kwargs)</code>	Return MLEs for shape (if applicable), location, and scale parameters from data.
<code>fit_loc_scale(self, data, *args)</code>	Estimate loc and scale parameters from data using 1st and 2nd moments.
<code>nllf(self, theta, x)</code>	Return negative loglikelihood function.
<code>support(self, *args, **kwargs)</code>	Return the support of the distribution.

**scipy.stats.rv\_continuous.rvs**

`rv_continuous.rvs(self, *args, **kwargs)`  
Random variates of given type.

**Parameters****arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional] Scale parameter (default=1).

**size** [int or tuple of ints, optional] Defining number of random variates (default is 1).

**random\_state**

[{None, int, `RandomState`, `Generator`}, optional] If `seed` is `None` the `RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `RandomState` or `Generator` instance, then that object is used. Default is `None`.

**Returns**

**rvs** [ndarray or scalar] Random variates of given `size`.

**scipy.stats.rv\_continuous.pdf**`rv_continuous.pdf` (*self*, *x*, \*args, \*\*kwargs)Probability density function at *x* of the given RV.**Parameters**

<b>x</b>	[array_like] quantiles
<b>arg1, arg2, arg3,...</b>	[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
<b>loc</b>	[array_like, optional] location parameter (default=0)
<b>scale</b>	[array_like, optional] scale parameter (default=1)

**Returns**

<b>pdf</b>	[ndarray] Probability density function evaluated at <i>x</i>
------------	--

**scipy.stats.rv\_continuous.logpdf**`rv_continuous.logpdf` (*self*, *x*, \*args, \*\*kwargs)Log of the probability density function at *x* of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters**

<b>x</b>	[array_like] quantiles
<b>arg1, arg2, arg3,...</b>	[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
<b>loc</b>	[array_like, optional] location parameter (default=0)
<b>scale</b>	[array_like, optional] scale parameter (default=1)

**Returns**

<b>logpdf</b>	[array_like] Log of the probability density function evaluated at <i>x</i>
---------------	--

**scipy.stats.rv\_continuous.cdf**`rv_continuous.cdf` (*self*, *x*, \*args, \*\*kwargs)

Cumulative distribution function of the given RV.

**Parameters**

<b>x</b>	[array_like] quantiles
<b>arg1, arg2, arg3,...</b>	[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
<b>loc</b>	[array_like, optional] location parameter (default=0)
<b>scale</b>	[array_like, optional] scale parameter (default=1)

**Returns**

<b>cdf</b>	[ndarray] Cumulative distribution function evaluated at <i>x</i>
------------	--

**scipy.stats.rv\_continuous.logcdf**

`rv_continuous.logcdf` (*self*, *x*, \*args, \*\*kwargs)

Log of the cumulative distribution function at *x* of the given RV.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logcdf** [array\_like] Log of the cumulative distribution function evaluated at *x*

**scipy.stats.rv\_continuous.sf**

`rv_continuous.sf` (*self*, *x*, \*args, \*\*kwargs)

Survival function ( $1 - cdf$ ) at *x* of the given RV.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**sf** [array\_like] Survival function evaluated at *x*

**scipy.stats.rv\_continuous.logsf**

`rv_continuous.logsf` (*self*, *x*, \*args, \*\*kwargs)

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as  $(1 - cdf)$ , evaluated at *x*.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logsf** [ndarray] Log of the survival function evaluated at *x*.

**scipy.stats.rv\_continuous.ppf**`rv_continuous.ppf` (*self*, *q*, \**args*, \*\**kwargs*)Percent point function (inverse of *cdf*) at *q* of the given RV.**Parameters**

**q** [array\_like] lower tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [array\_like] quantile corresponding to the lower tail probability *q*.

**scipy.stats.rv\_continuous.isf**`rv_continuous.isf` (*self*, *q*, \**args*, \*\**kwargs*)Inverse survival function (inverse of *sf*) at *q* of the given RV.**Parameters**

**q** [array\_like] upper tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [ndarray or scalar] Quantile corresponding to the upper tail probability *q*.

**scipy.stats.rv\_continuous.moment**`rv_continuous.moment` (*self*, *n*, \**args*, \*\**kwargs*)*n*-th order non-central moment of distribution.**Parameters**

**n** [int, *n* >= 1] Order of moment.  
**arg1, arg2, arg3,...** [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**scipy.stats.rv\_continuous.stats**

`rv_continuous.stats` (*self*, \*args, \*\*kwargs)  
Some statistics of the given RV.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)

**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns**

**stats** [sequence] of requested moments.

**scipy.stats.rv\_continuous.entropy**

`rv_continuous.entropy` (*self*, \*args, \*\*kwargs)  
Differential entropy of the RV.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional (continuous distributions only).] Scale parameter (default=1).

**Notes**

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

**scipy.stats.rv\_continuous.expect**

`rv_continuous.expect` (*self*, func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, \*\*kwargs)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[f(x)] = \int_{lb}^{ub} f(x) * dist.pdf(x),$$

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of `f(x)`. Also, the function `f(x)` may be defined such that `f(x)` is 0 outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

#### Parameters

**func** [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping `f(x) = x`.

**args** [tuple, optional] Shape parameters of the distribution.

**loc** [float, optional] Location parameter (default=0).

**scale** [float, optional] Scale parameter (default=1).

**lb, ub** [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.

**conditional** [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

**Additional keyword arguments are passed to the integration routine.**

#### Returns

**expect** [float] The calculated expected value.

#### Notes

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

The function is not vectorized.

#### Examples

To understand the effect of the bounds of integration consider

```
>>> from scipy.stats import expon
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

**scipy.stats.rv\_continuous.median**

`rv_continuous.median` (*self*, \*args, \*\*kwargs)  
Median of the distribution.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] Location parameter, Default is 0.

**scale** [array\_like, optional] Scale parameter, Default is 1.

**Returns**

**median** [float] The median of the distribution.

See also:

`rv_discrete.ppf`

Inverse of the CDF

**scipy.stats.rv\_continuous.mean**

`rv_continuous.mean` (*self*, \*args, \*\*kwargs)  
Mean of the distribution.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**mean** [float] the mean of the distribution

**scipy.stats.rv\_continuous.std**

`rv_continuous.std` (*self*, \*args, \*\*kwargs)  
Standard deviation of the distribution.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**std** [float] standard deviation of the distribution

### scipy.stats.rv\_continuous.var

`rv_continuous.var` (*self*, \*args, \*\*kwargs)  
 Variance of the distribution.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**var** [float] the variance of the distribution

### scipy.stats.rv\_continuous.interval

`rv_continuous.interval` (*self*, alpha, \*args, \*\*kwargs)  
 Confidence interval with equal areas around the median.

#### Parameters

**alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

**arg1, arg2, ...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

#### Returns

**a, b** [ndarray of float] end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

### scipy.stats.rv\_continuous.\_\_call\_\_

`rv_continuous.__call__` (*self*, \*args, \*\*kwargs)  
 Freeze the distribution for the given arguments.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

#### Returns

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

## scipy.stats.rv\_continuous.fit

`rv_continuous.fit` (*self*, *data*, \**args*, \*\**kwargs*)

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

### Parameters

**data** [array\_like] Data to use in calculating the MLEs.

**arg1, arg2, arg3,...**

[floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

**kwargs** [floats, optional]

- *loc*: initial guess of the distribution's location parameter.

- *scale*: initial guess of the distribution's scale parameter.

Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.

- `floc` : hold location parameter fixed to specified value.

- `fscale` : hold scale parameter fixed to specified value.

- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

### Returns

**mle\_tuple** [tuple of floats] MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

## Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether. If the data contain any of `np.nan`, `np.inf`, or `-np.inf`, the fit routine will throw a `RuntimeError`.

## Examples

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (*a*, *b*, *loc* and *scale*):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

### `scipy.stats.rv_continuous.fit_loc_scale`

`rv_continuous.fit_loc_scale` (*self*, *data*, \**args*)

Estimate `loc` and `scale` parameters from data using 1st and 2nd moments.

#### *Parameters*

**data** [array\_like] Data to fit.

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

#### *Returns*

**Lhat** [float] Estimated location parameter for the data.

**Shat** [float] Estimated scale parameter for the data.

### `scipy.stats.rv_continuous.nllf`

`rv_continuous.nllf` (*self*, *theta*, *x*)

Return negative loglikelihood function.

#### **Notes**

This is  $-\text{sum}(\log \text{pdf}(x, \text{theta}), \text{axis}=0)$  where *theta* are the parameters (including `loc` and `scale`).

**scipy.stats.rv\_continuous.support**

`rv_continuous.support` (*self*, \*args, \*\*kwargs)

Return the support of the distribution.

*Parameters*

**arg1, arg2, ...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [float] end-points of the distribution's support.

**6.29.2 scipy.stats.rv\_discrete**

**class** `scipy.stats.rv_discrete` (*a=0, b=inf, name=None, badvalue=None, moment\_tol=1e-08, values=None, inc=1, longname=None, shapes=None, extradoc=None, seed=None*)

A generic discrete random variable class meant for subclassing.

`rv_discrete` is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

*Parameters*

**a** [float, optional] Lower bound of the support of the distribution, default: 0

**b** [float, optional] Upper bound of the support of the distribution, default: plus infinity

**moment\_tol**

[float, optional] The tolerance for the generic calculation of moments.

**values** [tuple of two array\_like, optional] ( $x_k, p_k$ ) where  $x_k$  are integers and  $p_k$  are the non-zero probabilities between 0 and 1 with  $\sum(p_k) = 1$ .  $x_k$  and  $p_k$  must have the same shape.

**inc** [integer, optional] Increment for the support of the distribution. Default is 1. (other values have not been tested)

**badvalue** [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is `np.nan`.

**name** [str, optional] The name of the instance. This string is used to construct the default example for distributions.

**longname** [str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: *longname* exists for backwards compatibility, do not use for new subclasses.

**shapes** [str, optional] The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signatures of the private methods, `_pmf` and `_cdf` of the instance.

**extradoc** [str, optional] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: *extradoc* exists for backwards compatibility, do not use for new subclasses.

**seed** [{None, int, *RandomState*, *Generator*}, optional] This parameter defines the object to use for drawing random variates. If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*.

## Notes

This class is similar to `rv_continuous`. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.) The main differences are:

- the support of the distribution is a set of integers
- instead of the probability density function, `pdf` (and the corresponding private `_pdf`), this class defines the *probability mass function*, `pmf` (and the corresponding private `_pmf`.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
...     "Poisson distribution"
...     def _pmf(self, k, mu):
...         return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the `loc` parameter to the methods of the instance. For example, `poisson.pmf(x, mu, loc)` delegates the work to `poisson._pmf(x-loc, mu)`.

### Discrete distributions from a list of probabilities

Alternatively, you can construct an arbitrary discrete rv defined on a finite set of values `xk` with  $\text{Prob}\{X=x_k\} = p_k$  by using the `values` keyword argument to the `rv_discrete` constructor.

## Examples

Custom made discrete distribution:

```
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.1, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
>>>
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
>>> ax.plot(xk, custm.pmf(xk), 'ro', ms=12, mec='r')
>>> ax.vlines(xk, 0, custm.pmf(xk), colors='r', lw=4)
>>> plt.show()
```

Random number generation:

```
>>> R = custm.rvs(size=100)
```

### Attributes

#### `random_state`

Get or set the `RandomState` object for generating random variates.

## Methods

<code>rvs(self, *args, **kwargs)</code>	Random variates of given type.
<code>pmf(self, k, *args, **kwargs)</code>	Probability mass function at k of the given RV.
<code>logpmf(self, k, *args, **kwargs)</code>	Log of the probability mass function at k of the given RV.
<code>cdf(self, k, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>logcdf(self, k, *args, **kwargs)</code>	Log of the cumulative distribution function at k of the given RV.
<code>sf(self, k, *args, **kwargs)</code>	Survival function (1 - <code>cdf</code> ) at k of the given RV.
<code>logsf(self, k, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>ppf(self, q, *args, **kwargs)</code>	Percent point function (inverse of <code>cdf</code> ) at q of the given RV.
<code>isf(self, q, *args, **kwargs)</code>	Inverse survival function (inverse of <code>sf</code> ) at q of the given RV.
<code>moment(self, n, *args, **kwargs)</code>	n-th order non-central moment of distribution.
<code>stats(self, *args, **kwargs)</code>	Some statistics of the given RV.
<code>entropy(self, *args, **kwargs)</code>	Differential entropy of the RV.
<code>expect(self[, func, args, loc, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.
<code>median(self, *args, **kwargs)</code>	Median of the distribution.
<code>mean(self, *args, **kwargs)</code>	Mean of the distribution.
<code>std(self, *args, **kwargs)</code>	Standard deviation of the distribution.
<code>var(self, *args, **kwargs)</code>	Variance of the distribution.
<code>interval(self, alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>__call__(self, *args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>support(self, *args, **kwargs)</code>	Return the support of the distribution.

## scipy.stats.rv\_discrete.rvs

`rv_discrete.rvs` (*self*, \*args, \*\*kwargs)  
Random variates of given type.

## 6.29. Statistical functions (scipy.stats)

### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance)

**scipy.stats.rv\_discrete.pmf**`rv_discrete.pmf` (*self*, *k*, \**args*, \*\**kwargs*)Probability mass function at *k* of the given RV.**Parameters**

**k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**pmf** [array\_like] Probability mass function evaluated at *k*

**scipy.stats.rv\_discrete.logpmf**`rv_discrete.logpmf` (*self*, *k*, \**args*, \*\**kwargs*)Log of the probability mass function at *k* of the given RV.**Parameters**

**k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter. Default is 0.

**Returns**

**logpmf** [array\_like] Log of the probability mass function evaluated at *k*.

**scipy.stats.rv\_discrete.cdf**`rv_discrete.cdf` (*self*, *k*, \**args*, \*\**kwargs*)

Cumulative distribution function of the given RV.

**Parameters**

**k** [array\_like, int] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**cdf** [ndarray] Cumulative distribution function evaluated at *k*.

**scipy.stats.rv\_discrete.logcdf**

`rv_discrete.logcdf` (*self*, *k*, \*args, \*\*kwargs)

Log of the cumulative distribution function at *k* of the given RV.

**Parameters**

**k** [array\_like, int] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**logcdf** [array\_like] Log of the cumulative distribution function evaluated at *k*.

**scipy.stats.rv\_discrete.sf**

`rv_discrete.sf` (*self*, *k*, \*args, \*\*kwargs)

Survival function ( $1 - cdf$ ) at *k* of the given RV.

**Parameters**

**k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**sf** [array\_like] Survival function evaluated at *k*.

**scipy.stats.rv\_discrete.logsf**

`rv_discrete.logsf` (*self*, *k*, \*args, \*\*kwargs)

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as  $1 - cdf$ , evaluated at *k*.

**Parameters**

**k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**logsf** [ndarray] Log of the survival function evaluated at *k*.

**scipy.stats.rv\_discrete.ppf**`rv_discrete.ppf` (*self*, *q*, \**args*, \*\**kwds*)Percent point function (inverse of *cdf*) at *q* of the given RV.**Parameters**

**q** [array\_like] Lower tail probability.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**k** [array\_like] Quantile corresponding to the lower tail probability, *q*.

**scipy.stats.rv\_discrete.isf**`rv_discrete.isf` (*self*, *q*, \**args*, \*\**kwds*)Inverse survival function (inverse of *sf*) at *q* of the given RV.**Parameters**

**q** [array\_like] Upper tail probability.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**k** [ndarray or scalar] Quantile corresponding to the upper tail probability, *q*.

**scipy.stats.rv\_discrete.moment**`rv_discrete.moment` (*self*, *n*, \**args*, \*\**kwds*)*n*-th order non-central moment of distribution.**Parameters**

**n** [int, *n* >= 1] Order of moment.  
**arg1, arg2, arg3,...** [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**scipy.stats.rv\_discrete.stats**

`rv_discrete.stats` (*self*, \*args, \*\*kwargs)

Some statistics of the given RV.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)

**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

*Returns*

**stats** [sequence] of requested moments.

**scipy.stats.rv\_discrete.entropy**

`rv_discrete.entropy` (*self*, \*args, \*\*kwargs)

Differential entropy of the RV.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional (continuous distributions only).] Scale parameter (default=1).

**Notes**

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

**scipy.stats.rv\_discrete.expect**

`rv_discrete.expect` (*self*, func=None, args=(), loc=0, lb=None, ub=None, conditional=False, max-count=1000, tolerance=1e-10, chunksize=32)

Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.

*Parameters*

**func** [callable, optional] Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping  $f(k) = k$ .

**args** [tuple, optional] Shape parameters of the distribution.

**loc** [float, optional] Location parameter. Default is 0.

**lb, ub** [int, optional] Lower and upper bound for the summation, default is set to the support of the distribution, inclusive ( $lb \leq k \leq ub$ ).

**conditional**

[bool, optional] If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, *func*, conditional on being in the given interval ( $k$  such that  $lb \leq k \leq ub$ ). Default is False.

**maxcount** [int, optional] Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.

**tolerance** [float, optional] Absolute tolerance for the summation. Default is 1e-10.

**chunksize** [int, optional] Iterate over the support of a distributions in chunks of this size. Default is 32.

**Returns**

**expect** [float] Expected value.

**Notes**

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, *func*. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only 1e-5. increasing *maxcount* and/or *chunksize* may improve the result, but may also make `zipf` very slow.

The function is not vectorized.

**scipy.stats.rv\_discrete.median**

`rv_discrete.median` (*self*, \**args*, \*\**kws*)

Median of the distribution.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] Location parameter, Default is 0.

**scale** [array\_like, optional] Scale parameter, Default is 1.

**Returns**

**median** [float] The median of the distribution.

**See also:**

`rv_discrete.ppf`

Inverse of the CDF

**scipy.stats.rv\_discrete.mean**

`rv_discrete.mean` (*self*, \*args, \*\*kwargs)

Mean of the distribution.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

*Returns*

**mean** [float] the mean of the distribution

**scipy.stats.rv\_discrete.std**

`rv_discrete.std` (*self*, \*args, \*\*kwargs)

Standard deviation of the distribution.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

*Returns*

**std** [float] standard deviation of the distribution

**scipy.stats.rv\_discrete.var**

`rv_discrete.var` (*self*, \*args, \*\*kwargs)

Variance of the distribution.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

*Returns*

**var** [float] the variance of the distribution

**scipy.stats.rv\_discrete.interval**

`rv_discrete.interval` (*self*, *alpha*, \*args, \*\*kwargs)

Confidence interval with equal areas around the median.

**Parameters**

- alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].
- arg1, arg2, ...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** [array\_like, optional] location parameter, Default is 0.
- scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

- a, b** [ndarray of float] end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

**scipy.stats.rv\_discrete.\_\_call\_\_**

`rv_discrete.__call__` (*self*, \*args, \*\*kwargs)

Freeze the distribution for the given arguments.

**Parameters**

- arg1, arg2, arg3, ...** [array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns**

- rv\_frozen** [rv\_frozen instance] The frozen distribution.

**scipy.stats.rv\_discrete.support**

`rv_discrete.support` (*self*, \*args, \*\*kwargs)

Return the support of the distribution.

**Parameters**

- arg1, arg2, ...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** [array\_like, optional] location parameter, Default is 0.
- scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

- a, b** [float] end-points of the distribution's support.

### 6.29.3 `scipy.stats.rv_histogram`

**class** `scipy.stats.rv_histogram` (*histogram*, \*args, \*\*kwargs)

Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned datasample.

As a subclass of the `rv_continuous` class, `rv_histogram` inherits from it a collection of generic methods (see `rv_continuous` for the full list), and implements them based on the properties of the provided binned datasample.

#### Parameters

**histogram** [(tuple of array\_like)] Tuple containing two array\_like objects The first containing the content of n bins The second containing the (n+1) bin boundaries In particular the return value `np.histogram` is accepted

#### Notes

There are no additional shape parameters except for the loc and scale. The pdf is defined as a stepwise function from the provided histogram The cdf is a linear interpolation of the pdf.

New in version 0.19.0.

#### Examples

Create a `scipy.stats` distribution from a numpy histogram

```
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_
↳state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary `scipy rv_continuous` distribution

```
>>> hist_dist.pdf(1.0)
0.20538577847618705
>>> hist_dist.cdf(2.0)
0.90818568543056499
```

PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the max (min) of the original dataset

```
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.7591907244498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram

```

>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, density=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()

```

*Attributes*

**random\_state**

Get or set the RandomState object for generating random variates.

**Methods**

<code>__call__(self, *args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>cdf(self, x, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>entropy(self, *args, **kwargs)</code>	Differential entropy of the RV.
<code>expect(self[, func, args, loc, scale, lb, ...])</code>	Calculate expected value of a function with respect to the distribution by numerical integration.
<code>fit(self, data, *args, **kwargs)</code>	Return MLEs for shape (if applicable), location, and scale parameters from data.
<code>fit_loc_scale(self, data, *args)</code>	Estimate loc and scale parameters from data using 1st and 2nd moments.
<code>freeze(self, *args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>interval(self, alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>isf(self, q, *args, **kwargs)</code>	Inverse survival function (inverse of $sF$ ) at $q$ of the given RV.
<code>logcdf(self, x, *args, **kwargs)</code>	Log of the cumulative distribution function at $x$ of the given RV.

continues on next page

Table 257 – continued from previous page

<code>logpdf(self, x, *args, **kwargs)</code>	Log of the probability density function at $x$ of the given RV.
<code>logsf(self, x, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>mean(self, *args, **kwargs)</code>	Mean of the distribution.
<code>median(self, *args, **kwargs)</code>	Median of the distribution.
<code>moment(self, n, *args, **kwargs)</code>	$n$ -th order non-central moment of distribution.
<code>nllf(self, theta, x)</code>	Return negative loglikelihood function.
<code>pdf(self, x, *args, **kwargs)</code>	Probability density function at $x$ of the given RV.
<code>ppf(self, q, *args, **kwargs)</code>	Percent point function (inverse of <code>cdf</code> ) at $q$ of the given RV.
<code>rvs(self, *args, **kwargs)</code>	Random variates of given type.
<code>sf(self, x, *args, **kwargs)</code>	Survival function ( $1 - \text{cdf}$ ) at $x$ of the given RV.
<code>stats(self, *args, **kwargs)</code>	Some statistics of the given RV.
<code>std(self, *args, **kwargs)</code>	Standard deviation of the distribution.
<code>support(self, *args, **kwargs)</code>	Return the support of the distribution.
<code>var(self, *args, **kwargs)</code>	Variance of the distribution.

**scipy.stats.rv\_histogram.\_\_call\_\_**

`rv_histogram.__call__(self, *args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns**

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

**scipy.stats.rv\_histogram.cdf**

`rv_histogram.cdf(self, x, *args, **kwargs)`

Cumulative distribution function of the given RV.

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**cdf** [ndarray] Cumulative distribution function evaluated at  $x$

### scipy.stats.rv\_histogram.entropy

`rv_histogram.entropy` (*self*, \*args, \*\*kws)  
 Differential entropy of the RV.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc**  
 [array\_like, optional] Location parameter (default=0).

**scale**  
 [array\_like, optional (continuous distributions only).] Scale parameter (default=1).

#### Notes

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

### scipy.stats.rv\_histogram.expect

`rv_histogram.expect` (*self*, func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, \*\*kws)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[f(x)] = \int_{lb}^{ub} f(x) * dist.pdf(x),$$

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of  $f(x)$ . Also, the function  $f(x)$  may be defined such that  $f(x)$  is 0 outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

#### Parameters

**func**  
 [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping  $f(x) = x$ .

**args**  
 [tuple, optional] Shape parameters of the distribution.

**loc**  
 [float, optional] Location parameter (default=0).

**scale**  
 [float, optional] Scale parameter (default=1).

**lb, ub**  
 [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.

**conditional**  
 [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

**Additional keyword arguments are passed to the integration routine.**

#### Returns

**expect**  
 [float] The calculated expected value.

## Notes

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

The function is not vectorized.

## Examples

To understand the effect of the bounds of integration consider

```
>>> from scipy.stats import expon
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

## scipy.stats.rv\_histogram.fit

`rv_histogram.fit` (*self*, *data*, *\*args*, *\*\*kwargs*)

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

### Parameters

**data** [array\_like] Data to use in calculating the MLEs.

**arg1, arg2, arg3,...**

[floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

**kwargs** [floats, optional]

- *loc*: initial guess of the distribution's location parameter.
- *scale*: initial guess of the distribution's scale parameter.

Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.

- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

### Returns

**mle\_tuple** [tuple of floats] MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

### Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether. If the data contain any of `np.nan`, `np.inf`, or `-np.inf`, the fit routine will throw a `RuntimeError`.

### Examples

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

**scipy.stats.rv\_histogram.fit\_loc\_scale**

`rv_histogram.fit_loc_scale` (*self*, *data*, \**args*)

Estimate loc and scale parameters from data using 1st and 2nd moments.

**Parameters**

**data** [array\_like] Data to fit.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**Returns**

**Lhat** [float] Estimated location parameter for the data.  
**Shat** [float] Estimated scale parameter for the data.

**scipy.stats.rv\_histogram.freeze**

`rv_histogram.freeze` (*self*, \**args*, \*\**kws*)

Freeze the distribution for the given arguments.

**Parameters**

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns**

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

**scipy.stats.rv\_histogram.interval**

`rv_histogram.interval` (*self*, *alpha*, \**args*, \*\**kws*)

Confidence interval with equal areas around the median.

**Parameters**

**alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].  
**arg1, arg2, ...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter, Default is 0.  
**scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [ndarray of float] end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

**scipy.stats.rv\_histogram.isf**`rv_histogram.isf(self, q, *args, **kwargs)`Inverse survival function (inverse of *sf*) at *q* of the given RV.**Parameters**

**q** [array\_like] upper tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [ndarray or scalar] Quantile corresponding to the upper tail probability *q*.

**scipy.stats.rv\_histogram.logcdf**`rv_histogram.logcdf(self, x, *args, **kwargs)`Log of the cumulative distribution function at *x* of the given RV.**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logcdf** [array\_like] Log of the cumulative distribution function evaluated at *x*

**scipy.stats.rv\_histogram.logpdf**`rv_histogram.logpdf(self, x, *args, **kwargs)`Log of the probability density function at *x* of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logpdf** [array\_like] Log of the probability density function evaluated at *x*

**scipy.stats.rv\_histogram.logsf**

`rv_histogram.logsf` (*self*, *x*, \**args*, \*\**kws*)

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as  $(1 - cdf)$ , evaluated at *x*.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logsf** [ndarray] Log of the survival function evaluated at *x*.

**scipy.stats.rv\_histogram.mean**

`rv_histogram.mean` (*self*, \**args*, \*\**kws*)

Mean of the distribution.

**Parameters**

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**mean** [float] the mean of the distribution

**scipy.stats.rv\_histogram.median**

`rv_histogram.median` (*self*, \**args*, \*\**kws*)

Median of the distribution.

**Parameters**

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] Location parameter, Default is 0.  
**scale** [array\_like, optional] Scale parameter, Default is 1.

**Returns**

**median** [float] The median of the distribution.

See also:

[`rv\_discrete.ppf`](#)

Inverse of the CDF

### scipy.stats.rv\_histogram.moment

`rv_histogram.moment` (*self*, *n*, \**args*, \*\**kws*)  
 n-th order non-central moment of distribution.

#### Parameters

**n** [int, n >= 1] Order of moment.  
**arg1, arg2, arg3,...** [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

### scipy.stats.rv\_histogram.nnlf

`rv_histogram.nnlf` (*self*, *theta*, *x*)  
 Return negative loglikelihood function.

#### Notes

This is `-sum(log pdf(x, theta), axis=0)` where *theta* are the parameters (including loc and scale).

### scipy.stats.rv\_histogram.pdf

`rv_histogram.pdf` (*self*, *x*, \**args*, \*\**kws*)  
 Probability density function at x of the given RV.

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**pdf** [ndarray] Probability density function evaluated at x

### scipy.stats.rv\_histogram.ppf

`rv_histogram.ppf` (*self*, *q*, \**args*, \*\**kws*)  
 Percent point function (inverse of `cdf`) at q of the given RV.

#### Parameters

**q** [array\_like] lower tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [array\_like] quantile corresponding to the lower tail probability  $q$ .

**scipy.stats.rv\_histogram.rvs**

`rv_histogram.rvs` (*self*, \*args, \*\*kwds)

Random variates of given type.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional] Scale parameter (default=1).

**size** [int or tuple of ints, optional] Defining number of random variates (default is 1).

**random\_state**

[{None, int, *RandomState*, *Generator*}, optional] If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*.

**Returns**

**rvs** [ndarray or scalar] Random variates of given *size*.

**scipy.stats.rv\_histogram.sf**

`rv_histogram.sf` (*self*, *x*, \*args, \*\*kwds)

Survival function ( $1 - cdf$ ) at *x* of the given RV.

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**sf** [array\_like] Survival function evaluated at *x*

**scipy.stats.rv\_histogram.stats**

`rv_histogram.stats` (*self*, \*args, \*\*kwds)

Some statistics of the given RV.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)

**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns**

**stats** [sequence] of requested moments.

### scipy.stats.rv\_histogram.std

`rv_histogram.std` (*self*, \*args, \*\*kwargs)  
Standard deviation of the distribution.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**std** [float] standard deviation of the distribution

### scipy.stats.rv\_histogram.support

`rv_histogram.support` (*self*, \*args, \*\*kwargs)  
Return the support of the distribution.

**Parameters**

**arg1, arg2, ...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [float] end-points of the distribution's support.

### scipy.stats.rv\_histogram.var

`rv_histogram.var` (*self*, \*args, \*\*kwargs)  
Variance of the distribution.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**var** [float] the variance of the distribution

## 6.29.4 Continuous distributions

<code>alpha(*args, **kwargs)</code>	An alpha continuous random variable.
<code>anglit(*args, **kwargs)</code>	An anglit continuous random variable.
<code>arcsine(*args, **kwargs)</code>	An arcsine continuous random variable.
<code>argus(*args, **kwargs)</code>	Argus distribution
<code>beta(*args, **kwargs)</code>	A beta continuous random variable.
<code>betaprime(*args, **kwargs)</code>	A beta prime continuous random variable.
<code>bradford(*args, **kwargs)</code>	A Bradford continuous random variable.
<code>burr(*args, **kwargs)</code>	A Burr (Type III) continuous random variable.
<code>burr12(*args, **kwargs)</code>	A Burr (Type XII) continuous random variable.
<code>cauchy(*args, **kwargs)</code>	A Cauchy continuous random variable.
<code>chi(*args, **kwargs)</code>	A chi continuous random variable.
<code>chi2(*args, **kwargs)</code>	A chi-squared continuous random variable.
<code>cosine(*args, **kwargs)</code>	A cosine continuous random variable.
<code>crystalball(*args, **kwargs)</code>	Crystalball distribution
<code>dgamma(*args, **kwargs)</code>	A double gamma continuous random variable.
<code>dweibull(*args, **kwargs)</code>	A double Weibull continuous random variable.
<code>erlang(*args, **kwargs)</code>	An Erlang continuous random variable.
<code>expon(*args, **kwargs)</code>	An exponential continuous random variable.
<code>exponnorm(*args, **kwargs)</code>	An exponentially modified Normal continuous random variable.
<code>exponweib(*args, **kwargs)</code>	An exponentiated Weibull continuous random variable.
<code>exponpow(*args, **kwargs)</code>	An exponential power continuous random variable.
<code>f(*args, **kwargs)</code>	An F continuous random variable.
<code>fatiguelife(*args, **kwargs)</code>	A fatigue-life (Birnbaum-Saunders) continuous random variable.
<code>fisk(*args, **kwargs)</code>	A Fisk continuous random variable.
<code>foldcauchy(*args, **kwargs)</code>	A folded Cauchy continuous random variable.
<code>foldnorm(*args, **kwargs)</code>	A folded normal continuous random variable.
<code>genlogistic(*args, **kwargs)</code>	A generalized logistic continuous random variable.
<code>gennorm(*args, **kwargs)</code>	A generalized normal continuous random variable.
<code>genpareto(*args, **kwargs)</code>	A generalized Pareto continuous random variable.
<code>genexpon(*args, **kwargs)</code>	A generalized exponential continuous random variable.
<code>genextreme(*args, **kwargs)</code>	A generalized extreme value continuous random variable.
<code>gausshyper(*args, **kwargs)</code>	A Gauss hypergeometric continuous random variable.
<code>gamma(*args, **kwargs)</code>	A gamma continuous random variable.
<code>gengamma(*args, **kwargs)</code>	A generalized gamma continuous random variable.
<code>genhalflogistic(*args, **kwargs)</code>	A generalized half-logistic continuous random variable.
<code>geninvgauss(*args, **kwargs)</code>	A Generalized Inverse Gaussian continuous random variable.
<code>gilbrat(*args, **kwargs)</code>	A Gilbrat continuous random variable.
<code>gompertz(*args, **kwargs)</code>	A Gompertz (or truncated Gumbel) continuous random variable.
<code>gumbel_r(*args, **kwargs)</code>	A right-skewed Gumbel continuous random variable.
<code>gumbel_l(*args, **kwargs)</code>	A left-skewed Gumbel continuous random variable.
<code>halfcauchy(*args, **kwargs)</code>	A Half-Cauchy continuous random variable.
<code>halflogistic(*args, **kwargs)</code>	A half-logistic continuous random variable.
<code>halfnorm(*args, **kwargs)</code>	A half-normal continuous random variable.
<code>halfgennorm(*args, **kwargs)</code>	The upper half of a generalized normal continuous random variable.

Table 258 – continued from previous page

<i>hypsecant</i> (*args, **kwds)	A hyperbolic secant continuous random variable.
<i>invgamma</i> (*args, **kwds)	An inverted gamma continuous random variable.
<i>invgauss</i> (*args, **kwds)	An inverse Gaussian continuous random variable.
<i>invweibull</i> (*args, **kwds)	An inverted Weibull continuous random variable.
<i>johnsonsb</i> (*args, **kwds)	A Johnson SB continuous random variable.
<i>johnsonsu</i> (*args, **kwds)	A Johnson SU continuous random variable.
<i>kappa4</i> (*args, **kwds)	Kappa 4 parameter distribution.
<i>kappa3</i> (*args, **kwds)	Kappa 3 parameter distribution.
<i>ksone</i> (*args, **kwds)	Kolmogorov-Smirnov one-sided test statistic distribution.
<i>kstwo</i> (*args, **kwds)	Kolmogorov-Smirnov two-sided test statistic distribution.
<i>kstwobign</i> (*args, **kwds)	Limiting distribution of scaled Kolmogorov-Smirnov two-sided test statistic.
<i>laplace</i> (*args, **kwds)	A Laplace continuous random variable.
<i>laplace_asymmetric</i> (*args, **kwds)	An asymmetric Laplace continuous random variable.
<i>levy</i> (*args, **kwds)	A Levy continuous random variable.
<i>levy_l</i> (*args, **kwds)	A left-skewed Levy continuous random variable.
<i>levy_stable</i> (*args, **kwds)	A Levy-stable continuous random variable.
<i>logistic</i> (*args, **kwds)	A logistic (or Sech-squared) continuous random variable.
<i>loggamma</i> (*args, **kwds)	A log gamma continuous random variable.
<i>loglaplace</i> (*args, **kwds)	A log-Laplace continuous random variable.
<i>lognorm</i> (*args, **kwds)	A lognormal continuous random variable.
<i>loguniform</i> (*args, **kwds)	A loguniform or reciprocal continuous random variable.
<i>lomax</i> (*args, **kwds)	A Lomax (Pareto of the second kind) continuous random variable.
<i>maxwell</i> (*args, **kwds)	A Maxwell continuous random variable.
<i>mielke</i> (*args, **kwds)	A Mielke Beta-Kappa / Dagum continuous random variable.
<i>moyal</i> (*args, **kwds)	A Moyal continuous random variable.
<i>nakagami</i> (*args, **kwds)	A Nakagami continuous random variable.
<i>ncx2</i> (*args, **kwds)	A non-central chi-squared continuous random variable.
<i>ncf</i> (*args, **kwds)	A non-central F distribution continuous random variable.
<i>nct</i> (*args, **kwds)	A non-central Student's t continuous random variable.
<i>norm</i> (*args, **kwds)	A normal continuous random variable.
<i>norminvgauss</i> (*args, **kwds)	A Normal Inverse Gaussian continuous random variable.
<i>pareto</i> (*args, **kwds)	A Pareto continuous random variable.
<i>pearson3</i> (*args, **kwds)	A pearson type III continuous random variable.
<i>powerlaw</i> (*args, **kwds)	A power-function continuous random variable.
<i>powerlognorm</i> (*args, **kwds)	A power log-normal continuous random variable.
<i>powernorm</i> (*args, **kwds)	A power normal continuous random variable.
<i>rdist</i> (*args, **kwds)	An R-distributed (symmetric beta) continuous random variable.
<i>rayleigh</i> (*args, **kwds)	A Rayleigh continuous random variable.
<i>rice</i> (*args, **kwds)	A Rice continuous random variable.
<i>recipinvgauss</i> (*args, **kwds)	A reciprocal inverse Gaussian continuous random variable.
<i>semicircular</i> (*args, **kwds)	A semicircular continuous random variable.
<i>skewnorm</i> (*args, **kwds)	A skew-normal random variable.
<i>t</i> (*args, **kwds)	A Student's t continuous random variable.
<i>trapezoid</i> (*args, **kwds)	A trapezoidal continuous random variable.
<i>triang</i> (*args, **kwds)	A triangular continuous random variable.

Table 258 – continued from previous page

<code>truncexpon(*args, **kwargs)</code>	A truncated exponential continuous random variable.
<code>truncnorm(*args, **kwargs)</code>	A truncated normal continuous random variable.
<code>tukeylambd(*args, **kwargs)</code>	A Tukey-Lambda continuous random variable.
<code>uniform(*args, **kwargs)</code>	A uniform continuous random variable.
<code>vonmises(*args, **kwargs)</code>	A Von Mises continuous random variable.
<code>vonmises_line(*args, **kwargs)</code>	A Von Mises continuous random variable.
<code>wald(*args, **kwargs)</code>	A Wald continuous random variable.
<code>weibull_min(*args, **kwargs)</code>	Weibull minimum continuous random variable.
<code>weibull_max(*args, **kwargs)</code>	Weibull maximum continuous random variable.
<code>wrapcauchy(*args, **kwargs)</code>	A wrapped Cauchy continuous random variable.

## scipy.stats.alpha

`scipy.stats.alpha(*args, **kwargs)` = `<scipy.stats._continuous_distns.alpha_gen object>`

An alpha continuous random variable.

As an instance of the `rv_continuous` class, `alpha` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `alpha` ([1], [2]) is:

$$f(x, a) = \frac{1}{x^2 \Phi(a) \sqrt{2\pi}} * \exp\left(-\frac{1}{2}(a - 1/x)^2\right)$$

where  $\Phi$  is the normal CDF,  $x > 0$ , and  $a > 0$ .

`alpha` takes `a` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `alpha.pdf(x, a, loc, scale)` is identically equivalent to `alpha.pdf(y, a) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1], [2]

### Examples

```
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(alpha.ppf(0.01, a),
...                 alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = alpha.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats anglit

`scipy.stats.anglit(*args, **kws) = <scipy.stats._continuous_distns.anglit_gen object>`

An `anglit` continuous random variable.

As an instance of the `rv_continuous` class, `anglit` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `anglit` is:

$$f(x) = \sin(2x + \pi/2) = \cos(2x)$$

for  $-\pi/4 \leq x \leq \pi/4$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `anglit.pdf(x, loc, scale)` is identically equivalent to `anglit.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import anglit
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(anglit.ppf(0.01),
...                 anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
...         'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs</b> (loc=0, scale=1, size=1, random_state=None)	Random variates.

## scipy.stats.arcsine

```
scipy.stats.arcsine(*args, **kwargs) = <scipy.stats._continuous_distns.
    arcsine_gen object>
```

An arcsine continuous random variable.

As an instance of the *rv\_continuous* class, *arcsine* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *arcsine* is:

$$f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$$

for  $0 < x < 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *arcsine.pdf(x, loc, scale)* is identically equivalent to *arcsine.pdf(y) / scale* with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(arcsine.ppf(0.01),
...                 arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
...         'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.argus

```
scipy.stats.argus(*args, **kws) = <scipy.stats._continuous_distns.argus_gen
object>
```

Argus distribution

As an instance of the *rv\_continuous* class, *argus* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *argus* is:

$$f(x, \chi) = \frac{\chi^3}{\sqrt{2\pi}\Psi(\chi)} x \sqrt{1-x^2} \exp(-\chi^2(1-x^2)/2)$$

for  $0 < x < 1$  and  $\chi > 0$ , where

$$\Psi(\chi) = \Phi(\chi) - \chi\phi(\chi) - 1/2$$

with  $\Phi$  and  $\phi$  being the CDF and PDF of a standard normal distribution, respectively.

*argus* takes  $\chi$  as shape a parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `argus.pdf(x, chi, loc, scale)` is identically equivalent to `argus.pdf(y, chi) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

New in version 0.19.0.

## References

[1]

## Examples

```
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(argus.ppf(0.01, chi),
...                 argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi),
...        'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
True
```

Generate random numbers:

```

## scipy.stats.beta

`scipy.stats.beta(*args, **kwargs)` = <scipy.stats.\_continuous\_distns.beta\_gen object>

A beta continuous random variable.

As an instance of the `rv_continuous` class, `beta` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `beta` is:

$$f(x, a, b) = \frac{\Gamma(a+b)x^{a-1}(1-x)^{b-1}}{\Gamma(a)\Gamma(b)}$$

for  $0 \leq x \leq 1$ ,  $a > 0$ ,  $b > 0$ , where  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`beta` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `beta.pdf(x, a, b, loc, scale)` is identically equivalent to `beta.pdf(y, a, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(beta.ppf(0.01, a, b),
...                 beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.betaprime

```
scipy.stats.betaprime(*args, **kwds) = <scipy.stats._continuous_distns.
betaprime_gen object>
```

A beta prime continuous random variable.

As an instance of the *rv\_continuous* class, *betaprime* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *betaprime* is:

$$f(x, a, b) = \frac{x^{a-1}(1+x)^{-a-b}}{\beta(a, b)}$$

for  $x \geq 0$ ,  $a > 0$ ,  $b > 0$ , where  $\beta(a, b)$  is the beta function (see [scipy.special.beta](#)).

*betaprime* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `betaprime.pdf(x, a, b, loc, scale)` is identically equivalent to `betaprime.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(betaprime.ppf(0.01, a, b),
...                 betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='betaprime pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = betaprime(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

**scipy.stats.bradford**

```
scipy.stats.bradford(*args, **kwargs) = <scipy.stats._continuous_distns.
    bradford_gen object>
```

A Bradford continuous random variable.

As an instance of the *rv\_continuous* class, *bradford* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *bradford* is:

$$f(x, c) = \frac{c}{\log(1+c)(1+cx)}$$

for  $0 \leq x \leq 1$  and  $c > 0$ .

*bradford* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `bradford.pdf(x, c, loc, scale)` is identically equivalent to `bradford.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(bradford.ppf(0.01, c),
...                 bradford.ppf(0.99, c), 100)
>>> ax.plot(x, bradford.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], bradford.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.burr

`scipy.stats.burr(*args, **kws) = <scipy.stats._continuous_distns.burr_gen object>`

A Burr (Type III) continuous random variable.

As an instance of the `rv_continuous` class, `burr` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

### fisk

a special case of either `burr` or `burr12` with `d=1`

### burr12

Burr Type XII distribution

### mielke

Mielke Beta-Kappa / Dagum distribution

## Notes

The probability density function for *burr* is:

$$f(x, c, d) = cdx^{-c-1}/(1+x^{-c})^{d+1}$$

for  $x \geq 0$  and  $c, d > 0$ .

*burr* takes *c* and *d* as shape parameters.

This is the PDF corresponding to the third CDF given in Burr's list; specifically, it is equation (11) in Burr's paper [1]. The distribution is also commonly referred to as the Dagum distribution [2]. If the parameter  $c < 1$  then the mean of the distribution does not exist and if  $c < 2$  the variance does not exist [2]. The PDF is finite at the left endpoint  $x = 0$  if  $c * d \geq 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `burr.pdf(x, c, d, loc, scale)` is identically equivalent to `burr.pdf(y, c, d) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1], [2], [3]

## Examples

```
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 10.5, 4.3
>>> mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr.ppf(0.01, c, d),
...                 burr.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, d, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>mean(c, d, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, d, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, d, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, d, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.burr12

```
scipy.stats.burr12(*args, **kws) = <scipy.stats._continuous_distns.burr12_gen
object>
```

A Burr (Type XII) continuous random variable.

As an instance of the *rv\_continuous* class, *burr12* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

### fisk

a special case of either *burr* or *burr12* with *d*=1

### burr

Burr Type III distribution

## Notes

The probability density function for *burr* is:

$$f(x, c, d) = cdx^{c-1}/(1+x^c)^{d+1}$$

for  $x \geq 0$  and  $c, d > 0$ .

*burr12* takes *c* and *d* as shape parameters for *c* and *d*.

This is the PDF corresponding to the twelfth CDF given in Burr’s list; specifically, it is equation (20) in Burr’s paper [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `burr12.pdf(x, c, d, loc, scale)` is identically equivalent to `burr12.pdf(y, c, d) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [2].

## References

[1], [2], [3]

## Examples

```
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr12.ppf(0.01, c, d),
...                 burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr12 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr12.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.cauchy

`scipy.stats.cauchy(*args, **kwds) = <scipy.stats._continuous_distns.cauchy_gen object>`

A Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `cauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `cauchy` is

$$f(x) = \frac{1}{\pi(1+x^2)}$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cauchy.ppf(0.01),
...                 cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.

## scipy.stats.chi

```
scipy.stats.chi(*args, **kwargs) = <scipy.stats._continuous_distns.chi_gen object>
```

A chi continuous random variable.

As an instance of the `rv_continuous` class, `chi` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `chi` is:

$$f(x, k) = \frac{1}{2^{k/2-1}\Gamma(k/2)} x^{k-1} \exp(-x^2/2)$$

for  $x \geq 0$  and  $k > 0$  (degrees of freedom, denoted `df` in the implementation).  $\Gamma$  is the gamma function (`scipy.special.gamma`).

Special cases of `chi` are:

- `chi(1, loc, scale)` is equivalent to `halfnorm`
- `chi(2, 0, scale)` is equivalent to `rayleigh`
- `chi(3, 0, scale)` is equivalent to `maxwell`

`chi` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi.pdf(x, df, loc, scale)` is identically equivalent to `chi.pdf(y, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi.ppf(0.01, df),
...                 chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),
...        'r-', lw=5, alpha=0.6, label='chi pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.chi2**

```
scipy.stats.chi2(*args, **kws) = <scipy.stats._continuous_distns.chi2_gen object>
```

A chi-squared continuous random variable.

For the noncentral chi-square distribution, see [ncx2](#).

As an instance of the *rv\_continuous* class, *chi2* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[ncx2](#)

## Notes

The probability density function for `chi2` is:

$$f(x, k) = \frac{1}{2^{k/2} \Gamma(k/2)} x^{k/2-1} \exp(-x/2)$$

for  $x > 0$  and  $k > 0$  (degrees of freedom, denoted `df` in the implementation).

`chi2` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi2.ppf(0.01, df),
...                 chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
...        'r-', lw=5, alpha=0.6, label='chi2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi2.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs(df, loc=0, scale=1, size=1, random_state=None)</b>	Random variates.
<b>pdf(x, df, loc=0, scale=1)</b>	Probability density function.
<b>logpdf(x, df, loc=0, scale=1)</b>	Log of the probability density function.
<b>cdf(x, df, loc=0, scale=1)</b>	Cumulative distribution function.
<b>logcdf(x, df, loc=0, scale=1)</b>	Log of the cumulative distribution function.
<b>sf(x, df, loc=0, scale=1)</b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf(x, df, loc=0, scale=1)</b>	Log of the survival function.
<b>ppf(q, df, loc=0, scale=1)</b>	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf(q, df, loc=0, scale=1)</b>	Inverse survival function (inverse of <i>sf</i> ).
<b>moment(n, df, loc=0, scale=1)</b>	Non-central moment of order <i>n</i> .
<b>stats(df, loc=0, scale=1, moments='mv')</b>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy(df, loc=0, scale=1)</b>	(Differential) entropy of the RV.
<b>fit(data)</b>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b>expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</b>	Expected value of a function (of one argument) with respect to the distribution.
<b>median(df, loc=0, scale=1)</b>	Median of the distribution.
<b>mean(df, loc=0, scale=1)</b>	Mean of the distribution.
<b>var(df, loc=0, scale=1)</b>	Variance of the distribution.
<b>std(df, loc=0, scale=1)</b>	Standard deviation of the distribution.
<b>interval(alpha, df, loc=0, scale=1)</b>	Endpoints of the range that contains alpha percent of the distribution.

**scipy.stats.cosine**

```
scipy.stats.cosine(*args, **kwargs) = <scipy.stats._continuous_distns.cosine_gen
object>
```

A cosine continuous random variable.

As an instance of the *rv\_continuous* class, *cosine* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The cosine distribution is an approximation to the normal distribution. The probability density function for *cosine* is:

$$f(x) = \frac{1}{2\pi}(1 + \cos(x))$$

for  $-\pi \leq x \leq \pi$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `cosine.pdf(x, loc, scale)` is identically equivalent to `cosine.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cosine.ppf(0.01),
...                 cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x),
...        'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cosine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cosine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cosine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.crystalball

```
scipy.stats.crystalball(*args, **kws) = <scipy.stats._continuous_distns.
    crystalball_gen object>
```

Crystalball distribution

As an instance of the *rv\_continuous* class, *crystalball* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *crystalball* is:

$$f(x, \beta, m) = \begin{cases} N \exp(-x^2/2), & \text{for } x > -\beta \\ NA(B - x)^{-m} & \text{for } x \leq -\beta \end{cases}$$

where  $A = (m/|\beta|)^n \exp(-\beta^2/2)$ ,  $B = m/|\beta| - |\beta|$  and  $N$  is a normalisation constant.

*crystalball* takes  $\beta > 0$  and  $m > 1$  as shape parameters.  $\beta$  defines the point where the pdf changes from a power-law to a Gaussian distribution.  $m$  is the power of the power-law tail.

## References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `crystalball.pdf(x, beta, m, loc, scale)` is identically equivalent to `crystalball.pdf(y, beta, m) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

New in version 0.19.0.

[1]

## Examples

```
>>> from scipy.stats import crystalball
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta, m = 2, 3
>>> mean, var, skew, kurt = crystalball.stats(beta, m, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(crystalball.ppf(0.01, beta, m),
...                 crystalball.ppf(0.99, beta, m), 100)
>>> ax.plot(x, crystalball.pdf(x, beta, m),
...         'r-', lw=5, alpha=0.6, label='crystalball pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = crystalball(beta, m)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = crystalball.ppf([0.001, 0.5, 0.999], beta, m)
>>> np.allclose([0.001, 0.5, 0.999], crystalball.cdf(vals, beta, m))
True
```

Generate random numbers:

```
>>> r = crystalball.rvs(beta, m, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(beta, m, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, beta, m, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, beta, m, loc=0, scale=1)</code>	Log of the probability density function.

## scipy.stats.dgamma

`scipy.stats.dgamma(*args, **kwargs) = <scipy.stats._continuous_distns.dgamma_gen object>`

A double gamma continuous random variable.

As an instance of the `rv_continuous` class, `dgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `dgamma` is:

$$f(x, a) = \frac{1}{2\Gamma(a)} |x|^{a-1} \exp(-|x|)$$

for a real number  $x$  and  $a > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`dgamma` takes `a` as a shape parameter for  $a$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dgamma.ppf(0.01, a),
...                 dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.dweibull

```
scipy.stats.dweibull(*args, **kws) = <scipy.stats._continuous_distns.
dweibull_gen object>
```

A double Weibull continuous random variable.

As an instance of the *rv\_continuous* class, *dweibull* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *dweibull* is given by

$$f(x, c) = c/2|x|^{c-1} \exp(-|x|^c)$$

for a real number *x* and  $c > 0$ .

*dweibull* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `dweibull.pdf(x, c, loc, scale)` is identically equivalent to `dweibull.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 2.07
>>> mean, var, skew, kurt = dweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dweibull.ppf(0.01, c),
...                 dweibull.ppf(0.99, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## scipy.stats.erlang

`scipy.stats.erlang(*args, **kws)` = `<scipy.stats._continuous_distns.erlang_gen object>`

An Erlang continuous random variable.

As an instance of the `rv_continuous` class, `erlang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[gamma](#)

### Notes

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter  $a$  an integer. Note that this restriction is not enforced by `erlang`. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to [gamma](#) for examples.

### Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <code>sf</code> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order $n$
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.expon

`scipy.stats.expon(*args, **kws)` = `<scipy.stats._continuous_distns.expon_gen object>`

An exponential continuous random variable.

As an instance of the `rv_continuous` class, `expon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `expon` is:

$$f(x) = \exp(-x)$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `expon.pdf(x, loc, scale)` is identically equivalent to `expon.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A common parameterization for `expon` is in terms of the rate parameter `lambda`, such that `pdf = lambda * exp(-lambda * x)`. This parameterization corresponds to using `scale = 1 / lambda`.

### Examples

```
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(expon.ppf(0.01),
...                 expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
...         'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
True
```

Generate random numbers:

```
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.exponnorm

```
scipy.stats.exponnorm(*args, **kws) = <scipy.stats._continuous_distns.
    exponnorm_gen object>
```

An exponentially modified Normal continuous random variable.

As an instance of the *rv\_continuous* class, *exponnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *exponnorm* is:

$$f(x, K) = \frac{1}{2K} \exp\left(\frac{1}{2K^2} - x/K\right) \operatorname{erfc}\left(-\frac{x - 1/K}{\sqrt{2}}\right)$$

where *x* is a real number and *K* > 0.

It can be thought of as the sum of a standard normal random variable and an independent exponentially distributed random variable with rate 1/*K*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent to `exponnorm.pdf(y, K) / scale` with `y = (x - loc) / scale`. Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

An alternative parameterization of this distribution (for example, in [Wikipedia](#)) involves three parameters,  $\mu$ ,  $\lambda$  and  $\sigma$ . In the present parameterization this corresponds to having `loc` and `scale` equal to  $\mu$  and  $\sigma$ , respectively, and shape parameter  $K = 1/(\sigma\lambda)$ .

New in version 0.16.0.

## Examples

```
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponnorm.ppf(0.01, K),
...                 exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
...        'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
True
```

Generate random numbers:

```
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(K, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, K, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, K, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, K, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, K, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, K, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, K, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, K, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, K, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, K, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(K, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(K, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(K,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(K, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(K, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(K, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(K, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, K, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.exponweib

```
scipy.stats.exponweib(*args, **kws) = <scipy.stats._continuous_distns.
    exponweib_gen object>
```

An exponentiated Weibull continuous random variable.

As an instance of the *rv\_continuous* class, *exponweib* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[\*weibull\\_min\*](#), [\*numpy.random.RandomState.weibull\*](#)

### Notes

The probability density function for *exponweib* is:

$$f(x, a, c) = ac[1 - \exp(-x^c)]^{a-1} \exp(-x^c)x^{c-1}$$

and its cumulative distribution function is:

$$F(x, a, c) = [1 - \exp(-x^c)]^a$$

for  $x > 0, a > 0, c > 0$ .

*exponweib* takes *a* and *c* as shape parameters:

- *a* is the exponentiation parameter, with the special case  $a = 1$  corresponding to the (non-exponentiated) Weibull distribution [\*weibull\\_min\*](#).
- *c* is the shape parameter of the non-exponentiated Weibull law.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `exponweib.pdf(x, a, c, loc, scale)` is identically equivalent to `exponweib.pdf(y, a, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
...                  exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, c, loc=0, scale=1)</code>	Log of the probability density function.

## scipy.stats.exponpow

```
scipy.stats.exponpow(*args, **kwds) = <scipy.stats._continuous_distns.
    exponpow_gen object>
```

An exponential power continuous random variable.

As an instance of the *rv\_continuous* class, *exponpow* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *exponpow* is:

$$f(x, b) = bx^{b-1} \exp(1 + x^b - \exp(x^b))$$

for  $x \geq 0$ ,  $b > 0$ . Note that this is a different distribution from the exponential power distribution that is also known under the names “generalized normal” or “generalized Gaussian”.

*exponpow* takes *b* as a shape parameter for *b*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `exponpow.pdf(x, b, loc, scale)` is identically equivalent to `exponpow.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

## Examples

```
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponpow.ppf(0.01, b),
...                 exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.f**

`scipy.stats.f(*args, **kws) = <scipy.stats._continuous_distns.f_gen object>`  
 An F continuous random variable.

For the noncentral F distribution, see *ncf*.

As an instance of the *rv\_continuous* class, *f* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**ncf**

**Notes**

The probability density function for *f* is:

$$f(x, df_1, df_2) = \frac{df_2^{df_2/2} df_1^{df_1/2} x^{df_1/2-1}}{(df_2 + df_1 x)^{(df_1+df_2)/2} B(df_1/2, df_2/2)}$$

for  $x > 0$ .

*f* takes *dfn* and *dfd* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `f.pdf(x, dfn, dfd, loc, scale)` is identically equivalent to `f.pdf(y, dfn, dfd) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(f.ppf(0.01, dfn, dfd),
...                 f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd),
...         'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(dfn, dfd, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>std(dfn, dfd, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, dfn, dfd, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.fatiguelife

```
scipy.stats.fatiguelife(*args, **kwds) = <scipy.stats._continuous_distns.fatiguelife_gen object>
```

A fatigue-life (Birnbaum-Saunders) continuous random variable.

As an instance of the *rv\_continuous* class, *fatiguelife* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *fatiguelife* is:

$$f(x, c) = \frac{x + 1}{2c\sqrt{2\pi x^3}} \exp\left(-\frac{(x - 1)^2}{2xc^2}\right)$$

for  $x \geq 0$  and  $c > 0$ .

*fatiguelife* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `fatiguelife.pdf(x, c, loc, scale)` is identically equivalent to `fatiguelife.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that

shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 29
>>> mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fatiguelife.ppf(0.01, c),
...                 fatiguelife.ppf(0.99, c), 100)
>>> ax.plot(x, fatiguelife.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fatiguelife pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fatiguelife(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fatiguelife.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

**scipy.stats.fisk**

`scipy.stats.fisk(*args, **kws)` = <scipy.stats.\_continuous\_distns.fisk\_gen object>

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution.

As an instance of the `rv_continuous` class, `fisk` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[burr](#)

**Notes**

The probability density function for `fisk` is:

$$f(x, c) = cx^{-c-1}(1 + x^{-c})^{-2}$$

for  $x \geq 0$  and  $c > 0$ .

`fisk` takes `c` as a shape parameter for  $c$ .

`fisk` is a special case of `burr` or `burr12` with `d=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fisk.pdf(x, c, loc, scale)` is identically equivalent to `fisk.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fisk.ppf(0.01, c),
...                 fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fisk pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fisk(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fisk.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fisk.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fisk.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.foldcauchy

```
scipy.stats.foldcauchy(*args, **kws) = <scipy.stats._continuous_distns.
foldcauchy_gen object>
```

A folded Cauchy continuous random variable.

As an instance of the *rv\_continuous* class, *foldcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *foldcauchy* is:

$$f(x, c) = \frac{1}{\pi(1 + (x - c)^2)} + \frac{1}{\pi(1 + (x + c)^2)}$$

for  $x \geq 0$ .

*foldcauchy* takes *c* as a shape parameter for *c*.

## Examples

```
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 4.72
>>> mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldcauchy.ppf(0.01, c),
...                 foldcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, foldcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.foldnorm

`scipy.stats.foldnorm(*args, **kwargs)` = `<scipy.stats._continuous_distns.foldnorm_gen object>`

A folded normal continuous random variable.

As an instance of the `rv_continuous` class, `foldnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `foldnorm` is:

$$f(x, c) = \sqrt{2/\pi} \cosh(cx) \exp\left(-\frac{x^2 + c^2}{2}\right)$$

for  $c \geq 0$ .

`foldnorm` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `foldnorm.pdf(x, c, loc, scale)` is identically equivalent to `foldnorm.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.95
>>> mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldnorm.ppf(0.01, c),
...                 foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.genlogistic

`scipy.stats.genlogistic(*args, **kws) = <scipy.stats._continuous_distns.genlogistic_gen object>`

A generalized logistic continuous random variable.

As an instance of the *rv\_continuous* class, *genlogistic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *genlogistic* is:

$$f(x, c) = c \frac{\exp(-x)}{(1 + \exp(-x))^{c+1}}$$

for  $x \geq 0, c > 0$ .

*genlogistic* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `genlogistic.pdf(x, c, loc, scale)` is identically equivalent to `genlogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genlogistic.ppf(0.01, c),
...                 genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genlogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.gennorm

```
scipy.stats.gennorm(*args, **kwargs) = <scipy.stats._continuous_distns.
    gennorm_gen object>
```

A generalized normal continuous random variable.

As an instance of the *rv\_continuous* class, *gennorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

### laplace

Laplace distribution

### norm

normal distribution

## Notes

The probability density function for *gennorm* is [1]:

$$f(x, \beta) = \frac{\beta}{2\Gamma(1/\beta)} \exp(-|x|^\beta)$$

$\Gamma$  is the gamma function (*scipy.special.gamma*).

*gennorm* takes *beta* as a shape parameter for  $\beta$ . For  $\beta = 1$ , it is identical to a Laplace distribution. For  $\beta = 2$ , it is identical to a normal distribution (with *scale*=1/sqrt(2)).

## References

[1]

## Examples

```
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gennorm.ppf(0.01, beta),
...                 gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = gennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.genpareto

```
scipy.stats.genpareto(*args, **kws) = <scipy.stats._continuous_distns.genpareto_gen object>
```

A generalized Pareto continuous random variable.

As an instance of the *rv\_continuous* class, *genpareto* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *genpareto* is:

$$f(x, c) = (1 + cx)^{-1-1/c}$$

defined for  $x \geq 0$  if  $c \geq 0$ , and for  $0 \leq x \leq -1/c$  if  $c < 0$ .

*genpareto* takes *c* as a shape parameter for *c*.

For  $c = 0$ , *genpareto* reduces to the exponential distribution, *expon*:

$$f(x, 0) = \exp(-x)$$

For  $c = -1$ , `genpareto` is uniform on  $[0, 1]$ :

$$f(x, -1) = 1$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genpareto.pdf(x, c, loc, scale)` is identically equivalent to `genpareto.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.1
>>> mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genpareto.ppf(0.01, c),
...                 genpareto.ppf(0.99, c), 100)
>>> ax.plot(x, genpareto.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genpareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genpareto(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genpareto.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.genexpon

`scipy.stats.genexpon(*args, **kwargs)` = `<scipy.stats._continuous_distns.genexpon_gen object>`

A generalized exponential continuous random variable.

As an instance of the `rv_continuous` class, `genexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `genexpon` is:

$$f(x, a, b, c) = (a + b(1 - \exp(-cx))) \exp(-ax - bx + \frac{b}{c}(1 - \exp(-cx)))$$

for  $x \geq 0, a, b, c > 0$ .

`genexpon` takes  $a, b$  and  $c$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genexpon.pdf(x, a, b, c, loc, scale)` is identically equivalent to `genexpon.pdf(y, a, b, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

### Examples

```
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b, c = 9.13, 16.2, 3.28
>>> mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genexpon.ppf(0.01, a, b, c),
...                 genexpon.ppf(0.99, a, b, c), 100)
>>> ax.plot(x, genexpon.pdf(x, a, b, c),
...        'r-', lw=5, alpha=0.6, label='genexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genexpon(a, b, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
>>> np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
True
```

Generate random numbers:

```
>>> r = genexpon.rvs(a, b, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs(a, b, c, loc=0, scale=1, size=1, random_state=None)</b>	Random variates.
<b>pdf(x, a, b, c, loc=0, scale=1)</b>	Probability density function.
<b>logpdf(x, a, b, c, loc=0, scale=1)</b>	Log of the probability density function.
<b>cdf(x, a, b, c, loc=0, scale=1)</b>	Cumulative distribution function.
<b>logcdf(x, a, b, c, loc=0, scale=1)</b>	Log of the cumulative distribution function.
<b>sf(x, a, b, c, loc=0, scale=1)</b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).

**scipy.stats.genextreme**

```
scipy.stats.genextreme(*args, **kws) = <scipy.stats._continuous_distns.  
genextreme_gen object>
```

A generalized extreme value continuous random variable.

As an instance of the *rv\_continuous* class, *genextreme* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[gumbel\\_r](#)

## Notes

For  $c = 0$ , `genextreme` is equal to `gumbel_r`. The probability density function for `genextreme` is:

$$f(x, c) = \begin{cases} \exp(-\exp(-x)) \exp(-x) & \text{for } c = 0 \\ \exp(-(1 - cx)^{1/c})(1 - cx)^{1/c-1} & \text{for } x \leq 1/c, c > 0 \end{cases}$$

Note that several sources and software packages use the opposite convention for the sign of the shape parameter  $c$ . `genextreme` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genextreme.ppf(0.01, c),
...                 genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genextreme pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genextreme.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.gausshyper

```
scipy.stats.gausshyper(*args, **kwargs) = <scipy.stats._continuous_distns.
    gausshyper_gen object>
```

A Gauss hypergeometric continuous random variable.

As an instance of the *rv\_continuous* class, *gausshyper* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *gausshyper* is:

$$f(x, a, b, c, z) = Cx^{a-1}(1-x)^{b-1}(1+zx)^{-c}$$

for  $0 \leq x \leq 1$ ,  $a > 0$ ,  $b > 0$ ,  $z > -1$ , and  $C = \frac{1}{B(a,b)F[2,1](c,a;a+b;-z)}$ .  $F[2, 1]$  is the Gauss hypergeometric function *scipy.special.hyp2f1*.

*gausshyper* takes *a*, *b*, *c* and *z* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *gausshyper.pdf(x, a, b, c, z, loc, scale)* is identically equivalent to *gausshyper.pdf(y, a, b, c, z) / scale* with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1]

### Examples

```
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
...                 gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
...         'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
True
```

Generate random numbers:

```
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, c, z, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.gamma

```
scipy.stats.gamma(*args, **kwds) = <scipy.stats._continuous_distns.gamma_gen
object>
```

A gamma continuous random variable.

As an instance of the *rv\_continuous* class, *gamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[erlang](#), [expon](#)

## Notes

The probability density function for *gamma* is:

$$f(x, a) = \frac{x^{a-1}e^{-x}}{\Gamma(a)}$$

for  $x \geq 0$ ,  $a > 0$ . Here  $\Gamma(a)$  refers to the gamma function.

*gamma* takes *a* as a shape parameter for *a*.

When *a* is an integer, *gamma* reduces to the Erlang distribution, and when  $a = 1$  to the exponential distribution.

Gamma distributions are sometimes parameterized with two variables, with a probability density function of:

$$f(x, \alpha, \beta) = \frac{\beta^\alpha x^{\alpha-1} e^{-\beta x}}{\Gamma(\alpha)}$$

Note that this parameterization is equivalent to the above, with  $\text{scale} = 1 / \text{beta}$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gamma.pdf(x, a, loc, scale)` is identically equivalent to `gamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gamma.ppf(0.01, a),
...                 gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = gamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.gengamma`

```
scipy.stats.gengamma(*args, **kws) = <scipy.stats._continuous_distns.gengamma_gen object>
```

A generalized gamma continuous random variable.

As an instance of the `rv_continuous` class, `gengamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gamma`, `invgamma`, `weibull_min`

## Notes

The probability density function for *gengamma* is ([1]):

$$f(x, a, c) = \frac{|c|x^{ca-1} \exp(-x^c)}{\Gamma(a)}$$

for  $x \geq 0$ ,  $a > 0$ , and  $c \neq 0$ .  $\Gamma$  is the gamma function (*scipy.special.gamma*).

*gengamma* takes *a* and *c* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *gengamma.pdf(x, a, c, loc, scale)* is identically equivalent to *gengamma.pdf(y, a, c) / scale* with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gengamma.ppf(0.01, a, c),
...                 gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='gengamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gengamma(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gengamma.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], gengamma.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = gengamma.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, c, loc=0, scale=1)</code>	Probability density function.

<code>ppf(q, a, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.genhalflogistic

`scipy.stats.genhalflogistic(*args, **kwds) = <scipy.stats._continuous_distns.genhalflogistic_gen object>`

A generalized half-logistic continuous random variable.

As an instance of the *rv\_continuous* class, *genhalflogistic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *genhalflogistic* is:

$$f(x, c) = \frac{2(1 - cx)^{1/(c-1)}}{[1 + (1 - cx)^{1/c}]^2}$$

for  $0 \leq x \leq 1/c$ , and  $c > 0$ .

*genhalflogistic* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
...                 genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genhalflogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.geninvgauss

```
scipy.stats.geninvgauss(*args, **kwargs) = <scipy.stats._continuous_distns.
    geninvgauss_gen object>
```

A Generalized Inverse Gaussian continuous random variable.

As an instance of the *rv\_continuous* class, *geninvgauss* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *geninvgauss* is:

$$f(x, p, b) = x^{p-1} \exp(-b(x + 1/x)/2) / (2K_p(b))$$

where  $x > 0$ , and the parameters  $p, b$  satisfy  $b > 0$  ([1]).  $K_p$  is the modified Bessel function of second kind of order  $p$  (*scipy.special.kv*).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *geninvgauss.pdf(x, p, b, loc, scale)* is identically equivalent to *geninvgauss.pdf(y, p, b) / scale* with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The inverse Gaussian distribution *stats.invgauss(mu)* is a special case of *geninvgauss* with  $p = -1/2, b = 1 / \text{mu}$  and *scale = mu*.

Generating random variates is challenging for this distribution. The implementation is based on [2].

### References

[1], [2]

### Examples

```
>>> from scipy.stats import geninvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p, b = 2.3, 1.5
>>> mean, var, skew, kurt = geninvgauss.stats(p, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(geninvgauss.ppf(0.01, p, b),
...                 geninvgauss.ppf(0.99, p, b), 100)
>>> ax.plot(x, geninvgauss.pdf(x, p, b),
...         'r-', lw=5, alpha=0.6, label='geninvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = geninvgauss(p, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = geninvgauss.ppf([0.001, 0.5, 0.999], p, b)
>>> np.allclose([0.001, 0.5, 0.999], geninvgauss.cdf(vals, p, b))
True
```

Generate random numbers:

```
>>> r = geninvgauss.rvs(p, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>mean(p, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(p, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(p, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.gilbrat

```
scipy.stats.gilbrat(*args, **kwds) = <scipy.stats._continuous_distns.
    gilbrat_gen object>
```

A Gilbrat continuous random variable.

As an instance of the *rv\_continuous* class, *gilbrat* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *gilbrat* is:

$$f(x) = \frac{1}{x\sqrt{2\pi}} \exp\left(-\frac{1}{2}(\log(x))^2\right)$$

*gilbrat* is a special case of *lognorm* with *s*=1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gilbrat.ppf(0.01),
...                 gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.gompertz

```
scipy.stats.gompertz(*args, **kwargs) = <scipy.stats._continuous_distns.
    gompertz_gen object>
```

A Gompertz (or truncated Gumbel) continuous random variable.

As an instance of the *rv\_continuous* class, *gompertz* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *gompertz* is:

$$f(x, c) = c \exp(x) \exp(-c(e^x - 1))$$

for  $x \geq 0, c > 0$ .

*gompertz* takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `gompertz.pdf(x, c, loc, scale)` is identically equivalent to `gompertz.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gompertz.ppf(0.01, c),
...                 gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').

<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

**scipy.stats.gumbel\_r**

```
scipy.stats.gumbel_r(*args, **kws) = <scipy.stats._continuous_distns.gumbel_r_gen object>
```

A right-skewed Gumbel continuous random variable.

As an instance of the `rv_continuous` class, `gumbel_r` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gumbel_1`, `gompertz`, `genextreme`

## Notes

The probability density function for `gumbel_r` is:

$$f(x) = \exp(-(x + e^{-x}))$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_r.pdf(x, loc, scale)` is identically equivalent to `gumbel_r.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_r.ppf(0.01),
...                 gumbel_r.ppf(0.99), 100)
>>> ax.plot(x, gumbel_r.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs</b> (loc=0, scale=1, size=1, random_state=None)	Random variates.
<b>pdf</b> (x, loc=0, scale=1)	Probability density function.
<b>logpdf</b> (x, loc=0, scale=1)	Log of the probability density function.
<b>cdf</b> (x, loc=0, scale=1)	Cumulative distribution function.
<b>logcdf</b> (x, loc=0, scale=1)	Log of the cumulative distribution function.
<b>sf</b> (x, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf</b> (x, loc=0, scale=1)	Log of the survival function.
<b>ppf</b> (q, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf</b> (q, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i> ).
<b>moment</b> (n, loc=0, scale=1)	Non-central moment of order n
<b>stats</b> (loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy</b> (loc=0, scale=1)	(Differential) entropy of the RV.
<b>fit</b> (data)	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b>expect</b> (func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
<b>median</b> (loc=0, scale=1)	Median of the distribution.
<b>mean</b> (loc=0, scale=1)	Mean of the distribution.
<b>var</b> (loc=0, scale=1)	Variance of the distribution.
<b>std</b> (loc=0, scale=1)	Standard deviation of the distribution.

## scipy.stats.gumbel\_l

```
scipy.stats.gumbel_l(*args, **kws) = <scipy.stats._continuous_distns.
    gumbel_l_gen object>
```

A left-skewed Gumbel continuous random variable.

As an instance of the *rv\_continuous* class, *gumbel\_l* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[gumbel\\_r](#), [gompertz](#), [genextreme](#)

### Notes

The probability density function for *gumbel\_l* is:

$$f(x) = \exp(x - e^x)$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *gumbel\_l.pdf(x, loc, scale)* is identically equivalent to *gumbel\_l.pdf(y) / scale* with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import gumbel_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gumbel_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_l.ppf(0.01),
...                 gumbel_l.ppf(0.99), 100)
>>> ax.plot(x, gumbel_l.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gumbel_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.halfcauchy

```
scipy.stats.halfcauchy(*args, **kws) = <scipy.stats._continuous_distns.
halfcauchy_gen object>
```

A Half-Cauchy continuous random variable.

As an instance of the *rv\_continuous* class, *halfcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *halfcauchy* is:

$$f(x) = \frac{2}{\pi(1+x^2)}$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import halfcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halfcauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfcauchy.ppf(0.01),
...                 halfcauchy.ppf(0.99), 100)
>>> ax.plot(x, halfcauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfcauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfcauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfcauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfcauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.halflogistic

`scipy.stats.halflogistic(*args, **kwargs)` = `<scipy.stats._continuous_distns.halflogistic_gen object>`

A half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `halflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `halflogistic` is:

$$f(x) = \frac{2e^{-x}}{(1 + e^{-x})^2} = \frac{1}{2} \operatorname{sech}(x/2)^2$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halflogistic.pdf(x, loc, scale)` is identically equivalent to `halflogistic.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import halflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halflogistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halflogistic.ppf(0.01),
...                 halflogistic.ppf(0.99), 100)
>>> ax.plot(x, halflogistic.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halflogistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halflogistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halflogistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halflogistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.halfnorm

```
scipy.stats.halfnorm(*args, **kws) = <scipy.stats._continuous_distns.
    halfnorm_gen object>
```

A half-normal continuous random variable.

As an instance of the *rv\_continuous* class, *halfnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *halfnorm* is:

$$f(x) = \sqrt{2/\pi} \exp(-x^2/2)$$

for  $x \geq 0$ .

*halfnorm* is a special case of *chi* with *df*=1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *halfnorm.pdf(x, loc, scale)* is identically equivalent to *halfnorm.pdf(y) / scale* with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfnorm.ppf(0.01),
...                 halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfnorm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.

## scipy.stats.halfgennorm

`scipy.stats.halfgennorm(*args, **kws)` = `<scipy.stats._continuous_distns.halfgennorm_gen object>`

The upper half of a generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `halfgennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

### `gennorm`

generalized normal distribution

### `expon`

exponential distribution

### `halfnorm`

half normal distribution

## Notes

The probability density function for `halfgennorm` is:

$$f(x, \beta) = \frac{\beta}{\Gamma(1/\beta)} \exp(-|x|^\beta)$$

for  $x > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`gennorm` takes `beta` as a shape parameter for  $\beta$ . For  $\beta = 1$ , it is identical to an exponential distribution. For  $\beta = 2$ , it is identical to a half normal distribution (with `scale=1/sqrt(2)`).

## References

[1]

## Examples

```
>>> from scipy.stats import halfgennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta = 0.675
>>> mean, var, skew, kurt = halfgennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
...                 halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfgennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = halfgennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.hypsecant

```
scipy.stats.hypsecant(*args, **kws) = <scipy.stats._continuous_distns.
hypsecant_gen object>
```

A hyperbolic secant continuous random variable.

As an instance of the *rv\_continuous* class, *hypsecant* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *hypsecant* is:

$$f(x) = \frac{1}{\pi} \operatorname{sech}(x)$$

for a real number *x*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = hypsecant.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(hypsecant.ppf(0.01),
...                 hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
...         'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
True
```

Generate random numbers:

```
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs</b> (loc=0, scale=1, size=1, random_state=None)	Random variates.
<b>pdf</b> (x, loc=0, scale=1)	Probability density function.
<b>logpdf</b> (x, loc=0, scale=1)	Log of the probability density function.
<b>cdf</b> (x, loc=0, scale=1)	Cumulative distribution function.

<b>fit</b> (data)	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b>expect</b> (func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
<b>median</b> (loc=0, scale=1)	Median of the distribution.
<b>mean</b> (loc=0, scale=1)	Mean of the distribution.
<b>var</b> (loc=0, scale=1)	Variance of the distribution.
<b>std</b> (loc=0, scale=1)	Standard deviation of the distribution.
<b>interval</b> (alpha, loc=0, scale=1)	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.invgamma

```
scipy.stats.invgamma(*args, **kwargs) = <scipy.stats._continuous_distns.
    invgamma_gen object>
```

An inverted gamma continuous random variable.

As an instance of the *rv\_continuous* class, *invgamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *invgamma* is:

$$f(x, a) = \frac{x^{-a-1}}{\Gamma(a)} \exp\left(-\frac{1}{x}\right)$$

for  $x \geq 0, a > 0$ .  $\Gamma$  is the gamma function (*scipy.special.gamma*).

*invgamma* takes *a* as a shape parameter for *a*.

*invgamma* is a special case of *gengamma* with *c*=-1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *invgamma.pdf(x, a, loc, scale)* is identically equivalent to *invgamma.pdf(y, a) / scale* with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgamma.ppf(0.01, a),
...                 invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.invgauss

```
scipy.stats.invgauss(*args, **kws) = <scipy.stats._continuous_distns.
    invgauss_gen object>
```

An inverse Gaussian continuous random variable.

As an instance of the *rv\_continuous* class, *invgauss* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *invgauss* is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x - \mu)^2}{2x\mu^2}\right)$$

for  $x \geq 0$  and  $\mu > 0$ .

*invgauss* takes *mu* as a shape parameter for  $\mu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `invgauss.pdf(x, mu, loc, scale)` is identically equivalent to `invgauss.pdf(y, mu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

When  $\mu$  is too small, evaluating the cumulative distribution function will be inaccurate due to  $\text{cdf}(\mu \rightarrow 0) = \text{inf} * 0$ . NaNs are returned for  $\mu \leq 0.0028$ .

## Examples

```
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgauss.ppf(0.01, mu),
...                 invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
...         'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(mu, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, mu, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, mu, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, mu, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, mu, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, mu, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, mu, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, mu, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, mu, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(mu, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(mu, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(mu, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(mu, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.invweibull

```
scipy.stats.invweibull(*args, **kwargs) = <scipy.stats._continuous_distns.
    invweibull_gen object>
```

An inverted Weibull continuous random variable.

This distribution is also known as the Fréchet distribution or the type II extreme value distribution.

As an instance of the *rv\_continuous* class, *invweibull* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *invweibull* is:

$$f(x, c) = cx^{-c-1} \exp(-x^{-c})$$

for  $x > 0, c > 0$ .

*invweibull* takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c, loc, scale)` is identically equivalent to `invweibull.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

F.R.S. de Gusmao, E.M.M Ortega and G.M. Cordeiro, “The generalized inverse Weibull distribution”, Stat. Papers, vol. 52, pp. 591-619, 2011.

### Examples

```
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invweibull.ppf(0.01, c),
...                 invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.

<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.johnsonsb`

```
scipy.stats.johnsonsb(*args, **kws) = <scipy.stats._continuous_distns.
johnsonsb_gen object>
```

A Johnson SB continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsb` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[johnsonsu](#)

## Notes

The probability density function for *johnsonsb* is:

$$f(x, a, b) = \frac{b}{x(1-x)} \phi\left(a + b \log \frac{x}{1-x}\right)$$

for  $0 \leq x \leq 1$  and  $a, b > 0$ , and  $\phi$  is the normal pdf.

*johnsonsb* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `johnsonsb.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsb.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 4.32, 3.18
>>> mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b),
...                 johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsb.rvs(a, b, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

**scipy.stats.johnsonsu**

```
scipy.stats.johnsonsu(*args, **kws) = <scipy.stats._continuous_distns.
    johnsonsu_gen object>
```

A Johnson SU continuous random variable.

As an instance of the *rv\_continuous* class, *johnsonsu* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[johnsonsb](#)

**Notes**

The probability density function for *johnsonsu* is:

$$f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))$$

for all  $x, a, b > 0$ , and  $\phi$  is the normal pdf.

*johnsonsu* takes  $a$  and  $b$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsu.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsu.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b),
...                 johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.kappa4

`scipy.stats.kappa4(*args, **kwds) = <scipy.stats._continuous_distns.kappa4_gen object>`

Kappa 4 parameter distribution.

As an instance of the *rv\_continuous* class, *kappa4* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for kappa4 is:

$$f(x, h, k) = (1 - kx)^{1/k-1} (1 - h(1 - kx)^{1/k})^{1/h-1}$$

if *h* and *k* are not equal to 0.

If *h* or *k* are zero then the pdf can be simplified:

*h* = 0 and *k* != 0:

$$\text{kappa4.pdf}(x, h, k) = (1.0 - k*x) ** (1.0/k - 1.0) * \exp(-(1.0 - k*x) ** (1.0/k))$$

$h \neq 0$  and  $k = 0$ :

```
kappa4.pdf(x, h, k) = exp(-x) * (1.0 - h * exp(-x)) ** (1.0/h - 1.0)
```

$h = 0$  and  $k = 0$ :

```
kappa4.pdf(x, h, k) = exp(-x) * exp(-exp(-x))
```

`kappa4` takes  $h$  and  $k$  as shape parameters.

The `kappa4` distribution returns other distributions when certain  $h$  and  $k$  values are used.

h	k=0.0	k=1.0	-inf<=k<=inf
-1.0	Logistic logistic(x)		Generalized Logistic(1)
0.0	Gumbel gumbel_r(x)	Reverse Exponential(2)	Generalized Extreme Value genextreme(x, k)
1.0	Exponential expon(x)	Uniform uniform(x)	Generalized Pareto genpareto(x, -k)

- (1) There are at least five generalized logistic distributions. Four are described here: [https://en.wikipedia.org/wiki/Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Generalized_logistic_distribution) The “fifth” one is the one `kappa4` should match which currently isn’t implemented in `scipy`: [https://en.wikipedia.org/wiki/Talk:Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Talk:Generalized_logistic_distribution) [https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen\\_logistic.html](https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen_logistic.html)
- (2) This distribution is currently not in `scipy`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa4.pdf(x, h, k, loc, scale)` is identically equivalent to `kappa4.pdf(y, h, k) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
...                 kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
...        'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

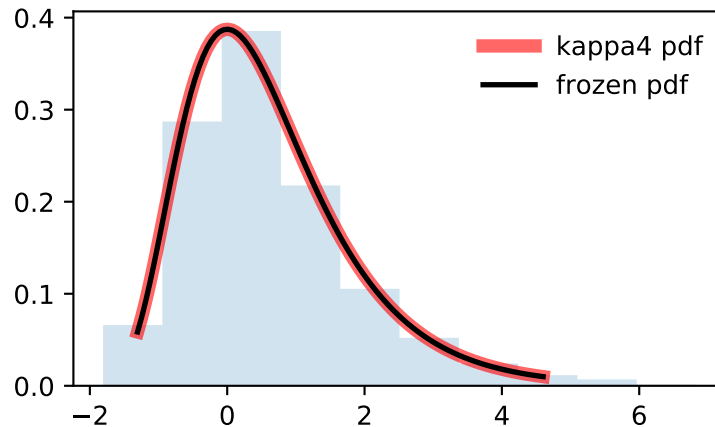

```
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
True
```

Generate random numbers:

```
>>> r = kappa4.rvs(h, k, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(h, k, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, h, k, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, h, k, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, h, k, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, h, k, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, h, k, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, h, k, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, h, k, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, h, k, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, h, k, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(h, k, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(h, k, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(h, k), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(h, k, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(h, k, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(h, k, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(h, k, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, h, k, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.kappa3

`scipy.stats.kappa3(*args, **kws) = <scipy.stats._continuous_distns.kappa3_gen object>`

Kappa 3 parameter distribution.

As an instance of the `rv_continuous` class, `kappa3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `kappa3` is:

$$f(x, a) = a(a + x^a)^{-(a+1)/a}$$

for  $x > 0$  and  $a > 0$ .

`kappa3` takes `a` as a shape parameter for  $a$ .

### References

P.W. Mielke and E.S. Johnson, “Three-Parameter Kappa Distribution Maximum Likelihood and Likelihood Ratio Tests”, *Methods in Weather Research*, 701-707, (September, 1973), DOI:10.1175/1520-0493(1973)101<0701:TKDMLE>2.3.CO;2

B. Kumphon, “Maximum Entropy and Maximum Likelihood Estimation for the Three-Parameter Kappa Distribution”, *Open Journal of Statistics*, vol 2, 415-419 (2012), DOI:10.4236/ojs.2012.24050

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa3.pdf(x, a, loc, scale)` is identically equivalent to `kappa3.pdf(y, a) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import kappa3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1
>>> mean, var, skew, kurt = kappa3.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa3.ppf(0.01, a),
...                 kappa3.ppf(0.99, a), 100)
>>> ax.plot(x, kappa3.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='kappa3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa3(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kappa3.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], kappa3.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = kappa3.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

**scipy.stats.ksone**

`scipy.stats.ksone(*args, **kws) = <scipy.stats._continuous_distns.ksone_gen object>`

Kolmogorov-Smirnov one-sided test statistic distribution.

This is the distribution of the one-sided Kolmogorov-Smirnov (KS) statistics  $D_n^+$  and  $D_n^-$  for a finite sample size *n* (the shape parameter).

As an instance of the `rv_continuous` class, `ksone` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`kstwobign`, `kstwo`, `kstest`

## Notes

$D_n^+$  and  $D_n^-$  are given by

$$D_n^+ = \sup_x (F_n(x) - F(x)),$$

$$D_n^- = \sup_x (F(x) - F_n(x)),$$

where  $F$  is a continuous CDF and  $F_n$  is an empirical CDF. `ksone` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to  $n$  i.i.d. random variates with CDF  $F$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ksone.pdf(x, n, loc, scale)` is identically equivalent to `ksone.pdf(y, n) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import ksone
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n = 1e+03
>>> mean, var, skew, kurt = ksone.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ksone.ppf(0.01, n),
...                 ksone.ppf(0.99, n), 100)
>>> ax.plot(x, ksone.pdf(x, n),
...         'r-', lw=5, alpha=0.6, label='ksone pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ksone(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ksone.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], ksone.cdf(vals, n))
True
```

Generate random numbers:

```
>>> r = ksone.rvs(n, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.kstwo**

```
scipy.stats.kstwo(*args, **kws) = <scipy.stats._continuous_distns.kstwo_gen
object>
```

Kolmogorov-Smirnov two-sided test statistic distribution.

This is the distribution of the two-sided Kolmogorov-Smirnov (KS) statistic  $D_n$  for a finite sample size n (the shape parameter).

As an instance of the *rv\_continuous* class, *kstwo* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[kstwobign](#), [ksone](#), [kstest](#)

## Notes

$D_n$  is given by

$$D_n = \sup_x |F_n(x) - F(x)|$$

where  $F$  is a (continuous) CDF and  $F_n$  is an empirical CDF. `kstwo` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to  $n$  i.i.d. random variates with CDF  $F$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kstwo.pdf(x, n, loc, scale)` is identically equivalent to `kstwo.pdf(y, n) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import kstwo
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n = 10
>>> mean, var, skew, kurt = kstwo.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwo.ppf(0.01, n),
...                 kstwo.ppf(0.99, n), 100)
>>> ax.plot(x, kstwo.pdf(x, n),
...         'r-', lw=5, alpha=0.6, label='kstwo pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwo(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kstwo.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], kstwo.cdf(vals, n))
True
```

Generate random numbers:

```
>>> r = kstwo.rvs(n, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.kstwobign

```
scipy.stats.kstwobign(*args, **kws) = <scipy.stats._continuous_distns.kstwobign_gen object>
```

Limiting distribution of scaled Kolmogorov-Smirnov two-sided test statistic.

This is the asymptotic distribution of the two-sided Kolmogorov-Smirnov statistic  $\sqrt{n}D_n$  that measures the maximum absolute distance of the theoretical (continuous) CDF from the empirical CDF. (see *kstest*).

As an instance of the *rv\_continuous* class, *kstwobign* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[ksone](#), [kstwo](#), [kstest](#)

## Notes

$\sqrt{n}D_n$  is given by

$$D_n = \sup_x |F_n(x) - F(x)|$$

where  $F$  is a continuous CDF and  $F_n$  is an empirical CDF. *kstwobign* describes the asymptotic distribution (i.e. the limit of  $\sqrt{n}D_n$ ) under the null hypothesis of the KS test that the empirical CDF corresponds to i.i.d. random variates with CDF  $F$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kstwobign.pdf(x, loc, scale)` is identically equivalent to `kstwobign.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

## Examples

```
>>> from scipy.stats import kstwobign
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = kstwobign.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwobign.ppf(0.01),
...                 kstwobign.ppf(0.99), 100)
>>> ax.plot(x, kstwobign.pdf(x),
...         'r-', lw=5, alpha=0.6, label='kstwobign pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwobign()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kstwobign.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], kstwobign.cdf(vals))
True
```

Generate random numbers:

```
>>> r = kstwobign.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.

## scipy.stats.laplace

```
scipy.stats.laplace(*args, **kwds) = <scipy.stats._continuous_distns.
laplace_gen object>
```

A Laplace continuous random variable.

As an instance of the *rv\_continuous* class, *laplace* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *laplace* is

$$f(x) = \frac{1}{2} \exp(-|x|)$$

for a real number *x*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `laplace.pdf(x, loc, scale)` is identically equivalent to `laplace.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace.ppf(0.01),
...                 laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x),
...         'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
True
```

Generate random numbers:

```
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>stats</b> (loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy</b> (loc=0, scale=1)	(Differential) entropy of the RV.
<b>fit</b> (data)	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b>expect</b> (func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
<b>median</b> (loc=0, scale=1)	Median of the distribution.
<b>mean</b> (loc=0, scale=1)	Mean of the distribution.
<b>var</b> (loc=0, scale=1)	Variance of the distribution.
<b>std</b> (loc=0, scale=1)	Standard deviation of the distribution.
<b>interval</b> (alpha, loc=0, scale=1)	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.laplace\_asymmetric

```
scipy.stats.laplace_asymmetric(*args, **kws) = <scipy.stats.
    _continuous_distns.laplace_asymmetric_gen
    object>
```

An asymmetric Laplace continuous random variable.

As an instance of the *rv\_continuous* class, *laplace\_asymmetric* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

### laplace

Laplace distribution

### Notes

The probability density function for *laplace\_asymmetric* is

$$f(x, \kappa) = \frac{1}{\kappa + \kappa^{-1}} \exp(-x\kappa), \quad x \geq 0$$

$$= \frac{1}{\kappa + \kappa^{-1}} \exp(x/\kappa), \quad x < 0$$

for  $-\infty < x < \infty, \kappa > 0$ .

*laplace\_asymmetric* takes kappa as a shape parameter for  $\kappa$ . For  $\kappa = 1$ , it is identical to a Laplace distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `laplace_asymmetric.pdf(x, kappa, loc, scale)` is identically equivalent to `laplace_asymmetric.pdf(y, kappa) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1], [2]

### Examples

```
>>> from scipy.stats import laplace_asymmetric
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 2
>>> mean, var, skew, kurt = laplace_asymmetric.stats(kappa, moments='mvsk
→')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace_asymmetric.ppf(0.01, kappa),
...                 laplace_asymmetric.ppf(0.99, kappa), 100)
>>> ax.plot(x, laplace_asymmetric.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='laplace_asymmetric pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace_asymmetric(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = laplace_asymmetric.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], laplace_asymmetric.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = laplace_asymmetric.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(kappa, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, kappa, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, kappa, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, kappa, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, kappa, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, kappa, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, kappa, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, kappa, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, kappa, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, kappa, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(kappa, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(kappa, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(kappa,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(kappa, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(kappa, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(kappa, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(kappa, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, kappa, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.levy

`scipy.stats.levy(*args, **kwds) = <scipy.stats._continuous_distns.levy_gen object>`

A Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`levy_stable`, `levy_1`

## Notes

The probability density function for `levy` is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{1}{2x}\right)$$

for  $x \geq 0$ .

This is the same as the Levy-stable distribution with  $a = 1/2$  and  $b = 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy.pdf(x, loc, scale)` is identically equivalent to `levy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy.ppf(0.01),
...                 levy.ppf(0.99), 100)
>>> ax.plot(x, levy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy.rvs(size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
    
```

## scipy.stats.levy\_l

`scipy.stats.levy_l(*args, **kwargs) = <scipy.stats._continuous_distns.levy_l_gen object>`

A left-skewed Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[levy](#), [levy\\_stable](#)

### Notes

The probability density function for `levy_l` is:

$$f(x) = \frac{1}{|x|\sqrt{2\pi|x|}} \exp\left(-\frac{1}{2|x|}\right)$$

for  $x \leq 0$ .

This is the same as the Levy-stable distribution with  $a = 1/2$  and  $b = -1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_l.pdf(x, loc, scale)` is identically equivalent to `levy_l.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import levy_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = levy_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_l.ppf(0.01),
...                 levy_l.ppf(0.99), 100)
>>> ax.plot(x, levy_l.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs</b> (loc=0, scale=1, size=1, random_state=None)	Random variates.
<b>pdf</b> (x, loc=0, scale=1)	Probability density function.
<b>logpdf</b> (x, loc=0, scale=1)	Log of the probability density function.
<b>cdf</b> (x, loc=0, scale=1)	Cumulative distribution function.
<b>logcdf</b> (x, loc=0, scale=1)	Log of the cumulative distribution function.
<b>sf</b> (x, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).

**scipy.stats.levy\_stable**

```
scipy.stats.levy_stable(*args, **kwds) = <scipy.stats._continuous_distns.levy_stable_gen object>
```

A Levy-stable continuous random variable.

As an instance of the *rv\_continuous* class, *levy\_stable* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[levy](#), [levy\\_1](#)

## Notes

The distribution for `levy_stable` has characteristic function:

$$\varphi(t, \alpha, \beta, c, \mu) = e^{it\mu - |ct|^\alpha (1 - i\beta \operatorname{sign}(t)\Phi(\alpha, t))}$$

where:

$$\Phi = \begin{cases} \tan\left(\frac{\pi\alpha}{2}\right) & \alpha \neq 1 \\ -\frac{2}{\pi} \log|t| & \alpha = 1 \end{cases}$$

The probability density function for `levy_stable` is:

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \varphi(t) e^{-ixt} dt$$

where  $-\infty < t < \infty$ . This integral does not have a known closed form.

For evaluation of pdf we use either Zolotarev  $S_0$  parameterization with integration, direct integration of standard parameterization of characteristic function or FFT of characteristic function. If set to other than None and if number of points is greater than `levy_stable.pdf_fft_min_points_threshold` (defaults to None) we use FFT otherwise we use one of the other methods.

The default method is ‘best’ which uses Zolotarev’s method if  $\alpha = 1$  and integration of characteristic function otherwise. The default method can be changed by setting `levy_stable.pdf_default_method` to either ‘zolotarev’, ‘quadrature’ or ‘best’.

To increase accuracy of FFT calculation one can specify `levy_stable.pdf_fft_grid_spacing` (defaults to 0.001) and `pdf_fft_n_points_two_power` (defaults to a value that covers the input range \* 4). Setting `pdf_fft_n_points_two_power` to 16 should be sufficiently accurate in most cases at the expense of CPU time.

For evaluation of cdf we use Zolotarev  $S_0$  parameterization with integration or integral of the pdf FFT interpolated spline. The settings affecting FFT calculation are the same as for pdf calculation. Setting the threshold to None (default) will disable FFT. For cdf calculations the Zolotarev method is superior in accuracy, so FFT is disabled by default.

Fitting estimate uses quantile estimation method in [MC]. MLE estimation of parameters in fit method uses this quantile estimate initially. Note that MLE doesn’t always converge if using FFT for pdf calculations; so it’s best that `pdf_fft_min_points_threshold` is left unset.

**Warning:** For pdf calculations implementation of Zolotarev is unstable for values where  $\alpha = 1$  and  $\beta \neq 0$ . In this case the quadrature method is recommended. FFT calculation is also considered experimental.

For cdf calculations FFT calculation is considered experimental. Use Zolotarev’s method instead (default).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_stable.pdf(x, alpha, beta, loc, scale)` is identically equivalent to `levy_stable.pdf(y, alpha, beta) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

## Examples

```
>>> from scipy.stats import levy_stable
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> alpha, beta = 1.8, -0.5
>>> mean, var, skew, kurt = levy_stable.stats(alpha, beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_stable.ppf(0.01, alpha, beta),
...                 levy_stable.ppf(0.99, alpha, beta), 100)
>>> ax.plot(x, levy_stable.pdf(x, alpha, beta),
...         'r-', lw=5, alpha=0.6, label='levy_stable pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_stable(alpha, beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

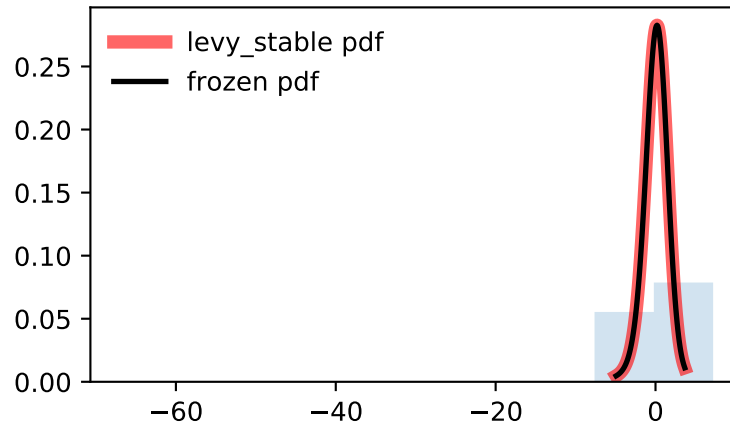

```
>>> vals = levy_stable.ppf([0.001, 0.5, 0.999], alpha, beta)
>>> np.allclose([0.001, 0.5, 0.999], levy_stable.cdf(vals, alpha, beta))
True
```

Generate random numbers:

```
>>> r = levy_stable.rvs(alpha, beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.logistic

```
scipy.stats.logistic(*args, **kwargs) = <scipy.stats._continuous_distns.
    logistic_gen object>
```

A logistic (or Sech-squared) continuous random variable.

As an instance of the *rv\_continuous* class, *logistic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *logistic* is:

$$f(x) = \frac{\exp(-x)}{(1 + \exp(-x))^2}$$

*logistic* is a special case of *genlogistic* with  $c=1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `logistic.pdf(x, loc, scale)` is identically equivalent to `logistic.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(logistic.ppf(0.01),
...                 logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x),
...         'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = logistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.loggamma

```
scipy.stats.loggamma(*args, **kws) = <scipy.stats._continuous_distns.
    loggamma_gen object>
```

A log gamma continuous random variable.

As an instance of the *rv\_continuous* class, *loggamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *loggamma* is:

$$f(x, c) = \frac{\exp(cx - \exp(x))}{\Gamma(c)}$$

for all  $x, c > 0$ . Here,  $\Gamma$  is the gamma function ([scipy.special.gamma](#)).

*loggamma* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `loggamma.pdf(x, c, loc, scale)` is identically equivalent to `loggamma.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loggamma.ppf(0.01, c),
...                 loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.loglaplace

`scipy.stats.loglaplace(*args, **kwargs) = <scipy.stats._continuous_distns.loglaplace_gen object>`

A log-Laplace continuous random variable.

As an instance of the `rv_continuous` class, `loglaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `loglaplace` is:

$$f(x, c) = \begin{cases} \frac{c}{2}x^{c-1} & \text{for } 0 < x < 1 \\ \frac{c}{2}x^{-c-1} & \text{for } x \geq 1 \end{cases}$$

for  $c > 0$ .

`loglaplace` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loglaplace.pdf(x, c, loc, scale)` is identically equivalent to `loglaplace.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

T.J. Kozubowski and K. Podgorski, “A log-Laplace growth rate model”, *The Mathematical Scientist*, vol. 28, pp. 49-60, 2003.

### Examples

```
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loglaplace.ppf(0.01, c),
...                 loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.lognorm

```
scipy.stats.lognorm(*args, **kwds) = <scipy.stats._continuous_distns.
    lognorm_gen object>
```

A lognormal continuous random variable.

As an instance of the *rv\_continuous* class, *lognorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *lognorm* is:

$$f(x, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{\log^2(x)}{2s^2}\right)$$

for  $x > 0, s > 0$ .

*lognorm* takes *s* as a shape parameter for *s*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `lognorm.pdf(x, s, loc, scale)` is identically equivalent to `lognorm.pdf(y, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A common parametrization for a lognormal random variable  $Y$  is in terms of the mean,  $\mu$ , and standard deviation,  $\sigma$ , of the unique normally distributed random variable  $X$  such that  $\exp(X) = Y$ . This parametrization corresponds to setting  $s = \sigma$  and  $\text{scale} = \exp(\mu)$ .

## Examples

```
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lognorm.ppf(0.01, s),
...                 lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s),
...         'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```
>>> r = lognorm.rvs(s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, s, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, s, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, s, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, s, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, s, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, s, loc=0, scale=1)</code>	Log of the survival function.

<code>median(s, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, s, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.loguniform

```
scipy.stats.loguniform(*args, **kwargs) = <scipy.stats._continuous_distns.
reciprocal_gen object>
```

A loguniform or reciprocal continuous random variable.

As an instance of the `rv_continuous` class, `loguniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for this class is:

$$f(x, a, b) = \frac{1}{x \log(b/a)}$$

for  $a \leq x \leq b, b > a > 0$ . This class takes  $a$  and  $b$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loguniform.pdf(x, a, b, loc, scale)` is identically equivalent to `loguniform.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import loguniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.01, 1
>>> mean, var, skew, kurt = loguniform.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loguniform.ppf(0.01, a, b),
...                 loguniform.ppf(0.99, a, b), 100)
>>> ax.plot(x, loguniform.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='loguniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loguniform(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loguniform.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], loguniform.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = loguniform.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

This doesn't show the equal probability of 0.01, 0.1 and 1. This is best when the x-axis is log-scaled:

```
>>> import numpy as np
>>> fig, ax = plt.subplots(1, 1)
>>> ax.hist(np.log10(r))
>>> ax.set_ylabel("Frequency")
>>> ax.set_xlabel("Value of random variable")
>>> ax.xaxis.set_major_locator(plt.FixedLocator([-2, -1, 0]))
>>> ticks = ["$10^{{{ }}}$".format(i) for i in [-2, -1, 0]]
>>> ax.set_xticklabels(ticks)
>>> plt.show()
```

This random variable will be log-uniform regardless of the base chosen for a and b. Let's specify with base 2 instead:

```
>>> rvs = loguniform(2**-2, 2**0).rvs(size=1000)
```

Values of 1/4, 1/2 and 1 are equally likely with this random variable. Here's the histogram:

```
>>> fig, ax = plt.subplots(1, 1)
>>> ax.hist(np.log2(rvs))
>>> ax.set_ylabel("Frequency")
>>> ax.set_xlabel("Value of random variable")
>>> ax.xaxis.set_major_locator(plt.FixedLocator([-2, -1, 0]))
>>> ticks = ["$2^{{{ }}}$".format(i) for i in [-2, -1, 0]]
```

(continues on next page)

(continued from previous page)

```
>>> ax.set_xticklabels(ticks)
>>> plt.show()
```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.lomax

```
scipy.stats.lomax(*args, **kws) = <scipy.stats._continuous_distns.lomax_gen
object>
```

A Lomax (Pareto of the second kind) continuous random variable.

As an instance of the *rv\_continuous* class, *lomax* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *lomax* is:

$$f(x, c) = \frac{c}{(1+x)^{c+1}}$$

for  $x \geq 0, c > 0$ .

*lomax* takes *c* as a shape parameter for *c*.

*lomax* is a special case of *pareto* with `loc=-1.0`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lomax.pdf(x, c, loc, scale)` is identically equivalent to `lomax.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of

a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lomax.ppf(0.01, c),
...                 lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='lomax pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = lomax.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.maxwell

```
scipy.stats.maxwell(*args, **kwargs) = <scipy.stats._continuous_distns.
maxwell_gen object>
```

A Maxwell continuous random variable.

As an instance of the *rv\_continuous* class, *maxwell* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

A special case of a *chi* distribution, with `df=3`, `loc=0.0`, and given `scale = a`, where `a` is the parameter used in the Mathworld description [1].

The probability density function for *maxwell* is:

$$f(x) = \sqrt{2/\pi} x^2 \exp(-x^2/2)$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1]

### Examples

```
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(maxwell.ppf(0.01),
...                 maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x),
...         'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True
```

Generate random numbers:

```
>>> r = maxwell.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.mielke

`scipy.stats.mielke(*args, **kws) = <scipy.stats._continuous_distns.mielke_gen object>`

A Mielke Beta-Kappa / Dagum continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `mielke` is:

$$f(x, k, s) = \frac{kx^{k-1}}{(1+x^s)^{1+k/s}}$$

for  $x > 0$  and  $k, s > 0$ . The distribution is sometimes called Dagum distribution ([2]). It was already defined in [3], called a Burr Type III distribution (`burr` with parameters  $c=s$  and  $d=k/s$ ).

`mielke` takes *k* and *s* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1], [2], [3]

## Examples

```
>>> from scipy.stats import mielke
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> k, s = 10.4, 4.6
>>> mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(mielke.ppf(0.01, k, s),
...                 mielke.ppf(0.99, k, s), 100)
>>> ax.plot(x, mielke.pdf(x, k, s),
...        'r-', lw=5, alpha=0.6, label='mielke pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = mielke(k, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
>>> np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
True
```

Generate random numbers:

```
>>> r = mielke.rvs(k, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(k, s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>entropy(k, s, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(k, s), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(k, s, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(k, s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(k, s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(k, s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, k, s, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.moyal

`scipy.stats.moyal(*args, **kwargs)` = `<scipy.stats._continuous_distns.moyal_gen object>`

A Moyal continuous random variable.

As an instance of the `rv_continuous` class, `moyal` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `moyal` is:

$$f(x) = \exp(-(x + \exp(-x))/2) / \sqrt{2\pi}$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `moyal.pdf(x, loc, scale)` is identically equivalent to `moyal.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

This distribution has utility in high-energy physics and radiation detection. It describes the energy loss of a charged relativistic particle due to ionization of the medium [1]. It also provides an approximation for the Landau distribution. For an in depth description see [2]. For additional description, see [3].

### References

New in version 1.1.0.

[1], [2], [3]

### Examples

```
>>> from scipy.stats import moyal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = moyal.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(moyal.ppf(0.01),
...                 moyal.ppf(0.99), 100)
>>> ax.plot(x, moyal.pdf(x),
...         'r-', lw=5, alpha=0.6, label='moyal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = moyal()  
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = moyal.ppf([0.001, 0.5, 0.999])  
>>> np.allclose([0.001, 0.5, 0.999], moyal.cdf(vals))  
True
```

Generate random numbers:

```
>>> r = moyal.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)  
>>> ax.legend(loc='best', frameon=False)  
>>> plt.show()
```

## scipy.stats.nakagami

```
scipy.stats.nakagami(*args, **kws) = <scipy.stats._continuous_distns.nakagami_gen object>
```

A Nakagami continuous random variable.

As an instance of the *rv\_continuous* class, *nakagami* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *nakagami* is:

$$f(x, \nu) = \frac{2\nu^\nu}{\Gamma(\nu)} x^{2\nu-1} \exp(-\nu x^2)$$

for  $x \geq 0, \nu > 0$ .

*nakagami* takes *nu* as a shape parameter for  $\nu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `nakagami.pdf(x, nu, loc, scale)` is identically equivalent to `nakagami.pdf(y, nu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nakagami.ppf(0.01, nu),
...                 nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu),
...         'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.ncx2

`scipy.stats.ncx2(*args, **kwargs)` = <scipy.stats.\_continuous\_distns.ncx2\_gen object>

A non-central chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `ncx2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `ncx2` is:

$$f(x, k, \lambda) = \frac{1}{2} \exp(-(\lambda + x)/2) (x/\lambda)^{(k-2)/4} I_{(k-2)/2}(\sqrt{\lambda x})$$

for  $x \geq 0$  and  $k, \lambda > 0$ .  $k$  specifies the degrees of freedom (denoted `df` in the implementation) and  $\lambda$  is the non-centrality parameter (denoted `nc` in the implementation).  $I_\nu$  denotes the modified Bessel function of first order of degree  $\nu$  (`scipy.special.iv`).

`ncx2` takes `df` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncx2.pdf(x, df, nc, loc, scale)` is identically equivalent to `ncx2.pdf(y, df, nc) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncx2.ppf(0.01, df, nc),
...                 ncx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc),
...        'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncx2.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncx2.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = ncx2.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(df, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, nc, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).

<code>entropy(df, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(df, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.ncf`

```
scipy.stats.ncf(*args, **kws) = <scipy.stats._continuous_distns.ncf_gen object>
```

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`scipy.stats.f`

Fisher distribution

## Notes

The probability density function for `ncf` is:

$$f(x, n_1, n_2, \lambda) = \exp\left(\frac{\lambda}{2} + \lambda n_1 \frac{x}{2(n_1 x + n_2)}\right) n_1^{n_1/2} n_2^{n_2/2} x^{n_1/2-1} \\ (n_2 + n_1 x)^{-(n_1+n_2)/2} \gamma(n_1/2) \gamma(1 + n_2/2) \\ \frac{L_{n_2/2}^{\frac{n_1}{2}-1}\left(-\lambda n_1 \frac{x}{2(n_1 x + n_2)}\right)}{B(n_1/2, n_2/2) \gamma\left(\frac{n_1+n_2}{2}\right)}$$

for  $n_1, n_2 > 0$ ,  $\lambda \geq 0$ . Here  $n_1$  is the degrees of freedom in the numerator,  $n_2$  the degrees of freedom in the denominator,  $\lambda$  the non-centrality parameter,  $\gamma$  is the logarithm of the Gamma function,  $L_n^k$  is a generalized Laguerre polynomial and  $B$  is the beta function.

`ncf` takes `df1`, `df2` and `nc` as shape parameters. If `nc=0`, the distribution becomes equivalent to the Fisher distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncf.pdf(x, dfn, dfd, nc, loc, scale)` is identically equivalent to `ncf.pdf(y, dfn, dfd, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc),
...                 ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc),
...         'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```

Generate random numbers:

```
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(df, d, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, d, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, d, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, d, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, d, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, d, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, d, nc, loc=0, scale=1)</code>	Log of the survival function.

<code>stats(df, d, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, d, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(df, d, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, d, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, d, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, d, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, d, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, d, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.nct

`scipy.stats.nct(*args, **kwds) = <scipy.stats._continuous_distns.nct_gen object>`

A non-central Student's t continuous random variable.

As an instance of the `rv_continuous` class, `nct` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

If  $Y$  is a standard normal random variable and  $V$  is an independent chi-square random variable (*chi2*) with  $k$  degrees of freedom, then

$$X = \frac{Y + c}{\sqrt{V/k}}$$

has a non-central Student's t distribution on the real line. The degrees of freedom parameter  $k$  (denoted `df` in the implementation) satisfies  $k > 0$  and the noncentrality parameter  $c$  (denoted `nc` in the implementation) is a real number.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nct.pdf(x, df, nc, loc, scale)` is identically equivalent

to `nct.pdf(y, df, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 14, 0.24
>>> mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nct.ppf(0.01, df, nc),
...                 nct.ppf(0.99, df, nc), 100)
>>> ax.plot(x, nct.pdf(x, df, nc),
...         'r-', lw=5, alpha=0.6, label='nct pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nct(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nct.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = nct.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(df, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, nc, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, df, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, df, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(df, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.norm

`scipy.stats.norm(*args, **kwargs)` = `<scipy.stats._continuous_distns.norm_gen object>`

A normal continuous random variable.

The location (`loc`) keyword specifies the mean. The scale (`scale`) keyword specifies the standard deviation.

As an instance of the `rv_continuous` class, `norm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `norm` is:

$$f(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}}$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norm.pdf(x, loc, scale)` is identically equivalent to `norm.pdf(y) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norm.ppf(0.01),
...                 norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
...        'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = norm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.norminvgauss

`scipy.stats.norminvgauss(*args, **kws) = <scipy.stats._continuous_distns.norminvgauss_gen object>`

A Normal Inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `norminvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `norminvgauss` is:

$$f(x, a, b) = \frac{a K_1(a\sqrt{1+x^2})}{\pi\sqrt{1+x^2}} \exp(\sqrt{a^2 - b^2} + bx)$$

where  $x$  is a real number, the parameter  $a$  is the tail heaviness and  $b$  is the asymmetry parameter satisfying  $a > 0$  and  $|b| \leq a$ .  $K_1$  is the modified Bessel function of second kind (`scipy.special.k1`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norminvgauss.pdf(x, a, b, loc, scale)` is identically equivalent to `norminvgauss.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A normal inverse Gaussian random variable  $Y$  with parameters  $a$  and  $b$  can be expressed as a normal mean-variance mixture:  $Y = b * V + \text{sqr}(V) * X$  where  $X$  is  $\text{norm}(0,1)$  and  $V$  is  $\text{invgauss}(\text{mu}=1/\text{sqr}(a**2 - b**2))$ . This representation is used to generate random variates.

## Examples

```
>>> from scipy.stats import norminvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 1, 0.5
>>> mean, var, skew, kurt = norminvgauss.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norminvgauss.ppf(0.01, a, b),
...                 norminvgauss.ppf(0.99, a, b), 100)
>>> ax.plot(x, norminvgauss.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='norminvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norminvgauss(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norminvgauss.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], norminvgauss.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = norminvgauss.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.pareto

`scipy.stats.pareto(*args, **kwargs) = <scipy.stats._continuous_distns.pareto_gen object>`

A Pareto continuous random variable.

As an instance of the `rv_continuous` class, `pareto` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `pareto` is:

$$f(x, b) = \frac{b}{x^{b+1}}$$

for  $x \geq 1, b > 0$ .

`pareto` takes `b` as a shape parameter for  $b$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pareto.pdf(x, b, loc, scale)` is identically equivalent to `pareto.pdf(y, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pareto.ppf(0.01, b),
...                 pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='pareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.

## scipy.stats.pearson3

```
scipy.stats.pearson3(*args, **kws) = <scipy.stats._continuous_distns.
    pearson3_gen object>
```

A pearson type III continuous random variable.

As an instance of the `rv_continuous` class, `pearson3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `pearson3` is:

$$f(x, \kappa) = \frac{|\beta|}{\Gamma(\alpha)} (\beta(x - \zeta))^{\alpha-1} \exp(-\beta(x - \zeta))$$

where:

$$\begin{aligned} \beta &= \frac{2}{\kappa} \\ \alpha &= \beta^2 = \frac{4}{\kappa^2} \\ \zeta &= -\frac{\alpha}{\beta} = -\beta \end{aligned}$$

$\Gamma$  is the gamma function (`scipy.special.gamma`). Pass the skew  $\kappa$  into `pearson3` as the shape parameter `skew`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pearson3.pdf(x, skew, loc, scale)` is identically equivalent to `pearson3.pdf(y, skew) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import pearson3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> skew = 0.1
>>> mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pearson3.ppf(0.01, skew),
...                 pearson3.ppf(0.99, skew), 100)
>>> ax.plot(x, pearson3.pdf(x, skew),
...         'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pearson3(skew)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True
```

Generate random numbers:

```
>>> r = pearson3.rvs(skew, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.powerlaw

```
scipy.stats.powerlaw(*args, **kwds) = <scipy.stats._continuous_distns.
powerlaw_gen object>
```

A power-function continuous random variable.

As an instance of the *rv\_continuous* class, *powerlaw* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *powerlaw* is:

$$f(x, a) = ax^{a-1}$$

for  $0 \leq x \leq 1, a > 0$ .

*powerlaw* takes *a* as a shape parameter for *a*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `powerlaw.pdf(x, a, loc, scale)` is identically equivalent to `powerlaw.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

`powerlaw` is a special case of `beta` with `b=1`.

## Examples

```
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlaw.ppf(0.01, a),
...                 powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
...        'r-', lw=5, alpha=0.6, label='powerlaw pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = powerlaw.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b><code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code></b>	Random variates.
<b><code>pdf(x, a, loc=0, scale=1)</code></b>	Probability density function.
<b><code>logpdf(x, a, loc=0, scale=1)</code></b>	Log of the probability density function.
<b><code>cdf(x, a, loc=0, scale=1)</code></b>	Cumulative distribution function.
<b><code>logcdf(x, a, loc=0, scale=1)</code></b>	Log of the cumulative distribution function.
<b><code>sf(x, a, loc=0, scale=1)</code></b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b><code>logsf(x, a, loc=0, scale=1)</code></b>	Log of the survival function.
<b><code>ppf(q, a, loc=0, scale=1)</code></b>	Percent point function (inverse of <i>cdf</i> — percentiles).
<b><code>isf(q, a, loc=0, scale=1)</code></b>	Inverse survival function (inverse of <i>sf</i> ).
<b><code>moment(n, a, loc=0, scale=1)</code></b>	Non-central moment of order <i>n</i>
<b><code>stats(a, loc=0, scale=1, moments='mv')</code></b>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b><code>entropy(a, loc=0, scale=1)</code></b>	(Differential) entropy of the RV.
<b><code>fit(data)</code></b>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b><code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code></b>	Expected value of a function (of one argument) with respect to the distribution.
<b><code>median(a, loc=0, scale=1)</code></b>	Median of the distribution.
<b><code>mean(a, loc=0, scale=1)</code></b>	Mean of the distribution.
<b><code>var(a, loc=0, scale=1)</code></b>	Variance of the distribution.
<b><code>std(a, loc=0, scale=1)</code></b>	Standard deviation of the distribution.
<b><code>interval(alpha, a, loc=0, scale=1)</code></b>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

**scipy.stats.powerlognorm**

```
scipy.stats.powerlognorm(*args, **kwargs) = <scipy.stats._continuous_distns.
powerlognorm_gen object>
```

A power log-normal continuous random variable.

As an instance of the *rv\_continuous* class, *powerlognorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *powerlognorm* is:

$$f(x, c, s) = \frac{c}{xs} \phi(\log(x)/s) (\Phi(-\log(x)/s))^{c-1}$$

where  $\phi$  is the normal pdf, and  $\Phi$  is the normal cdf, and  $x > 0$ ,  $s, c > 0$ .

*powerlognorm* takes  $c$  and  $s$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *powerlognorm.pdf(x, c, s, loc, scale)* is identically equivalent to *powerlognorm.pdf(y, c, s) / scale* with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
...                 powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
...         'r-', lw=5, alpha=0.6, label='powerlognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```

Generate random numbers:

```
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, s, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, s, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, s, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, s, loc=0, scale=1)</code>	Log of the cumulative distribution function.

<code>mean(c, s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, s, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.powernorm

```
scipy.stats.powernorm(*args, **kwds) = <scipy.stats._continuous_distns.
powernorm_gen object>
```

A power normal continuous random variable.

As an instance of the *rv\_continuous* class, *powernorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *powernorm* is:

$$f(x, c) = c\phi(x)(\Phi(-x))^{c-1}$$

where  $\phi$  is the normal pdf, and  $\Phi$  is the normal cdf, and  $x \geq 0$ ,  $c > 0$ .

*powernorm* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `powernorm.pdf(x, c, loc, scale)` is identically equivalent to `powernorm.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powernorm.ppf(0.01, c),
...                 powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='powernorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = powernorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.

<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.rdist

`scipy.stats.rdist(*args, **kwargs) = <scipy.stats._continuous_distns.rdist_gen object>`

An R-distributed (symmetric beta) continuous random variable.

As an instance of the `rv_continuous` class, `rdist` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `rdist` is:

$$f(x, c) = \frac{(1 - x^2)^{c/2-1}}{B(1/2, c/2)}$$

for  $-1 \leq x \leq 1$ ,  $c > 0$ . `rdist` is also called the symmetric beta distribution: if `B` has a `beta` distribution with parameters  $(c/2, c/2)$ , then  $X = 2*B - 1$  follows a R-distribution with parameter  $c$ .

`rdist` takes `c` as a shape parameter for  $c$ .

This distribution includes the following distribution kernels as special cases:

```
c = 2: uniform
c = 3: `semicircular`
c = 4: Epanechnikov (parabolic)
c = 6: quartic (biweight)
c = 8: triweight
```

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rdist.pdf(x, c, loc, scale)` is identically equivalent to `rdist.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.6
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rdist.ppf(0.01, c),
...                 rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.rayleigh

```
scipy.stats.rayleigh(*args, **kws) = <scipy.stats._continuous_distns.
rayleigh_gen object>
```

A Rayleigh continuous random variable.

As an instance of the *rv\_continuous* class, *rayleigh* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *rayleigh* is:

$$f(x) = x \exp(-x^2/2)$$

for  $x \geq 0$ .

*rayleigh* is a special case of *chi* with *df*=2.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `rayleigh.pdf(x, loc, scale)` is identically equivalent to `rayleigh.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rayleigh.ppf(0.01),
...                 rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x),
...         'r-', lw=5, alpha=0.6, label='rayleigh pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
True
```

Generate random numbers:

```
>>> r = rayleigh.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs</b> (loc=0, scale=1, size=1, random_state=None)	Random variates.
<b>pdf</b> (x, loc=0, scale=1)	Probability density function.
<b>logpdf</b> (x, loc=0, scale=1)	Log of the probability density function.
<b>cdf</b> (x, loc=0, scale=1)	Cumulative distribution function.
<b>logcdf</b> (x, loc=0, scale=1)	Log of the cumulative distribution function.
<b>sf</b> (x, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).

<b>ppf</b> (q, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf</b> (q, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i> ).
<b>moment</b> (n, loc=0, scale=1)	Non-central moment of order <i>n</i>
<b>stats</b> (loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy</b> (loc=0, scale=1)	(Differential) entropy of the RV.
<b>fit</b> (data)	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b>expect</b> (func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
<b>median</b> (loc=0, scale=1)	Median of the distribution.
<b>mean</b> (loc=0, scale=1)	Mean of the distribution.
<b>var</b> (loc=0, scale=1)	Variance of the distribution.
<b>std</b> (loc=0, scale=1)	Standard deviation of the distribution.
<b>interval</b> (alpha, loc=0, scale=1)	Endpoints of the range that contains alpha percent of the distribution

**scipy.stats.rice**

```
scipy.stats.rice(*args,**kws) = <scipy.stats._continuous_distns.rice_gen object>
```

A Rice continuous random variable.

As an instance of the `rv_continuous` class, `rice` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `rice` is:

$$f(x, b) = x \exp\left(-\frac{x^2 + b^2}{2}\right) I_0(xb)$$

for  $x \geq 0, b > 0$ .  $I_0$  is the modified Bessel function of order zero (`scipy.special.i0`).

`rice` takes `b` as a shape parameter for  $b$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rice.pdf(x, b, loc, scale)` is identically equivalent to `rice.pdf(y, b) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The Rice distribution describes the length,  $r$ , of a 2-D vector with components  $(U + u, V + v)$ , where  $U, V$  are constant,  $u, v$  are independent Gaussian random variables with standard deviation  $s$ . Let  $R = \sqrt{U^2 + V^2}$ . Then the pdf of  $r$  is `rice.pdf(x, R/s, scale=s)`.

**Examples**

```
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rice.ppf(0.01, b),
...                 rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b),
...        'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = rice.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.

<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.recipinvgauss

`scipy.stats.recipinvgauss(*args, **kws) = <scipy.stats._continuous_distns.recipinvgauss_gen object>`

A reciprocal inverse Gaussian continuous random variable.

As an instance of the *rv\_continuous* class, *recipinvgauss* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *recipinvgauss* is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x}} \exp\left(\frac{-(1 - \mu x)^2}{2\mu^2 x}\right)$$

for  $x \geq 0$ .

*recipinvgauss* takes *mu* as a shape parameter for  $\mu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `recipinvgauss.pdf(x, mu, loc, scale)` is identically equivalent to `recipinvgauss.pdf(y, mu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu),
...                 recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu),
...         'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs(mu, loc=0, scale=1, size=1, random_state=None)</b>	Random variates.
<b>pdf(x, mu, loc=0, scale=1)</b>	Probability density function.
<b>logpdf(x, mu, loc=0, scale=1)</b>	Log of the probability density function.
<b>cdf(x, mu, loc=0, scale=1)</b>	Cumulative distribution function.
<b>logcdf(x, mu, loc=0, scale=1)</b>	Log of the cumulative distribution function.
<b>sf(x, mu, loc=0, scale=1)</b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf(x, mu, loc=0, scale=1)</b>	Log of the survival function.
<b>ppf(q, mu, loc=0, scale=1)</b>	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf(q, mu, loc=0, scale=1)</b>	Inverse survival function (inverse of <i>sf</i> ).
<b>moment(n, mu, loc=0, scale=1)</b>	Non-central moment of order n
<b>stats(mu, loc=0, scale=1, moments='mv')</b>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy(mu, loc=0, scale=1)</b>	(Differential) entropy of the RV.
<b>fit(data)</b>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b>expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</b>	Expected value of a function (of one argument) with respect to the distribution.
<b>median(mu, loc=0, scale=1)</b>	Median of the distribution.
<b>mean(mu, loc=0, scale=1)</b>	Mean of the distribution.
<b>var(mu, loc=0, scale=1)</b>	Variance of the distribution.
<b>std(mu, loc=0, scale=1)</b>	Standard deviation of the distribution.
<b>interval(alpha, mu, loc=0, scale=1)</b>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.semicircular

`scipy.stats.semicircular(*args, **kwargs) = <scipy.stats._continuous_distns.semicircular_gen object>`

A semicircular continuous random variable.

As an instance of the `rv_continuous` class, `semicircular` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`rdist`

### Notes

The probability density function for `semicircular` is:

$$f(x) = \frac{2}{\pi} \sqrt{1 - x^2}$$

for  $-1 \leq x \leq 1$ .

The distribution is a special case of `rdist` with  $c = 3$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `semicircular.pdf(x, loc, scale)` is identically equivalent to `semicircular.pdf(y) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1]

### Examples

```
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(semicircular.ppf(0.01),
...                 semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x),
...         'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = semicircular()  
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])  
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))  
True
```

Generate random numbers:

```
>>> r = semicircular.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)  
>>> ax.legend(loc='best', frameon=False)  
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.skewnorm

```
scipy.stats.skewnorm(*args, **kws) = <scipy.stats._continuous_distns.
skew_norm_gen object>
```

A skew-normal random variable.

As an instance of the *rv\_continuous* class, *skewnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The pdf is:

$$\text{skewnorm.pdf}(x, a) = 2 * \text{norm.pdf}(x) * \text{norm.cdf}(a*x)$$

*skewnorm* takes a real number *a* as a skewness parameter. When *a* = 0 the distribution is identical to a normal distribution (*norm*). *rvs* implements the method of [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `skewnorm.pdf(x, a, loc, scale)` is identically equivalent to `skewnorm.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(skewnorm.ppf(0.01, a),
...                 skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.t

`scipy.stats.t(*args, **kwargs)` = `<scipy.stats._continuous_distns.t_gen object>`  
 A Student's t continuous random variable.

For the noncentral t distribution, see `nct`.

As an instance of the `rv_continuous` class, `t` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`nct`

## Notes

The probability density function for `t` is:

$$f(x, \nu) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)} (1 + x^2/\nu)^{-(\nu+1)/2}$$

where  $x$  is a real number and the degrees of freedom parameter  $\nu$  (denoted `df` in the implementation) satisfies  $\nu > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `t.pdf(x, df, loc, scale)` is identically equivalent to `t.pdf(y, df) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(t.ppf(0.01, df),
...                 t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs(df, loc=0, scale=1, size=1, random_state=None)</b>	Random variates.
<b>pdf(x, df, loc=0, scale=1)</b>	Probability density function.
<b>logpdf(x, df, loc=0, scale=1)</b>	Log of the probability density function.
<b>cdf(x, df, loc=0, scale=1)</b>	Cumulative distribution function.
<b>logcdf(x, df, loc=0, scale=1)</b>	Log of the cumulative distribution function.
<b>sf(x, df, loc=0, scale=1)</b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf(x, df, loc=0, scale=1)</b>	Log of the survival function.
<b>ppf(q, df, loc=0, scale=1)</b>	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf(q, df, loc=0, scale=1)</b>	Inverse survival function (inverse of <i>sf</i> ).

<b>median(df, loc=0, scale=1)</b>	Median of the distribution.
<b>mean(df, loc=0, scale=1)</b>	Mean of the distribution.
<b>var(df, loc=0, scale=1)</b>	Variance of the distribution.
<b>std(df, loc=0, scale=1)</b>	Standard deviation of the distribution.
<b>interval(alpha, df, loc=0, scale=1)</b>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.trapezoid

```
scipy.stats.trapezoid(*args, **kwds) = <scipy.stats._continuous_distns.
trapezoid_gen object>
```

A trapezoidal continuous random variable.

As an instance of the *rv\_continuous* class, *trapezoid* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The trapezoidal distribution can be represented with an up-sloping line from *loc* to  $(loc + c*scale)$ , then constant to  $(loc + d*scale)$  and then downsloping from  $(loc + d*scale)$  to  $(loc+scale)$ . This defines the trapezoid base from *loc* to  $(loc+scale)$  and the flat top from *c* to *d* proportional to the position along the base with  $0 \leq c \leq d \leq 1$ . When *c=d*, this is equivalent to *triang* with the same values for *loc*, *scale* and *c*. The method of [1] is used for computing moments.

*trapezoid* takes *c* and *d* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `trapezoid.pdf(x, c, d, loc, scale)` is identically equivalent to `trapezoid.pdf(y, c, d) / scale` with  $y = (x - loc) / scale$ . Note that

shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The standard form is in the range  $[0, 1]$  with  $c$  the mode. The location parameter shifts the start to *loc*. The scale parameter changes the width from 1 to *scale*.

## References

[1]

## Examples

```
>>> from scipy.stats import trapezoid
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapezoid.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(trapezoid.ppf(0.01, c, d),
...                 trapezoid.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapezoid.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='trapezoid pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = trapezoid(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = trapezoid.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapezoid.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = trapezoid.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.triang

```
scipy.stats.triang(*args, **kws) = <scipy.stats._continuous_distns.triang_gen
object>
```

A triangular continuous random variable.

As an instance of the `rv_continuous` class, `triang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The triangular distribution can be represented with an up-sloping line from `loc` to `(loc + c*scale)` and then downsloping for `(loc + c*scale)` to `(loc + scale)`.

`triang` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `triang.pdf(x, c, loc, scale)` is identically equivalent to `triang.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The standard form is in the range `[0, 1]` with `c` the mode. The location parameter shifts the start to `loc`. The scale parameter changes the width from 1 to `scale`.

### Examples

```
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.158
>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(triang.ppf(0.01, c),
...                 triang.ppf(0.99, c), 100)
>>> ax.plot(x, triang.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='triang pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = triang(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.truncexpon

```
scipy.stats.truncexpon(*args, **kws) = <scipy.stats._continuous_distns.
truncexpon_gen object>
```

A truncated exponential continuous random variable.

As an instance of the `rv_continuous` class, `truncexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `truncexpon` is:

$$f(x, b) = \frac{\exp(-x)}{1 - \exp(-b)}$$

for  $0 \leq x \leq b$ .

`truncexpon` takes `b` as a shape parameter for *b*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncexpon.pdf(x, b, loc, scale)` is identically equivalent to `truncexpon.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 4.69
>>> mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncexpon.ppf(0.01, b),
...                 truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

**scipy.stats.truncnorm**

```
scipy.stats.truncnorm(*args, **kws) = <scipy.stats._continuous_distns.
truncnorm_gen object>
```

A truncated normal continuous random variable.

As an instance of the *rv\_continuous* class, *truncnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The standard form of this distribution is a standard normal truncated to the range [a, b] — notice that a and b are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

```
a, b = (myclip_a - my_mean) / my_std, (myclip_b - my_mean) / my_std
```

*truncnorm* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `truncnorm.pdf(x, a, b, loc, scale)` is identically equivalent to `truncnorm.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncnorm.ppf(0.01, a, b),
...                 truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = truncnorm.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.tukeylambda

```
scipy.stats.tukeylambda(*args, **kws) = <scipy.stats._continuous_distns.
    tukeylambda_gen object>
```

A Tukey-Lambda continuous random variable.

As an instance of the *rv\_continuous* class, *tukeylambda* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy (*lambda* = -1)
- logistic (*lambda* = 0)
- approx Normal (*lambda* = 0.14)
- uniform from -1 to 1 (*lambda* = 1)

*tukeylambda* takes a real number *lambda* (denoted *lam* in the implementation) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `tukeylambda.pdf(x, lam, loc, scale)` is identically

equivalent to `tukeylambda.pdf(y, lam) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import tukeylambda
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(tukeylambda.ppf(0.01, lam),
...                 tukeylambda.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambda.pdf(x, lam),
...        'r-', lw=5, alpha=0.6, label='tukeylambda pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = tukeylambda(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = tukeylambda.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambda.cdf(vals, lam))
True
```

Generate random numbers:

```
>>> r = tukeylambda.rvs(lam, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(lam, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, lam, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, lam, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, lam, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, lam, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, lam, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, lam, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, lam, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, lam, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, lam, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(lam, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lam, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(lam,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lam, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(lam, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(lam, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(lam, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, lam, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.uniform

```
scipy.stats.uniform(*args, **kwargs) = <scipy.stats._continuous_distns.
    uniform_gen object>
```

A uniform continuous random variable.

In the standard form, the distribution is uniform on  $[0, 1]$ . Using the parameters `loc` and `scale`, one obtains the uniform distribution on  $[loc, loc + scale]$ .

As an instance of the `rv_continuous` class, `uniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(uniform.ppf(0.01),
...                 uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x),
...         'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
True
```

Generate random numbers:

```
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs</b> (loc=0, scale=1, size=1, random_state=None)	Random variates.
<b>pdf</b> (x, loc=0, scale=1)	Probability density function.
<b>logpdf</b> (x, loc=0, scale=1)	Log of the probability density function.
<b>cdf</b> (x, loc=0, scale=1)	Cumulative distribution function.
<b>logcdf</b> (x, loc=0, scale=1)	Log of the cumulative distribution function.
<b>sf</b> (x, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf</b> (x, loc=0, scale=1)	Log of the survival function.
<b>ppf</b> (q, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf</b> (q, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i> ).
<b>moment</b> (n, loc=0, scale=1)	Non-central moment of order <i>n</i>
<b>stats</b> (loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy</b> (loc=0, scale=1)	(Differential) entropy of the RV.
<b>fit</b> (data)	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b>expect</b> (func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
<b>median</b> (loc=0, scale=1)	Median of the distribution.
<b>mean</b> (loc=0, scale=1)	Mean of the distribution.
<b>var</b> (loc=0, scale=1)	Variance of the distribution.
<b>std</b> (loc=0, scale=1)	Standard deviation of the distribution.
<b>interval</b> (alpha, loc=0, scale=1)	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.vonmises

```
scipy.stats.vonmises(*args, **kwargs) = <scipy.stats._continuous_distns.
    vonmises_gen object>
```

A Von Mises continuous random variable.

As an instance of the *rv\_continuous* class, *vonmises* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *vonmises* and *vonmises\_line* is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for  $-\pi \leq x \leq \pi$ ,  $\kappa > 0$ .  $I_0$  is the modified Bessel function of order zero (*scipy.special.i0*).

*vonmises* is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in *scipy*. The cdf is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

*vonmises\_line* is the same distribution, defined on  $[-\pi, \pi]$  on the real line. This is a regular (i.e. non-circular) distribution.

*vonmises* and *vonmises\_line* take *kappa* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `vonmises.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises.pdf(y, kappa) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import vonmises
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises.ppf(0.01, kappa),
...                 vonmises.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(kappa, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, kappa, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, kappa, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, kappa, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, kappa, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, kappa, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, kappa, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, kappa, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, kappa, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, kappa, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(kappa, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(kappa, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(kappa,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(kappa, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(kappa, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(kappa, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(kappa, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, kappa, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.vonmises\_line

`scipy.stats.vonmises_line(*args, **kwds) = <scipy.stats._continuous_distns.vonmises_gen object>`

A Von Mises continuous random variable.

As an instance of the *rv\_continuous* class, *vonmises\_line* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *vonmises* and *vonmises\_line* is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for  $-\pi \leq x \leq \pi$ ,  $\kappa > 0$ .  $I_0$  is the modified Bessel function of order zero (*scipy.special.i0*).

*vonmises* is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in *scipy*. The *cdf* is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

*vonmises\_line* is the same distribution, defined on  $[-\pi, \pi]$  on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises_line.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises_line.pdf(y, kappa) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises_line.ppf(0.01, kappa),
...                 vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='vonmises_line pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises_line.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<b>rvs(kappa, loc=0, scale=1, size=1, random_state=None)</b>	Random variates.
<b>pdf(x, kappa, loc=0, scale=1)</b>	Probability density function.
<b>logpdf(x, kappa, loc=0, scale=1)</b>	Log of the probability density function.
<b>cdf(x, kappa, loc=0, scale=1)</b>	Cumulative distribution function.
<b>logcdf(x, kappa, loc=0, scale=1)</b>	Log of the cumulative distribution function.
<b>sf(x, kappa, loc=0, scale=1)</b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf(x, kappa, loc=0, scale=1)</b>	Log of the survival function.
<b>ppf(q, kappa, loc=0, scale=1)</b>	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf(q, kappa, loc=0, scale=1)</b>	Inverse survival function (inverse of <i>sf</i> ).
<b>moment(n, kappa, loc=0, scale=1)</b>	Non-central moment of order <i>n</i>
<b>stats(kappa, loc=0, scale=1, moments='mv')</b>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy(kappa, loc=0, scale=1)</b>	(Differential) entropy of the RV.
<b>fit(data)</b>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<b>expect(func, args=(kappa,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</b>	Expected value of a function (of one argument) with respect to the distribution.
<b>median(kappa, loc=0, scale=1)</b>	Median of the distribution.
<b>mean(kappa, loc=0, scale=1)</b>	Mean of the distribution.
<b>var(kappa, loc=0, scale=1)</b>	Variance of the distribution.
<b>std(kappa, loc=0, scale=1)</b>	Standard deviation of the distribution.
<b>interval(alpha, kappa, loc=0, scale=1)</b>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

**scipy.stats.wald**

```
scipy.stats.wald(*args, **kws) = <scipy.stats._continuous_distns.wald_gen object>
```

A Wald continuous random variable.

As an instance of the *rv\_continuous* class, *wald* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for *wald* is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x-1)^2}{2x}\right)$$

for  $x \geq 0$ .

*wald* is a special case of *invgauss* with  $\mu=1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `wald.pdf(x, loc, scale)` is identically equivalent to `wald.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wald.ppf(0.01),
...                 wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x),
...        'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
True
```

Generate random numbers:

```
>>> r = wald.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.weibull\_min

```
scipy.stats.weibull_min(*args, **kws) = <scipy.stats._continuous_distns.
    weibull_min_gen object>
```

Weibull minimum continuous random variable.

The Weibull Minimum Extreme Value distribution, from extreme value theory (Fisher-Gnedenko theorem), is also often simply called the Weibull distribution. It arises as the limiting distribution of the rescaled minimum of iid random variables.

As an instance of the *rv\_continuous* class, *weibull\_min* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[weibull\\_max](#), [numpy.random.RandomState.weibull](#), [exponweib](#)

## Notes

The probability density function for `weibull_min` is:

$$f(x, c) = cx^{c-1} \exp(-x^c)$$

for  $x > 0, c > 0$ .

`weibull_min` takes `c` as a shape parameter for  $c$ . (named  $k$  in Wikipedia article and  $a$  in `numpy.random.weibull`). Special shape values are  $c = 1$  and  $c = 2$  where Weibull distribution reduces to the `expon` and `rayleigh` distributions respectively.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_min.pdf(x, c, loc, scale)` is identically equivalent to `weibull_min.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

[https://en.wikipedia.org/wiki/Fisher-Tippett-Gnedenko\\_theorem](https://en.wikipedia.org/wiki/Fisher-Tippett-Gnedenko_theorem)

## Examples

```
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_min.ppf(0.01, c),
...                 weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.

<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

`scipy.stats.weibull_max`

```
scipy.stats.weibull_max(*args, **kws) = <scipy.stats._continuous_distns.
weibull_max_gen object>
```

Weibull maximum continuous random variable.

The Weibull Maximum Extreme Value distribution, from extreme value theory (Fisher-Gnedenko theorem), is the limiting distribution of rescaled maximum of iid random variables. This is the distribution of  $-X$  if  $X$  is from the `weibull_min` function.

As an instance of the `rv_continuous` class, `weibull_max` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`weibull_min`

## Notes

The probability density function for `weibull_max` is:

$$f(x, c) = c(-x)^{c-1} \exp(-(-x)^c)$$

for  $x < 0, c > 0$ .

`weibull_max` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_max.pdf(x, c, loc, scale)` is identically equivalent to `weibull_max.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

[https://en.wikipedia.org/wiki/Fisher-Tippett-Gnedenko\\_theorem](https://en.wikipedia.org/wiki/Fisher-Tippett-Gnedenko_theorem)

## Examples

```
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_max.ppf(0.01, c),
...                 weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_max.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.wrapcauchy

`scipy.stats.wrapcauchy(*args, **kws) = <scipy.stats._continuous_distns.wrapcauchy_gen object>`

A wrapped Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `wrapcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `wrapcauchy` is:

$$f(x, c) = \frac{1 - c^2}{2\pi(1 + c^2 - 2c \cos(x))}$$

for  $0 \leq x \leq 2\pi, 0 < c < 1$ .

`wrapcauchy` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wrapcauchy.pdf(x, c, loc, scale)` is identically equivalent to `wrapcauchy.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.0311
>>> mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wrapcauchy.ppf(0.01, c),
...                 wrapcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, wrapcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wrapcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = wrapcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments.

<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## 6.29.5 Multivariate distributions

<code>multivariate_normal</code> ([mean, cov, ...])	A multivariate normal random variable.
<code>matrix_normal</code> ([mean, rowcov, colcov, seed])	A matrix normal random variable.
<code>dirichlet</code> (alpha[, seed])	A Dirichlet random variable.
<code>wishart</code> ([df, scale, seed])	A Wishart random variable.
<code>invwishart</code> ([df, scale, seed])	An inverse Wishart random variable.
<code>multinomial</code> (n, p[, seed])	A multinomial random variable.
<code>special_ortho_group</code> ([dim, seed])	A matrix-valued SO(N) random variable.
<code>ortho_group</code>	A matrix-valued O(N) random variable.
<code>unitary_group</code>	A matrix-valued U(N) random variable.
<code>random_correlation</code>	A random correlation matrix.
<code>multivariate_t</code> ([loc, shape, df, ...])	A multivariate t-distributed random variable.
<code>multivariate_hypergeom</code> (m, n[, seed])	A multivariate hypergeometric random variable.

### scipy.stats.multivariate\_normal

```
scipy.stats.multivariate_normal(mean=None, cov=1, allow_singular=False, seed=None)
                                = <scipy.stats._multivariate.
                                multivariate_normal_gen object>
```

A multivariate normal random variable.

The *mean* keyword specifies the mean. The *cov* keyword specifies the covariance matrix.

#### Parameters

- x** [array\_like] Quantiles, with the last axis of *x* denoting the components.
- mean** [array\_like, optional] Mean of the distribution (default zero)
- cov** [array\_like, optional] Covariance matrix of the distribution (default one)
- allow\_singular** [bool, optional] Whether to allow a singular covariance matrix. (Default: False)
- random\_state** [{None, int, np.random.RandomState, np.random.Generator}, optional] Used for drawing random variates. If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*.

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” multivariate normal random variable:

```
rv = multivariate_normal(mean=None, cov=1, allow_singular=False)
```

- Frozen object with the same methods but holding the given mean and covariance fixed.

#### Notes

##### Setting the parameter mean to None is equivalent to having mean

be the zero-vector. The parameter *cov* can be a scalar, in which case the covariance matrix is the identity times that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array\_like.

The covariance matrix *cov* must be a (symmetric) positive semi-definite matrix. The determinant and inverse of *cov* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *cov* does not need to have full rank.

The probability density function for `multivariate_normal` is

$$f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp\left(-\frac{1}{2}(x - \mu)^T \Sigma^{-1}(x - \mu)\right),$$

where  $\mu$  is the mean,  $\Sigma$  the covariance matrix, and  $k$  is the dimension of the space where  $x$  takes values.

New in version 0.14.0.

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal
```

```
>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([ 0.00108914,  0.01033349,  0.05946514,  0.20755375,  0.43939129,
         0.56418958,  0.43939129,  0.20755375,  0.05946514,  0.01033349])
>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)
```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```
>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))
```

## Methods

<code>pdf(x, mean=None, cov=1, allow_singular=False)</code>	Probability density function.
<code>logpdf(x, mean=None, cov=1, allow_singular=False)</code>	Log of the probability density function.
<code>cdf(x, mean=None, cov=1, allow_singular=False, maxpts=100000*dim, abseps=1e-5, releps=1e-5)</code>	Cumulative distribution function.
<code>logcdf(x, mean=None, cov=1, allow_singular=False, maxpts=100000*dim, abseps=1e-5, releps=1e-5)</code>	Log of the cumulative distribution function.
<code>rvs(mean=None, cov=1, size=1, random_state=None)</code>	Draw random samples from a multivariate normal distribution.
<code>entropy()</code>	Compute the differential entropy of the multivariate normal.

## scipy.stats.matrix\_normal

`scipy.stats.matrix_normal(mean=None, rowcov=1, colcov=1, seed=None) = <scipy.stats._multivariate.matrix_normal_gen object>`

A matrix normal random variable.

The *mean* keyword specifies the mean. The *rowcov* keyword specifies the among-row covariance matrix. The *colcov* keyword specifies the among-column covariance matrix.

### Parameters

<b>X</b>	[array_like] Quantiles, with the last two axes of <i>X</i> denoting the components.
<b>mean</b>	[array_like, optional] Mean of the distribution (default: <i>None</i> )
<b>rowcov</b>	[array_like, optional] Among-row covariance matrix of the distribution (default: <i>1</i> )
<b>colcov</b>	[array_like, optional] Among-column covariance matrix of the distribution (default: <i>1</i> )
<b>random_state</b>	[{None, int, np.random.RandomState, np.random.Generator}, optional] Used for drawing random variates. If <i>seed</i> is <i>None</i> the <i>RandomState</i> singleton is used. If <i>seed</i> is an int, a new <i>RandomState</i> instance is used, seeded with <i>seed</i> . If <i>seed</i> is already a <i>RandomState</i> or <i>Generator</i> instance, then that object is used. Default is <i>None</i> .

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” matrix normal random variable:

```
rv = matrix_normal(mean=None, rowcov=1, colcov=1)
```

- Frozen object with the same methods but holding the given mean and covariance fixed.

## Notes

*If mean is set to None then a matrix of zeros is used for the mean.*

The dimensions of this matrix are inferred from the shape of *rowcov* and *colcov*, if these are provided, or set to *1* if ambiguous.

*rowcov* and *colcov* can be two-dimensional array\_likes specifying the covariance matrices directly. Alternatively, a one-dimensional array will be interpreted as the entries of a diagonal matrix, and a scalar or zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by *rowcov* and *colcov* must be (symmetric) positive definite. If the samples in *X* are  $m \times n$ , then *rowcov* must be  $m \times m$  and *colcov* must be  $n \times n$ . *mean* must be the same shape as *X*.

The probability density function for *matrix\_normal* is

$$f(X) = (2\pi)^{-\frac{mn}{2}} |U|^{-\frac{n}{2}} |V|^{-\frac{m}{2}} \exp\left(-\frac{1}{2} \text{Tr}[U^{-1}(X-M)V^{-1}(X-M)^T]\right),$$

where *M* is the mean, *U* the among-row covariance matrix, *V* the among-column covariance matrix.

The *allow\_singular* behaviour of the *multivariate\_normal* distribution is not currently supported. Covariance matrices must be full rank.

The *matrix\_normal* distribution is closely related to the *multivariate\_normal* distribution. Specifically,  $\text{Vec}(X)$  (the vector formed by concatenating the columns of *X*) has a multivariate normal distribution with mean  $\text{Vec}(M)$  and covariance  $V \otimes U$  (where  $\otimes$  is the Kronecker product). Sampling and pdf evaluation are  $\mathcal{O}(m^3 + n^3 + m^2n + mn^2)$  for the matrix normal, but  $\mathcal{O}(m^3n^3)$  for the equivalent multivariate normal, making this equivalent form algorithmically inefficient.

New in version 0.17.0.

## Examples

```
>>> from scipy.stats import matrix_normal
```

```
>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]])
>>> V = 0.3*np.identity(2); V
array([[ 0.3,  0. ],
       [ 0. ,  0.3]])
>>> X = M + 0.1; X
```

(continues on next page)

(continued from previous page)

```
array([[ 0.1,  1.1],
       [ 2.1,  3.1],
       [ 4.1,  5.1]])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054
```

```
>>> # Equivalent multivariate normal
>>> from scipy.stats import multivariate_normal
>>> vectorised_X = X.T.flatten()
>>> equiv_mean = M.T.flatten()
>>> equiv_cov = np.kron(V,U)
>>> multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
0.023410202050005054
```

## Methods

<code>pdf(X, mean=None, rowcov=1, colcov=1)</code>	Probability density function.
<code>logpdf(X, mean=None, rowcov=1, colcov=1)</code>	Log of the probability density function.
<code>rvs(mean=None, rowcov=1, colcov=1, size=1, random_state=None)</code>	Draw random samples.

## scipy.stats.dirichlet

`scipy.stats.dirichlet(alpha, seed=None)` = `<scipy.stats._multivariate.dirichlet_gen object>`

A Dirichlet random variable.

The `alpha` keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

### Parameters

- x** [array\_like] Quantiles, with the last axis of *x* denoting the components.
- alpha** [array\_like] The concentration parameters. The number of entries determines the dimensionality of the distribution.
- random\_state** [{None, int, np.random.RandomState, np.random.Generator}, optional] Used for drawing random variates. If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*.

Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:

```
rv = dirichlet(alpha)
```

- Frozen object with the same methods but holding the given concentration parameters fixed.

## Notes

Each  $\alpha$  entry must be positive. The distribution has only support on the simplex defined by

$$\sum_{i=1}^K x_i = 1$$

where  $0 < x_i < 1$ .

If the quantiles don't lie within the simplex, a `ValueError` is raised.

The probability density function for `dirichlet` is

$$f(x) = \frac{1}{B(\alpha)} \prod_{i=1}^K x_i^{\alpha_i - 1}$$

where

$$B(\alpha) = \frac{\prod_{i=1}^K \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^K \alpha_i)}$$

and  $\alpha = (\alpha_1, \dots, \alpha_K)$ , the concentration parameters and  $K$  is the dimension of the space where  $x$  takes values.

Note that the dirichlet interface is somewhat inconsistent. The array returned by the rvs function is transposed with respect to the format expected by the pdf and logpdf.

## Examples

```
>>> from scipy.stats import dirichlet
```

Generate a dirichlet random variable

```
>>> quantiles = np.array([0.2, 0.2, 0.6]) # specify quantiles
>>> alpha = np.array([0.4, 5, 15]) # specify concentration parameters
>>> dirichlet.pdf(quantiles, alpha)
0.2843831684937255
```

The same PDF but following a log scale

```
>>> dirichlet.logpdf(quantiles, alpha)
-1.2574327653159187
```

Once we specify the dirichlet distribution we can then calculate quantities of interest

```
>>> dirichlet.mean(alpha) # get the mean of the distribution
array([0.01960784, 0.24509804, 0.73529412])
>>> dirichlet.var(alpha) # get variance
array([0.00089829, 0.00864603, 0.00909517])
>>> dirichlet.entropy(alpha) # calculate the differential entropy
-4.3280162474082715
```

We can also return random samples from the distribution

```
>>> dirichlet.rvs(alpha, size=1, random_state=1)
array([[0.00766178, 0.24670518, 0.74563305]])
>>> dirichlet.rvs(alpha, size=2, random_state=2)
array([[0.01639427, 0.1292273 , 0.85437844],
       [0.00156917, 0.19033695, 0.80809388]])
```

## Methods

<code>pdf(x, alpha)</code>	Probability density function.
<code>logpdf(x, alpha)</code>	Log of the probability density function.
<code>rvs(alpha, size=1, random_state=None)</code>	Draw random samples from a Dirichlet distribution.
<code>mean(alpha)</code>	The mean of the Dirichlet distribution
<code>var(alpha)</code>	The variance of the Dirichlet distribution
<code>entropy(alpha)</code>	Compute the differential entropy of the Dirichlet distribution.

## scipy.stats.wishart

`scipy.stats.wishart` (*df=None, scale=None, seed=None*) = `<scipy.stats._multivariate.wishart_gen object>`

A Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix).

### Parameters

**x** [array\_like] Quantiles, with the last axis of *x* denoting the components.  
**df** [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix  
**scale** [array\_like] Symmetric positive definite scale matrix of the distribution  
**random\_state** [{None, int, np.random.RandomState, np.random.Generator}, optional] Used for drawing random variates. If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:

```
rv = wishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

`invwishart`, `chi2`

## Notes

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

$$W_p(\nu, \Sigma)$$

where  $\nu$  is the degrees of freedom and  $\Sigma$  is the  $p \times p$  scale matrix.

The probability density function for *wishart* has support over positive definite matrices  $S$ ; if  $S \sim W_p(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|S|^{\frac{\nu-p-1}{2}}}{2^{\frac{\nu p}{2}} |\Sigma|^{\frac{\nu}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-tr(\Sigma^{-1}S)/2)$$

If  $S \sim W_p(\nu, \Sigma)$  (Wishart) then  $S^{-1} \sim W_p^{-1}(\nu, \Sigma^{-1})$  (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution  $W_1(\nu, 1)$  collapses to the  $\chi^2(\nu)$  distribution.

New in version 0.16.0.

## References

[1], [2]

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2
>>> x = np.linspace(1e-5, 8, 100)
>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
array([ 0.00126156,  0.10892176,  0.14793434,  0.17400548,  0.1929669 ])
>>> c = chi2.pdf(x, 3); c[:5]
array([ 0.00126156,  0.10892176,  0.14793434,  0.17400548,  0.1929669 ])
>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

## Methods

<code>pdf(x, df, scale)</code>	Probability density function.
<code>logpdf(x, df, scale)</code>	Log of the probability density function.
<code>rvs(df, scale, size=1, random_state=None)</code>	Draw random samples from a Wishart distribution.
<code>entropy()</code>	Compute the differential entropy of the Wishart distribution.

### scipy.stats.invwishart

`scipy.stats.invwishart` (*df=None*, *scale=None*, *seed=None*) = `<scipy.stats._multivariate.invwishart_gen object>`

An inverse Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

#### Parameters

**x** [array\_like] Quantiles, with the last axis of *x* denoting the components.  
**df** [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix  
**scale** [array\_like] Symmetric positive definite scale matrix of the distribution  
**random\_state** [{None, int, np.random.RandomState, np.random.Generator}, optional] Used for drawing random variates. If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*.

**Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:**

```
rv = invwishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

[wishart](#)

## Notes

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted

$$W_p^{-1}(\nu, \Psi)$$

where  $\nu$  is the degrees of freedom and  $\Psi$  is the  $p \times p$  scale matrix.

The probability density function for `invwishart` has support over positive definite matrices  $S$ ; if  $S \sim W_p^{-1}(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|\Sigma|^{\frac{\nu}{2}}}{2^{\frac{\nu p}{2}} |S|^{\frac{\nu+p+1}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-\text{tr}(\Sigma S^{-1})/2)$$

If  $S \sim W_p^{-1}(\nu, \Psi)$  (inverse Wishart) then  $S^{-1} \sim W_p(\nu, \Psi^{-1})$  (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution  $W_1(\nu, 1)$  collapses to the inverse Gamma distribution with parameters shape =  $\frac{\nu}{2}$  and scale =  $\frac{1}{2}$ .

New in version 0.16.0.

## References

[1], [2]

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import invwishart, invgamma
>>> x = np.linspace(0.01, 1, 100)
>>> iw = invwishart.pdf(x, df=6, scale=1)
>>> iw[:3]
array([ 1.20546865e-15,  5.42497807e-06,  4.45813929e-03])
>>> ig = invgamma.pdf(x, 6/2., scale=1./2)
>>> ig[:3]
array([ 1.20546865e-15,  5.42497807e-06,  4.45813929e-03])
>>> plt.plot(x, iw)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

## Methods

<code>pdf(x, df, scale)</code>	Probability density function.
<code>logpdf(x, df, scale)</code>	Log of the probability density function.
<code>rvs(df, scale, size=1, random_state=None)</code>	Draw random samples from an inverse Wishart distribution.

### scipy.stats.multinomial

`scipy.stats.multinomial(n, p, seed=None)` = `<scipy.stats._multivariate.multinomial_gen object>`

A multinomial random variable.

#### Parameters

**x** [array\_like] Quantiles, with the last axis of  $x$  denoting the components.  
**n** [int] Number of trials  
**p** [array\_like] Probability of a trial falling into each category; should sum to 1  
**random\_state**

[{None, int, np.random.RandomState, np.random.Generator}, optional] Used for drawing random variates. If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*.

#### See also:

##### `scipy.stats.binom`

The binomial distribution.

##### `numpy.random.Generator.multinomial`

Sampling from the multinomial distribution.

##### `scipy.stats.multivariate_hypergeom`

The multivariate hypergeometric distribution.

## Notes

$n$  should be a positive integer. Each element of  $p$  should be in the interval  $[0, 1]$  and the elements should sum to 1. If they do not sum to 1, the last element of the  $p$  array is not used and is replaced with the remaining probability left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the  $n$  and  $p$  parameters, returning a “frozen” multinomial random variable:

The probability mass function for *multinomial* is

$$f(x) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k},$$

supported on  $x = (x_1, \dots, x_k)$  where each  $x_i$  is a nonnegative integer and their sum is  $n$ .

New in version 0.19.0.

## Examples

```
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [0.3, 0.2, 0.5])
>>> rv.pmf([1, 3, 4])
0.0420000000000000072
```

The multinomial distribution for  $k = 2$  is identical to the corresponding binomial distribution (tiny numerical differences notwithstanding):

```
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[0.4, 0.6])
0.290303999999999973
>>> binom.pmf(3, 7, 0.4)
0.290304000000000012
```

The functions `pmf`, `logpmf`, `entropy`, and `cov` support broadcasting, under the convention that the vector parameters ( $x$  and  $p$ ) are interpreted as if each row along the last axis is a single object. For instance:

```
>>> multinomial.pmf([[3, 4], [3, 5]], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```

Here, `x.shape == (2, 2)`, `n.shape == (2,)`, and `p.shape == (2,)`, but following the rules mentioned above they behave as if the rows `[3, 4]` and `[3, 5]` in `x` and `[.3, .7]` in `p` were a single object, and as if we had `x.shape = (2,)`, `n.shape = (2,)`, and `p.shape = ()`. To obtain the individual elements without broadcasting, we would do this:

```
>>> multinomial.pmf([3, 4], n=7, p=[.3, .7])
0.2268945
>>> multinomial.pmf([3, 5], 8, p=[.3, .7])
0.25412184
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `p.shape[-1]`. For example:

```
>>> multinomial.cov([4, 5], [[.3, .7], [.4, .6]])
array([[ [ 0.84, -0.84],
```

(continues on next page)

(continued from previous page)

```

    [-0.84,  0.84]],
    [[ 1.2 , -1.2 ],
     [-1.2 ,  1.2 ]]])

```

In this example, `n.shape == (2,)` and `p.shape == (2, 2)`, and following the rules above, these broadcast as if `p.shape == (2,)`. Thus the result should also be of shape `(2,)`, but since each output is a  $2 \times 2$  matrix, the result in fact has shape `(2, 2, 2)`, where `result[0]` is equal to `multinomial.cov(n=4, p=[.3, .7])` and `result[1]` is equal to `multinomial.cov(n=5, p=[.4, .6])`.

## Methods

<code>pmf(x, n, p)</code>	Probability mass function.
<code>logpmf(x, n, p)</code>	Log of the probability mass function.
<code>rvs(n, p, size=1, random_state=None)</code>	Draw random samples from a multinomial distribution.
<code>entropy(n, p)</code>	Compute the entropy of the multinomial distribution.
<code>cov(n, p)</code>	Compute the covariance matrix of the multinomial distribution.

## scipy.stats.special\_ortho\_group

```

scipy.stats.special_ortho_group(dim=None, seed=None) = <scipy.stats.
    _multivariate.special_ortho_group_gen
    object>

```

A matrix-valued SO(N) random variable.

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)).

The `dim` keyword specifies the dimension N.

### Parameters

**dim** [scalar] Dimension of matrices

See also:

`ortho_group`, `scipy.spatial.transform.Rotation.random`

## Notes

This class is wrapping the `random_rot` code from the MDP Toolkit, <https://github.com/mdp-toolkit/mdp-toolkit>

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)). The algorithm is described in the paper Stewart, G.W., “The efficient generation of random orthogonal matrices with an application to condition estimators”, SIAM Journal on Numerical Analysis, 17(3), pp. 403-409, 1980. For more information see [https://en.wikipedia.org/wiki/Orthogonal\\_matrix#Randomization](https://en.wikipedia.org/wiki/Orthogonal_matrix#Randomization)

See also the similar `ortho_group`. For a random rotation in three dimensions, see `scipy.spatial.transform.Rotation.random`.

## Examples

```
>>> from scipy.stats import special_ortho_group
>>> x = special_ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> scipy.linalg.det(x)
1.0
```

This generates one random matrix from SO(3). It is orthogonal and has a determinant of 1.

## Methods

<code>rvs(dim=None, size=1, random_state=None)</code>	Draw random samples from SO(N).
---	---------------------------------

## scipy.stats.ortho\_group

`scipy.stats.ortho_group` = <scipy.stats.\_multivariate.ortho\_group\_gen object>

A matrix-valued O(N) random variable.

Return a random orthogonal matrix, drawn from the O(N) Haar distribution (the only uniform distribution on O(N)).

The *dim* keyword specifies the dimension N.

### Parameters

**dim** [scalar] Dimension of matrices

## Notes

This class is closely related to *special\_ortho\_group*.

Some care is taken to avoid numerical error, as per the paper by Mezzadri.

## References

[1]

## Examples

```
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from  $O(3)$ . It is orthogonal and has a determinant of +1 or -1.

## Methods

<code>rvs(dim=None, size=1, random_state=None)</code>	Draw random samples from $O(N)$ .
---	-----------------------------------

## scipy.stats.unitary\_group

`scipy.stats.unitary_group` = <scipy.stats.\_multivariate.unitary\_group\_gen object>  
A matrix-valued  $U(N)$  random variable.

Return a random unitary matrix.

The *dim* keyword specifies the dimension  $N$ .

### Parameters

**dim** [scalar] Dimension of matrices

## Notes

This class is similar to `ortho_group`.

## References

[1]

## Examples

```
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(3)
```

```
>>> np.dot(x, x.conj().T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

This generates one random matrix from  $U(3)$ . The dot product confirms that it is unitary up to machine precision.

## Methods

<code>``rvs(dim=None, size=1, random_state=None)``</code>	Draw random samples from $U(N)$ .
---	-----------------------------------

## scipy.stats.random\_correlation

`scipy.stats.random_correlation = <scipy.stats._multivariate.random_correlation_gen object>`

A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The *eigs* keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

### Parameters

**eigs** [1d ndarray] Eigenvalues of correlation matrix.

## Notes

Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single  $O(N)$  similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

## References

[1]

## Examples

```
>>> from scipy.stats import random_correlation
>>> np.random.seed(514)
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5))
>>> x
array([[ 1.          , -0.20387311,  0.18366501, -0.04953711],
       [-0.20387311,  1.          , -0.24351129,  0.06703474],
       [ 0.18366501, -0.24351129,  1.          ,  0.38530195],
       [-0.04953711,  0.06703474,  0.38530195,  1.          ]])
```

(continues on next page)

(continued from previous page)

```
>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([ 0.5,  0.8,  1.2,  1.5])
```

## Methods

```
``rvs(eigs=None, random_state=None)`` Draw random correlation matrices, all with eigenvalues eigs.
```

## scipy.stats.multivariate\_t

```
scipy.stats.multivariate_t(loc=None, shape=1, df=1, allow_singular=False, seed=None) =
    <scipy.stats._multivariate.multivariate_t_gen
    object>
```

A multivariate t-distributed random variable.

The *loc* parameter specifies the location. The *shape* parameter specifies the positive semidefinite shape matrix. The *df* parameter specifies the degrees of freedom.

In addition to calling the methods below, the object itself may be called as a function to fix the location, shape matrix, and degrees of freedom parameters, returning a “frozen” multivariate t-distribution random.

### Parameters

**x** [array\_like] Quantiles, with the last axis of *x* denoting the components.

**loc** [array\_like, optional] Location of the distribution. (default 0)

**shape** [array\_like, optional] Positive semidefinite matrix of the distribution. (default 1)

**df** [float, optional] Degrees of freedom of the distribution; must be greater than zero. If `np.inf` then results are multivariate normal. The default is 1.

**allow\_singular** [bool, optional] Whether to allow a singular matrix. (default `False`)

**random\_state** [{None, int, np.random.RandomState, np.random.Generator}, optional] Used for drawing random variates. If *seed* is `None` the `RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `RandomState` or `Generator` instance, then that object is used. Default is `None`.

## Notes

Setting the parameter *loc* to `None` is equivalent to having *loc* be the zero-vector. The parameter *shape* can be a scalar, in which case the shape matrix is the identity times that value, a vector of diagonal entries for the shape matrix, or a two-dimensional array\_like. The matrix *shape* must be a (symmetric) positive semidefinite matrix. The determinant and inverse of *shape* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *shape* does not need to have full rank.

The probability density function for `multivariate_t` is

$$f(x) = \frac{\Gamma(\nu + p)/2}{\Gamma(\nu/2)\nu^{p/2}\pi^{p/2}|\Sigma|^{1/2}} \exp\left[1 + \frac{1}{\nu}(\mathbf{x} - \boldsymbol{\mu})^\top \Sigma^{-1}(\mathbf{x} - \boldsymbol{\mu})\right]^{-(\nu+p)/2},$$

where *p* is the dimension of **x**, **μ** is the *p*-dimensional location, **Σ** the *p* × *p*-dimensional shape matrix, and *ν* is the degrees of freedom.

New in version 1.6.0.

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_t
>>> x, y = np.mgrid[-1:3:.01, -2:1.5:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_t([1.0, -0.5], [[2.1, 0.3], [0.3, 1.5]], df=2)
>>> fig, ax = plt.subplots(1, 1)
>>> ax.set_aspect('equal')
>>> plt.contourf(x, y, rv.pdf(pos))
```

## Methods

<code>pdf(x, loc=None, shape=1, df=1, allow_singular=False)</code>	Probability density function.
<code>logpdf(x, loc=None, shape=1, df=1, allow_singular=False)</code>	Log of the probability density function.
<code>rvs(loc=None, shape=1, df=1, size=1, random_state=None)</code>	Draw random samples from a multivariate t-distribution.

**scipy.stats.multivariate\_hypergeom**

```
scipy.stats.multivariate_hypergeom(m, n, seed=None) = <scipy.
stats._multivariate.
multivariate_hypergeom_gen object>
```

A multivariate hypergeometric random variable.

**Parameters**

- m** [array\_like] The number of each type of object in the population. That is,  $m[i]$  is the number of objects of type  $i$ .
- n** [array\_like] The number of samples taken from the population.
- random\_state** [{None, int, np.random.RandomState, np.random.Generator}, optional] Used for drawing random variates. If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*.

See also:

**scipy.stats.hypergeom**

The hypergeometric distribution.

**scipy.stats.multinomial**

The multinomial distribution.

**Notes**

$m$  must be an array of positive integers. If the quantile  $i$  contains values out of the range  $[0, m_i]$  where  $m_i$  is the number of objects of type  $i$  in the population or if the parameters are inconsistent with one another (e.g.  $x \cdot \text{sum}() \neq n$ ), methods return the appropriate value (e.g. 0 for pmf). If  $m$  or  $n$  contain negative values, the result will contain *nan* there.

The probability mass function for *multivariate\_hypergeom* is

$$P(X_1 = x_1, X_2 = x_2, \dots, X_k = x_k) = \frac{\binom{m_1}{x_1} \binom{m_2}{x_2} \dots \binom{m_k}{x_k}}{\binom{M}{n}},$$

$$(x_1, x_2, \dots, x_k) \in \mathbb{N}^k \text{ with } \sum_{i=1}^k x_i = n$$

where  $m_i$  are the number of objects of type  $i$ ,  $M$  is the total number of objects in the population (sum of all the  $m_i$ ), and  $n$  is the size of the sample to be taken from the population.

New in version 1.6.0.

## References

[1], [2]

## Examples

To evaluate the probability mass function of the multivariate hypergeometric distribution, with a dichotomous population of size 10 and 20, at a sample of size 12 with 8 objects of the first type and 4 objects of the second type, use:

```
>>> from scipy.stats import multivariate_hypergeom
>>> multivariate_hypergeom.pmf(x=[8, 4], m=[10, 20], n=12)
0.0025207176631464523
```

The *multivariate\_hypergeom* distribution is identical to the corresponding *hypergeom* distribution (tiny numerical differences notwithstanding) when only two types (good and bad) of objects are present in the population as in the example above. Consider another example for a comparison with the hypergeometric distribution:

```
>>> from scipy.stats import hypergeom
>>> multivariate_hypergeom.pmf(x=[3, 1], m=[10, 5], n=4)
0.4395604395604395
>>> hypergeom.pmf(k=3, M=15, n=4, N=10)
0.43956043956044005
```

The functions `pmf`, `logpmf`, `mean`, `var`, `cov`, and `rvs` support broadcasting, under the convention that the vector parameters (`x`, `m`, and `n`) are interpreted as if each row along the last axis is a single object. For instance, we can combine the previous two calls to *multivariate\_hypergeom* as

```
>>> multivariate_hypergeom.pmf(x=[[8, 4], [3, 1]], m=[[10, 20], [10, 5]],
...                             n=[12, 4])
array([0.00252072, 0.43956044])
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `m.shape[-1]`. For example:

```
>>> multivariate_hypergeom.cov(m=[[7, 9], [10, 15]], n=[8, 12])
array([[ [ 1.05, -1.05],
        [-1.05,  1.05]],
       [[ 1.56, -1.56],
        [-1.56,  1.56]]])
```

That is, `result[0]` is equal to `multivariate_hypergeom.cov(m=[7, 9], n=8)` and `result[1]` is equal to `multivariate_hypergeom.cov(m=[10, 15], n=12)`.

Alternatively, the object may be called (as a function) to fix the *m* and *n* parameters, returning a “frozen” multivariate hypergeometric random variable.

```
>>> rv = multivariate_hypergeom(m=[10, 20], n=12)
>>> rv.pmf(x=[8, 4])
0.0025207176631464523
```

## Methods

<code>pmf(x, m, n)</code>	Probability mass function.
<code>logpmf(x, m, n)</code>	Log of the probability mass function.
<code>rvs(m, n, size=1, random_state=None)</code>	Draw random samples from a multivariate hypergeometric distribution.
<code>mean(m, n)</code>	Mean of the multivariate hypergeometric distribution.
<code>var(m, n)</code>	Variance of the multivariate hypergeometric distribution.
<code>cov(m, n)</code>	Compute the covariance matrix of the multivariate hypergeometric distribution.

## 6.29.6 Discrete distributions

<code>bernoulli(*args, **kwargs)</code>	A Bernoulli discrete random variable.
<code>betabinom(*args, **kwargs)</code>	A beta-binomial discrete random variable.
<code>binom(*args, **kwargs)</code>	A binomial discrete random variable.
<code>boltzmann(*args, **kwargs)</code>	A Boltzmann (Truncated Discrete Exponential) random variable.
<code>dlaplace(*args, **kwargs)</code>	A Laplacian discrete random variable.
<code>geom(*args, **kwargs)</code>	A geometric discrete random variable.
<code>hypergeom(*args, **kwargs)</code>	A hypergeometric discrete random variable.
<code>logser(*args, **kwargs)</code>	A Logarithmic (Log-Series, Series) discrete random variable.
<code>nbinom(*args, **kwargs)</code>	A negative binomial discrete random variable.
<code>nhypergeom(*args, **kwargs)</code>	A negative hypergeometric discrete random variable.
<code>planck(*args, **kwargs)</code>	A Planck discrete exponential random variable.
<code>poisson(*args, **kwargs)</code>	A Poisson discrete random variable.
<code>randint(*args, **kwargs)</code>	A uniform discrete random variable.
<code>skellam(*args, **kwargs)</code>	A Skellam discrete random variable.
<code>zipf(*args, **kwargs)</code>	A Zipf discrete random variable.
<code>yulesimon(*args, **kwargs)</code>	A Yule-Simon discrete random variable.

### scipy.stats.bernoulli

```
scipy.stats.bernoulli(*args, **kwargs) = <scipy.stats._discrete_distns.bernoulli_gen object>
```

A Bernoulli discrete random variable.

As an instance of the `rv_discrete` class, `bernoulli` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *bernoulli* is:

$$f(k) = \begin{cases} 1-p & \text{if } k = 0 \\ p & \text{if } k = 1 \end{cases}$$

for  $k$  in  $\{0, 1\}$ ,  $0 \leq p \leq 1$

*bernoulli* takes  $p$  as shape parameter, where  $p$  is the probability of a single success and  $1 - p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `bernoulli.pmf(k, p, loc)` is identically equivalent to `bernoulli.pmf(k - loc, p)`.

## Examples

```
>>> from scipy.stats import bernoulli
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.3
>>> mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(bernoulli.ppf(0.01, p),
...              bernoulli.ppf(0.99, p))
>>> ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
>>> ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = bernoulli(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = bernoulli.cdf(x, p)
>>> np.allclose(x, bernoulli.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = bernoulli.rvs(p, size=1000)
```

## Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

**scipy.stats.betabinom**

`scipy.stats.betabinom(*args, **kwargs)` = `<scipy.stats._discrete_distns.betabinom_gen object>`

A beta-binomial discrete random variable.

As an instance of the `rv_discrete` class, `betabinom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[beta](#), [binom](#)

**Notes**

The beta-binomial distribution is a binomial distribution with a probability of success  $p$  that follows a beta distribution.

The probability mass function for `betabinom` is:

$$f(k) = \binom{n}{k} \frac{B(k+a, n-k+b)}{B(a, b)}$$

for  $k$  in  $\{0, 1, \dots, n\}$ ,  $n \geq 0$ ,  $a > 0$ ,  $b > 0$ , where  $B(a, b)$  is the beta function.

`betabinom` takes  $n$ ,  $a$ , and  $b$  as shape parameters.

**References**

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `betabinom.pmf(k, n, a, b, loc)` is identically equivalent to `betabinom.pmf(k - loc, n, a, b)`.

New in version 1.4.0.

[1]

**Examples**

```
>>> from scipy.stats import betabinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n, a, b = 5, 2.3, 0.63
>>> mean, var, skew, kurt = betabinom.stats(n, a, b, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(betabinom.ppf(0.01, n, a, b),
...               betabinom.ppf(0.99, n, a, b))
>>> ax.plot(x, betabinom.pmf(x, n, a, b), 'bo', ms=8, label='betabinom pmf
→')
>>> ax.vlines(x, 0, betabinom.pmf(x, n, a, b), colors='b', lw=5, alpha=0.
→5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = betabinom(n, a, b)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = betabinom.cdf(x, n, a, b)
>>> np.allclose(x, betabinom.ppf(prob, n, a, b))
True
```

Generate random numbers:

```
>>> r = betabinom.rvs(n, a, b, size=1000)
```

## Methods

<code>rvs(n, a, b, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, n, a, b, loc=0)</code>	Probability mass function.
<code>logpmf(k, n, a, b, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, n, a, b, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, n, a, b, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, n, a, b, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, n, a, b, loc=0)</code>	Log of the survival function.
<code>ppf(q, n, a, b, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, n, a, b, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(n, a, b, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(n, a, b, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(n, a, b), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(n, a, b, loc=0)</code>	Median of the distribution.
<code>mean(n, a, b, loc=0)</code>	Mean of the distribution.
<code>var(n, a, b, loc=0)</code>	Variance of the distribution.
<code>std(n, a, b, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, n, a, b, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.binom

`scipy.stats.binom(*args, **kwargs) = <scipy.stats._discrete_distns.binom_gen object>`

A binomial discrete random variable.

As an instance of the *rv\_discrete* class, *binom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[hypergeom](#), [nbinom](#), [nhypergeom](#)

## Notes

The probability mass function for *binom* is:

$$f(k) = \binom{n}{k} p^k (1-p)^{n-k}$$

for  $k$  in  $\{0, 1, \dots, n\}$ ,  $0 \leq p \leq 1$

*binom* takes  $n$  and  $p$  as shape parameters, where  $p$  is the probability of a single success and  $1-p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `binom.pmf(k, n, p, loc)` is identically equivalent to `binom.pmf(k - loc, n, p)`.

## Examples

```
>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(binom.ppf(0.01, n, p),
...               binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = binom.rvs(n, p, size=1000)
```

## scipy.stats.boltzmann

```
scipy.stats.boltzmann(*args, **kwargs) = <scipy.stats._discrete_distns.  
boltzmann_gen object>
```

A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the *rv\_discrete* class, *boltzmann* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *boltzmann* is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k) / (1 - \exp(-\lambda N))$$

for  $k = 0, \dots, N - 1$ .

*boltzmann* takes  $\lambda > 0$  and  $N > 0$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `boltzmann.pmf(k, lambda_, N, loc)` is identically equivalent to `boltzmann.pmf(k - loc, lambda_, N)`.

## Examples

```
>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N),
...               boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann_
→pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5,
→alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = boltzmann(lambda_, N)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = boltzmann.cdf(x, lambda_, N)
>>> np.allclose(x, boltzmann.ppf(prob, lambda_, N))
True
```

Generate random numbers:

```
>>> r = boltzmann.rvs(lambda_, N, size=1000)
```

## Methods

<b>rvs</b> (lambda_, N, loc=0, size=1, random_state=None)	Random variates.
<b>pmf</b> (k, lambda_, N, loc=0)	Probability mass function.
<b>logpmf</b> (k, lambda_, N, loc=0)	Log of the probability mass function.
<b>cdf</b> (k, lambda_, N, loc=0)	Cumulative distribution function.
<b>logcdf</b> (k, lambda_, N, loc=0)	Log of the cumulative distribution function.
<b>sf</b> (k, lambda_, N, loc=0)	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf</b> (k, lambda_, N, loc=0)	Log of the survival function.
<b>ppf</b> (q, lambda_, N, loc=0)	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf</b> (q, lambda_, N, loc=0)	Inverse survival function (inverse of <i>sf</i> ).
<b>stats</b> (lambda_, N, loc=0, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy</b> (lambda_, N, loc=0)	(Differential) entropy of the RV.
<b>expect</b> (func, args=(lambda_, N), loc=0, lb=None, ub=None, conditional=False)	Expected value of a function (of one argument) with respect to the distribution.
<b>median</b> (lambda_, N, loc=0)	Median of the distribution.
<b>mean</b> (lambda_, N, loc=0)	Mean of the distribution.
<b>var</b> (lambda_, N, loc=0)	Variance of the distribution.
<b>std</b> (lambda_, N, loc=0)	Standard deviation of the distribution.
<b>interval</b> (alpha, lambda_, N, loc=0)	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.dlaplace

```
scipy.stats.dlaplace(*args, **kwargs) = <scipy.stats._discrete_distns.
    dlaplace_gen object>
```

A Laplacian discrete random variable.

As an instance of the *rv\_discrete* class, *dlaplace* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for *dlaplace* is:

$$f(k) = \tanh(a/2) \exp(-a|k|)$$

for integers  $k$  and  $a > 0$ .

*dlaplace* takes  $a$  as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `dlaplace.pmf(k, a, loc)` is identically equivalent to `dlaplace.pmf(k - loc, a)`.

### Examples

```
>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(dlaplace.ppf(0.01, a),
...               dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = dlaplace.cdf(x, a)
>>> np.allclose(x, dlaplace.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = dlaplace.rvs(a, size=1000)
```

## Methods

<code>rvs(a, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(a, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0)</code>	Median of the distribution.
<code>mean(a, loc=0)</code>	Mean of the distribution.
<code>var(a, loc=0)</code>	Variance of the distribution.
<code>std(a, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.geom

```
scipy.stats.geom(*args, **kws) = <scipy.stats._discrete_distns.geom_gen object>
```

A geometric discrete random variable.

As an instance of the *rv\_discrete* class, *geom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[planck](#)

### Notes

The probability mass function for *geom* is:

$$f(k) = (1 - p)^{k-1}p$$

for  $k \geq 1, 0 < p \leq 1$

*geom* takes  $p$  as shape parameter, where  $p$  is the probability of a single success and  $1 - p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `geom.pmf(k, p, loc)` is identically equivalent to `geom.pmf(k - loc, p)`.

### Examples

```
>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(geom.ppf(0.01, p),
...               geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = geom.rvs(p, size=1000)
```

## Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.hypergeom

`scipy.stats.hypergeom(*args, **kwargs)` = `<scipy.stats._discrete_distns.hypergeom_gen object>`

A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin.  $M$  is the total number of objects,  $n$  is total number of Type I objects. The random variate represents the number of Type I objects in  $N$  drawn without replacement from the total population.

As an instance of the `rv_discrete` class, `hypergeom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[nhypergeom](#), [binom](#), [nbinom](#)

### Notes

The symbols used to denote the shape parameters ( $M$ ,  $n$ , and  $N$ ) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$p(k, M, n, N) = \frac{\binom{n}{k} \binom{M-n}{N-k}}{\binom{M}{N}}$$

for  $k \in [\max(0, N - M + n), \min(n, N)]$ , where the binomial coefficients are defined as,

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}$$

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `hypergeom.pmf(k, M, n, N, loc)` is identically equivalent to `hypergeom.pmf(k - loc, M, n, N)`.

### Examples

```
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```
>>> [M, n, N] = [20, 7, 12]
>>> rv = hypergeom(M, n, N)
>>> x = np.arange(0, n+1)
>>> pmf_dogs = rv.pmf(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
```

(continues on next page)

(continued from previous page)

```
>>> ax.set_xlabel('# of dogs in our group of chosen animals')
>>> ax.set_ylabel('hypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use *hypergeom* methods directly. To for example obtain the cumulative distribution function, use:

```
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```
>>> R = hypergeom.rvs(M, n, N, size=10)
```

## Methods

<code>rvs(M, n, N, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, M, n, N, loc=0)</code>	Probability mass function.
<code>logpmf(k, M, n, N, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, M, n, N, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, M, n, N, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, M, n, N, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, M, n, N, loc=0)</code>	Log of the survival function.
<code>ppf(q, M, n, N, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, M, n, N, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(M, n, N, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(M, n, N, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(M, n, N), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(M, n, N, loc=0)</code>	Median of the distribution.
<code>mean(M, n, N, loc=0)</code>	Mean of the distribution.
<code>var(M, n, N, loc=0)</code>	Variance of the distribution.
<code>std(M, n, N, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, M, n, N, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.logser

`scipy.stats.logser(*args, **kwargs) = <scipy.stats._discrete_distns.logser_gen object>`

A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the *rv\_discrete* class, *logser* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *logser* is:

$$f(k) = -\frac{p^k}{k \log(1-p)}$$

for  $k \geq 1, 0 < p < 1$

*logser* takes *p* as shape parameter, where *p* is the probability of a single success and  $1 - p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

## Examples

```
>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(logser.ppf(0.01, p),
...               logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = logser.rvs(p, size=1000)
```

## Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.nbinom

```
scipy.stats.nbinom(*args, **kwargs) = <scipy.stats._discrete_distns.nbinom_gen
object>
```

A negative binomial discrete random variable.

As an instance of the *rv\_discrete* class, *nbinom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[hypergeom](#), [binom](#), [nhypergeom](#)

## Notes

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for *nbinom* is:

$$f(k) = \binom{k+n-1}{n-1} p^n (1-p)^k$$

for  $k \geq 0, 0 < p \leq 1$

*nbinom* takes *n* and *p* as shape parameters where *n* is the number of successes, *p* is the probability of a single success, and  $1 - p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nbinom.pmf(k, n, p, loc)` is identically equivalent to `nbinom.pmf(k - loc, n, p)`.

## Examples

```
>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n, p = 0.4, 0.4
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(nbinom.ppf(0.01, n, p),
...               nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = nbinom.rvs(n, p, size=1000)
```

## Methods

<code>rvs(n, p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, n, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, n, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, n, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, n, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, n, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, n, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, n, p, loc=0)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, n, p, loc=0)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>stats(n, p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(n, p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(n, p), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(n, p, loc=0)</code>	Median of the distribution.
<code>mean(n, p, loc=0)</code>	Mean of the distribution.
<code>var(n, p, loc=0)</code>	Variance of the distribution.
<code>std(n, p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, n, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.nhypergeom

```
scipy.stats.nhypergeom(*args, **kwargs) = <scipy.stats._discrete_distns.
nhypergeom_gen object>
```

A negative hypergeometric discrete random variable.

Consider a box containing  $M$  balls:  $n$  red and  $M - n$  blue. We randomly sample balls from the box, one at a time and *without* replacement, until we have picked  $r$  blue balls. *nhypergeom* is the distribution of the number of red balls  $k$  we have picked.

As an instance of the *rv\_discrete* class, *nhypergeom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[hypergeom](#), [binom](#), [nbinom](#)

## Notes

The symbols used to denote the shape parameters ( $M$ ,  $n$ , and  $r$ ) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$f(k; M, n, r) = \frac{\binom{k+r-1}{k} \binom{M-r-k}{n-k}}{\binom{M}{n}}$$

for  $k \in [0, n]$ ,  $n \in [0, M]$ ,  $r \in [0, M - n]$ , and the binomial coefficient is:

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

It is equivalent to observing  $k$  successes in  $k + r - 1$  samples with  $k + r$ 'th sample being a failure. The former can be modelled as a hypergeometric distribution. The probability of the latter is simply the number of failures remaining  $M - n - (r - 1)$  divided by the size of the remaining population  $M - (k + r - 1)$ . This relationship can be shown as:

$$NHG(k; M, n, r) = HG(k; M, n, k + r - 1) \frac{(M - n - (r - 1))}{(M - (k + r - 1))}$$

where  $NHG$  is probability mass function (PMF) of the negative hypergeometric distribution and  $HG$  is the PMF of the hypergeometric distribution.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nhypergeom.pmf(k, M, n, r, loc)` is identically equivalent to `nhypergeom.pmf(k - loc, M, n, r)`.

## References

[1], [2]

## Examples

```
>>> from scipy.stats import nhypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs (successes) in a sample with exactly 12 animals that aren't dogs (failures), we can initialize a frozen distribution and plot the probability mass function:

```
>>> M, n, r = [20, 7, 12]
>>> rv = nhypergeom(M, n, r)
>>> x = np.arange(0, n+2)
>>> pmf_dogs = rv.pmf(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group with given 12 failures')
>>> ax.set_ylabel('nhypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use `nhypergeom` methods directly. To for example obtain the probability mass function, use:

```
>>> prb = nhypergeom.pmf(x, M, n, r)
```

And to generate random numbers:

```
>>> R = nhypergeom.rvs(M, n, r, size=10)
```

To verify the relationship between `hypergeom` and `nhypergeom`, use:

```
>>> from scipy.stats import hypergeom, nhypergeom
>>> M, n, r = 45, 13, 8
>>> k = 6
>>> nhypergeom.pmf(k, M, n, r)
0.06180776620271643
>>> hypergeom.pmf(k, M, n, k+r-1) * (M - n - (r-1)) / (M - (k+r-1))
0.06180776620271644
```

## Methods

<code>rvs(M, n, r, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, M, n, r, loc=0)</code>	Probability mass function.
<code>logpmf(k, M, n, r, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, M, n, r, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, M, n, r, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, M, n, r, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, M, n, r, loc=0)</code>	Log of the survival function.
<code>ppf(q, M, n, r, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, M, n, r, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(M, n, r, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(M, n, r, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(M, n, r), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(M, n, r, loc=0)</code>	Median of the distribution.
<code>mean(M, n, r, loc=0)</code>	Mean of the distribution.
<code>var(M, n, r, loc=0)</code>	Variance of the distribution.
<code>std(M, n, r, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, M, n, r, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.planck

`scipy.stats.planck(*args, **kwargs) = <scipy.stats._discrete_distns.planck_gen object>`

A Planck discrete exponential random variable.

As an instance of the *rv\_discrete* class, *planck* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[geom](#)

## Notes

The probability mass function for *planck* is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k)$$

for  $k \geq 0$  and  $\lambda > 0$ .

*planck* takes  $\lambda$  as shape parameter. The Planck distribution can be written as a geometric distribution (*geom*) with  $p = 1 - \exp(-\lambda)$  shifted by  $loc = -1$ .

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `planck.pmf(k, lambda_, loc)` is identically equivalent to `planck.pmf(k - loc, lambda_)`.

## Examples

```
>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(planck.ppf(0.01, lambda_),
...               planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='--', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))
True
```

Generate random numbers:

```
>>> r = planck.rvs(lambda_, size=1000)
```

## Methods

<code>rvs(lambda_, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, lambda_, loc=0)</code>	Probability mass function.
<code>logpmf(k, lambda_, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, lambda_, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, lambda_, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, lambda_, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, lambda_, loc=0)</code>	Log of the survival function.
<code>ppf(q, lambda_, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, lambda_, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(lambda_, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lambda_, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(lambda_), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lambda_, loc=0)</code>	Median of the distribution.
<code>mean(lambda_, loc=0)</code>	Mean of the distribution.
<code>var(lambda_, loc=0)</code>	Variance of the distribution.
<code>std(lambda_, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, lambda_, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.poisson

`scipy.stats.poisson(*args, **kws) = <scipy.stats._discrete_distns.poisson_gen object>`

A Poisson discrete random variable.

As an instance of the *rv\_discrete* class, *poisson* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *poisson* is:

$$f(k) = \exp(-\mu) \frac{\mu^k}{k!}$$

for  $k \geq 0$ .

*poisson* takes  $\mu$  as shape parameter. When  $\mu = 0$  then at quantile  $k = 0$ , *pmf* method returns *1.0*.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `poisson.pmf(k, mu, loc)` is identically equivalent to `poisson.pmf(k - loc, mu)`.

## Examples

```
>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(poisson.ppf(0.01, mu),
...               poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
>>> ax.vlines(x, 0, poisson.pmf(x, mu), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = poisson(mu)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:

```
>>> r = poisson.rvs(mu, size=1000)
```

## Methods

<code>rvs(mu, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, mu, loc=0)</code>	Probability mass function.
<code>logpmf(k, mu, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, mu, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, mu, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, mu, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, mu, loc=0)</code>	Log of the survival function.
<code>ppf(q, mu, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(mu, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(mu,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu, loc=0)</code>	Median of the distribution.
<code>mean(mu, loc=0)</code>	Mean of the distribution.
<code>var(mu, loc=0)</code>	Variance of the distribution.
<code>std(mu, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.randint

`scipy.stats.randint(*args, **kwargs) = <scipy.stats._discrete_distns.randint_gen object>`

A uniform discrete random variable.

As an instance of the *rv\_discrete* class, *randint* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *randint* is:

$$f(k) = \frac{1}{\text{high} - \text{low}}$$

for  $k = \text{low}, \dots, \text{high} - 1$ .

*randint* takes *low* and *high* as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `randint.pmf(k, low, high, loc)` is identically equivalent to `randint.pmf(k - loc, low, high)`.

## Examples

```
>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> low, high = 7, 31
>>> mean, var, skew, kurt = randint.stats(low, high, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(randint.ppf(0.01, low, high),
...               randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.
→5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = randint.cdf(x, low, high)
>>> np.allclose(x, randint.ppf(prob, low, high))
True
```

Generate random numbers:

```
>>> r = randint.rvs(low, high, size=1000)
```

## Methods

<code>rvs(low, high, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, low, high, loc=0)</code>	Probability mass function.
<code>logpmf(k, low, high, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, low, high, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, low, high, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, low, high, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, low, high, loc=0)</code>	Log of the survival function.
<code>ppf(q, low, high, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, low, high, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(low, high, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(low, high, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(low, high), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(low, high, loc=0)</code>	Median of the distribution.
<code>mean(low, high, loc=0)</code>	Mean of the distribution.
<code>var(low, high, loc=0)</code>	Variance of the distribution.
<code>std(low, high, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, low, high, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.skellam

`scipy.stats.skellam(*args, **kwargs) = <scipy.stats._discrete_distns.skellam_gen object>`

A Skellam discrete random variable.

As an instance of the *rv\_discrete* class, *skellam* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let  $k_1$  and  $k_2$  be two Poisson-distributed r.v. with expected values  $\lambda_1$  and  $\lambda_2$ . Then,  $k_1 - k_2$  follows a Skellam distribution with parameters  $\mu_1 = \lambda_1 - \rho\sqrt{\lambda_1\lambda_2}$  and  $\mu_2 = \lambda_2 - \rho\sqrt{\lambda_1\lambda_2}$ , where  $\rho$  is the correlation coefficient between  $k_1$  and  $k_2$ . If the two Poisson-distributed r.v. are independent then  $\rho = 0$ .

Parameters  $\mu_1$  and  $\mu_2$  must be strictly positive.

For details see: [https://en.wikipedia.org/wiki/Skellam\\_distribution](https://en.wikipedia.org/wiki/Skellam_distribution)

*skellam* takes  $\mu_1$  and  $\mu_2$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `skellam.pmf(k, mu1, mu2, loc)` is identically equivalent to `skellam.pmf(k - loc, mu1, mu2)`.

## Examples

```
>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2),
...               skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

## Methods

<b>rvs(mu1, mu2, loc=0, size=1, random_state=None)</b>	Random variates.
<b>pmf(k, mu1, mu2, loc=0)</b>	Probability mass function.
<b>logpmf(k, mu1, mu2, loc=0)</b>	Log of the probability mass function.
<b>cdf(k, mu1, mu2, loc=0)</b>	Cumulative distribution function.

## scipy.stats.zipf

`scipy.stats.zipf(*args, **kws)` = `<scipy.stats._discrete_distns.zipf_gen object>`  
 A Zipf discrete random variable.

As an instance of the `rv_discrete` class, `zipf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `zipf` is:

$$f(k, a) = \frac{1}{\zeta(a)k^a}$$

for  $k \geq 1$ .

`zipf` takes  $a$  as shape parameter.  $\zeta$  is the Riemann zeta function (`scipy.special.zeta`)

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `zipf.pmf(k, a, loc)` is identically equivalent to `zipf.pmf(k - loc, a)`.

### Examples

```
>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(zipf.ppf(0.01, a),
...               zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = zipf.cdf(x, a)
>>> np.allclose(x, zipf.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = zipf.rvs(a, size=1000)
```

## Methods

<code>rvs(a, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(a, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0)</code>	Median of the distribution.
<code>mean(a, loc=0)</code>	Mean of the distribution.
<code>var(a, loc=0)</code>	Variance of the distribution.
<code>std(a, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.yulesimon

```
scipy.stats.yulesimon(*args, **kwargs) = <scipy.stats._discrete_distns.
    yulesimon_gen object>
```

A Yule-Simon discrete random variable.

As an instance of the *rv\_discrete* class, *yulesimon* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for the *yulesimon* is:

$$f(k) = \alpha B(k, \alpha + 1)$$

for  $k = 1, 2, 3, \dots$ , where  $\alpha > 0$ . Here  $B$  refers to the *scipy.special.beta* function.

The sampling of random variates is based on pg 553, Section 6.3 of [1]. Our notation maps to the referenced logic via  $\alpha = a - 1$ .

For details see the wikipedia entry [2].

### References

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, *yulesimon.pmf(k, alpha, loc)* is identically equivalent to *yulesimon.pmf(k - loc, alpha)*.

[1], [2]

### Examples

```
>>> from scipy.stats import yulesimon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> alpha = 11
>>> mean, var, skew, kurt = yulesimon.stats(alpha, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(yulesimon.ppf(0.01, alpha),
...              yulesimon.ppf(0.99, alpha))
>>> ax.plot(x, yulesimon.pmf(x, alpha), 'bo', ms=8, label='yulesimon pmf')
>>> ax.vlines(x, 0, yulesimon.pmf(x, alpha), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = yulesimon(alpha)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = yulesimon.cdf(x, alpha)
>>> np.allclose(x, yulesimon.ppf(prob, alpha))
True
```

Generate random numbers:

```
>>> r = yulesimon.rvs(alpha, size=1000)
```

## Methods

<code>rvs(alpha, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, alpha, loc=0)</code>	Probability mass function.
<code>logpmf(k, alpha, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, alpha, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, alpha, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, alpha, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, alpha, loc=0)</code>	Log of the survival function.
<code>ppf(q, alpha, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, alpha, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(alpha, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(alpha, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(alpha,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(alpha, loc=0)</code>	Median of the distribution.
<code>mean(alpha, loc=0)</code>	Mean of the distribution.
<code>var(alpha, loc=0)</code>	Variance of the distribution.
<code>std(alpha, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, alpha, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

An overview of statistical functions is given below. Several of these functions have a similar version in `scipy.stats.mstats` which work for masked arrays.

### 6.29.7 Summary statistics

<code>describe(a[, axis, ddof, bias, nan_policy])</code>	Compute several descriptive statistics of the passed array.
<code>gmean(a[, axis, dtype])</code>	Compute the geometric mean along the specified axis.
<code>hmean(a[, axis, dtype])</code>	Calculate the harmonic mean along the specified axis.
<code>kurtosis(a[, axis, fisher, bias, nan_policy])</code>	Compute the kurtosis (Fisher or Pearson) of a dataset.
<code>mode(a[, axis, nan_policy])</code>	Return an array of the modal (most common) value in the passed array.
<code>moment(a[, moment, axis, nan_policy])</code>	Calculate the nth moment about the mean for a sample.
<code>skew(a[, axis, bias, nan_policy])</code>	Compute the sample skewness of a data set.
<code>kstat(data[, n])</code>	Return the nth k-statistic ( $1 \leq n \leq 4$ so far).
<code>kstatvar(data[, n])</code>	Return an unbiased estimator of the variance of the k-statistic.
<code>tmean(a[, limits, inclusive, axis])</code>	Compute the trimmed mean.
<code>tvar(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed variance.
<code>tmin(a[, lowerlimit, axis, inclusive, ...])</code>	Compute the trimmed minimum.
<code>tmax(a[, upperlimit, axis, inclusive, ...])</code>	Compute the trimmed maximum.
<code>tstd(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed sample standard deviation.
<code>tsem(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed standard error of the mean.
<code>variation(a[, axis, nan_policy])</code>	Compute the coefficient of variation.
<code>find_repeats(arr)</code>	Find repeats and repeat counts.

continues on next page

Table 261 – continued from previous page

<code>trim_mean(a, proportiontocut[, axis])</code>	Return mean of array after trimming distribution from both tails.
<code>gstd(a[, axis, ddof])</code>	Calculate the geometric standard deviation of an array.
<code>iqr(x[, axis, rng, scale, nan_policy, ...])</code>	Compute the interquartile range of the data along the specified axis.
<code>sem(a[, axis, ddof, nan_policy])</code>	Compute standard error of the mean.
<code>bayes_mvs(data[, alpha])</code>	Bayesian confidence intervals for the mean, var, and std.
<code>mvstdist(data)</code>	'Frozen' distributions for mean, variance, and standard deviation of data.
<code>entropy(pk[, qk, base, axis])</code>	Calculate the entropy of a distribution for given probability values.
<code>median_absolute_deviation(*args, **kwargs)</code>	<code>median_absolute_deviation</code> is deprecated, use <code>median_abs_deviation</code> instead!
<code>median_abs_deviation(x[, axis, center, ...])</code>	Compute the median absolute deviation of the data along the given axis.

## scipy.stats.describe

`scipy.stats.describe(a, axis=0, ddof=1, bias=True, nan_policy='propagate')`

Compute several descriptive statistics of the passed array.

### Parameters

- a** [array\_like] Input data.
- axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees of freedom (only for variance). Default is 1.
- bias** [bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.
- nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

### Returns

- nobs** [int or ndarray of ints] Number of observations (length of data along *axis*). When 'omit' is chosen as *nan\_policy*, each column is counted separately.
- minmax: tuple of ndarrays or floats** Minimum and maximum value of data array.
- mean** [ndarray or float] Arithmetic mean of data along axis.
- variance** [ndarray or float] Unbiased variance of the data along axis, denominator is number of observations minus one.
- skewness** [ndarray or float] Skewness, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.
- kurtosis** [ndarray or float] Kurtosis (Fisher). The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

See also:

[skew, kurtosis](#)

## Examples

```

>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5, variance=9.
→166666666666666666,
                skewness=0.0, kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
              mean=array([2., 3.]), variance=array([2., 2.]),
              skewness=array([0., 0.]), kurtosis=array([-2., -2.]))

```

## scipy.stats.gmean

`scipy.stats.gmean(a, axis=0, dtype=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is:  $n$ -th root of  $(x_1 * x_2 * \dots * x_n)$

### Parameters

- a** [array\_like] Input array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

### Returns

- gmean** [ndarray] See *dtype* parameter above.

See also:

[\*numpy.mean\*](#)

Arithmetic average

[\*numpy.average\*](#)

Weighted average

[\*hmean\*](#)

Harmonic mean

## Notes

The geometric average is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. `float64` intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

## Examples

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

## `scipy.stats.hmean`

`scipy.stats.hmean(a, axis=0, dtype=None)`

Calculate the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

### Parameters

- a** [array\_like] Input array, masked array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

### Returns

- hmean** [ndarray] See *dtype* parameter above.

See also:

### `numpy.mean`

Arithmetic average

### `numpy.average`

Weighted average

### `gmean`

Geometric mean

## Notes

The harmonic mean is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

## Examples

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

## scipy.stats.kurtosis

`scipy.stats.kurtosis(a, axis=0, fisher=True, bias=True, nan_policy='propagate')`

Compute the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If `bias` is `False` then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

### Parameters

<b>a</b>	[array] Data for which the kurtosis is calculated.
<b>axis</b>	[int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array <i>a</i> .
<b>fisher</b>	[bool, optional] If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
<b>bias</b>	[bool, optional] If False, then the calculations are corrected for statistical bias.
<b>nan_policy</b>	[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

<b>kurtosis</b>	[array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.
-----------------	--

## References

[1]

## Examples

In Fisher's definition, the kurtosis of the normal distribution is zero. In the following example, the kurtosis is close to zero, because it was calculated from the dataset, not from the continuous distribution.

```
>>> from scipy.stats import norm, kurtosis
>>> data = norm.rvs(size=1000, random_state=3)
>>> kurtosis(data)
-0.06928694200380558
```

The distribution with a higher kurtosis has a heavier tail. The zero valued kurtosis of the normal distribution in Fisher's definition can serve as a reference point.

```
>>> import matplotlib.pyplot as plt
>>> import scipy.stats as stats
>>> from scipy.stats import kurtosis
```

```
>>> x = np.linspace(-5, 5, 100)
>>> ax = plt.subplot()
>>> distnames = ['laplace', 'norm', 'uniform']
```

```
>>> for distname in distnames:
...     if distname == 'uniform':
...         dist = getattr(stats, distname)(loc=-2, scale=4)
...     else:
...         dist = getattr(stats, distname)
...     data = dist.rvs(size=1000)
...     kur = kurtosis(data, fisher=True)
...     y = dist.pdf(x)
...     ax.plot(x, y, label="{}, {}".format(distname, round(kur, 3)))
...     ax.legend()
```

The Laplace distribution has a heavier tail than the normal distribution. The uniform distribution (which has negative kurtosis) has the thinnest tail.

## scipy.stats.mode

`scipy.stats.mode` (*a*, *axis=0*, *nan\_policy='propagate'*)

Return an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

### Parameters

- a** [array\_like] n-dimensional array of which to find mode(s).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- ‘propagate’: returns nan
- ‘raise’: throws an error
- ‘omit’: performs the calculations ignoring nan values

#### Returns

- mode** [ndarray] Array of modal values.  
**count** [ndarray] Array of counts for each mode.

#### Examples

```
>>> a = np.array([[6, 8, 3, 0],
...               [3, 2, 1, 7],
...               [8, 1, 8, 4],
...               [5, 3, 0, 5],
...               [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
ModeResult(mode=array([[3, 1, 0, 0]]), count=array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify `axis=None`:

```
>>> stats.mode(a, axis=None)
ModeResult(mode=array([3]), count=array([3]))
```

## scipy.stats.moment

`scipy.stats.moment` (*a*, *moment*=1, *axis*=0, *nan\_policy*='propagate')

Calculate the nth moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

### Parameters

- a** [array\_like] Input array.
- moment** [int or array\_like of ints, optional] Order of central moment that is returned. Default is 1.
- axis** [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
- ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values

### Returns

#### n-th central moment

[ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

See also:

[kurtosis](#), [skew](#), [describe](#)

### Notes

The k-th central moment of a data sample is:

$$m_k = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^k$$

Where n is the number of samples and x-bar is the mean. This function uses exponentiation by squares [1] for efficiency.

### References

[1]

## Examples

```
>>> from scipy.stats import moment
>>> moment([1, 2, 3, 4, 5], moment=1)
0.0
>>> moment([1, 2, 3, 4, 5], moment=2)
2.0
```

## scipy.stats.skew

`scipy.stats.skew` (*a*, *axis=0*, *bias=True*, *nan\_policy='propagate'*)

Compute the sample skewness of a data set.

For normally distributed data, the skewness should be about zero. For unimodal continuous distributions, a skewness value greater than zero means that there is more weight in the right tail of the distribution. The function `skewtest` can be used to determine if the skewness value is close enough to zero, statistically speaking.

### Parameters

- a** [ndarray] Input array.
- axis** [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.
- bias** [bool, optional] If False, then the calculations are corrected for statistical bias.
- nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is "propagate"):
  - "propagate": returns nan
  - "raise": throws an error
  - "omit": performs the calculations ignoring nan values

### Returns

- skewness** [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

## Notes

The sample skewness is computed as the Fisher-Pearson coefficient of skewness, i.e.

$$g_1 = \frac{m_3}{m_2^{3/2}}$$

where

$$m_i = \frac{1}{N} \sum_{n=1}^N (x[n] - \bar{x})^i$$

is the biased sample *i*th central moment, and  $\bar{x}$  is the sample mean. If `bias` is False, the calculations are corrected for bias and the value computed is the adjusted Fisher-Pearson standardized moment coefficient, i.e.

$$G_1 = \frac{k_3}{k_2^{3/2}} = \frac{\sqrt{N(N-1)}}{N-2} \frac{m_3}{m_2^{3/2}}$$

## References

[1]

## Examples

```
>>> from scipy.stats import skew
>>> skew([1, 2, 3, 4, 5])
0.0
>>> skew([2, 8, 0, 4, 1, 9, 9, 0])
0.2650554122698573
```

## scipy.stats.kstat

`scipy.stats.kstat` (*data*, *n=2*)

Return the *n*th k-statistic (1<=*n*<=4 so far).

The *n*th k-statistic *k<sub>n</sub>* is the unique symmetric unbiased estimator of the *n*th cumulant *kappa<sub>n</sub>*.

### Parameters

**data** [array\_like] Input array. Note that n-D input gets flattened.  
**n** [int, {1, 2, 3, 4}, optional] Default is equal to 2.

### Returns

**kstat** [float] The *n*th k-statistic.

See also:

### [kstatvar](#)

Returns an unbiased estimator of the variance of the k-statistic.

### [moment](#)

Returns the *n*-th central moment about the mean for a sample.

## Notes

For a sample size *n*, the first few k-statistics are given by:

$$k_1 = \mu k_2 = \frac{n}{n-1} m_2 k_3 = \frac{n^2}{(n-1)(n-2)} m_3 k_4 = \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)}$$

where  $\mu$  is the sample mean,  $m_2$  is the sample variance, and  $m_i$  is the *i*-th sample central moment.

## References

<http://mathworld.wolfram.com/k-Statistic.html>

<http://mathworld.wolfram.com/Cumulant.html>

## Examples

```
>>> from scipy import stats
>>> rndm = np.random.RandomState(1234)
```

As sample size increases, n-th moment and n-th k-statistic converge to the same number (although they aren't identical). In the case of the normal distribution, they converge to zero.

```
>>> for n in [2, 3, 4, 5, 6, 7]:
...     x = rndm.normal(size=10**n)
...     m, k = stats.moment(x, 3), stats.kstat(x, 3)
...     print("%.3g %.3g %.3g" % (m, k, m-k))
-0.631 -0.651 0.0194
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```

## scipy.stats.kstatvar

`scipy.stats.kstatvar` (*data*, *n*=2)

Return an unbiased estimator of the variance of the k-statistic.

See *kstat* for more details of the k-statistic.

### Parameters

**data** [array\_like] Input array. Note that n-D input gets flattened.  
**n** [int, {1, 2}, optional] Default is equal to 2.

### Returns

**kstatvar** [float] The nth k-statistic variance.

See also:

### kstat

Returns the n-th k-statistic.

### moment

Returns the n-th central moment about the mean for a sample.

## Notes

The variances of the first few k-statistics are given by:

$$\text{var}(k_1) = \frac{\kappa^2}{n} \text{var}(k_2) = \frac{\kappa^4}{n} + \frac{2\kappa_2^2}{n-1} \text{var}(k_3) = \frac{\kappa^6}{n} + \frac{9\kappa_2\kappa_4}{n-1} + \frac{9\kappa_3^2}{n-1} + \frac{6n\kappa_2^3}{(n-1)(n-2)} \text{var}(k_4) = \frac{\kappa^8}{n} + \frac{16\kappa_2\kappa_6}{n-1} + \frac{48\kappa_3\kappa_5}{n-1}$$

## scipy.stats.tmean

`scipy.stats.tmean(a, limits=None, inclusive=True, True, axis=None)`

Compute the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given *limits*.

### Parameters

- a** [array\_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to compute test. Default is None.

### Returns

- tmean** [float] Trimmed mean.

See also:

### trim\_mean

Returns mean after trimming a proportion from both tails.

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3, 17))
10.0
```

## scipy.stats.tvar

`scipy.stats.tvar(a, limits=None, inclusive=True, True, axis=0, ddof=1)`

Compute the trimmed variance.

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

### Parameters

- a** [array\_like] Array of values.

<b>limits</b>	[None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
<b>inclusive</b>	[(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
<b>axis</b>	[int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array <i>a</i> .
<b>ddof</b>	[int, optional] Delta degrees of freedom. Default is 1.

**Returns**

**tvar** [float] Trimmed variance.

**Notes**

*tvar* computes the unbiased sample variance, i.e. it uses a correction factor  $n / (n - 1)$ .

**Examples**

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3,17))
20.0
```

**scipy.stats.tmin**

`scipy.stats.tmin` (*a*, *lowerlimit*=None, *axis*=0, *inclusive*=True, *nan\_policy*='propagate')

Compute the trimmed minimum.

This function finds the minimum value of an array *a* along the specified axis, but only considering values greater than a specified lower limit.

**Parameters**

<b>a</b>	[array_like] Array of values.
<b>lowerlimit</b>	[None or float, optional] Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
<b>axis</b>	[int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array <i>a</i> .
<b>inclusive</b>	[[True, False], optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.
<b>nan_policy</b>	<p>['propagate', 'raise', 'omit'], optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):</p> <ul style="list-style-type: none"> <li>• 'propagate': returns nan</li> <li>• 'raise': throws an error</li> <li>• 'omit': performs the calculations ignoring nan values</li> </ul>

**Returns**

**tmin** [float, int or ndarray] Trimmed minimum.

### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0
```

```
>>> stats.tmin(x, 13)
13
```

```
>>> stats.tmin(x, 13, inclusive=False)
14
```

### scipy.stats.tmax

`scipy.stats.tmax` (*a*, *upperlimit=None*, *axis=0*, *inclusive=True*, *nan\_policy='propagate'*)  
Compute the trimmed maximum.

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

#### Parameters

- a** [array\_like] Array of values.
- upperlimit** [None or float, optional] Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
- 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

#### Returns

**tmax** [float, int or ndarray] Trimmed maximum.

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19
```

```
>>> stats.tmax(x, 13)
13
```

```
>>> stats.tmax(x, 13, inclusive=False)
12
```

## scipy.stats.tstd

`scipy.stats.tstd(a, limits=None, inclusive=True, True, axis=0, ddof=1)`

Compute the trimmed sample standard deviation.

This function finds the sample standard deviation of given values, ignoring values outside the given *limits*.

### Parameters

- a** [array\_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is *None*, then all values are used. Either of the limit values in the tuple can also be *None* representing a half-open interval. The default value is *None*.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If *None*, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees of freedom. Default is 1.

### Returns

- tstd** [float] Trimmed sample standard deviation.

## Notes

*tstd* computes the unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161
>>> stats.tstd(x, (3, 17))
4.4721359549995796
```

## scipy.stats.tsem

`scipy.stats.tsem(a, limits=None, inclusive=True, True, axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

### Parameters

<b>a</b>	[array_like] Array of values.
<b>limits</b>	[None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
<b>inclusive</b>	[(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
<b>axis</b>	[int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array <i>a</i> .
<b>ddof</b>	[int, optional] Delta degrees of freedom. Default is 1.

### Returns

**tsem** [float] Trimmed standard error of the mean.

## Notes

*tsem* uses unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3, 17))
1.1547005383792515
```

## scipy.stats.variation

`scipy.stats.variation(a, axis=0, nan_policy='propagate')`

Compute the coefficient of variation.

The coefficient of variation is the ratio of the biased standard deviation to the mean.

### Parameters

<b>a</b>	[array_like] Input array.
<b>axis</b>	[int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array <i>a</i> .
<b>nan_policy</b>	[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'): <ul style="list-style-type: none"><li>• 'propagate': returns nan</li><li>• 'raise': throws an error</li></ul>

- ‘omit’: performs the calculations ignoring nan values

**Returns**

**variation** [ndarray] The calculated variation along the requested axis.

**References**

[1]

**Examples**

```
>>> from scipy.stats import variation
>>> variation([1, 2, 3, 4, 5])
0.47140452079103173
```

**scipy.stats.find\_repeats**

`scipy.stats.find_repeats(arr)`

Find repeats and repeat counts.

**Parameters**

**arr** [array\_like] Input array. This is cast to float64.

**Returns**

**values** [ndarray] The unique values from the (flattened) input that are repeated.

**counts** [ndarray] Number of times the corresponding ‘value’ is repeated.

**Notes**

In numpy >= 1.9 `numpy.unique` provides similar functionality. The main difference is that `find_repeats` only returns repeated values.

**Examples**

```
>>> from scipy import stats
>>> stats.find_repeats([2, 1, 2, 3, 2, 2, 5])
RepeatedResults(values=array([2.]), counts=array([4]))
```

```
>>> stats.find_repeats([[10, 20, 1, 2], [5, 5, 4, 4]])
RepeatedResults(values=array([4., 5.]), counts=array([2, 2]))
```

## scipy.stats.trim\_mean

`scipy.stats.trim_mean(a, proportiontocut, axis=0)`

Return mean of array after trimming distribution from both tails.

If `proportiontocut = 0.1`, slices off 'leftmost' and 'rightmost' 10% of scores. The input is sorted before slicing. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off `proportiontocut` ).

### Parameters

**a** [array\_like] Input array.

**proportiontocut** [float] Fraction to cut off of both tails of the distribution.

**axis** [int or None, optional] Axis along which the trimmed means are computed. Default is 0. If None, compute over the whole array *a*.

### Returns

**trim\_mean** [ndarray] Mean of trimmed array.

See also:

[trimboth](#)

[tmean](#)

Compute the trimmed mean ignoring values outside given *limits*.

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.trim_mean(x, 0.1)
9.5
>>> x2 = x.reshape(5, 4)
>>> x2
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15],
       [16, 17, 18, 19]])
>>> stats.trim_mean(x2, 0.25)
array([ 8.,  9., 10., 11.])
>>> stats.trim_mean(x2, 0.25, axis=1)
array([ 1.5,  5.5,  9.5, 13.5, 17.5])
```

**scipy.stats.gstd**

`scipy.stats.gstd(a, axis=0, ddof=1)`

Calculate the geometric standard deviation of an array.

The geometric standard deviation describes the spread of a set of numbers where the geometric mean is preferred. It is a multiplicative factor, and so a dimensionless quantity.

It is defined as the exponent of the standard deviation of  $\log(a)$ . Mathematically the population geometric standard deviation can be evaluated as:

```
gstd = exp(std(log(a)))
```

New in version 1.3.0.

**Parameters**

- a** [array\_like] An array like object containing the sample data.
- axis** [int, tuple or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Degree of freedom correction in the calculation of the geometric standard deviation. Default is 1.

**Returns****ndarray or float**

An array of the geometric standard deviation. If *axis* is None or *a* is a 1d array a float is returned.

**Notes**

As the calculation requires the use of logarithms the geometric standard deviation only supports strictly positive values. Any non-positive or infinite values will raise a *ValueError*. The geometric standard deviation is sometimes confused with the exponent of the standard deviation,  $\exp(\text{std}(a))$ . Instead the geometric standard deviation is  $\exp(\text{std}(\log(a)))$ . The default value for *ddof* is different to the default value (0) used by other *ddof* containing functions, such as `np.std` and `np.nanstd`.

**Examples**

Find the geometric standard deviation of a log-normally distributed sample. Note that the standard deviation of the distribution is one, on a log scale this evaluates to approximately  $\exp(1)$ .

```
>>> from scipy.stats import gstd
>>> np.random.seed(123)
>>> sample = np.random.lognormal(mean=0, sigma=1, size=1000)
>>> gstd(sample)
2.7217860664589946
```

Compute the geometric standard deviation of a multidimensional array and of a given axis.

```
>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> gstd(a, axis=None)
2.2944076136018947
>>> gstd(a, axis=2)
array([[1.82424757, 1.22436866, 1.13183117],
```

(continues on next page)

(continued from previous page)

```

    [1.09348306, 1.07244798, 1.05914985]])
>>> gstd(a, axis=(1,2))
array([2.12939215, 1.22120169])

```

The geometric standard deviation further handles masked arrays.

```

>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> ma = np.ma.masked_where(a > 16, a)
>>> ma
masked_array(
  data=[[ [1, 2, 3, 4],
          [5, 6, 7, 8],
          [9, 10, 11, 12]],
        [[13, 14, 15, 16],
          [--, --, --, --],
          [--, --, --, --]]],
  mask=[[ [False, False, False, False],
          [False, False, False, False],
          [False, False, False, False]],
        [[False, False, False, False],
          [ True,  True,  True,  True],
          [ True,  True,  True,  True]]],
  fill_value=999999)
>>> gstd(ma, axis=2)
masked_array(
  data=[[1.8242475707663655, 1.2243686572447428, 1.1318311657788478],
        [1.0934830582350938, --, --]],
  mask=[[False, False, False],
        [False, True, True]],
  fill_value=999999)

```

## scipy.stats.iqr

`scipy.stats.iqr(x, axis=None, rng=25, 75, scale=1.0, nan_policy='propagate', interpolation='linear', keepdims=False)`

Compute the interquartile range of the data along the specified axis.

The interquartile range (IQR) is the difference between the 75th and 25th percentile of the data. It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers [2].

The `rng` parameter allows this function to compute other percentile ranges than the actual IQR. For example, setting `rng=(0, 100)` is equivalent to `numpy.ptp`.

The IQR of an empty array is `np.nan`.

New in version 0.18.0.

### Parameters

- x** [array\_like] Input array or object that can be converted to an array.
- axis** [int or sequence of int, optional] Axis along which the range is computed. The default is to compute the IQR for the entire array.
- rng** [Two-element sequence containing floats in range of [0,100] optional] Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important.

- scale** [scalar or str, optional] The numerical value of scale will be divided out of the final result. The following string values are recognized:
- ‘raw’: No scaling, just return the raw IQR. **Deprecated!** Use `scale=1` instead.
  - ‘normal’: Scale by  $2\sqrt{2}erf^{-1}(\frac{1}{2}) \approx 1.349$ .
- The default is 1.0. The use of `scale='raw'` is deprecated. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that `out / scale` is a valid operation. The output dimensions depend on the input array, `x`, the `axis` argument, and the `keepdims` flag.
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
- ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values
- interpolation** [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}, optional] Specifies the interpolation method to use when the percentile boundaries lie between two data points `i` and `j`. The following options are available (default is ‘linear’):
- ‘linear’:  $i + (j - i) * fraction$ , where `fraction` is the fractional part of the index surrounded by `i` and `j`.
  - ‘lower’: `i`.
  - ‘higher’: `j`.
  - ‘nearest’: `i` or `j` whichever is nearest.
  - ‘midpoint’:  $(i + j) / 2$ .
- keepdims** [bool, optional] If this is set to `True`, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array `x`.

**Returns**

- iqr** [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

See also:

`numpy.std`, `numpy.var`

**Notes**

This function is heavily dependent on the version of `numpy` that is installed. Versions greater than 1.11.0b3 are highly recommended, as they include a number of enhancements and fixes to `numpy.percentile` and `numpy.nanpercentile` that affect the operation of this function. The following modifications apply:

**Below 1.10.0**

[`nan_policy` is poorly defined.] The default behavior of `numpy.percentile` is used for ‘propagate’. This is a hybrid of ‘omit’ and ‘propagate’ that mostly yields a skewed version of ‘omit’ since NaNs are sorted to the end of the data. A warning is raised if there are NaNs in the data.

**Below 1.9.0: `numpy.nanpercentile` does not exist.**

This means that `numpy.percentile` is used regardless of `nan_policy` and a warning is issued. See previous item for a description of the behavior.

**Below 1.9.0: `keepdims` and `interpolation` are not supported.**

The keywords get ignored with a warning if supplied with non-default values. However, multiple axes are still supported.

## References

[1], [2], [3]

## Examples

```
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> iqr(x)
4.0
>>> iqr(x, axis=0)
array([ 3.5,  2.5,  1.5])
>>> iqr(x, axis=1)
array([ 3.,  1.])
>>> iqr(x, axis=1, keepdims=True)
array([[ 3.],
       [ 1.]])
```

## scipy.stats.sem

`scipy.stats.sem(a, axis=0, ddof=1, nan_policy='propagate')`

Compute standard error of the mean.

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

### Parameters

- a** [array\_like] An array containing the values for which the standard error is returned.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
- 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

### Returns

- s** [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

## Notes

The default value for *ddof* is different to the default (0) used by other *ddof* containing routines, such as `np.std` and `np.nanstd`.

## Examples

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> stats.sem(a)
array([ 2.8284,  2.8284,  2.8284,  2.8284])
```

Find standard error across the whole array, using *n* degrees of freedom:

```
>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628
```

## scipy.stats.bayes\_mvs

`scipy.stats.bayes_mvs` (*data*, *alpha*=0.9)

Bayesian confidence intervals for the mean, var, and std.

### Parameters

- data** [array\_like] Input data, if multi-dimensional it is flattened to 1-D by `bayes_mvs`. Requires 2 or more data points.
- alpha** [float, optional] Probability that the returned confidence interval contains the true parameter.

### Returns

**mean\_cntr, var\_cntr, std\_cntr**

[tuple] The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

```
(center, (lower, upper))
```

with *center* the mean of the conditional pdf of the value given the data, and (*lower*, *upper*) a confidence interval, centered on the median, containing the estimate to a probability *alpha*.

See also:

`mvstdist`

## Notes

Each tuple of mean, variance, and standard deviation estimates represent the (*center*, (*lower*, *upper*)) with *center* the mean of the conditional pdf of the value given the data and (*lower*, *upper*) is a confidence interval centered on the median, containing the estimate to a probability *alpha*.

Converts data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey's prior for variance and std.

Equivalent to `tuple((x.mean(), x.interval(alpha)) for x in mvstdist(dat))`

## References

T.E. Oliphant, “A Bayesian perspective on estimating mean, variance, and standard-deviation from data”, <https://scholarsarchive.byu.edu/facpub/278>, 2006.

## Examples

First a basic example to demonstrate the outputs:

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.103650222612533, 10.896349777387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.7823367265645143, 4.
→945614605014631))
```

Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)
```

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.hist(data, bins=100, density=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated_
→mean')
>>> ax.axvspan(res_mean.minmax[0], res_mean.minmax[1], facecolor='r',
...           alpha=0.2, label=r'Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated_
→scale')
>>> ax.axvspan(res_std.minmax[0], res_std.minmax[1], facecolor='g',
→alpha=0.2,
...           label=r'Estimated scale (95% limits)')
```

```
>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()
```

## scipy.stats.mvstdist

`scipy.stats.mvstdist` (*data*)

'Frozen' distributions for mean, variance, and standard deviation of data.

### Parameters

**data** [array\_like] Input array. Converted to 1-D using `ravel`. Requires 2 or more data-points.

### Returns

**mdist** ["frozen" distribution object] Distribution object representing the mean of the data.  
**vdist** ["frozen" distribution object] Distribution object representing the variance of the data.  
**sdist** ["frozen" distribution object] Distribution object representing the standard deviation of the data.

### See also:

[bayes\\_mvs](#)

### Notes

The return values from `bayes_mvs(data)` is equivalent to `tuple((x.mean(), x.interval(0.90)) for x in mvstdist(data))`.

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from `bayes_mvs`.

## References

T.E. Oliphant, “A Bayesian perspective on estimating mean, variance, and standard-deviation from data”, <https://scholarsarchive.byu.edu/facpub/278>, 2006.

## Examples

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvstdist(data)
```

We now have frozen distribution objects “mean”, “var” and “std” that we can examine:

```
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

## scipy.stats.entropy

`scipy.stats.entropy(pk, qk=None, base=None, axis=0)`

Calculate the entropy of a distribution for given probability values.

If only probabilities  $pk$  are given, the entropy is calculated as  $S = -\sum(pk * \log(pk), axis=axis)$ .

If  $qk$  is not None, then compute the Kullback-Leibler divergence  $S = \sum(pk * \log(pk / qk), axis=axis)$ .

This routine will normalize  $pk$  and  $qk$  if they don't sum to 1.

### Parameters

- pk** [sequence] Defines the (discrete) distribution.  $pk[i]$  is the (possibly unnormalized) probability of event  $i$ .
- qk** [sequence, optional] Sequence against which the relative entropy is computed. Should be in the same format as  $pk$ .
- base** [float, optional] The logarithmic base to use, defaults to  $e$  (natural logarithm).
- axis: int, optional**  
The axis along which the entropy is calculated. Default is 0.

### Returns

- S** [float] The calculated entropy.

## Examples

```
>>> from scipy.stats import entropy
```

Bernoulli trial with different p. The outcome of a fair coin is the most uncertain:

```
>>> entropy([1/2, 1/2], base=2)
1.0
```

The outcome of a biased coin is less uncertain:

```
>>> entropy([9/10, 1/10], base=2)
0.46899559358928117
```

Relative entropy:

```
>>> entropy([1/2, 1/2], qk=[9/10, 1/10])
0.5108256237659907
```

## scipy.stats.median\_absolute\_deviation

`scipy.stats.median_absolute_deviation(*args, **kwargs)`

*median\_absolute\_deviation* is deprecated, use *median\_abs\_deviation* instead!

To preserve the existing default behavior, use `scipy.stats.median_abs_deviation(..., scale=1/1.4826)`. The value 1.4826 is not numerically precise for scaling with a normal distribution. For a numerically precise value, use `scipy.stats.median_abs_deviation(..., scale='normal')`.

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation but more robust to outliers [2].

The MAD of an empty array is `np.nan`.

New in version 1.3.0.

### Parameters

- |                   |  |
|-------------------|--|
| <b>x</b>          | [array_like] Input array or object that can be converted to an array.  |
| <b>axis</b>       | [int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.  |
| <b>center</b>     | [callable, optional] A function that will return the central value. The default is to use <code>np.median</code> . Any user defined function used will need to have the function signature <code>func(arr, axis)</code> .  |
| <b>scale</b>      | [int, optional] The scaling factor applied to the MAD. The default scale (1.4826) ensures consistency with the standard deviation for normally distributed data.   |
| <b>nan_policy</b> | <p>[[‘propagate’, ‘raise’, ‘omit’], optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):</p> <ul style="list-style-type: none"> <li>• ‘propagate’: returns nan</li> <li>• ‘raise’: throws an error</li> <li>• ‘omit’: performs the calculations ignoring nan values</li> </ul> |

### Returns

**mad** [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

See also:

`numpy.std`, `numpy.var`, `numpy.median`, `scipy.stats.iqr`, `scipy.stats.tmean`  
`scipy.stats.tstd`, `scipy.stats.tvar`

## Notes

The `center` argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=np.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

## References

[1], [2]

## Examples

When comparing the behavior of `median_absolute_deviation` with `np.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_absolute_deviation(x)
1.2280762773108278
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_absolute_deviation(x)
1.2340335571164334
```

Axis handling example:

```
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> stats.median_absolute_deviation(x)
array([5.1891, 3.7065, 2.2239])
>>> stats.median_absolute_deviation(x, axis=None)
2.9652
```

## scipy.stats.median\_abs\_deviation

`scipy.stats.median_abs_deviation(x, axis=0, center=<function median at 0x7f069c55db00>, scale=1.0, nan_policy='propagate')`

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation but more robust to outliers [2].

The MAD of an empty array is `np.nan`.

New in version 1.5.0.

### Parameters

- |                   |   |
|-------------------|---|
| <b>x</b>          | [array_like] Input array or object that can be converted to an array.   |
| <b>axis</b>       | [int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.   |
| <b>center</b>     | [callable, optional] A function that will return the central value. The default is to use <code>np.median</code> . Any user defined function used will need to have the function signature <code>func(arr, axis)</code> .   |
| <b>scale</b>      | [scalar or str, optional] The numerical value of scale will be divided out of the final result. The default is 1.0. The string “normal” is also accepted, and results in <i>scale</i> being the inverse of the standard normal quantile function at 0.75, which is approximately 0.67449. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that <code>out / scale</code> is a valid operation. The output dimensions depend on the input array, <i>x</i> , and the <i>axis</i> argument. |
| <b>nan_policy</b> | [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'): <ul style="list-style-type: none"> <li>• 'propagate': returns nan</li> <li>• 'raise': throws an error</li> <li>• 'omit': performs the calculations ignoring nan values</li> </ul>   |

### Returns

- |            |   |
|------------|---|
| <b>mad</b> | [scalar or ndarray] If <code>axis=None</code> , a scalar is returned. If the input contains integers or floats of smaller precision than <code>np.float64</code> , then the output data-type is <code>np.float64</code> . Otherwise, the output data-type is the same as that of the input. |
|------------|---|

[`numpy.std`](#), [`numpy.var`](#), [`numpy.median`](#), [`scipy.stats.iqr`](#), [`scipy.stats.tmean`](#)

[`scipy.stats.tstd`](#), [`scipy.stats.tvar`](#)

### Notes

The *center* argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=np.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

The input array may contain *inf*, but if *center* returns *inf*, the corresponding MAD for that data will be *nan*.

## References

[1], [2]

## Examples

When comparing the behavior of `median_abs_deviation` with `np.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_abs_deviation(x)
0.82832610097857
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_abs_deviation(x)
0.8323442311590675
```

Axis handling example:

```
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
       [ 3, 2, 1]])
>>> stats.median_abs_deviation(x)
array([3.5, 2.5, 1.5])
>>> stats.median_abs_deviation(x, axis=None)
2.0
```

Scale normal example:

```
>>> x = stats.norm.rvs(size=1000000, scale=2, random_state=123456)
>>> stats.median_abs_deviation(x)
1.3487398527041636
>>> stats.median_abs_deviation(x, scale='normal')
1.9996446978061115
```

## 6.29.8 Frequency statistics

<code>cumfreq(a[, numbins, defaultreallimits, weights])</code>	Return a cumulative frequency histogram, using the histogram function.
<code>itemfreq(*args, **kwargs)</code>	<code>itemfreq</code> is deprecated! <code>itemfreq</code> is deprecated and will be removed in a future version.
<code>percentileofscore(a, score[, kind])</code>	Compute the percentile rank of a score relative to a list of scores.
<code>scoreatpercentile(a, per[, limit, ...])</code>	Calculate the score at a given percentile of the input sequence.

continues on next page

Table 262 – continued from previous page

<code>relfreq(a[, numbins, defaultreallimits, weights])</code>	Return a relative frequency histogram, using the histogram function.
--	--

**scipy.stats.cumfreq**

`scipy.stats.cumfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a cumulative frequency histogram, using the histogram function.

A cumulative histogram is a mapping that counts the cumulative number of observations in all of the bins up to the specified bin.

**Parameters**

- a** [array\_like] Input array.
- numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\min() - s, a.\max() + s)$ , where  $s = (1/2)(a.\max() - a.\min()) / (\text{numbins} - 1)$ .
- weights** [array\_like, optional] The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

**Returns**

- cumcount** [ndarray] Binned values of cumulative frequency.
- lowerlimit** [float] Lower real limit
- binsize** [float] Width of each bin.
- extrapoints** [int] Extra points.

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> x = [1, 4, 2, 1, 3, 1]
>>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
>>> res.cumcount
array([ 1.,  2.,  3.,  3.])
>>> res.extrapoints
3
```

Create a normal distribution with 1000 random values

```
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate cumulative frequencies

```
>>> res = stats.cumfreq(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size,
...                                  res.cumcount.size)
```

Plot histogram and cumulative histogram

```
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

### scipy.stats.itemfreq

`scipy.stats.itemfreq(*args, **kwargs)`

*itemfreq* is deprecated! *itemfreq* is deprecated and will be removed in a future version. Use instead `np.unique(..., return_counts=True)`

Return a 2-D array of item frequencies.

#### Parameters

**a** [(N,) array\_like] Input array.

#### Returns

**itemfreq** [(K, 2) ndarray] A 2-D frequency table. Column 1 contains sorted, unique values from *a*, column 2 contains their respective counts.

## Examples

```
>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
array([[ 0.,  2.],
       [ 1.,  4.],
       [ 2.,  2.],
       [ 4.,  1.],
       [ 5.,  1.]])
>>> np.bincount(a)
array([2, 4, 2, 0, 1, 1])
```

```
>>> stats.itemfreq(a/10.)
array([[ 0. ,  2. ],
       [ 0.1,  4. ],
       [ 0.2,  2. ],
       [ 0.4,  1. ],
       [ 0.5,  1. ]])
```

### scipy.stats.percentileofscore

`scipy.stats.percentileofscore` (*a*, *score*, *kind*='rank')

Compute the percentile rank of a score relative to a list of scores.

A *percentileofscore* of, for example, 80% means that 80% of the scores in *a* are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, *kind*.

#### Parameters

- |              |  |
|--------------|--|
| <b>a</b>     | [array_like] Array of scores to which <i>score</i> is compared.  |
| <b>score</b> | [int or float] Score that is compared to the elements in <i>a</i> .  |
| <b>kind</b>  | [{'rank', 'weak', 'strict', 'mean'}, optional] Specifies the interpretation of the resulting score. The following options are available (default is 'rank'): |
- 'rank': Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores.
  - 'weak': This kind corresponds to the definition of a cumulative distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score.
  - 'strict': Similar to "weak", except that only values that are strictly less than the given score are counted.
  - 'mean': The average of the "weak" and "strict" scores, often used in testing. See [https://en.wikipedia.org/wiki/Percentile\\_rank](https://en.wikipedia.org/wiki/Percentile_rank)

#### Returns

- |             |   |
|-------------|---|
| <b>pcos</b> | [float] Percentile-position of score (0-100) relative to <i>a</i> . |
|-------------|---|

See also:

[\*numpy.percentile\*](#)

## Examples

Three-quarters of the given values lie below a given score:

```
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='strict')
40.0
```

But 4/5 values are less than or equal to 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='mean')
60.0
```

## scipy.stats.scoreatpercentile

`scipy.stats.scoreatpercentile(a, per, limit=(), interpolation_method='fraction', axis=None)`

Calculate the score at a given percentile of the input sequence.

For example, the score at *per*=50 is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of *interpolation*. If the parameter *limit* is provided, it should be a tuple (lower, upper) of two values.

### Parameters

- a** [array\_like] A 1-D array of values from which to extract score.
- per** [array\_like] Percentile(s) at which to extract score. Values should be in range [0,100].
- limit** [tuple, optional] Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of *a* outside this (closed) interval will be ignored.
- interpolation\_method** [{‘fraction’, ‘lower’, ‘higher’}, optional] Specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*. The following options are available (default is ‘fraction’):
  - ‘fraction’:  $i + (j - i) * \text{fraction}$  where *fraction* is the fractional part of the index surrounded by *i* and *j*
  - ‘lower’: *i*
  - ‘higher’: *j*
- axis** [int, optional] Axis along which the percentiles are computed. Default is None. If None, compute over the whole array *a*.

### Returns

**score** [float or ndarray] Score at percentile(s).

**See also:**

`percentileofscore`, `numpy.percentile`

### Notes

This function will become obsolete in the future. For NumPy 1.9 and higher, `numpy.percentile` provides all the functionality that `scoreatpercentile` provides. And it's significantly faster. Therefore it's recommended to use `numpy.percentile` for users that have `numpy >= 1.9`.

### Examples

```
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```

## scipy.stats.relfreq

`scipy.stats.relfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.

#### Parameters

**a** [array\_like] Input array.  
**numbins** [int, optional] The number of bins to use for the histogram. Default is 10.  
**defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.min() - s, a.max() + s)$ , where  $s = (1/2)(a.max() - a.min()) / (numbins - 1)$ .  
**weights** [array\_like, optional] The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

#### Returns

**frequency** [ndarray] Binned values of relative frequency.  
**lowerlimit** [float] Lower real limit.  
**binsize** [float] Width of each bin.  
**extrapoints** [int] Extra points.

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfrac(a, numbins=4)
>>> res.frequency
array([ 0.16666667, 0.5          , 0.16666667, 0.16666667])
>>> np.sum(res.frequency) # relative frequencies should add up to 1
1.0
```

Create a normal distribution with 1000 random values

```
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate relative frequencies

```
>>> res = stats.relfrac(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size,
...                                 res.frequency.size)
```

Plot relative frequency histogram

```
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.binsize)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

<code>binned_statistic(x, values[, statistic, ...])</code>	Compute a binned statistic for one or more sets of data.
<code>binned_statistic_2d(x, y, values[, ...])</code>	Compute a bidimensional binned statistic for one or more sets of data.
<code>binned_statistic_dd(sample, values[, ...])</code>	Compute a multidimensional binned statistic for a set of data.

## scipy.stats.binned\_statistic

`scipy.stats.binned_statistic(x, values, statistic='mean', bins=10, range=None)`

Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

### Parameters

**x** [(N,) array\_like] A sequence of values to be binned.

<b>values</b>	[(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as <i>x</i> , or a set of sequences - each the same shape as <i>x</i> . If <i>values</i> is a set of sequences, the statistic will be computed on each independently.
<b>statistic</b>	[string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available: <ul style="list-style-type: none"> <li>• 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'std': compute the standard deviation within each bin. This is implicitly calculated with <code>ddof=0</code>.</li> <li>• 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'count': compute the count of points within each bin. This is identical to an unweighted histogram. <i>values</i> array is not referenced.</li> <li>• 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.</li> <li>• 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.</li> <li>• function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by <code>function([])</code>, or NaN if this returns an error.</li> </ul>
<b>bins</b>	[int or sequence of scalars, optional] If <i>bins</i> is an int, it defines the number of equal-width bins in the given range (10 by default). If <i>bins</i> is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in <i>x</i> that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to <code>bins[-1]</code> . If the bin edges are specified, the number of bins will be, $(n_x = \text{len}(\text{bins}) - 1)$ .
<b>range</b>	[(float, float) or [(float, float)], optional] The lower and upper range of the bins. If not pro-

vided, range is simply `(x.min(), x.max())`. Values outside the range are ignored.

### Returns

**statistic** [array] The values of the selected statistic in each bin.  
**bin\_edges** [array of dtype float] Return the bin edges (`length(statistic)+1`).  
**binnumber: 1-D ndarray of ints**  
Indices of the bins (corresponding to *bin\_edges*) in which each value of *x* belongs. Same length as *values*. A binnumber of *i* means the corresponding value is between (`bin_edges[i-1]`, `bin_edges[i]`).

See also:

`numpy.digitize`, `numpy.histogram`, `binned_statistic_2d`, `binned_statistic_dd`

### Notes

All but the last (righthand-most) bin is half-open. In other words, if *bins* is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which includes 4.

New in version 0.11.0.

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

First some basic examples:

Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```
>>> values = [1.0, 1.0, 2.0, 1.5, 3.0]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
BinnedStatisticResult(statistic=array([4. , 4.5]),
                      bin_edges=array([1., 4., 7.]), binnumber=array([1, 1, 1, 2, 2]))
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```
>>> values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
BinnedStatisticResult(statistic=array([[4. , 4.5],
      [8. , 9. ]]), bin_edges=array([1., 4., 7.]),
                      binnumber=array([1, 1, 1, 2, 2]))
```

```
>>> stats.binned_statistic([1, 2, 1, 2, 4], np.arange(5), statistic='mean',
...
...
...
...
...
                      bins=3)
BinnedStatisticResult(statistic=array([1., 2., 4.]),
                      bin_edges=array([1., 2., 3., 4.]),
                      binnumber=array([1, 2, 1, 2, 3]))
```

As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```

>>> windspeed = 8 * np.random.rand(500)
>>> boatspeed = .3 * windspeed**.5 + .2 * np.random.rand(500)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed,
...
...                               boatspeed, statistic='median', bins=[1,2,3,4,5,6,7])
>>> plt.figure()
>>> plt.plot(windspeed, boatspeed, 'b.', label='raw data')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=5,
...
...           label='binned statistic of data')
>>> plt.legend()

```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

```

>>> low_boatspeed = boatspeed[binnumber == 0]

```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```

>>> x = np.linspace(0, 5, num=500)
>>> x_pdf = stats.maxwell.pdf(x)
>>> samples = stats.maxwell.rvs(size=10000)

```

```

>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf,
...
...                               statistic='mean', bins=25)
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2

```

```

>>> plt.figure()
>>> plt.hist(samples, bins=50, density=True, histtype='stepfilled',
...
...         alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
...
...           label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()

```

## scipy.stats.binned\_statistic\_2d

`scipy.stats.binned_statistic_2d(x, y, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)`

Compute a bidimensional binned statistic for one or more sets of data.

This is a generalization of a `histogram2d` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

### Parameters

- x** [(N,) array\_like] A sequence of values to be binned along the first dimension.
- y** [(N,) array\_like] A sequence of values to be binned along the second dimension.
- values** [(N,) array\_like or list of (N,) array\_like] The data on which the statistic will be computed. This must be the same shape as `x`, or a list of sequences - each with the same shape as `x`. If `values` is such a list, the statistic will be computed on each independently.

- statistic** [string or callable, optional] The statistic to compute (default is ‘mean’). The following statistics are available:
- ‘mean’: compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - ‘std’: compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`.
  - ‘median’: compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - ‘count’: compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
  - ‘sum’: compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - ‘min’: compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - ‘max’: compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.
- bins** [int or [int, int] or array\_like or [array, array], optional] The bin specification:
- the number of bins for the two dimensions (`nx = ny = bins`),
  - the number of bins in each dimension (`nx, ny = bins`),
  - the bin edges for the two dimensions (`x_edge = y_edge = bins`),
  - the bin edges in each dimension (`x_edge, y_edge = bins`).
- If the bin edges are specified, the number of bins will be, (`nx = len(x_edge)-1`, `ny = len(y_edge)-1`).
- range** [(2,2) array\_like, optional] The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the *bins* parameters): `[[xmin, xmax], [ymin, ymax]]`. All values outside of this range will be considered outliers and not tallied in the histogram.
- expand\_binnumbers** [bool, optional] ‘False’ (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. ‘True’: the returned *binnumber* is ‘unraveled’ into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section.
- New in version 0.17.0.

**Returns**

- statistic** [(nx, ny) ndarray] The values of the selected statistic in each two-dimensional bin.
- x\_edge** [(nx + 1) ndarray] The bin edges along the first dimension.
- y\_edge** [(ny + 1) ndarray] The bin edges along the second dimension.
- binnumber** [(N,) array of ints or (2,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

[numpy.digitize](#), [numpy.histogram2d](#), [binned\\_statistic](#), [binned\\_statistic\\_dd](#)

## Notes

**Binedges:** All but the last (righthand-most) bin is half-open. In other words, if *bins* is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which *includes* 4.

***binnumber*:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If `'False'` (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If `'True'`: The returned *binnumber* is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a *binnumber* of *i* means the corresponding value is between `(D_edge[i-1], D_edge[i])`, where `'D'` is either `'x'` or `'y'`.

New in version 0.11.0.

## Examples

```
>>> from scipy import stats
```

Calculate the counts with explicit bin-edges:

```
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,
↳biny])
>>> ret.statistic
array([[2., 1.],
       [1., 0.]])
```

The bin in which each sample is placed is given by the *binnumber* returned parameter. By default, these are the linearized bin indices:

```
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the *expand\_binnumbers* parameter:

```
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,
↳biny],
...                                 expand_binnumbers=True)
>>> ret.binnumber
array([[1, 1, 1, 2],
       [1, 2, 1, 1]])
```

Which shows that the first three elements belong in the *xbin* 1, and the fourth into *xbin* 2; and so on for *y*.

**scipy.stats.binned\_statistic\_dd**

`scipy.stats.binned_statistic_dd`(*sample*, *values*, *statistic*='mean', *bins*=10, *range*=None, *expand\_binnumbers*=False, *binned\_statistic\_result*=None)

Compute a multidimensional binned statistic for a set of data.

This is a generalization of a `histogramdd` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

**Parameters**

- sample** [array\_like] Data to histogram passed as a sequence of N arrays of length D, or as an (N,D) array.
- values** [(N,) array\_like or list of (N,) array\_like] The data on which the statistic will be computed. This must be the same shape as *sample*, or a list of sequences - each with the same shape as *sample*. If *values* is such a list, the statistic will be computed on each independently.
- statistic** [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
- 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - 'count': compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
  - 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - 'std': compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`. If the number of values within a given bin is 0 or 1, the computed standard deviation value will be 0 for the bin.
  - 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.
- bins** [sequence or positive int, optional] The bin specification must be in one of the following forms:
- A sequence of arrays describing the bin edges along each dimension.
  - The number of bins for each dimension (`nx, ny, ... = bins`).
  - The number of bins for all dimensions (`nx = ny = ... = bins`).
- range** [sequence, optional] A sequence of lower and upper bin edges to be used if the edges are not given explicitly in *bins*. Defaults to the minimum and maximum values along each dimension.
- expand\_binnumbers** [bool, optional] 'False' (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. 'True': the returned *binnumber* is 'unraveled' into a shape (D,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section of `binned_statistic_2d`.
- binned\_statistic\_result** [binnedStatisticddResult] Result of a previous call to the function in order to reuse bin edges and bin numbers with new values and/or a different statistic. To reuse bin numbers, *expand\_binnumbers* must have been set to False (the default)  
New in version 0.17.0.

**Returns**

**statistic** [ndarray, shape(nx1, nx2, nx3,...)] The values of the selected statistic in each two-dimensional bin.

**bin\_edges** [list of ndarrays] A list of  $D$  arrays describing the  $(n_x + 1)$  bin edges for each dimension.

**binnumber** [(N,) array of ints or (D,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

`numpy.digitize`, `numpy.histogramdd`, `binned_statistic`, `binned_statistic_2d`

### Notes

**Binedges:** All but the last (righthand-most) bin is half-open in each dimension. In other words, if *bins* is  $[1, 2, 3, 4]$ , then the first bin is  $[1, 2)$  (including 1, but excluding 2) and the second  $[2, 3)$ . The last bin, however, is  $[3, 4]$ , which *includes* 4.

**binnumber:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (D,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of  $i$  means the corresponding value is between  $(\text{bin\_edges}[D][i-1], \text{bin\_edges}[D][i])$ , for each dimension 'D'.

New in version 0.11.0.

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D
```

Take an array of 600 (x, y) coordinates as an example. *binned\_statistic\_dd* can handle arrays of higher dimension  $D$ . But a plot of dimension  $D+1$  is required.

```
>>> mu = np.array([0., 1.])
>>> sigma = np.array([[1., -0.5], [-0.5, 1.5]])
>>> multinormal = stats.multivariate_normal(mu, sigma)
>>> data = multinormal.rvs(size=600, random_state=235412)
>>> data.shape
(600, 2)
```

Create bins and count how many arrays fall in each bin:

```
>>> N = 60
>>> x = np.linspace(-3, 3, N)
>>> y = np.linspace(-3, 4, N)
>>> ret = stats.binned_statistic_dd(data, np.arange(600), bins=[x, y],
...                               statistic='count')
>>> bincounts = ret.statistic
```

Set the volume and the location of bars:

```
>>> dx = x[1] - x[0]
>>> dy = y[1] - y[0]
>>> x, y = np.meshgrid(x[:-1]+dx/2, y[:-1]+dy/2)
>>> z = 0
```

```
>>> bincounts = bincounts.ravel()
>>> x = x.ravel()
>>> y = y.ravel()
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> with np.errstate(divide='ignore'): # silence random axes3d warning
...     ax.bar3d(x, y, z, dx, dy, bincounts)
```

Reuse bin numbers and bin edges with new values:

```
>>> ret2 = stats.binned_statistic_dd(data, -np.arange(600),
...                                  binned_statistic_result=ret,
...                                  statistic='mean')
```

## 6.29.9 Correlation functions

<code>f_oneway(*args[, axis])</code>	Perform one-way ANOVA.
<code>pearsonr(x, y)</code>	Pearson correlation coefficient and p-value for testing non-correlation.
<code>spearmanr(a[, b, axis, nan_policy])</code>	Calculate a Spearman correlation coefficient with associated p-value.
<code>pointbiserialr(x, y)</code>	Calculate a point biserial correlation coefficient and its p-value.
<code>kendalltau(x, y[, initial_lexsort, ...])</code>	Calculate Kendall's tau, a correlation measure for ordinal data.

continues on next page

Table 264 – continued from previous page

<code>weightedtau(x, y[, rank, weigher, additive])</code>	Compute a weighted version of Kendall's $\tau$ .
<code>linregress(x[, y])</code>	Calculate a linear least-squares regression for two sets of measurements.
<code>siegelslopes(y[, x, method])</code>	Computes the Siegel estimator for a set of points (x, y).
<code>theilslopes(y[, x, alpha])</code>	Computes the Theil-Sen estimator for a set of points (x, y).
<code>multiscale_graphcorr(x, y[, ...])</code>	Computes the Multiscale Graph Correlation (MGC) test statistic.

## scipy.stats.f\_oneway

`scipy.stats.f_oneway(*args, axis=0)`

Perform one-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The test is applied to samples from two or more groups, possibly with differing sizes.

### Parameters

#### sample1, sample2, ...

[array\_like] The sample measurements for each group. There must be at least two arguments. If the arrays are multidimensional, then all the dimensions of the array must be the same except for *axis*.

**axis** [int, optional] Axis of the input arrays along which the test is applied. Default is 0.

### Returns

**statistic** [float] The computed F statistic of the test.

**pvalue** [float] The associated p-value from the F distribution.

### Warns

#### F\_onewayConstantInputWarning

Raised if each of the input arrays is constant array. In this case the F statistic is either infinite or isn't defined, so `np.inf` or `np.nan` is returned.

#### F\_onewayBadInputSizesWarning

Raised if the length of any input array is 0, or if all the input arrays have length 1. `np.nan` is returned for the F statistic and the p-value in these cases.

## Notes

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test (`scipy.stats.kruskal`) although with some loss of power.

The length of each group must be at least one, and there must be at least one group with length greater than one. If these conditions are not satisfied, a warning is generated and `(np.nan, np.nan)` is returned.

If each group contains constant values, and there exist at least two groups with different values, the function generates a warning and returns `(np.inf, 0)`.

If all values in all groups are the same, function generates a warning and returns `(np.nan, np.nan)`.

The algorithm is from Heiman [2], pp.394-7.

## Examples

```
>>> from scipy.stats import f_oneway
```

Here are some data [3] on a shell measurement (the length of the anterior adductor muscle scar, standardized by dividing by length) in the mussel *Mytilus trossulus* from five locations: Tillamook, Oregon; Newport, Oregon; Petersburg, Alaska; Magadan, Russia; and Tvarminne, Finland, taken from a much larger data set used in McDonald et al. (1991).

```
>>> tillamook = [0.0571, 0.0813, 0.0831, 0.0976, 0.0817, 0.0859, 0.0735,
...             0.0659, 0.0923, 0.0836]
>>> newport = [0.0873, 0.0662, 0.0672, 0.0819, 0.0749, 0.0649, 0.0835,
...            0.0725]
>>> petersburg = [0.0974, 0.1352, 0.0817, 0.1016, 0.0968, 0.1064, 0.105]
>>> magadan = [0.1033, 0.0915, 0.0781, 0.0685, 0.0677, 0.0697, 0.0764,
...            0.0689]
>>> tvarminne = [0.0703, 0.1026, 0.0956, 0.0973, 0.1039, 0.1045]
>>> f_oneway(tillamook, newport, petersburg, magadan, tvarminne)
F_onewayResult(statistic=7.121019471642447, pvalue=0.0002812242314534544)
```

`f_oneway` accepts multidimensional input arrays. When the inputs are multidimensional and *axis* is not given, the test is performed along the first axis of the input arrays. For the following data, the test is performed three times, once for each column.

```
>>> a = np.array([[9.87, 9.03, 6.81],
...              [7.18, 8.35, 7.00],
...              [8.39, 7.58, 7.68],
...              [7.45, 6.33, 9.35],
...              [6.41, 7.10, 9.33],
...              [8.00, 8.24, 8.44]])
>>> b = np.array([[6.35, 7.30, 7.16],
...              [6.65, 6.68, 7.63],
...              [5.72, 7.73, 6.72],
...              [7.01, 9.19, 7.41],
...              [7.75, 7.87, 8.30],
...              [6.90, 7.97, 6.97]])
>>> c = np.array([[3.31, 8.77, 1.01],
...              [8.25, 3.24, 3.62],
...              [6.32, 8.81, 5.19],
...              [7.48, 8.83, 8.91],
...              [8.59, 6.01, 6.07],
...              [3.07, 9.72, 7.48]])
>>> F, p = f_oneway(a, b, c)
>>> F
```

(continues on next page)

(continued from previous page)

```
array([1.75676344, 0.03701228, 3.76439349])

```

## scipy.stats.pearsonr

`scipy.stats.pearsonr(x, y)`

Pearson correlation coefficient and p-value for testing non-correlation.

The Pearson correlation coefficient [1] measures the linear relationship between two datasets. The calculation of the p-value relies on the assumption that each dataset is normally distributed. (See Kowalski [3] for a discussion of the effects of non-normality of the input on the distribution of the correlation coefficient.) Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets.

### Parameters

**x** [(N,) array\_like] Input array.  
**y** [(N,) array\_like] Input array.

### Returns

**r** [float] Pearson's correlation coefficient.  
**p-value** [float] Two-tailed p-value.

### Warns

#### **PearsonRConstantInputWarning**

Raised if an input is a constant array. The correlation coefficient is not defined in this case, so `np.nan` is returned.

#### **PearsonRNearConstantInputWarning**

Raised if an input is “nearly” constant. The array  $x$  is considered nearly constant if  $\text{norm}(x - \text{mean}(x)) < 1e-13 * \text{abs}(\text{mean}(x))$ . Numerical errors in the calculation  $x - \text{mean}(x)$  in this case might result in an inaccurate calculation of  $r$ .

See also:

### [spearmannr](#)

Spearman rank-order correlation coefficient.

### [kendalltau](#)

Kendall's tau, a correlation measure for ordinal data.

## Notes

The correlation coefficient is calculated as follows:

$$r = \frac{\sum(x - m_x)(y - m_y)}{\sqrt{\sum(x - m_x)^2 \sum(y - m_y)^2}}$$

where  $m_x$  is the mean of the vector  $x$  and  $m_y$  is the mean of the vector  $y$ .

Under the assumption that  $x$  and  $m_y$  are drawn from independent normal distributions (so the population correlation coefficient is 0), the probability density function of the sample correlation coefficient  $r$  is ([1], [2]):

$$f(r) = \frac{(1 - r^2)^{n/2-2}}{B(\frac{1}{2}, \frac{n}{2} - 1)}$$

where  $n$  is the number of samples, and  $B$  is the beta function. This is sometimes referred to as the exact distribution of  $r$ . This is the distribution that is used in `pearsonr` to compute the p-value. The distribution is a beta distribution on the interval  $[-1, 1]$ , with equal shape parameters  $a = b = n/2 - 1$ . In terms of SciPy's implementation of the beta distribution, the distribution of  $r$  is:

```
dist = scipy.stats.beta(n/2 - 1, n/2 - 1, loc=-1, scale=2)
```

The p-value returned by `pearsonr` is a two-sided p-value. For a given sample with correlation coefficient  $r$ , the p-value is the probability that  $\text{abs}(r')$  of a random sample  $x'$  and  $y'$  drawn from the population with zero correlation would be greater than or equal to  $\text{abs}(r)$ . In terms of the object `dist` shown above, the p-value for a given  $r$  and length  $n$  can be computed as:

```
p = 2*dist.cdf(-abs(r))
```

When  $n$  is 2, the above continuous distribution is not well-defined. One can interpret the limit of the beta distribution as the shape parameters  $a$  and  $b$  approach  $a = b = 0$  as a discrete distribution with equal probability masses at  $r = 1$  and  $r = -1$ . More directly, one can observe that, given the data  $x = [x_1, x_2]$  and  $y = [y_1, y_2]$ , and assuming  $x_1 \neq x_2$  and  $y_1 \neq y_2$ , the only possible values for  $r$  are 1 and -1. Because  $\text{abs}(r')$  for any sample  $x'$  and  $y'$  with length 2 will be 1, the two-sided p-value for a sample of length 2 is always 1.

## Examples

```
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pearsonr(a, b)
(0.8660254037844386, 0.011724811003954649)
```

```
>>> stats.pearsonr([1, 2, 3, 4, 5], [10, 9, 2.5, 6, 4])
(-0.7426106572325057, 0.1505558088534455)
```

**scipy.stats.spearmanr**

`scipy.stats.spearmanr` (*a*, *b=None*, *axis=0*, *nan\_policy='propagate'*)

Calculate a Spearman correlation coefficient with associated p-value.

The Spearman rank-order correlation coefficient is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

- a, b** [1D or 2D array\_like, *b* is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under `axis`, below. Both arrays need to have the same length in the `axis` dimension.
- axis** [int or None, optional] If `axis=0` (default), then each column represents a variable, with observations in the rows. If `axis=1`, the relationship is transposed: each row represents a variable, while the columns contain observations. If `axis=None`, then both arrays will be raveled.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
- 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

**Returns**

- correlation** [float or ndarray (2-D square)] Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters. Correlation matrix is square with length equal to total number of variables (columns or rows) in *a* and *b* combined.
- pvalue** [float] The two-sided p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated, has same dimension as rho.

```

## scipy.stats.pointbiserialr

`scipy.stats.pointbiserialr(x, y)`

Calculate a point biserial correlation coefficient and its p-value.

The point biserial correlation is used to measure the relationship between a binary variable,  $x$ , and a continuous variable,  $y$ . Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a determinative relationship.

This function uses a shortcut formula but produces the same result as `pearsonr`.

### Parameters

**x** [array\_like of bools] Input array.  
**y** [array\_like] Input array.

### Returns

**correlation** [float] R value.  
**pvalue** [float] Two-sided p-value.

## Notes

`pointbiserialr` uses a t-test with  $n-1$  degrees of freedom. It is equivalent to `pearsonr`.

The value of the point-biserial correlation can be calculated from:

$$r_{pb} = \frac{\bar{Y}_1 - \bar{Y}_0}{s_y} \sqrt{\frac{N_1 N_2}{N(N-1)}}$$

Where  $Y_0$  and  $Y_1$  are means of the metric observations coded 0 and 1 respectively;  $N_0$  and  $N_1$  are number of observations coded 0 and 1 respectively;  $N$  is the total number of observations and  $s_y$  is the standard deviation of all the metric observations.

A value of  $r_{pb}$  that is significantly different from zero is completely equivalent to a significant difference in means between the two groups. Thus, an independent groups t Test with  $N - 2$  degrees of freedom may be used to test whether  $r_{pb}$  is nonzero. The relation between the t-statistic for comparing two independent groups and  $r_{pb}$  is given by:

$$t = \sqrt{N-2} \frac{r_{pb}}{\sqrt{1-r_{pb}^2}}$$

## Examples

```
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pointbiserialr(a, b)
(0.8660254037844386, 0.011724811003954652)
>>> stats.pearsonr(a, b)
(0.86602540378443871, 0.011724811003954626)
>>> np.corrcoef(a, b)
array([[ 1.          ,  0.8660254 ],
       [ 0.8660254 ,  1.          ]])
```

## scipy.stats.kendalltau

`scipy.stats.kendalltau`(*x*, *y*, *initial\_lexsort=None*, *nan\_policy='propagate'*, *method='auto'*, *variant='b'*)

Calculate Kendall's tau, a correlation measure for ordinal data.

Kendall's tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, and values close to -1 indicate strong disagreement. This implements two variants of Kendall's tau: tau-b (the default) and tau-c (also known as Stuart's tau-c). These differ only in how they are normalized to lie within the range -1 to 1; the hypothesis tests (their p-values) are identical. Kendall's original tau-a is not implemented separately because both tau-b and tau-c reduce to tau-a in the absence of ties.

### Parameters

**x, y** [array\_like] Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

**initial\_lexsort**

[bool, optional] Unused (deprecated).

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

**method**

[{'auto', 'asymptotic', 'exact'}, optional] Defines which method is used to calculate the p-value [5]. The following options are available (default is 'auto'):

- 'auto': selects the appropriate method based on a trade-off between speed and accuracy
- 'asymptotic': uses a normal approximation valid for large samples
- 'exact': computes the exact p-value, but can only be used if no ties are present. As the sample size increases, the 'exact' computation time may grow and the result may lose some precision.

**variant: {'b', 'c'}, optional**

Defines which variant of Kendall's tau is returned. Default is 'b'.

**Returns****correlation**

[float] The tau statistic.

**pvalue**[float] The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association,  $\tau = 0$ .**See also:****spearmanr**

Calculates a Spearman rank-order correlation coefficient.

**theilslopes**

Computes the Theil-Sen estimator for a set of points (x, y).

**weightedtau**

Computes a weighted version of Kendall's tau.

**Notes**

The definition of Kendall's tau that is used is [2]:

$$\text{tau}_b = (P - Q) / \text{sqrt}((P + Q + T) * (P + Q + U))$$

$$\text{tau}_c = 2 (P - Q) / (n**2 * (m - 1) / m)$$

where P is the number of concordant pairs, Q the number of discordant pairs, T the number of ties only in x, and U the number of ties only in y. If a tie occurs for the same pair in both x and y, it is not added to either T or U. n is the total number of samples, and m is the number of unique values in either x or y, whichever is smaller.

## Examples

```
>>> from scipy import stats
>>> x1 = [12, 2, 1, 12, 2]
>>> x2 = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.kendalltau(x1, x2)
>>> tau
-0.47140452079103173
>>> p_value
0.2827454599327748
```

## scipy.stats.weightedtau

`scipy.stats.weightedtau` (*x*, *y*, *rank=True*, *weigher=None*, *additive=True*)

Compute a weighted version of Kendall's  $\tau$ .

The weighted  $\tau$  is a weighted version of Kendall's  $\tau$  in which exchanges of high weight are more influential than exchanges of low weight. The default parameters compute the additive hyperbolic version of the index,  $\tau_h$ , which has been shown to provide the best balance between important and unimportant elements [1].

The weighting is defined by means of a rank array, which assigns a nonnegative rank to each element, and a weigher function, which assigns a weight based from the rank to each element. The weight of an exchange is then the sum or the product of the weights of the ranks of the exchanged elements. The default parameters compute  $\tau_h$ : an exchange between elements with rank  $r$  and  $s$  (starting from zero) has weight  $1/(r + 1) + 1/(s + 1)$ .

Specifying a rank array is meaningful only if you have in mind an external criterion of importance. If, as it usually happens, you do not have in mind a specific rank, the weighted  $\tau$  is defined by averaging the values obtained using the decreasing lexicographical rank by  $(x, y)$  and by  $(y, x)$ . This is the behavior with default parameters.

Note that if you are computing the weighted  $\tau$  on arrays of ranks, rather than of scores (i.e., a larger value implies a lower rank) you must negate the ranks, so that elements of higher rank are associated with a larger value.

### Parameters

<b>x, y</b>	[array_like] Arrays of scores, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.
<b>rank</b>	[array_like of ints or bool, optional] A nonnegative rank assigned to each element. If it is <code>None</code> , the decreasing lexicographical rank by $(x, y)$ will be used: elements of higher rank will be those with larger $x$ -values, using $y$ -values to break ties (in particular, swapping $x$ and $y$ will give a different result). If it is <code>False</code> , the element indices will be used directly as ranks. The default is <code>True</code> , in which case this function returns the average of the values obtained using the decreasing lexicographical rank by $(x, y)$ and by $(y, x)$ .
<b>weigher</b>	[callable, optional] The weigher function. Must map nonnegative integers (zero representing the most important element) to a nonnegative weight. The default, <code>None</code> , provides hyperbolic weighing, that is, rank $r$ is mapped to weight $1/(r + 1)$ .
<b>additive</b>	[bool, optional] If <code>True</code> , the weight of an exchange is computed by adding the weights of the ranks of the exchanged elements; otherwise, the weights are multiplied. The default is <code>True</code> .

### Returns

<b>correlation</b>	[float] The weighted $\tau$ correlation index.
--------------------	--

**pvalue** [float] Presently `np.nan`, as the null statistics is unknown (even in the additive hyperbolic case).

**See also:**

**kendalltau**

Calculates Kendall's tau.

**spearmanr**

Calculates a Spearman rank-order correlation coefficient.

**theilslopes**

Computes the Theil-Sen estimator for a set of points (x, y).

**Notes**

This function uses an  $O(n \log n)$ , mergesort-based algorithm [1] that is a weighted extension of Knight's algorithm for Kendall's  $\tau$  [2]. It can compute Shieh's weighted  $\tau$  [3] between rankings without ties (i.e., permutations) by setting *additive* and *rank* to `False`, as the definition given in [1] is a generalization of Shieh's.

NaNs are considered the smallest possible score.

New in version 0.19.0.

**References**

[1], [2], [3]

**Examples**

```
>>> from scipy import stats
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
>>> p_value
nan
>>> tau, p_value = stats.weightedtau(x, y, additive=False)
>>> tau
-0.62205716951801038
```

NaNs are considered the smallest possible score:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, np.nan]
>>> tau, _ = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
```

This is exactly Kendall's tau:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, _ = stats.weightedtau(x, y, weigher=lambda x: 1)
>>> tau
-0.47140452079103173
```

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> stats.weightedtau(x, y, rank=None)
WeightedTauResult(correlation=-0.4157652301037516, pvalue=nan)
>>> stats.weightedtau(y, x, rank=None)
WeightedTauResult(correlation=-0.7181341329699028, pvalue=nan)
```

## scipy.stats.linregress

`scipy.stats.linregress(x, y=None)`

Calculate a linear least-squares regression for two sets of measurements.

### Parameters

**x, y** [array\_like] Two sets of measurements. Both arrays should have the same length. If only *x* is given (and *y=None*), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension. In the case where *y=None* and *x* is a 2x2 array, `linregress(x)` is equivalent to `linregress(x[0], x[1])`.

### Returns

**result** [LinregressResult instance] The return value is an object with the following attributes:

- slope** [float] Slope of the regression line.
- intercept** [float] Intercept of the regression line.
- rvalue** [float] Correlation coefficient.
- pvalue** [float] Two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t-distribution of the test statistic.
- stderr** [float] Standard error of the estimated slope (gradient), under the assumption of residual normality.
- intercept\_stderr** [float] Standard error of the estimated intercept, under the assumption of residual normality.

See also:

[`scipy.optimize.curve\_fit`](#)

Use non-linear least squares to fit a function to data.

[`scipy.optimize.leastsq`](#)

Minimize the sum of squares of a set of equations.

## Notes

Missing values are considered pair-wise: if a value is missing in  $x$ , the corresponding value in  $y$  is masked.

For compatibility with older versions of SciPy, the return value acts like a `namedtuple` of length 5, with fields `slope`, `intercept`, `rvalue`, `pvalue` and `stderr`, so one can continue to write:

```
slope, intercept, r, p, se = linregress(x, y)
```

With that style, however, the standard error of the intercept is not available. To have access to all the computed values, including the standard error of the intercept, use the return value as an object with attributes, e.g.:

```
result = linregress(x, y)
print(result.intercept, result.intercept_stderr)
```

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
```

Generate some data:

```
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = 1.6*x + np.random.random(10)
```

Perform the linear regression:

```
>>> res = stats.linregress(x, y)
```

Coefficient of determination (R-squared):

```
>>> print(f"R-squared: {res.rvalue**2:.6f}")
R-squared: 0.735498
```

Plot the data along with the fitted line:

```
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, res.intercept + res.slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

Calculate 95% confidence interval on slope and intercept:

```
>>> # Two-sided inverse Students t-distribution
>>> # p - probability, df - degrees of freedom
>>> from scipy.stats import t
>>> tinv = lambda p, df: abs(t.ppf(p/2, df))
```

```
>>> ts = tinv(0.05, len(x)-2)
>>> print(f"slope (95%): {res.slope:.6f} +/- {ts*res.stderr:.6f}")
slope (95%): 1.944864 +/- 0.950885
>>> print(f"intercept (95%): {res.intercept:.6f}")
```

(continues on next page)

(continued from previous page)

```
...         f" +/- {ts*res.intercept_stderr:.6f}")
intercept (95%): 0.268578 +/- 0.488822
```

## scipy.stats.siegelslopes

`scipy.stats.siegelslopes` (*y*, *x=None*, *method='hierarchical'*)

Computes the Siegel estimator for a set of points (*x*, *y*).

`siegelslopes` implements a method for robust linear regression using repeated medians (see [1]) to fit a line to the points (*x*, *y*). The method is robust to outliers with an asymptotic breakdown point of 50%.

### Parameters

- y** [array\_like] Dependent variable.
- x** [array\_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- method** [{"hierarchical", "separate"}] If 'hierarchical', estimate the intercept using the estimated slope `medslope` (default option). If 'separate', estimate the intercept independent of the estimated slope. See Notes for details.

### Returns

- medslope** [float] Estimate of the slope of the regression line.
- medintercept** [float] Estimate of the intercept of the regression line.

See also:

### `theilslopes`

a similar technique without repeated medians

## Notes

With  $n = \text{len}(y)$ , compute  $m_j$  as the median of the slopes from the point  $(x[j], y[j])$  to all other  $n-1$  points. `medslope` is then the median of all slopes  $m_j$ . Two ways are given to estimate the intercept in [1] which can be chosen via the parameter `method`. The hierarchical approach uses the estimated slope `medslope` and computes `medintercept` as the median of  $y - \text{medslope} * x$ . The other approach estimates the intercept separately as follows: for each point  $(x[j], y[j])$ , compute the intercepts of all the  $n-1$  lines through the remaining points and take the median  $i_j$ . `medintercept` is the median of the  $i_j$ .

The implementation computes  $n$  times the median of a vector of size  $n$  which can be slow for large vectors. There are more efficient algorithms (see [2]) which are not implemented here.

## References

[1], [2]

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10 # add outliers
>>> y[-5:] -= 7
```

Compute the slope and intercept. For comparison, also compute the least-squares fit with `linregress`:

```
>>> res = stats.siegelslopes(y, x)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Siegel regression line is shown in red. The green line shows the least-squares fit for comparison.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

## scipy.stats.theilslopes

`scipy.stats.theilslopes` ( $y, x=None, \text{alpha}=0.95$ )

Computes the Theil-Sen estimator for a set of points  $(x, y)$ .

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

### Parameters

<b>y</b>	[array_like] Dependent variable.
<b>x</b>	[array_like or None, optional] Independent variable. If None, use <code>arange(len(y))</code> instead.

**alpha** [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that *alpha* is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

**Returns**

**medslope** [float] Theil slope.  
**medintercept** [float] Intercept of the Theil line, as  $\text{median}(y) - \text{medslope} * \text{median}(x)$ .  
**lo\_slope** [float] Lower bound of the confidence interval on *medslope*.  
**up\_slope** [float] Upper bound of the confidence interval on *medslope*.

See also:

**siegelslopes**

a similar technique using repeated medians

**Notes**

The implementation of *theilslopes* follows [1]. The intercept is not defined in [1], and here it is defined as  $\text{median}(y) - \text{medslope} * \text{median}(x)$ , which is given in [3]. Other definitions of the intercept exist in the literature. A confidence interval for the intercept is not given as this question is not addressed in [1].

**References**

[1], [2], [3]

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10 # add outliers
>>> y[-5:] -= 7
```

Compute the slope, intercept and 90% confidence interval. For comparison, also compute the least-squares fit with `linregress`:

```
>>> res = stats.theilslopes(y, x, 0.90)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Theil-Sen regression line is shown in red, with the dashed red lines illustrating the confidence interval of the slope (note that the dashed red lines are not the confidence interval of the regression as the confidence interval of the intercept is not included). The green line shows the least-squares fit for comparison.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, res[1] + res[2] * x, 'r--')
>>> ax.plot(x, res[1] + res[3] * x, 'r--')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

**scipy.stats.multiscale\_graphcorr**

```
scipy.stats.multiscale_graphcorr(x, y, compute_distance=<function _euclidean_dist at
                                0x7f0687b19710>, reps=1000, workers=1, is_twosamp=False,
                                random_state=None)
```

Computes the Multiscale Graph Correlation (MGC) test statistic.

Specifically, for each point, MGC finds the  $k$ -nearest neighbors for one property (e.g. cloud density), and the  $l$ -nearest neighbors for the other property (e.g. grass wetness) [1]. This pair  $(k, l)$  is called the “scale”. A priori, however, it is not known which scales will be most informative. So, MGC computes all distance pairs, and then efficiently computes the distance correlations for all scales. The local correlations illustrate which scales are relatively informative about the relationship. The key, therefore, to successfully discover and decipher relationships between disparate data modalities is to adaptively determine which scales are the most informative, and the geometric implication for the most informative scales. Doing so not only provides an estimate of whether the modalities are related, but also provides insight into how the determination was made. This is especially important in high-dimensional data, where simple visualizations do not reveal relationships to the unaided human eye. Characterizations of this implementation in particular have been derived from and benchmarked within in [2].

**Parameters**

**x, y** [ndarray] If  $x$  and  $y$  have shapes  $(n, p)$  and  $(n, q)$  where  $n$  is the number of samples and  $p$  and  $q$  are the number of dimensions, then the MGC independence test will be run. Alternatively,  $x$  and  $y$  can have shapes  $(n, n)$  if they are distance or similarity matrices, and `compute_distance` must be sent to `None`. If  $x$  and  $y$  have shapes  $(n, p)$  and  $(m, p)$ , an unpaired two-sample MGC test will be run.

**compute\_distance**

[callable, optional] A function that computes the distance or similarity among the samples within each data matrix. Set to `None` if  $x$  and  $y$  are already distance matrices. The default uses the euclidean norm metric. If you are calling a custom function, either create the distance matrix before-hand or create a function of the form `compute_distance(x)` where  $x$  is the data matrix for which pairwise distances are calculated.

**reps** [int, optional] The number of replications used to estimate the null when using the permutation test. The default is 1000.

**workers** [int or map-like callable, optional] If `workers` is an int the population is subdivided into `workers` sections and evaluated in parallel (uses `multiprocessing.Pool` `<multiprocessing>`). Supply `-1` to use all cores available to the Process. Alternatively supply a map-like callable, such as `multiprocessing.Pool.map` for evaluating the p-value in parallel. This evaluation is carried out as `workers(func, iterable)`. Requires that `func` be pickleable. The default is 1.

**is\_twosamp**

[bool, optional] If `True`, a two sample test will be run. If  $x$  and  $y$  have shapes  $(n, p)$  and  $(m, p)$ , this optional will be overridden and set to `True`. Set to `True` if  $x$  and  $y$  both have shapes  $(n, p)$  and a two sample test is desired. The default is `False`. Note that this will not run if inputs are distance matrices.

**random\_state**

[int or `np.random.RandomState` instance, optional] If already a `RandomState` instance, use it. If `seed` is an int, return a new `RandomState` instance seeded with `seed`. If `None`, use `np.random.RandomState`. Default is `None`.

**Returns**

**stat** [float] The sample MGC test statistic within  $[-1, 1]$ .

**pvalue** [float] The p-value obtained via permutation.

**mgc\_dict** [dict] Contains additional useful additional returns containing the following keys:

- **mgc\_map** [ndarray] A 2D representation of the latent geometry of the relationship. of the relationship.
- **opt\_scale** [(int, int)] The estimated optimal scale as a  $(x, y)$  pair.

- **null\_dist** [list] The null distribution derived from the permuted matrices

**See also:**

**pearsonr**

Pearson correlation coefficient and p-value for testing non-correlation.

**kendalltau**

Calculates Kendall's tau.

**spearmanr**

Calculates a Spearman rank-order correlation coefficient.

## Notes

A description of the process of MGC and applications on neuroscience data can be found in [1]. It is performed using the following steps:

1. Two distance matrices  $D^X$  and  $D^Y$  are computed and modified to be mean zero columnwise. This results in two  $n \times n$  distance matrices  $A$  and  $B$  (the centering and unbiased modification) [3].
2. For all values  $k$  and  $l$  from  $1, \dots, n$ ,
  - The  $k$ -nearest neighbor and  $l$ -nearest neighbor graphs are calculated for each property. Here,  $G_k(i, j)$  indicates the  $k$ -smallest values of the  $i$ -th row of  $A$  and  $H_l(i, j)$  indicates the  $l$  smallest values of the  $i$ -th row of  $B$
  - Let  $\circ$  denotes the entry-wise matrix product, then local correlations are summed and normalized using the following statistic:

$$c^{kl} = \frac{\sum_{ij} AG_k BH_l}{\sqrt{\sum_{ij} A^2 G_k \times \sum_{ij} B^2 H_l}}$$

1. The MGC test statistic is the smoothed optimal local correlation of  $\{c^{kl}\}$ . Denote the smoothing operation as  $R(\cdot)$  (which essentially set all isolated large correlations) as 0 and connected large correlations the same as before, see [3].) MGC is,

$$MGC_n(x, y) = \max_{(k,l)} R(c^{kl}(x_n, y_n))$$

The test statistic returns a value between  $(-1, 1)$  since it is normalized.

The p-value returned is calculated using a permutation test. This process is completed by first randomly permuting  $y$  to estimate the null distribution and then calculating the probability of observing a test statistic, under the null, at least as extreme as the observed test statistic.

MGC requires at least 5 samples to run with reliable results. It can also handle high-dimensional data sets. In addition, by manipulating the input data matrices, the two-sample testing problem can be reduced to the independence testing problem [4]. Given sample data  $U$  and  $V$  of sizes  $p \times n$  and  $p \times m$ , data matrix  $X$  and  $Y$  can be created as follows:

$$X = [U|V] \in \mathcal{R}^{p \times (n+m)} \quad Y = [0_{1 \times n} | 1_{1 \times m}] \in \mathcal{R}^{(n+m)}$$

Then, the MGC statistic can be calculated as normal. This methodology can be extended to similar tests such as distance correlation [4].

New in version 1.4.0.

## References

## Examples

```
>>> from scipy.stats import multiscale_graphcorr
>>> x = np.arange(100)
>>> y = x
>>> stat, pvalue, _ = multiscale_graphcorr(x, y, workers=-1)
>>> '%.1f, %.3f' % (stat, pvalue)
'1.0, 0.001'
```

Alternatively,

```
>>> x = np.arange(100)
>>> y = x
>>> mgc = multiscale_graphcorr(x, y)
>>> '%.1f, %.3f' % (mgc.stat, mgc.pvalue)
'1.0, 0.001'
```

To run an unpaired two-sample test,

```
>>> x = np.arange(100)
>>> y = np.arange(79)
>>> mgc = multiscale_graphcorr(x, y, random_state=1)
>>> '%.3f, %.2f' % (mgc.stat, mgc.pvalue)
'0.033, 0.02'
```

or, if shape of the inputs are the same,

```
>>> x = np.arange(100)
>>> y = x
>>> mgc = multiscale_graphcorr(x, y, is_twosamp=True)
>>> '%.3f, %.1f' % (mgc.stat, mgc.pvalue)
'-0.008, 1.0'
```

### 6.29.10 Statistical tests

<code>ttest_1samp(a, popmean[, axis, nan_policy, ...])</code>	Calculate the T-test for the mean of ONE group of scores.
<code>ttest_ind(a, b[, axis, equal_var, ...])</code>	Calculate the T-test for the means of <i>two independent</i> samples of scores.
<code>ttest_ind_from_stats(mean1, std1, nobs1, ...)</code>	T-test for means of two independent samples from descriptive statistics.
<code>ttest_rel(a, b[, axis, nan_policy, alternative])</code>	Calculate the t-test on TWO RELATED samples of scores, a and b.
<code>chisquare(f_obs[, f_exp, ddof, axis])</code>	Calculate a one-way chi-square test.
<code>cramervonmises(rvs, cdf[, args])</code>	Perform the Cramér-von Mises test for goodness of fit.
<code>power_divergence(f_obs[, f_exp, ddof, axis, ...])</code>	Cressie-Read power divergence statistic and goodness of fit test.

continues on next page

Table 265 – continued from previous page

<code>kstest(rvs, cdf[, args, N, alternative, mode])</code>	Performs the (one sample or two samples) Kolmogorov-Smirnov test for goodness of fit.
<code>ks_1samp(x, cdf[, args, alternative, mode])</code>	Performs the Kolmogorov-Smirnov test for goodness of fit.
<code>ks_2samp(data1, data2[, alternative, mode])</code>	Compute the Kolmogorov-Smirnov statistic on 2 samples.
<code>epps_singleton_2samp(x, y[, t])</code>	Compute the Epps-Singleton (ES) test statistic.
<code>mannwhitneyu(x, y[, use_continuity, alternative])</code>	Compute the Mann-Whitney rank test on samples <i>x</i> and <i>y</i> .
<code>tiecorrect(rankvals)</code>	Tie correction factor for Mann-Whitney U and Kruskal-Wallis H tests.
<code>rankdata(a[, method, axis])</code>	Assign ranks to data, dealing with ties appropriately.
<code>ranksums(x, y)</code>	Compute the Wilcoxon rank-sum statistic for two samples.
<code>wilcoxon(x[, y, zero_method, correction, ...])</code>	Calculate the Wilcoxon signed-rank test.
<code>kruskal(*args[, nan_policy])</code>	Compute the Kruskal-Wallis H-test for independent samples.
<code>friedmanchisquare(*args)</code>	Compute the Friedman test for repeated measurements.
<code>brunnermunzel(x, y[, alternative, ...])</code>	Compute the Brunner-Munzel test on samples <i>x</i> and <i>y</i> .
<code>combine_pvalues(pvalues[, method, weights])</code>	Combine p-values from independent tests bearing upon the same hypothesis.
<code>jarque_bera(x)</code>	Perform the Jarque-Bera goodness of fit test on sample data.

### scipy.stats.ttest\_1samp

`scipy.stats.ttest_1samp(a, popmean, axis=0, nan_policy='propagate', alternative='two-sided')`

Calculate the T-test for the mean of ONE group of scores.

This is a two-sided test for the null hypothesis that the expected value (mean) of a sample of independent observations *a* is equal to the given population mean, *popmean*.

#### Parameters

- a** [array\_like] Sample observation.
- popmean** [float or array\_like] Expected value in null hypothesis. If array\_like, then it must have the same shape as *a* excluding the axis dimension.
- axis** [int or None, optional] Axis along which to compute test; default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
  - ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
  - ‘two-sided’
  - ‘less’: one-sided
  - ‘greater’: one-sided
 New in version 1.6.0.

#### Returns

**statistic** [float or array] t-statistic.  
**pvalue** [float or array] Two-sided p-value.

## Examples

```
>>> from scipy import stats
```

```
>>> np.random.seed(7654567) # fix seed to get the same result
>>> rvs = stats.norm.rvs(loc=5, scale=10, size=(50,2))
```

Test if mean of random sample is equal to true mean, and different mean. We reject the null hypothesis in the second case and don't reject it in the first case.

```
>>> stats.ttest_1samp(rvs, 5.0)
(array([-0.68014479, -0.04323899]), array([ 0.49961383,  0.96568674]))
>>> stats.ttest_1samp(rvs, 0.0)
(array([ 2.77025808,  4.11038784]), array([ 0.00789095,  0.00014999]))
```

Examples using axis and non-scalar dimension for population mean.

```
>>> result = stats.ttest_1samp(rvs, [5.0, 0.0])
>>> result.statistic
array([-0.68014479,  4.11038784]),
>>> result.pvalue
array([4.99613833e-01,  1.49986458e-04])
```

```
>>> result = stats.ttest_1samp(rvs.T, [5.0, 0.0], axis=1)
>>> result.statistic
array([-0.68014479,  4.11038784])
>>> result.pvalue
array([4.99613833e-01,  1.49986458e-04])
```

```
>>> result = stats.ttest_1samp(rvs, [[5.0], [0.0]])
>>> result.statistic
array([[ -0.68014479, -0.04323899],
       [ 2.77025808,  4.11038784]])
>>> result.pvalue
array([[4.99613833e-01,  9.65686743e-01],
       [7.89094663e-03,  1.49986458e-04]])
```

## scipy.stats.ttest\_ind

`scipy.stats.ttest_ind(a, b, axis=0, equal_var=True, nan_policy='propagate', alternative='two-sided')`

Calculate the T-test for the means of *two independent* samples of scores.

This is a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

### Parameters

**a, b** [array\_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).

<b>axis</b>	[int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, <i>a</i> , and <i>b</i> .
<b>equal_var</b>	[bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch's t-test, which does not assume equal population variance [2]. New in version 0.11.0.
<b>nan_policy</b>	[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'): <ul style="list-style-type: none"> <li>• 'propagate': returns nan</li> <li>• 'raise': throws an error</li> <li>• 'omit': performs the calculations ignoring nan values</li> </ul>
<b>alternative</b>	[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'): <ul style="list-style-type: none"> <li>• 'two-sided'</li> <li>• 'less': one-sided</li> <li>• 'greater': one-sided</li> </ul> New in version 1.6.0.

**Returns**

<b>statistic</b>	[float or array] The calculated t-statistic.
<b>pvalue</b>	[float or array] The two-tailed p-value.

**Notes**

We can use this test, if we observe two independent samples from the same or different population, e.g. exam scores of boys and girls or of two ethnic groups. The test measures whether the average (expected) value differs significantly across samples. If we observe a large p-value, for example larger than 0.05 or 0.1, then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages.

**References**

[1], [2]

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(12345678)
```

Test with sample with identical means:

```
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> stats.ttest_ind(rvs1, rvs2)
(0.26833823296239279, 0.78849443369564776)
>>> stats.ttest_ind(rvs1, rvs2, equal_var = False)
(0.26833823296239279, 0.78849452749500748)
```

`ttest_ind` underestimates p for unequal variances:

```
>>> rvs3 = stats.norm.rvs(loc=5, scale=20, size=500)
>>> stats.ttest_ind(rvs1, rvs3)
(-0.46580283298287162, 0.64145827413436174)
>>> stats.ttest_ind(rvs1, rvs3, equal_var = False)
(-0.46580283298287162, 0.64149646246569292)
```

When  $n1 \neq n2$ , the equal variance t-statistic is no longer equal to the unequal variance t-statistic:

```
>>> rvs4 = stats.norm.rvs(loc=5, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs4)
(-0.99882539442782481, 0.3182832709103896)
>>> stats.ttest_ind(rvs1, rvs4, equal_var = False)
(-0.69712570584654099, 0.48716927725402048)
```

T-test with different means, variance, and n:

```
>>> rvs5 = stats.norm.rvs(loc=8, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs5)
(-1.4679669854490653, 0.14263895620529152)
>>> stats.ttest_ind(rvs1, rvs5, equal_var = False)
(-0.94365973617132992, 0.34744170334794122)
```

### scipy.stats.ttest\_ind\_from\_stats

`scipy.stats.ttest_ind_from_stats(mean1, std1, nobs1, mean2, std2, nobs2, equal_var=True, alternative='two-sided')`

T-test for means of two independent samples from descriptive statistics.

This is a two-sided test for the null hypothesis that two independent samples have identical average (expected) values.

#### Parameters

- mean1** [array\_like] The mean(s) of sample 1.
- std1** [array\_like] The standard deviation(s) of sample 1.
- nobs1** [array\_like] The number(s) of observations of sample 1.
- mean2** [array\_like] The mean(s) of sample 2.
- std2** [array\_like] The standard deviations(s) of sample 2.
- nobs2** [array\_like] The number(s) of observations of sample 2.
- equal\_var** [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch's t-test, which does not assume equal population variance [2].
- alternative** [{"two-sided", "less", "greater"}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):
  - 'two-sided'
  - 'less': one-sided
  - 'greater': one-sided
 New in version 1.6.0.

#### Returns

- statistic** [float or array] The calculated t-statistics.
- pvalue** [float or array] The two-tailed p-value.

`scipy.stats.ttest_ind`

## Notes

New in version 0.16.0.

## References

[1], [2]

## Examples

Suppose we have the summary data for two samples, as follows:

	Size	Sample Mean	Sample Variance
Sample 1	13	15.0	87.5
Sample 2	11	12.0	39.0

Apply the t-test to this data (with the assumption that the population variances are equal):

```
>>> from scipy.stats import ttest_ind_from_stats
>>> ttest_ind_from_stats(mean1=15.0, std1=np.sqrt(87.5), nobs1=13,
...                      mean2=12.0, std2=np.sqrt(39.0), nobs2=11)
Ttest_indResult(statistic=0.9051358093310269, pvalue=0.3751996797581487)
```

For comparison, here is the data from which those summary statistics were taken. With this data, we can compute the same result using `scipy.stats.ttest_ind`:

```
>>> a = np.array([1, 3, 4, 6, 11, 13, 15, 19, 22, 24, 25, 26, 26])
>>> b = np.array([2, 4, 6, 9, 11, 13, 14, 15, 18, 19, 21])
>>> from scipy.stats import ttest_ind
>>> ttest_ind(a, b)
Ttest_indResult(statistic=0.905135809331027, pvalue=0.3751996797581486)
```

Suppose we instead have binary data and would like to apply a t-test to compare the proportion of 1s in two independent groups:

	Size	Number of ones	Sample Mean	Sample Variance
Sample 1	150	30	0.2	0.16
Sample 2	200	45	0.225	0.174375

The sample mean  $\hat{p}$  is the proportion of ones in the sample and the variance for a binary observation is estimated by  $\hat{p}(1 - \hat{p})$ .

```
>>> ttest_ind_from_stats(mean1=0.2, std1=np.sqrt(0.16), nobs1=150,
...                      mean2=0.225, std2=np.sqrt(0.174375), nobs2=200)
Ttest_indResult(statistic=-0.564327545549774, pvalue=0.5728947691244874)
```

For comparison, we could compute the t statistic and p-value using arrays of 0s and 1s and `scipy.stat.ttest_ind`, as above.

```
>>> group1 = np.array([1]*30 + [0]*(150-30))
>>> group2 = np.array([1]*45 + [0]*(200-45))
>>> ttest_ind(group1, group2)
Ttest_indResult(statistic=-0.5627179589855622, pvalue=0.573989277115258)
```

## scipy.stats.ttest\_rel

`scipy.stats.ttest_rel(a, b, axis=0, nan_policy='propagate', alternative='two-sided')`

Calculate the t-test on TWO RELATED samples of scores, *a* and *b*.

This is a two-sided test for the null hypothesis that 2 related or repeated samples have identical average (expected) values.

### Parameters

- a, b** [array\_like] The arrays must have the same shape.
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
- ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
- ‘two-sided’
  - ‘less’: one-sided
  - ‘greater’: one-sided
- New in version 1.6.0.

### Returns

- statistic** [float or array] t-statistic.
- pvalue** [float or array] Two-sided p-value.

## Notes

Examples for use are scores of the same set of student in different exams, or repeated sampling from the same units. The test measures whether the average score differs significantly across samples (e.g. exams). If we observe a large p-value, for example greater than 0.05 or 0.1 then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages. Small p-values are associated with large t-statistics.

## Examples

```
>>> from scipy import stats
>>> np.random.seed(12345678) # fix random seed to get same numbers
```

```
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = (stats.norm.rvs(loc=5, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs2)
(0.24101764965300962, 0.80964043445811562)
>>> rvs3 = (stats.norm.rvs(loc=8, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs3)
(-3.9995108708727933, 7.3082402191726459e-005)
```

## scipy.stats.chisquare

`scipy.stats.chisquare` (*f\_obs*, *f\_exp*=None, *ddof*=0, *axis*=0)

Calculate a one-way chi-square test.

The chi-square test tests the null hypothesis that the categorical data has the given frequencies.

### Parameters

<b>f_obs</b>	[array_like] Observed frequencies in each category.
<b>f_exp</b>	[array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
<b>ddof</b>	[int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with $k - 1 - \text{ddof}$ degrees of freedom, where $k$ is the number of observed frequencies. The default value of <i>ddof</i> is 0.
<b>axis</b>	[int or None, optional] The axis of the broadcast result of <i>f_obs</i> and <i>f_exp</i> along which to apply the test. If <i>axis</i> is None, all values in <i>f_obs</i> are treated as a single data set. Default is 0.

### Returns

<b>chisq</b>	[float or ndarray] The chi-squared test statistic. The value is a float if <i>axis</i> is None or <i>f_obs</i> and <i>f_exp</i> are 1-D.
<b>p</b>	[float or ndarray] The p-value of the test. The value is a float if <i>ddof</i> and the return value <i>chisq</i> are scalars.

See also:

`scipy.stats.power_divergence`

## Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom,  $k-1$ , are for the case when no parameters of the distribution are estimated. If  $p$  parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are  $k-1-p$ . If the parameters are estimated in a different way, then the dof can be between  $k-1-p$  and  $k-1$ . However, it is also possible that the asymptotic distribution is not chi-square, in which case this test is not appropriate.

## References

[1], [2]

## Examples

When just  $f_{obs}$  is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With  $f_{exp}$  the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When  $f_{obs}$  is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting  $axis=None$ , the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

$ddof$  is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with  $ddof$ .

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

$f_{obs}$  and  $f_{exp}$  are also broadcast. In the following,  $f_{obs}$  has shape (6,) and  $f_{exp}$  has shape (2, 6), so the result of broadcasting  $f_{obs}$  and  $f_{exp}$  has shape (2, 6). To compute the desired chi-squared statistics, we use `axis=1`:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...           f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...           axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

## scipy.stats.cramervonmises

`scipy.stats.cramervonmises` (*rvs*, *cdf*, *args*=())

Perform the Cramér-von Mises test for goodness of fit.

This performs a test of the goodness of fit of a cumulative distribution function (cdf)  $F$  compared to the empirical distribution function  $F_n$  of observed random variates  $X_1, \dots, X_n$  that are assumed to be independent and identically distributed ([1]). The null hypothesis is that the  $X_i$  have cumulative distribution  $F$ .

### Parameters

**rvs** [array\_like] A 1-D array of observed values of the random variables  $X_i$ .

**cdf** [str or callable] The cumulative distribution function  $F$  to test the observations against. If a string, it should be the name of a distribution in `scipy.stats`. If a callable, that callable is used to calculate the cdf: `cdf(x, *args) -> float`.

**args** [tuple, optional] Distribution parameters. These are assumed to be known; see Notes.

### Returns

**res** [object with attributes]

**statistic** [float] Cramér-von Mises statistic.

**pvalue** [float] The p-value.

See also:

[kstest](#)

### Notes

New in version 1.6.0.

The p-value relies on the approximation given by equation 1.8 in [2]. It is important to keep in mind that the p-value is only accurate if one tests a simple hypothesis, i.e. the parameters of the reference distribution are known. If the parameters are estimated from the data (composite hypothesis), the computed p-value is not reliable.

### References

[1], [2]

## Examples

Suppose we wish to test whether data generated by `scipy.stats.norm.rvs` were, in fact, drawn from the standard normal distribution. We choose a significance level of  $\alpha=0.05$ .

```
>>> import numpy as np
>>> from scipy import stats
>>> np.random.seed(626)
>>> x = stats.norm.rvs(size=500)
>>> res = stats.cramervonmises(x, 'norm')
>>> res.statistic, res.pvalue
(0.06342154705518796, 0.792680516270629)
```

The p-value 0.79 exceeds our chosen significance level, so we do not reject the null hypothesis that the observed sample is drawn from the standard normal distribution.

Now suppose we wish to check whether the same samples shifted by 2.1 is consistent with being drawn from a normal distribution with a mean of 2.

```
>>> y = x + 2.1
>>> res = stats.cramervonmises(y, 'norm', args=(2,))
>>> res.statistic, res.pvalue
(0.4798693195559657, 0.044782228803623814)
```

Here we have used the `args` keyword to specify the mean (`loc`) of the normal distribution to test the data against. This is equivalent to the following, in which we create a frozen normal distribution with mean 2.1, then pass its `cdf` method as an argument.

```
>>> frozen_dist = stats.norm(loc=2)
>>> res = stats.cramervonmises(y, frozen_dist.cdf)
>>> res.statistic, res.pvalue
(0.4798693195559657, 0.044782228803623814)
```

In either case, we would reject the null hypothesis that the observed sample is drawn from a normal distribution with a mean of 2 (and default variance of 1) because the p-value 0.04 is less than our chosen significance level.

## scipy.stats.power\_divergence

`scipy.stats.power_divergence` (*f\_obs*, *f\_exp*=None, *ddof*=0, *axis*=0, *lambda\_*=None)

Cressie-Read power divergence statistic and goodness of fit test.

This function tests the null hypothesis that the categorical data has the given frequencies, using the Cressie-Read power divergence statistic.

### Parameters

<b>f_obs</b>	[array_like] Observed frequencies in each category.
<b>f_exp</b>	[array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
<b>ddof</b>	[int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with $k - 1 - \text{ddof}$ degrees of freedom, where $k$ is the number of observed frequencies. The default value of <i>ddof</i> is 0.
<b>axis</b>	[int or None, optional] The axis of the broadcast result of <i>f_obs</i> and <i>f_exp</i> along which to apply the test. If <i>axis</i> is None, all values in <i>f_obs</i> are treated as a single data set. Default is 0.

**lambda\_** [float or str, optional] The power in the Cressie-Read power divergence statistic. The default is 1. For convenience, *lambda\_* may be assigned one of the following strings, in which case the corresponding numerical value is used:

String	Value	Description
"pearson" ↪statistic.	1	Pearson's chi-squared.  In this case, the function is equivalent to `stats.chisquare`.
"log-likelihood" ↪known as	0	Log-likelihood ratio. Also known as the G-test [Rf6c2a1ea428c-3].
"freeman-tukey"	-1/2	Freeman-Tukey statistic.
"mod-log-likelihood"	-1	Modified log-likelihood ratio.
"neyman"	-2	Neyman's statistic.
"cressie-read" ↪[Rf6c2a1ea428c-5].	2/3	The power recommended in [Rf6c2a1ea428c-5].

### Returns

**statistic** [float or ndarray] The Cressie-Read power divergence test statistic. The value is a float if *axis* is None or if *f\_obs* and *f\_exp* are 1-D.

**pvalue** [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *stat* are scalars.

See also:

[chisquare](#)

### Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

When *lambda\_* is less than zero, the formula for the statistic involves dividing by *f\_obs*, so a warning or error may be generated if any value in *f\_obs* is 0.

Similarly, a warning or error may be generated if any value in *f\_exp* is zero when *lambda\_*  $\geq$  0.

The default degrees of freedom,  $k-1$ , are for the case when no parameters of the distribution are estimated. If  $p$  parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are  $k-1-p$ . If the parameters are estimated in a different way, then the dof can be between  $k-1-p$  and  $k-1$ . However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

This function handles masked arrays. If an element of *f\_obs* or *f\_exp* is masked, then data at that position is ignored, and does not count towards the size of the data set.

New in version 0.13.0.

## References

[1], [2], [3], [4], [5]

## Examples

(See `chisquare` for more examples.)

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies. Here we perform a G-test (i.e. use the log-likelihood ratio statistic):

```
>>> from scipy.stats import power_divergence
>>> power_divergence([16, 18, 16, 14, 12, 12], lambda_='log-likelihood')
(2.006573162632538, 0.84823476779463769)
```

The expected frequencies can be given with the `f_exp` argument:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[16, 16, 16, 16, 16, 8],
...                  lambda_='log-likelihood')
(3.3281031458963746, 0.6495419288047497)
```

When `f_obs` is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> power_divergence(obs, lambda_="log-likelihood")
(array([ 2.00657316,  6.77634498]), array([ 0.84823477,  0.23781225]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> power_divergence(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> power_divergence(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the test statistic with `ddof`.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=[0, 1, 2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

`f_obs` and `f_exp` are also broadcast. In the following, `f_obs` has shape (6,) and `f_exp` has shape (2, 6), so the result of broadcasting `f_obs` and `f_exp` has shape (2, 6). To compute the desired chi-squared statistics, we must use `axis=1`:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[[16, 16, 16, 16, 16, 8],
```

(continues on next page)

(continued from previous page)

```

...             [8, 20, 20, 16, 12, 12]],
...             axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))

```

**scipy.stats.kstest**

`scipy.stats.kstest` (*rvs*, *cdf*, *args=()*, *N=20*, *alternative='two-sided'*, *mode='auto'*)

Performs the (one sample or two samples) Kolmogorov-Smirnov test for goodness of fit.

The one-sample test performs a test of the distribution  $F(x)$  of an observed random variable against a given distribution  $G(x)$ . Under the null hypothesis, the two distributions are identical,  $F(x)=G(x)$ . The alternative hypothesis can be either 'two-sided' (default), 'less' or 'greater'. The KS test is only valid for continuous distributions. The two-sample test tests whether the two independent samples are drawn from the same continuous distribution.

**Parameters**

- rvs** [str, array\_like, or callable] If an array, it should be a 1-D array of observations of random variables. If a callable, it should be a function to generate random variables; it is required to have a keyword argument *size*. If a string, it should be the name of a distribution in `scipy.stats`, which will be used to generate random variables.
- cdf** [str, array\_like or callable] If array\_like, it should be a 1-D array of observations of random variables, and the two-sample test is performed (and *rvs* must be array\_like) If a callable, that callable is used to calculate the cdf. If a string, it should be the name of a distribution in `scipy.stats`, which will be used as the cdf function.
- args** [tuple, sequence, optional] Distribution parameters, used if *rvs* or *cdf* are strings or callables.
- N** [int, optional] Sample size if *rvs* is string or callable. Default is 20.
- alternative** [{"two-sided", "less", "greater"}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):
- 'two-sided'
  - 'less': one-sided, see explanation in Notes
  - 'greater': one-sided, see explanation in Notes
- mode** [{"auto", "exact", "approx", "asympt"}, optional] Defines the distribution used for calculating the p-value. The following options are available (default is 'auto'):
- 'auto': selects one of the other options.
  - 'exact': uses the exact distribution of test statistic.
  - 'approx': approximates the two-sided probability with twice the one-sided probability
  - 'asympt': uses asymptotic distribution of test statistic

**Returns**

- statistic** [float] KS test statistic, either D, D+ or D-.
- pvalue** [float] One-tailed or two-tailed p-value.

See also:

[ks\\_2samp](#)

## Notes

In the one-sided test, the alternative is that the empirical cumulative distribution function of the random variable is “less” or “greater” than the cumulative distribution function  $G(x)$  of the hypothesis,  $F(x) \leq G(x)$ , resp.  $F(x) \geq G(x)$ .

## Examples

```
>>> from scipy import stats
```

```
>>> x = np.linspace(-15, 15, 9)
>>> stats.kstest(x, 'norm')
(0.44435602715924361, 0.0388501427051711065)
```

```
>>> np.random.seed(987654321) # set random seed to get the same result
>>> stats.kstest(stats.norm.rvs(size=100), stats.norm.cdf)
(0.058352892479417884, 0.8653960860778898)
```

The above lines are equivalent to:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.norm.rvs, 'norm', N=100)
(0.058352892479417884, 0.8653960860778898)
```

*Test against one-sided alternative hypothesis*

Shift distribution to larger values, so that  $\text{CDF}(x) < \text{norm.cdf}(x)$ :

```
>>> np.random.seed(987654321)
>>> x = stats.norm.rvs(loc=0.2, size=100)
>>> stats.kstest(x, 'norm', alternative='less')
(0.12464329735846891, 0.040989164077641749)
```

Reject equal distribution against alternative hypothesis: less

```
>>> stats.kstest(x, 'norm', alternative='greater')
(0.0072115233216311081, 0.98531158590396395)
```

Don't reject equal distribution against alternative hypothesis: greater

```
>>> stats.kstest(x, 'norm')
(0.12464329735846891, 0.08197335233541582)
```

*Testing t distributed random variables against normal distribution*

With 100 degrees of freedom the t distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(100, size=100), 'norm')
(0.072018929165471257, 0.6505883498379312)
```

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(3, size=100), 'norm')
(0.131016895759829, 0.058826222555312224)
```

## scipy.stats.ks\_1samp

`scipy.stats.ks_1samp(x, cdf, args=(), alternative='two-sided', mode='auto')`

Performs the Kolmogorov-Smirnov test for goodness of fit.

This performs a test of the distribution  $F(x)$  of an observed random variable against a given distribution  $G(x)$ . Under the null hypothesis, the two distributions are identical,  $F(x)=G(x)$ . The alternative hypothesis can be either 'two-sided' (default), 'less' or 'greater'. The KS test is only valid for continuous distributions.

### Parameters

<b>x</b>	[array_like] a 1-D array of observations of iid random variables.
<b>cdf</b>	[callable] callable used to calculate the cdf.
<b>args</b>	[tuple, sequence, optional] Distribution parameters, used with <i>cdf</i> .
<b>alternative</b>	[[ 'two-sided', 'less', 'greater' ], optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'): <ul style="list-style-type: none"> <li>• 'two-sided'</li> <li>• 'less': one-sided, see explanation in Notes</li> <li>• 'greater': one-sided, see explanation in Notes</li> </ul>
<b>mode</b>	[[ 'auto', 'exact', 'approx', 'asympt' ], optional] Defines the distribution used for calculating the p-value. The following options are available (default is 'auto'): <ul style="list-style-type: none"> <li>• 'auto': selects one of the other options.</li> <li>• 'exact': uses the exact distribution of test statistic.</li> <li>• 'approx': approximates the two-sided probability with twice the one-sided probability</li> <li>• 'asympt': uses asymptotic distribution of test statistic</li> </ul>

### Returns

<b>statistic</b>	[float] KS test statistic, either D, D+ or D- (depending on the value of 'alternative')
<b>pvalue</b>	[float] One-tailed or two-tailed p-value.

See also:

[ks\\_2samp](#), [kstest](#)

### Notes

In the one-sided test, the alternative is that the empirical cumulative distribution function of the random variable is "less" or "greater" than the cumulative distribution function  $G(x)$  of the hypothesis,  $F(x) \leq G(x)$ , resp.  $F(x) \geq G(x)$ .

## Examples

```
>>> from scipy import stats
```

```
>>> x = np.linspace(-15, 15, 9)
>>> stats.ks_1samp(x, stats.norm.cdf)
(0.44435602715924361, 0.0388501427051711065)
```

```
>>> np.random.seed(987654321) # set random seed to get the same result
>>> stats.ks_1samp(stats.norm.rvs(size=100), stats.norm.cdf)
(0.058352892479417884, 0.8653960860778898)
```

*Test against one-sided alternative hypothesis*

Shift distribution to larger values, so that  $\text{CDF}(x) < \text{norm.cdf}(x)$ :

```
>>> np.random.seed(987654321)
>>> x = stats.norm.rvs(loc=0.2, size=100)
>>> stats.ks_1samp(x, stats.norm.cdf, alternative='less')
(0.12464329735846891, 0.040989164077641749)
```

Reject equal distribution against alternative hypothesis: less

```
>>> stats.ks_1samp(x, stats.norm.cdf, alternative='greater')
(0.0072115233216311081, 0.98531158590396395)
```

Don't reject equal distribution against alternative hypothesis: greater

```
>>> stats.ks_1samp(x, stats.norm.cdf)
(0.12464329735846891, 0.08197335233541582)
```

Don't reject equal distribution against alternative hypothesis: two-sided

*Testing t distributed random variables against normal distribution*

With 100 degrees of freedom the t distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```
>>> np.random.seed(987654321)
>>> stats.ks_1samp(stats.t.rvs(100, size=100), stats.norm.cdf)
(0.072018929165471257, 0.6505883498379312)
```

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```
>>> np.random.seed(987654321)
>>> stats.ks_1samp(stats.t.rvs(3, size=100), stats.norm.cdf)
(0.131016895759829, 0.058826222555312224)
```

## scipy.stats.ks\_2samp

`scipy.stats.ks_2samp` (*data1*, *data2*, *alternative*='two-sided', *mode*='auto')

Compute the Kolmogorov-Smirnov statistic on 2 samples.

This is a two-sided test for the null hypothesis that 2 independent samples are drawn from the same continuous distribution. The alternative hypothesis can be either 'two-sided' (default), 'less' or 'greater'.

### Parameters

#### **data1, data2**

[array\_like, 1-Dimensional] Two arrays of sample observations assumed to be drawn from a continuous distribution, sample sizes can be different.

#### **alternative**

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):

- 'two-sided'
- 'less': one-sided, see explanation in Notes
- 'greater': one-sided, see explanation in Notes

#### **mode**

[{'auto', 'exact', 'asympt'}, optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'):

- 'auto': use 'exact' for small size arrays, 'asympt' for large
- 'exact': use exact distribution of test statistic
- 'asympt': use asymptotic distribution of test statistic

### Returns

**statistic** [float] KS statistic.

**pvalue** [float] Two-tailed p-value.

See also:

[kstest](#), [ks\\_1samp](#), [epps\\_singleton\\_2samp](#), [anderson\\_ksamp](#)

## Notes

This tests whether 2 samples are drawn from the same distribution. Note that, like in the case of the one-sample KS test, the distribution is assumed to be continuous.

In the one-sided test, the alternative is that the empirical cumulative distribution function  $F(x)$  of the *data1* variable is "less" or "greater" than the empirical cumulative distribution function  $G(x)$  of the *data2* variable,  $F(x) \leq G(x)$ , resp.  $F(x) \geq G(x)$ .

If the KS statistic is small or the p-value is high, then we cannot reject the hypothesis that the distributions of the two samples are the same.

If the mode is 'auto', the computation is exact if the sample sizes are less than 10000. For larger sizes, the computation uses the Kolmogorov-Smirnov distributions to compute an approximate value.

The 'two-sided' 'exact' computation computes the complementary probability and then subtracts from 1. As such, the minimum probability it can return is about 1e-16. While the algorithm itself is exact, numerical errors may accumulate for large sample sizes. It is most suited to situations in which one of the sample sizes is only a few thousand.

We generally follow Hodges' treatment of Drion/Gnedenko/Korolyuk [1].

## References

[1]

## Examples

```
>>> from scipy import stats
>>> np.random.seed(12345678) #fix random seed to get the same result
>>> n1 = 200 # size of first sample
>>> n2 = 300 # size of second sample
```

For a different distribution, we can reject the null hypothesis since the pvalue is below 1%:

```
>>> rvs1 = stats.norm.rvs(size=n1, loc=0., scale=1)
>>> rvs2 = stats.norm.rvs(size=n2, loc=0.5, scale=1.5)
>>> stats.ks_2samp(rvs1, rvs2)
(0.20833333333333334, 5.129279597781977e-05)
```

For a slightly different distribution, we cannot reject the null hypothesis at a 10% or lower alpha since the p-value at 0.144 is higher than 10%

```
>>> rvs3 = stats.norm.rvs(size=n2, loc=0.01, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs3)
(0.10333333333333333, 0.14691437867433876)
```

For an identical distribution, we cannot reject the null hypothesis since the p-value is high, 41%:

```
>>> rvs4 = stats.norm.rvs(size=n2, loc=0.0, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs4)
(0.079999999999999996, 0.41126949729859719)
```

## scipy.stats.epps\_singleton\_2samp

`scipy.stats.epps_singleton_2samp(x, y, t=(0.4, 0.8))`

Compute the Epps-Singleton (ES) test statistic.

Test the null hypothesis that two samples have the same underlying probability distribution.

### Parameters

<b>x, y</b>	[array-like] The two samples of observations to be tested. Input must not have more than one dimension. Samples can have different lengths.
<b>t</b>	[array-like, optional] The points (t1, ..., tn) where the empirical characteristic function is to be evaluated. It should be positive distinct numbers. The default value (0.4, 0.8) is proposed in [1]. Input must not have more than one dimension.

### Returns

<b>statistic</b>	[float] The test statistic.
<b>pvalue</b>	[float] The associated p-value based on the asymptotic chi2-distribution.

See also:

[ks\\_2samp](#), [anderson\\_ksamp](#)

## Notes

Testing whether two samples are generated by the same underlying distribution is a classical question in statistics. A widely used test is the Kolmogorov-Smirnov (KS) test which relies on the empirical distribution function. Epps and Singleton introduce a test based on the empirical characteristic function in [1].

One advantage of the ES test compared to the KS test is that it does not assume a continuous distribution. In [1], the authors conclude that the test also has a higher power than the KS test in many examples. They recommend the use of the ES test for discrete samples as well as continuous samples with at least 25 observations each, whereas `anderson_ksamp` is recommended for smaller sample sizes in the continuous case.

The p-value is computed from the asymptotic distribution of the test statistic which follows a `chi2` distribution. If the sample size of both `x` and `y` is below 25, the small sample correction proposed in [1] is applied to the test statistic.

The default values of `t` are determined in [1] by considering various distributions and finding good values that lead to a high power of the test in general. Table III in [1] gives the optimal values for the distributions tested in that study. The values of `t` are scaled by the semi-interquartile range in the implementation, see [1].

## scipy.stats.mannwhitneyu

`scipy.stats.mannwhitneyu(x, y, use_continuity=True, alternative=None)`

Compute the Mann-Whitney rank test on samples `x` and `y`.

### Parameters

- x, y** [array\_like] Array of samples, should be one-dimensional.
- use\_continuity** [bool, optional] Whether a continuity correction (1/2.) should be taken into account. Default is True.
- alternative** [{None, 'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is None):
- None: computes p-value half the size of the 'two-sided' p-value and a different U statistic. The default behavior is not the same as using 'less' or 'greater'; it only exists for backward compatibility and is deprecated.
  - 'two-sided'
  - 'less': one-sided
  - 'greater': one-sided
- Use of the None option is deprecated.

### Returns

- statistic** [float] The Mann-Whitney U statistic, equal to  $\min(U \text{ for } x, U \text{ for } y)$  if `alternative` is equal to None (deprecated; exists for backward compatibility), and U for `y` otherwise.
- pvalue** [float] p-value assuming an asymptotic normal distribution. One-sided or two-sided, depending on the choice of `alternative`.

## Notes

Use only when the number of observation in each sample is  $> 20$  and you have 2 independent samples of ranks. Mann-Whitney U is significant if the u-obtained is LESS THAN or equal to the critical value of U.

This test corrects for ties and by default uses a continuity correction.

## References

[1], [2]

## scipy.stats.tiecorrect

`scipy.stats.tiecorrect` (*rankvals*)

Tie correction factor for Mann-Whitney U and Kruskal-Wallis H tests.

### Parameters

**rankvals** [array\_like] A 1-D sequence of ranks. Typically this will be the array returned by *rankdata*.

### Returns

**factor** [float] Correction factor for U or H.

### See also:

#### `rankdata`

Assign ranks to the data

#### `mannwhitneyu`

Mann-Whitney rank test

#### `kruskal`

Kruskal-Wallis H test

## Examples

```
>>> from scipy.stats import tiecorrect, rankdata
>>> tiecorrect([1, 2.5, 2.5, 4])
0.9
>>> ranks = rankdata([1, 3, 2, 4, 5, 7, 2, 8, 4])
>>> ranks
array([ 1. ,  4. ,  2.5,  5.5,  7. ,  8. ,  2.5,  9. ,  5.5])
>>> tiecorrect(ranks)
0.9833333333333333
```

## scipy.stats.rankdata

`scipy.stats.rankdata` (*a*, *method*='average', \*, *axis*=None)

Assign ranks to data, dealing with ties appropriately.

By default (*axis*=None), the data array is first flattened, and a flat array of ranks is returned. Separately reshape the rank array to the shape of the data array if desired (see Examples).

Ranks begin at 1. The *method* argument controls how ranks are assigned to equal values. See [1] for further discussion of ranking methods.

### Parameters

<b>a</b>	[array_like] The array of values to be ranked.
<b>method</b>	[{'average', 'min', 'max', 'dense', 'ordinal'}, optional] The method used to assign ranks to tied elements. The following methods are available (default is 'average'): <ul style="list-style-type: none"> <li>• 'average': The average of the ranks that would have been assigned to all the tied values is assigned to each value.</li> <li>• 'min': The minimum of the ranks that would have been assigned to all the tied values is assigned to each value. (This is also referred to as "competition" ranking.)</li> <li>• 'max': The maximum of the ranks that would have been assigned to all the tied values is assigned to each value.</li> <li>• 'dense': Like 'min', but the rank of the next highest element is assigned the rank immediately after those assigned to the tied elements.</li> <li>• 'ordinal': All values are given a distinct rank, corresponding to the order that the values occur in <i>a</i>.</li> </ul>
<b>axis</b>	[{None, int}, optional] Axis along which to perform the ranking. If None, the data array is first flattened.

### Returns

<b>ranks</b>	[ndarray] An array of size equal to the size of <i>a</i> , containing rank scores.
--------------	--

[1]

## Examples

```
>>> from scipy.stats import rankdata
>>> rankdata([0, 2, 3, 2])
array([ 1. ,  2.5,  4. ,  2.5])
>>> rankdata([0, 2, 3, 2], method='min')
array([ 1,  2,  4,  2])
>>> rankdata([0, 2, 3, 2], method='max')
array([ 1,  3,  4,  3])
>>> rankdata([0, 2, 3, 2], method='dense')
array([ 1,  2,  3,  2])
>>> rankdata([0, 2, 3, 2], method='ordinal')
array([ 1,  2,  4,  3])
>>> rankdata([[0, 2], [3, 2]].reshape(2,2)
array([[1. ,  2.5],
       [4. ,  2.5]])
>>> rankdata([[0, 2, 2], [3, 2, 5]], axis=1)
```

(continues on next page)

(continued from previous page)

```
array([[1. , 2.5, 2.5],
       [2. , 1. , 3. ]])
```

## scipy.stats.ranksums

`scipy.stats.ranksums(x, y)`

Compute the Wilcoxon rank-sum statistic for two samples.

The Wilcoxon rank-sum test tests the null hypothesis that two sets of measurements are drawn from the same distribution. The alternative hypothesis is that values in one sample are more likely to be larger than the values in the other sample.

This test should be used to compare two samples from continuous distributions. It does not handle ties between measurements in `x` and `y`. For tie-handling and an optional continuity correction see `scipy.stats.mannwhitneyu`.

### Parameters

**x,y** [array\_like] The data from the two samples.

### Returns

**statistic** [float] The test statistic under the large-sample approximation that the rank sum statistic is normally distributed.

**pvalue** [float] The two-sided p-value of the test.

## References

[1]

## Examples

We can test the hypothesis that two independent unequal-sized samples are drawn from the same distribution with computing the Wilcoxon rank-sum statistic.

```
>>> from scipy.stats import ranksums
>>> sample1 = np.random.uniform(-1, 1, 200)
>>> sample2 = np.random.uniform(-0.5, 1.5, 300) # a shifted distribution
>>> ranksums(sample1, sample2)
RanksumsResult(statistic=-7.887059, pvalue=3.09390448e-15) # may vary
```

The p-value of less than 0.05 indicates that this test rejects the hypothesis at the 5% significance level.

**scipy.stats.wilcoxon**

`scipy.stats.wilcoxon(x, y=None, zero_method='wilcox', correction=False, alternative='two-sided', mode='auto')`

Calculate the Wilcoxon signed-rank test.

The Wilcoxon signed-rank test tests the null hypothesis that two related paired samples come from the same distribution. In particular, it tests whether the distribution of the differences  $x - y$  is symmetric about zero. It is a non-parametric version of the paired T-test.

**Parameters**

- x** [array\_like] Either the first set of measurements (in which case  $y$  is the second set of measurements), or the differences between two sets of measurements (in which case  $y$  is not to be specified.) Must be one-dimensional.
- y** [array\_like, optional] Either the second set of measurements (if  $x$  is the first set of measurements), or not specified (if  $x$  is the differences between two sets of measurements.) Must be one-dimensional.
- zero\_method** [{"pratt", "wilcox", "zsplit"}, optional] The following options are available (default is "wilcox"):
- "pratt": Includes zero-differences in the ranking process, but drops the ranks of the zeros, see [4], (more conservative).
  - "wilcox": Discards all zero-differences, the default.
  - "zsplit": Includes zero-differences in the ranking process and split the zero rank between positive and negative ones.
- correction** [bool, optional] If True, apply continuity correction by adjusting the Wilcoxon rank statistic by 0.5 towards the mean value when computing the z-statistic if a normal approximation is used. Default is False.
- alternative** [{"two-sided", "greater", "less"}, optional] The alternative hypothesis to be tested, see Notes. Default is "two-sided".
- mode** [{"auto", "exact", "approx"}] Method to calculate the p-value, see Notes. Default is "auto".

**Returns**

- statistic** [float] If `alternative` is "two-sided", the sum of the ranks of the differences above or below zero, whichever is smaller. Otherwise the sum of the ranks of the differences above zero.
- pvalue** [float] The p-value for the test depending on `alternative` and `mode`.

See also:

[kruskal](#), [mannwhitneyu](#)

**Notes**

The test has been introduced in [4]. Given  $n$  independent samples  $(x_i, y_i)$  from a bivariate distribution (i.e. paired samples), it computes the differences  $d_i = x_i - y_i$ . One assumption of the test is that the differences are symmetric, see [2]. The two-sided test has the null hypothesis that the median of the differences is zero against the alternative that it is different from zero. The one-sided test has the null hypothesis that the median is positive against the alternative that it is negative (`alternative == 'less'`), or vice versa (`alternative == 'greater'`).

To derive the p-value, the exact distribution (`mode == 'exact'`) can be used for sample sizes of up to 25. The default `mode == 'auto'` uses the exact distribution if there are at most 25 observations and no ties, otherwise a normal approximation is used (`mode == 'approx'`).

The treatment of ties can be controlled by the parameter `zero_method`. If `zero_method == 'pratt'`, the normal approximation is adjusted as in [5]. A typical rule is to require that  $n > 20$  ([2], p. 383).

## References

[1], [2], [3], [4], [5]

## Examples

In [4], the differences in height between cross- and self-fertilized corn plants is given as follows:

```
>>> d = [6, 8, 14, 16, 23, 24, 28, 29, 41, -48, 49, 56, 60, -67, 75]
```

Cross-fertilized plants appear to be higher. To test the null hypothesis that there is no height difference, we can apply the two-sided test:

```
>>> from scipy.stats import wilcoxon
>>> w, p = wilcoxon(d)
>>> w, p
(24.0, 0.041259765625)
```

Hence, we would reject the null hypothesis at a confidence level of 5%, concluding that there is a difference in height between the groups. To confirm that the median of the differences can be assumed to be positive, we use:

```
>>> w, p = wilcoxon(d, alternative='greater')
>>> w, p
(96.0, 0.0206298828125)
```

This shows that the null hypothesis that the median is negative can be rejected at a confidence level of 5% in favor of the alternative that the median is greater than zero. The p-values above are exact. Using the normal approximation gives very similar values:

```
>>> w, p = wilcoxon(d, mode='approx')
>>> w, p
(24.0, 0.04088813291185591)
```

Note that the statistic changed to 96 in the one-sided case (the sum of ranks of positive differences) whereas it is 24 in the two-sided case (the minimum of sum of ranks above and below zero).

## scipy.stats.kruskal

`scipy.stats.kruskal` (\*args, nan\_policy='propagate')

Compute the Kruskal-Wallis H-test for independent samples.

The Kruskal-Wallis H-test tests the null hypothesis that the population median of all of the groups are equal. It is a non-parametric version of ANOVA. The test works on 2 or more independent samples, which may have different sizes. Note that rejecting the null hypothesis does not indicate which of the groups differs. Post hoc comparisons between groups are required to determine which groups are different.

### Parameters

**sample1, sample2, ...**

[array\_like] Two or more arrays with the sample measurements can be given as arguments.

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

**Returns**

**statistic** [float] The Kruskal-Wallis H statistic, corrected for ties.

**pvalue** [float] The p-value for the test using the assumption that H has a chi square distribution. The p-value returned is the survival function of the chi square distribution evaluated at H.

**See also:****f\_oneway**

1-way ANOVA.

**mannwhitneyu**

Mann-Whitney rank test on two samples.

**friedmanchisquare**

Friedman test for repeated measurements.

**Notes**

Due to the assumption that H has a chi square distribution, the number of samples in each group must not be too small. A typical rule is that each sample must have at least 5 measurements.

**References**

[1], [2]

**Examples**

```
>>> from scipy import stats
>>> x = [1, 3, 5, 7, 9]
>>> y = [2, 4, 6, 8, 10]
>>> stats.kruskal(x, y)
KruskalResult(statistic=0.2727272727272734, pvalue=0.6015081344405895)
```

```
>>> x = [1, 1, 1]
>>> y = [2, 2, 2]
>>> z = [2, 2]
>>> stats.kruskal(x, y, z)
KruskalResult(statistic=7.0, pvalue=0.0301973834223185)
```

## scipy.stats.friedmanchisquare

`scipy.stats.friedmanchisquare` (\*args)

Compute the Friedman test for repeated measurements.

The Friedman test tests the null hypothesis that repeated measurements of the same individuals have the same distribution. It is often used to test for consistency among measurements obtained in different ways. For example, if two measurement techniques are used on the same set of individuals, the Friedman test can be used to determine if the two measurement techniques are consistent.

### Parameters

**measurements1, measurements2, measurements3...**

[array\_like] Arrays of measurements. All of the arrays must have the same number of elements. At least 3 sets of measurements must be given.

### Returns

**statistic** [float] The test statistic, correcting for ties.

**pvalue** [float] The associated p-value assuming that the test statistic has a chi squared distribution.

### Notes

Due to the assumption that the test statistic has a chi squared distribution, the p-value is only reliable for  $n > 10$  and more than 6 repeated measurements.

### References

[1]

## scipy.stats.brunnermunzel

`scipy.stats.brunnermunzel` (x, y, *alternative='two-sided', distribution='t', nan\_policy='propagate'*)

Compute the Brunner-Munzel test on samples x and y.

The Brunner-Munzel test is a nonparametric test of the null hypothesis that when values are taken one by one from each group, the probabilities of getting large values in both groups are equal. Unlike the Wilcoxon-Mann-Whitney's U test, this does not require the assumption of equivariance of two groups. Note that this does not assume the distributions are same. This test works on two independent samples, which may have different sizes.

### Parameters

**x, y** [array\_like] Array of samples, should be one-dimensional.

**alternative**

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):

- 'two-sided'
- 'less': one-sided
- 'greater': one-sided

**distribution**

[{'t', 'normal'}, optional] Defines how to get the p-value. The following options are available (default is 't'):

- 't': get the p-value by t-distribution
- 'normal': get the p-value by standard normal distribution.

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

**Returns**

**statistic** [float] The Brunner-Munzer W statistic.

**pvalue** [float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of *alternative* and *distribution*.

**See also:****mannwhitneyu**

Mann-Whitney rank test on two samples.

**Notes**

Brunner and Munzel recommended to estimate the p-value by t-distribution when the size of data is 50 or less. If the size is lower than 10, it would be better to use permuted Brunner Munzel test (see [2]).

**References**

[1], [2]

**Examples**

```
>>> from scipy import stats
>>> x1 = [1, 2, 1, 1, 1, 1, 1, 1, 1, 1, 2, 4, 1, 1]
>>> x2 = [3, 3, 4, 3, 1, 2, 3, 1, 1, 5, 4]
>>> w, p_value = stats.brunnermunzel(x1, x2)
>>> w
3.1374674823029505
>>> p_value
0.0057862086661515377
```

**scipy.stats.combine\_pvalues**

`scipy.stats.combine_pvalues` (*pvalues*, *method*='fisher', *weights*=None)

Combine p-values from independent tests bearing upon the same hypothesis.

**Parameters**

**pvalues** [array\_like, 1-D] Array of p-values assumed to come from independent tests.

**method** [{'fisher', 'pearson', 'tippett', 'stouffer', 'mudholkar\_george'}, optional] Name of method to use to combine p-values. The following methods are available (default is 'fisher'):

- 'fisher': Fisher's method (Fisher's combined probability test), the sum of the logarithm of the p-values
- 'pearson': Pearson's method (similar to Fisher's but uses sum of the complement of the p-values inside the logarithms)

- ‘tippett’: Tippett’s method (minimum of p-values)
  - ‘stouffer’: Stouffer’s Z-score method
  - ‘mudholkar\_george’: the difference of Fisher’s and Pearson’s methods divided by 2
- weights** [array\_like, 1-D, optional] Optional array of weights used only for Stouffer’s Z-score method.

**Returns**

- statistic: float** The statistic calculated by the specified method.
- pval: float** The combined p-value.

**Notes**

Fisher’s method (also known as Fisher’s combined probability test) [1] uses a chi-squared statistic to compute a combined p-value. The closely related Stouffer’s Z-score method [2] uses Z-scores rather than p-values. The advantage of Stouffer’s method is that it is straightforward to introduce weights, which can make Stouffer’s method more powerful than Fisher’s method when the p-values are from studies of different size [6] [7]. The Pearson’s method uses  $\log(1 - p_i)$  inside the sum whereas Fisher’s method uses  $\log(p_i)$  [4]. For Fisher’s and Pearson’s method, the sum of the logarithms is multiplied by -2 in the implementation. This quantity has a chi-square distribution that determines the p-value. The *mudholkar\_george* method is the difference of the Fisher’s and Pearson’s test statistics, each of which include the -2 factor [4]. However, the *mudholkar\_george* method does not include these -2 factors. The test statistic of *mudholkar\_george* is the sum of logistic random variables and equation 3.6 in [3] is used to approximate the p-value based on Student’s t-distribution.

Fisher’s method may be extended to combine p-values from dependent tests [5]. Extensions such as Brown’s method and Kost’s method are not currently implemented.

New in version 0.15.0.

**References**

- [1], [2], [3], [4], [5], [6], [7]

**scipy.stats.jarque\_bera**

`scipy.stats.jarque_bera(x)`  
 Perform the Jarque-Bera goodness of fit test on sample data.

The Jarque-Bera test tests whether the sample data has the skewness and kurtosis matching a normal distribution.

Note that this test only works for a large enough number of data samples (>2000) as the test statistic asymptotically has a Chi-squared distribution with 2 degrees of freedom.

**Parameters**

- x** [array\_like] Observations of a random variable.

**Returns**

- jb\_value** [float] The test statistic.
- p** [float] The p-value for the hypothesis test.

>>> x = np.random.normal(0, 1, 100000)
>>> jarque_bera_test = stats.jarque_bera(x)
>>> jarque_bera_test
Jarque_beraResult(statistic=4.716570798957913, pvalue=0.0945822550304295)
>>> jarque_bera_test.statistic
4.716570798957913
>>> jarque_bera_test.pvalue
0.0945822550304295
```

<i>ansari</i> (x, y)	Perform the Ansari-Bradley test for equal scale parameters.
<i>bartlett</i> (*args)	Perform Bartlett's test for equal variances.
<i>levene</i> (*args[, center, proportiontocut])	Perform Levene test for equal variances.
<i>shapiro</i> (x)	Perform the Shapiro-Wilk test for normality.
<i>anderson</i> (x[, dist])	Anderson-Darling test for data coming from a particular distribution.
<i>anderson_ksamp</i> (samples[, midrank])	The Anderson-Darling test for k-samples.
<i>binom_test</i> (x[, n, p, alternative])	Perform a test that the probability of success is p.
<i>fligner</i> (*args[, center, proportiontocut])	Perform Fligner-Killeen test for equality of variance.
<i>median_test</i> (*args[, ties, correction, ...])	Perform a Mood's median test.
<i>mood</i> (x, y[, axis])	Perform Mood's test for equal scale parameters.
<i>skewtest</i> (a[, axis, nan_policy])	Test whether the skew is different from the normal distribution.
<i>kurtosistest</i> (a[, axis, nan_policy])	Test whether a dataset has normal kurtosis.
<i>normaltest</i> (a[, axis, nan_policy])	Test whether a sample differs from a normal distribution.

## scipy.stats.ansari

`scipy.stats.ansari(x, y)`

Perform the Ansari-Bradley test for equal scale parameters.

The Ansari-Bradley test ([1], [2]) is a non-parametric test for the equality of the scale parameter of the distributions from which two samples were drawn.

### Parameters

**x, y** [array\_like] Arrays of sample data.

### Returns

**statistic** [float] The Ansari-Bradley test statistic.  
**pvalue** [float] The p-value of the hypothesis test.

See also:

### `fligner`

A non-parametric test for the equality of  $k$  variances

### `mood`

A non-parametric test for the equality of two scale parameters

## Notes

The p-value given is exact when the sample sizes are both less than 55 and there are no ties, otherwise a normal approximation for the p-value is used.

## References

[1], [2]

## Examples

```
>>> from scipy.stats import ansari
```

For these examples, we'll create three random data sets. The first two, with sizes 35 and 25, are drawn from a normal distribution with mean 0 and standard deviation 2. The third data set has size 25 and is drawn from a normal distribution with standard deviation 1.25.

```
>>> np.random.seed(1234567890)
>>> x1 = np.random.normal(loc=0, scale=2, size=35)
>>> x2 = np.random.normal(loc=0, scale=2, size=25)
>>> x3 = np.random.normal(loc=0, scale=1.25, size=25)
```

First we apply `ansari` to `x1` and `x2`. These samples are drawn from the same distribution, so we expect the Ansari-Bradley test should not lead us to conclude that the scales of the distributions are different.

```
>>> ansari(x1, x2)
AnsariResult(statistic=511.0, pvalue=0.35506083719834347)
```

With a p-value of 0.355, we cannot conclude that there is a significant difference in the scales (as expected).

Now apply the test to `x1` and `x3`:

```
>>> ansari(x1, x3)
AnsariResult(statistic=452.0, pvalue=0.006280278681971285)
```

With a p-value of 0.00628, the test provides strong evidence that the scales of the distributions from which the samples were drawn are not equal.

## scipy.stats.bartlett

`scipy.stats.bartlett` (\*args)

Perform Bartlett's test for equal variances.

Bartlett's test tests the null hypothesis that all input samples are from populations with equal variances. For samples from significantly non-normal populations, Levene's test *levene* is more robust.

### Parameters

**sample1, sample2,...**

[array\_like] arrays of sample data. Only 1d arrays are accepted, they may have different lengths.

### Returns

**statistic** [float] The test statistic.  
**pvalue** [float] The p-value of the test.

See also:

### [fligner](#)

A non-parametric test for the equality of k variances

### [levene](#)

A robust parametric test for equality of k variances

## Notes

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power ([3]).

## References

[1], [2], [3], [4]

## Examples

Test whether or not the lists *a*, *b* and *c* come from populations with equal variances.

```

>>> from scipy.stats import bartlett
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.08, 9.01, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = bartlett(a, b, c)
>>> p
1.1254782518834628e-05

```

The very small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of *b* is much larger than that of *a* and *c*:

```

>>> [np.var(x, ddof=1) for x in [a, b, c]]
[0.007054444444444413, 0.13073888888888888, 0.008890000000000002]

```

## scipy.stats.levene

```
scipy.stats.levene(*args, center='median', proportiontocut=0.05)
```

Perform Levene test for equal variances.

The Levene test tests the null hypothesis that all input samples are from populations with equal variances. Levene's test is an alternative to Bartlett's test *bartlett* in the case where there are significant deviations from normality.

### Parameters

**sample1, sample2, ...**

[array\_like] The sample data, possibly with different lengths. Only one-dimensional samples are accepted.

**center** [{"mean", "median", "trimmed"}, optional] Which function of the data to use in the test. The default is "median".

**proportiontocut**

[float, optional] When *center* is "trimmed", this gives the proportion of data points to cut from each end. (See *scipy.stats.trim\_mean*.) Default is 0.05.

### Returns

**statistic** [float] The test statistic.

**pvalue** [float] The p-value for the test.

## Notes

Three variations of Levene's test are possible. The possibilities and their recommended usages are:

- 'median' : Recommended for skewed (non-normal) distributions>
- 'mean' : Recommended for symmetric, moderate-tailed distributions.
- 'trimmed' : Recommended for heavy-tailed distributions.

The test version using the mean was proposed in the original article of Levene ([2]) while the median and trimmed mean have been studied by Brown and Forsythe ([3]), sometimes also referred to as Brown-Forsythe test.

## References

[1], [2], [3]

## Examples

Test whether or not the lists *a*, *b* and *c* come from populations with equal variances.

```
>>> from scipy.stats import levene
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.08, 9.01, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = levene(a, b, c)
>>> p
0.002431505967249681
```

The small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of *b* is much larger than that of *a* and *c*:

```
>>> [np.var(x, ddof=1) for x in [a, b, c]]
[0.007054444444444413, 0.13073888888888888, 0.008890000000000002]
```

## scipy.stats.shapiro

`scipy.stats.shapiro(x)`

Perform the Shapiro-Wilk test for normality.

The Shapiro-Wilk test tests the null hypothesis that the data was drawn from a normal distribution.

### Parameters

**x** [array\_like] Array of sample data.

### Returns

**statistic** [float] The test statistic.

**p-value** [float] The p-value for the hypothesis test.

See also:

### anderson

The Anderson-Darling test for normality

### kstest

The Kolmogorov-Smirnov test for goodness of fit.

## Notes

The algorithm used is described in [4] but censoring parameters as described are not implemented. For  $N > 5000$  the  $W$  test statistic is accurate but the p-value may not be.

The chance of rejecting the null hypothesis when it is true is close to 5% regardless of sample size.

## Examples

```
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = stats.norm.rvs(loc=5, scale=3, size=100)
>>> shapiro_test = stats.shapiro(x)
>>> shapiro_test
ShapiroResult(statistic=0.9772805571556091, pvalue=0.08144091814756393)
>>> shapiro_test.statistic
0.9772805571556091
>>> shapiro_test.pvalue
0.08144091814756393
```

## scipy.stats.anderson

`scipy.stats.anderson` (*x*, *dist*='norm')

Anderson-Darling test for data coming from a particular distribution.

The Anderson-Darling test tests the null hypothesis that a sample is drawn from a population that follows a particular distribution. For the Anderson-Darling test, the critical values depend on which distribution is being tested against. This function works for normal, exponential, logistic, or Gumbel (Extreme Value Type I) distributions.

### Parameters

**x** [array\_like] Array of sample data.  
**dist** [{‘norm’, ‘expon’, ‘logistic’, ‘gumbel’, ‘gumbel\_l’, ‘gumbel\_r’, ‘extreme1’}, optional] The type of distribution to test against. The default is ‘norm’. The names ‘extreme1’, ‘gumbel\_l’ and ‘gumbel’ are synonyms for the same distribution.

### Returns

**statistic** [float] The Anderson-Darling test statistic.  
**critical\_values** [list] The critical values for this distribution.  
**significance\_level** [list] The significance levels for the corresponding critical values in percents. The function returns critical values for a differing set of significance levels depending on the distribution that is being tested against.

### See also:

#### [kstest](#)

The Kolmogorov-Smirnov test for goodness-of-fit.

### Notes

Critical values provided are for the following significance levels:

#### *normal/exponential*

15%, 10%, 5%, 2.5%, 1%

#### *logistic*

25%, 10%, 5%, 2.5%, 1%, 0.5%

#### *Gumbel*

25%, 10%, 5%, 2.5%, 1%

If the returned statistic is larger than these critical values then for the corresponding significance level, the null hypothesis that the data come from the chosen distribution can be rejected. The returned statistic is referred to as ‘A2’ in the references.

[1], [2], [3], [4], [5], [6]

### scipy.stats.anderson\_ksamp

`scipy.stats.anderson_ksamp` (*samples*, *midrank=True*)

The Anderson-Darling test for k-samples.

The k-sample Anderson-Darling test is a modification of the one-sample Anderson-Darling test. It tests the null hypothesis that k-samples are drawn from the same population without having to specify the distribution function of that population. The critical values depend on the number of samples.

#### Parameters

**samples** [sequence of 1-D array\_like] Array of sample data in arrays.  
**midrank** [bool, optional] Type of Anderson-Darling test which is computed. Default (True) is the midrank test applicable to continuous and discrete populations. If False, the right side empirical distribution is used.

#### Returns

**statistic** [float] Normalized k-sample Anderson-Darling test statistic.  
**critical\_values** [array] The critical values for significance levels 25%, 10%, 5%, 2.5%, 1%, 0.5%, 0.1%.  
**significance\_level** [float] An approximate significance level at which the null hypothesis for the provided samples can be rejected. The value is floored / capped at 0.1% / 25%.

#### Raises

**ValueError**  
 If less than 2 samples are provided, a sample is empty, or no distinct observations are in the samples.

See also:

#### [ks\\_2samp](#)

2 sample Kolmogorov-Smirnov test

#### [anderson](#)

1 sample Anderson-Darling test

## Notes

[1] defines three versions of the k-sample Anderson-Darling test: one for continuous distributions and two for discrete distributions, in which ties between samples may occur. The default of this routine is to compute the version based on the midrank empirical distribution function. This test is applicable to continuous and discrete data. If midrank is set to False, the right side empirical distribution is used for a test for discrete data. According to [1], the two discrete test statistics differ only slightly if a few collisions due to round-off errors occur in the test not adjusted for ties between samples.

The critical values corresponding to the significance levels from 0.01 to 0.25 are taken from [1]. p-values are floored / capped at 0.1% / 25%. Since the range of critical values might be extended in future releases, it is recommended not to test  $p == 0.25$ , but rather  $p >= 0.25$  (analogously for the lower bound).

New in version 0.14.0.

## References

[1]

## Examples

```
>>> from scipy import stats
>>> np.random.seed(314159)
```

The null hypothesis that the two random samples come from the same distribution can be rejected at the 5% level because the returned test value is greater than the critical value for 5% (1.961) but not at the 2.5% level. The interpolation gives an approximate significance level of 3.2%:

```
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(loc=0.5, size=30)])
(2.4615796189876105,
 array([ 0.325,  1.226,  1.961,  2.718,  3.752,  4.592,  6.546]),
 0.03176687568842282)
```

The null hypothesis cannot be rejected for three samples from an identical distribution. The reported p-value (25%) has been capped and may not be very accurate (since it corresponds to the value 0.449 whereas the statistic is -0.731):

```
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(size=30), np.random.normal(size=20)])
(-0.73091722665244196,
 array([ 0.44925884,  1.3052767 ,  1.9434184 ,  2.57696569,  3.41634856,
 4.07210043,  5.56419101]),
 0.25)
```

## scipy.stats.binom\_test

`scipy.stats.binom_test(x, n=None, p=0.5, alternative='two-sided')`

Perform a test that the probability of success is  $p$ .

This is an exact, two-sided test of the null hypothesis that the probability of success in a Bernoulli experiment is  $p$ .

### Parameters

- |                    |  |
|--------------------|--|
| <b>x</b>           | [int or array_like] The number of successes, or if x has length 2, it is the number of successes and the number of failures. |
| <b>n</b>           | [int] The number of trials. This is ignored if x gives both the number of successes and failures.                            |
| <b>p</b>           | [float, optional] The hypothesized probability of success. $0 \leq p \leq 1$ . The default value is $p = 0.5$ .              |
| <b>alternative</b> | ['two-sided', 'greater', 'less'], optional] Indicates the alternative hypothesis. The default value is 'two-sided'.          |

### Returns

- |                |   |
|----------------|---|
| <b>p-value</b> | [float] The p-value of the hypothesis test. |
|----------------|---|

## References

[1]

## Examples

```
>>> from scipy import stats
```

A car manufacturer claims that no more than 10% of their cars are unsafe. 15 cars are inspected for safety, 3 were found to be unsafe. Test the manufacturer's claim:

```
>>> stats.binom_test(3, n=15, p=0.1, alternative='greater')
0.18406106910639114
```

The null hypothesis cannot be rejected at the 5% level of significance because the returned p-value is greater than the critical value of 5%.

## scipy.stats.fligner

`scipy.stats.fligner` (\*args, center='median', proportiontocut=0.05)

Perform Fligner-Killeen test for equality of variance.

Fligner's test tests the null hypothesis that all input samples are from populations with equal variances. Fligner-Killeen's test is distribution free when populations are identical [2].

### Parameters

**sample1, sample2, ...**

[array\_like] Arrays of sample data. Need not be the same length.

**center** [{"mean", "median", "trimmed"}, optional] Keyword argument controlling which function of the data is used in computing the test statistic. The default is 'median'.

**proportiontocut**

[float, optional] When *center* is 'trimmed', this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.

### Returns

**statistic** [float] The test statistic.

**pvalue** [float] The p-value for the hypothesis test.

See also:

### bartlett

A parametric test for equality of k variances in normal samples

### levene

A robust parametric test for equality of k variances

## Notes

As with Levene's test there are three variants of Fligner's test that differ by the measure of central tendency used in the test. See *levene* for more information.

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [3].

## References

[1], [2], [3], [4]

## Examples

Test whether or not the lists *a*, *b* and *c* come from populations with equal variances.

```
>>> from scipy.stats import fligner
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.08, 9.01, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = fligner(a, b, c)
>>> p
0.00450826080004775
```

The small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of *b* is much larger than that of *a* and *c*:

```
>>> [np.var(x, ddof=1) for x in [a, b, c]]
[0.007054444444444413, 0.13073888888888888, 0.008890000000000002]
```

## scipy.stats.median\_test

`scipy.stats.median_test` (\*args, ties='below', correction=True, lambda\_=1, nan\_policy='propagate')

Perform a Mood's median test.

Test that two or more samples come from populations with the same median.

Let  $n = \text{len}(\text{args})$  be the number of samples. The “grand median” of all the data is computed, and a contingency table is formed by classifying the values in each sample as being above or below the grand median. The contingency table, along with *correction* and *lambda\_*, are passed to `scipy.stats.chi2_contingency` to compute the test statistic and p-value.

### Parameters

#### sample1, sample2, ...

[array\_like] The set of samples. There must be at least two samples. Each sample must be a one-dimensional sequence containing at least one value. The samples are not required to have the same length.

**ties** [str, optional] Determines how values equal to the grand median are classified in the contingency table. The string must be one of:

```

"below":
    Values equal to the grand median are counted as "below
↔".
"above":
    Values equal to the grand median are counted as "above
↔".
"ignore":
    Values equal to the grand median are not counted.

```

The default is “below”.

- correction** [bool, optional] If True, *and* there are just two samples, apply Yates’ correction for continuity when computing the test statistic associated with the contingency table. Default is True.
- lambda\_** [float or str, optional] By default, the statistic computed in this test is Pearson’s chi-squared statistic. *lambda\_* allows a statistic from the Cressie-Read power divergence family to be used instead. See *power\_divergence* for details. Default is 1 (Pearson’s chi-squared statistic).
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

### Returns

- stat** [float] The test statistic. The statistic that is returned is determined by *lambda\_*. The default is Pearson’s chi-squared statistic.
- p** [float] The p-value of the test.
- m** [float] The grand median.
- table** [ndarray] The contingency table. The shape of the table is (2, n), where n is the number of samples. The first row holds the counts of the values above the grand median, and the second row holds the counts of the values below the grand median. The table allows further analysis with, for example, *scipy.stats.chi2\_contingency*, or with *scipy.stats.fisher\_exact* if there are two samples, without having to recompute the table. If *nan\_policy* is “propagate” and there are nans in the input, the return value for *table* is None.

[1], [2]

## Examples

A biologist runs an experiment in which there are three groups of plants. Group 1 has 16 plants, group 2 has 15 plants, and group 3 has 17 plants. Each plant produces a number of seeds. The seed counts for each group are:

```
Group 1: 10 14 14 18 20 22 24 25 31 31 32 39 43 43 48 49
Group 2: 28 30 31 33 34 35 36 40 44 55 57 61 91 92 99
Group 3: 0 3 9 22 23 25 25 33 34 34 40 45 46 48 62 67 84
```

The following code applies Mood's median test to these samples.

```
>>> g1 = [10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 43, 48, 49]
>>> g2 = [28, 30, 31, 33, 34, 35, 36, 40, 44, 55, 57, 61, 91, 92, 99]
>>> g3 = [0, 3, 9, 22, 23, 25, 25, 33, 34, 34, 40, 45, 46, 48, 62, 67, 84]
>>> from scipy.stats import median_test
>>> stat, p, med, tbl = median_test(g1, g2, g3)
```

The median is

```
>>> med
34.0
```

and the contingency table is

```
>>> tbl
array([[ 5, 10,  7],
       [11,  5, 10]])
```

$p$  is too large to conclude that the medians are not the same:

```
>>> p
0.12609082774093244
```

The “G-test” can be performed by passing `lambda_="log-likelihood"` to `median_test`.

```
>>> g, p, med, tbl = median_test(g1, g2, g3, lambda_="log-likelihood")
>>> p
0.12224779737117837
```

The median occurs several times in the data, so we'll get a different result if, for example, `ties="above"` is used:

```
>>> stat, p, med, tbl = median_test(g1, g2, g3, ties="above")
>>> p
0.063873276069553273
```

```
>>> tbl
array([[ 5, 11,  9],
       [11,  4,  8]])
```

This example demonstrates that if the data set is not large and there are values equal to the median, the p-value can be sensitive to the choice of *ties*.

## scipy.stats.mood

`scipy.stats.mood(x, y, axis=0)`

Perform Mood's test for equal scale parameters.

Mood's two-sample test for scale parameters is a non-parametric test for the null hypothesis that two samples are drawn from the same distribution with the same scale parameter.

### Parameters

**x, y** [array\_like] Arrays of sample data.  
**axis** [int, optional] The axis along which the samples are tested. *x* and *y* can be of different length along *axis*. If *axis* is None, *x* and *y* are flattened and the test is done on all values in the flattened arrays.

### Returns

**z** [scalar or ndarray] The z-score for the hypothesis test. For 1-D inputs a scalar is returned.  
**p-value** [scalar ndarray] The p-value for the hypothesis test.

See also:

### [fligner](#)

A non-parametric test for the equality of k variances

### [ansari](#)

A non-parametric test for the equality of 2 variances

### [bartlett](#)

A parametric test for equality of k variances in normal samples

### [levene](#)

A parametric test for equality of k variances

## Notes

The data are assumed to be drawn from probability distributions  $f(x)$  and  $f(x/s) / s$  respectively, for some probability density function  $f$ . The null hypothesis is that  $s == 1$ .

For multi-dimensional arrays, if the inputs are of shapes  $(n_0, n_1, n_2, n_3)$  and  $(n_0, m_1, n_2, n_3)$ , then if `axis=1`, the resulting z and p values will have shape  $(n_0, n_2, n_3)$ . Note that  $n_1$  and  $m_1$  don't have to be equal, but the other dimensions do.

## Examples

```
>>> from scipy import stats
>>> np.random.seed(1234)
>>> x2 = np.random.randn(2, 45, 6, 7)
>>> x1 = np.random.randn(2, 30, 6, 7)
>>> z, p = stats.mood(x1, x2, axis=1)
>>> p.shape
(2, 6, 7)
```

Find the number of points where the difference in scale is not significant:

```
>>> (p > 0.1).sum()
74
```

Perform the test with different scales:

```
>>> x1 = np.random.randn(2, 30)
>>> x2 = np.random.randn(2, 35) * 10.0
>>> stats.mood(x1, x2, axis=1)
(array([-5.7178125 , -5.25342163]), array([ 1.07904114e-08,  1.
→49299218e-07]))
```

## scipy.stats.skewtest

`scipy.stats.skewtest` (*a*, *axis=0*, *nan\_policy='propagate'*)

Test whether the skew is different from the normal distribution.

This function tests the null hypothesis that the skewness of the population that the sample was drawn from is the same as that of a corresponding normal distribution.

### Parameters

- a** [array] The data to be tested.
- axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
  - ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values

### Returns

- statistic** [float] The computed z-score for this test.
- pvalue** [float] Two-sided p-value for the hypothesis test.

## Notes

The sample size must be at least 8.

## References

[1]

## Examples

```

>>> from scipy.stats import skewtest
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8])
SkewtestResult(statistic=1.0108048609177787, pvalue=0.3121098361421897)
>>> skewtest([2, 8, 0, 4, 1, 9, 9, 0])
SkewtestResult(statistic=0.44626385374196975, pvalue=0.6554066631275459)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8000])
SkewtestResult(statistic=3.571773510360407, pvalue=0.0003545719905823133)
>>> skewtest([100, 100, 100, 100, 100, 100, 100, 101])
SkewtestResult(statistic=3.5717766638478072, pvalue=0.000354567720281634)

```

## scipy.stats.kurtosistest

`scipy.stats.kurtosistest` (*a*, *axis=0*, *nan\_policy='propagate'*)

Test whether a dataset has normal kurtosis.

This function tests the null hypothesis that the kurtosis of the population from which the sample was drawn is that of the normal distribution:  $kurtosis = 3(n-1)/(n+1)$ .

### Parameters

- a** [array] Array of the sample data.
- axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
  - ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values

### Returns

- statistic** [float] The computed z-score for this test.
- pvalue** [float] The two-sided p-value for the hypothesis test.

## Notes

Valid only for  $n > 20$ . This function uses the method described in [1].

## References

[1]

## Examples

```
>>> from scipy.stats import kurtosistest
>>> kurtosistest(list(range(20)))
KurtosistestResult(statistic=-1.7058104152122062, pvalue=0.
↳08804338332528348)
```

```
>>> np.random.seed(28041990)
>>> s = np.random.normal(0, 1, 1000)
>>> kurtosistest(s)
KurtosistestResult(statistic=1.2317590987707365, pvalue=0.
↳21803908613450895)
```

## scipy.stats.normaltest

`scipy.stats.normaltest` (*a*, *axis=0*, *nan\_policy='propagate'*)

Test whether a sample differs from a normal distribution.

This function tests the null hypothesis that a sample comes from a normal distribution. It is based on D'Agostino and Pearson's [1], [2] test that combines skew and kurtosis to produce an omnibus test of normality.

### Parameters

- a** [array\_like] The array containing the sample to be tested.
- axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
- 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

### Returns

- statistic** [float or array]  $s^2 + k^2$ , where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.
- pvalue** [float or array] A 2-sided chi squared probability for the hypothesis test.

## References

## Examples

```
>>> from scipy import stats
>>> pts = 1000
>>> np.random.seed(28041990)
>>> a = np.random.normal(0, 1, size=pts)
>>> b = np.random.normal(2, 1, size=pts)
>>> x = np.concatenate((a, b))
>>> k2, p = stats.normaltest(x)
>>> alpha = 1e-3
>>> print("p = {:g}".format(p))
p = 3.27207e-11
>>> if p < alpha: # null hypothesis: x comes from a normal distribution
...     print("The null hypothesis can be rejected")
... else:
...     print("The null hypothesis cannot be rejected")
The null hypothesis can be rejected
```

### 6.29.11 Transformations

<code>boxcox(x[, lmbda, alpha])</code>	Return a dataset transformed by a Box-Cox power transformation.
<code>boxcox_normmax(x[, brack, method])</code>	Compute optimal Box-Cox transform parameter for input data.
<code>boxcox_llf(lmb, data)</code>	The boxcox log-likelihood function.
<code>yeojohnson(x[, lmbda])</code>	Return a dataset transformed by a Yeo-Johnson power transformation.
<code>yeojohnson_normmax(x[, brack])</code>	Compute optimal Yeo-Johnson transform parameter.
<code>yeojohnson_llf(lmb, data)</code>	The yeojohnson log-likelihood function.
<code>obrientransform(*args)</code>	Compute the O'Brien transform on input data (any number of arrays).
<code>sigmaclip(a[, low, high])</code>	Perform iterative sigma-clipping of array elements.
<code>trimboth(a, proportiontocut[, axis])</code>	Slice off a proportion of items from both ends of an array.
<code>trim1(a, proportiontocut[, tail, axis])</code>	Slice off a proportion from ONE end of the passed array distribution.
<code>zmap(scores, compare[, axis, ddof])</code>	Calculate the relative z-scores.
<code>zscore(a[, axis, ddof, nan_policy])</code>	Compute the z score.

**scipy.stats.boxcox**`scipy.stats.boxcox(x, lambda=None, alpha=None)`

Return a dataset transformed by a Box-Cox power transformation.

**Parameters**

- x** [ndarray] Input array. Must be positive 1-dimensional. Must not be constant.
- lambda** [{None, scalar}, optional] If *lambda* is not None, do the transformation for that value. If *lambda* is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument.
- alpha** [{None, float}, optional] If *alpha* is not None, return the  $100 * (1-\alpha)\%$  confidence interval for *lambda* as the third output argument. Must be between 0.0 and 1.0.

**Returns**

- boxcox** [ndarray] Box-Cox power transformed array.
- maxlog** [float, optional] If the *lambda* parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.
- (min\_ci, max\_ci)** [tuple of float, optional] If *lambda* parameter is None and *alpha* is not None, this returned tuple of floats represents the minimum and maximum confidence limits given *alpha*.

**See also:**`probplot, boxcox_normplot, boxcox_normmax, boxcox_llf`**Notes**

The Box-Cox transform is given by:

$y = \begin{cases} (x^{*\lambda} - 1) / \lambda, & \text{for } \lambda \neq 0 \\ \log(x), & \text{for } \lambda = 0 \end{cases}$
--

`boxcox` requires the input data to be positive. Sometimes a Box-Cox transformation provides a shift parameter to achieve this; `boxcox` does not. Such a shift parameter is equivalent to adding a positive constant to *x* before calling `boxcox`.

The confidence limits returned when *alpha* is provided give the interval where:

$$llf(\hat{\lambda}) - llf(\lambda) < \frac{1}{2}\chi^2(1 - \alpha, 1),$$

with `llf` the log-likelihood function and  $\chi^2$  the chi-squared function.**References**

G.E.P. Box and D.R. Cox, "An Analysis of Transformations", Journal of the Royal Statistical Society B, 26, 211-252 (1964).

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `boxcox` to transform the data so it's closest to normal:

```
>>> ax2 = fig.add_subplot(212)
>>> xt, _ = stats.boxcox(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Box-Cox transformation')
```

```
>>> plt.show()
```

**scipy.stats.boxcox\_normmax**

`scipy.stats.boxcox_normmax(x, brack=(-2.0, 2.0), method='pearsonr')`

Compute optimal Box-Cox transform parameter for input data.

**Parameters**

<b>x</b>	[array_like] Input array.
<b>brack</b>	[2-tuple, optional] The starting interval for a downhill bracket search with <i>optimize.brent</i> . Note that this is in most cases not critical; the final result is allowed to be outside this bracket.
<b>method</b>	[str, optional] The method to determine the optimal transform parameter ( <i>boxcox</i> lambda parameter). Options are: <ul style="list-style-type: none"> <li><b>'pearsonr' (default)</b> Maximizes the Pearson correlation coefficient between <math>y = \text{boxcox}(x)</math> and the expected values for <math>y</math> if <math>x</math> would be normally-distributed.</li> <li><b>'mle'</b> Minimizes the log-likelihood <i>boxcox_llf</i>. This is the method used in <i>boxcox</i>.</li> <li><b>'all'</b> Use all optimization methods available, and return all results. Useful to compare different methods.</li> </ul>

**Returns**

<b>maxlog</b>	[float or ndarray] The optimal transform parameter found. An array instead of a scalar for <code>method='all'</code> .
---------------	--

See also:

[boxcox](#), [boxcox\\_llf](#), [boxcox\\_normplot](#)

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234) # make this example reproducible
```

Generate some data and determine optimal lambda in various ways:

```
>>> x = stats.loggamma.rvs(5, size=30) + 5
>>> y, lmax_mle = stats.boxcox(x)
>>> lmax_pearsonr = stats.boxcox_normmax(x)
```

```
>>> lmax_mle
7.177...
>>> lmax_pearsonr
7.916...
>>> stats.boxcox_normmax(x, method='all')
array([ 7.91667384,  7.17718692])
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax_mle, color='r')
>>> ax.axvline(lmax_pearsonr, color='g', ls='--')
```

```
>>> plt.show()
```

### scipy.stats.boxcox\_llf

scipy.stats.**boxcox\_llf** (*lmb*, *data*)

The boxcox log-likelihood function.

#### Parameters

**lmb** [scalar] Parameter for Box-Cox transformation. See [boxcox](#) for details.  
**data** [array\_like] Data to calculate Box-Cox log-likelihood for. If *data* is multi-dimensional, the log-likelihood is calculated along the first axis.

#### Returns

**llf** [float or ndarray] Box-Cox log-likelihood of *data* given *lmb*. A float for 1-D *data*, an array otherwise.

See also:

[boxcox](#), [probplot](#), [boxcox\\_normplot](#), [boxcox\\_normmax](#)

#### Notes

The Box-Cox log-likelihood function is defined here as

$$llf = (\lambda - 1) \sum_i (\log(x_i)) - N/2 \log(\sum_i (y_i - \bar{y})^2 / N),$$

where  $y$  is the Box-Cox transformed input data  $x$ .

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
>>> np.random.seed(1245)
```

Generate some random variates and calculate Box-Cox log-likelihood values for them for a range of lambda values:

```
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lambda in enumerate(lmbdas):
...     llf[ii] = stats.boxcox_llf(lambda, x)
```

Also find the optimal lambda value with `boxcox`:

```
>>> x_most_normal, lambda_optimal = stats.boxcox(x)
```

Plot the log-likelihood as function of lambda. Add the optimal lambda as a horizontal line to check that that's really the optimum:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.boxcox_llf(lambda_optimal, x), color='r')
>>> ax.set_xlabel('lambda parameter')
>>> ax.set_ylabel('Box-Cox log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `boxcox` looks closest to normal:

```
>>> locs = [3, 10, 4] # 'lower left', 'center', 'lower right'
>>> for lambda, loc in zip([-1, lambda_optimal, 9], locs):
...     xt = stats.boxcox(x, lambda=lambda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title(r'$\lambda=%1.2f$' % lambda)
```

```
>>> plt.show()
```

## scipy.stats.yeojohnson

`scipy.stats.yeojohnson` (*x*, *lmbda=None*)

Return a dataset transformed by a Yeo-Johnson power transformation.

### Parameters

- x** [ndarray] Input array. Should be 1-dimensional.
- lmbda** [float, optional] If *lmbda* is `None`, find the lambda that maximizes the log-likelihood function and return it as the second output argument. Otherwise the transformation is done for the given value.

### Returns

- yeojohnson:** ndarray  
Yeo-Johnson power transformed array.
- maxlog** [float, optional] If the *lmbda* parameter is `None`, the second returned argument is the lambda that maximizes the log-likelihood function.

See also:

[probplot](#), [yeojohnson\\_normplot](#), [yeojohnson\\_normmax](#), [yeojohnson\\_llf](#), [boxcox](#)

## Notes

The Yeo-Johnson transform is given by:

$y = ((x + 1)**lmbda - 1) / lmbda,$	<b>for</b> $x \geq 0, lmbda \neq 0$
$\log(x + 1),$	<b>for</b> $x \geq 0, lmbda = 0$
$-((-x + 1)**(2 - lmbda) - 1) / (2 - lmbda),$	<b>for</b> $x < 0, lmbda \neq 2$
$-\log(-x + 1),$	<b>for</b> $x < 0, lmbda = 2$

Unlike `boxcox`, `yeojohnson` does not require the input data to be positive.

New in version 1.2.0.

## References

I. Yeo and R.A. Johnson, “A New Family of Power Transformations to Improve Normality or Symmetry”, *Biometrika* 87.4 (2000):

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `yeojohnson` to transform the data so it's closest to normal:

```
>>> ax2 = fig.add_subplot(212)
>>> xt, lambda = stats.yeojohnson(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Yeo-Johnson transformation')
```

```
>>> plt.show()
```

## scipy.stats.yeojohnson\_normmax

`scipy.stats.yeojohnson_normmax(x, brack=-2, 2)`

Compute optimal Yeo-Johnson transform parameter.

Compute optimal Yeo-Johnson transform parameter for input data, using maximum likelihood estimation.

### Parameters

<b>x</b>	[array_like] Input array.
<b>brack</b>	[2-tuple, optional] The starting interval for a downhill bracket search with <i>optimize.brent</i> . Note that this is in most cases not critical; the final result is allowed to be outside this bracket.

### Returns

<b>maxlog</b>	[float] The optimal transform parameter found.
---------------	--

See also:

[yeojohnson](#), [yeojohnson\\_llf](#), [yeojohnson\\_normplot](#)

### Notes

New in version 1.2.0.

### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234) # make this example reproducible
```

Generate some data and determine optimal lambda

```
>>> x = stats.loggamma.rvs(5, size=30) + 5
>>> lmax = stats.yeojohnson_normmax(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.yeojohnson_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax, color='r')
```

```
>>> plt.show()
```

## scipy.stats.yeojohnson\_llf

`scipy.stats.yeojohnson_llf(lmb, data)`

The yeojohnson log-likelihood function.

### Parameters

<b>lmb</b>	[scalar] Parameter for Yeo-Johnson transformation. See <a href="#">yeojohnson</a> for details.
<b>data</b>	[array_like] Data to calculate Yeo-Johnson log-likelihood for. If <i>data</i> is multi-dimensional, the log-likelihood is calculated along the first axis.

### Returns

**llf** [float] Yeo-Johnson log-likelihood of *data* given *lmb*.

See also:

[yeojohnson](#), [probplot](#), [yeojohnson\\_normplot](#), [yeojohnson\\_normmax](#)

## Notes

The Yeo-Johnson log-likelihood function is defined here as

$$llf = N/2 \log(\hat{\sigma}^2) + (\lambda - 1) \sum_i \text{sign}(x_i) \log(|x_i| + 1)$$

where  $\hat{\sigma}^2$  is estimated variance of the the Yeo-Johnson transformed input data  $x$ .

New in version 1.2.0.

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
>>> np.random.seed(1245)
```

Generate some random variates and calculate Yeo-Johnson log-likelihood values for them for a range of *lmbda* values:

```
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lmbda in enumerate(lmbdas):
...     llf[ii] = stats.yeojohnson_llf(lmbda, x)
```

Also find the optimal *lmbda* value with [yeojohnson](#):

```
>>> x_most_normal, lambda_optimal = stats.yeojohnson(x)
```

Plot the log-likelihood as function of lambda. Add the optimal lambda as a horizontal line to check that that's really the optimum:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.yeojohnson_llf(lambda_optimal, x), color='r')
>>> ax.set_xlabel('lambda parameter')
>>> ax.set_ylabel('Yeo-Johnson log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with *yeojohnson* looks closest to normal:

```
>>> locs = [3, 10, 4] # 'lower left', 'center', 'lower right'
>>> for lambda, loc in zip([-1, lambda_optimal, 9], locs):
...     xt = stats.yeojohnson(x, lambda=lambda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title(r'$\lambda=%1.2f$' % lambda)
```

```
>>> plt.show()
```

## scipy.stats.obrienttransform

`scipy.stats.obrienttransform(*args)`

Compute the O'Brien transform on input data (any number of arrays).

Used to test for homogeneity of variance prior to running one-way stats. Each array in `*args` is one level of a factor. If `f_oneway` is run on the transformed data and found significant, the variances are unequal. From Maxwell and Delaney [1], p.112.

### Parameters

**args** [tuple of array\_like] Any number of arrays.

### Returns

#### **obrienttransform**

[ndarray] Transformed data for use in an ANOVA. The first dimension of the result corresponds to the sequence of transformed arrays. If the arrays given are all 1-D of the same length, the return value is a 2-D array; otherwise it is a 1-D array of type object, with each element being an ndarray.

## References

[1]

## Examples

We'll test the following data sets for differences in their variance.

```
>>> x = [10, 11, 13, 9, 7, 12, 12, 9, 10]
>>> y = [13, 21, 5, 10, 8, 14, 10, 12, 7, 15]
```

Apply the O'Brien transform to the data.

```
>>> from scipy.stats import obrienttransform
>>> tx, ty = obrienttransform(x, y)
```

Use `scipy.stats.f_oneway` to apply a one-way ANOVA test to the transformed data.

```
>>> from scipy.stats import f_oneway
>>> F, p = f_oneway(tx, ty)
>>> p
0.1314139477040335
```

If we require that  $p < 0.05$  for significance, we cannot conclude that the variances are different.

**scipy.stats.sigmaclip**

`scipy.stats.sigmaclip(a, low=4.0, high=4.0)`

Perform iterative sigma-clipping of array elements.

Starting from the full sample, all elements outside the critical range are removed, i.e. all elements of the input array *c* that satisfy either of the following conditions:

```
c < mean(c) - std(c)*low
c > mean(c) + std(c)*high
```

The iteration continues with the updated sample until no elements are outside the (updated) range.

**Parameters**

**a** [array\_like] Data array, will be raveled if not 1-D.  
**low** [float, optional] Lower bound factor of sigma clipping. Default is 4.  
**high** [float, optional] Upper bound factor of sigma clipping. Default is 4.

**Returns**

**clipped** [ndarray] Input array with clipped elements removed.  
**lower** [float] Lower threshold value use for clipping.  
**upper** [float] Upper threshold value use for clipping.

**Examples**

```
>>> from scipy.stats import sigmaclip
>>> a = np.concatenate((np.linspace(9.5, 10.5, 31),
...                    np.linspace(0, 20, 5)))
>>> fact = 1.5
>>> c, low, upp = sigmaclip(a, fact, fact)
>>> c
array([ 9.96666667, 10.          , 10.03333333, 10.          ])
>>> c.var(), c.std()
(0.00055555555555555165, 0.023570226039551501)
>>> low, c.mean() - fact*c.std(), c.min()
(9.9646446609406727, 9.9646446609406727, 9.9666666666666668)
>>> upp, c.mean() + fact*c.std(), c.max()
(10.035355339059327, 10.035355339059327, 10.033333333333333)
```

```
>>> a = np.concatenate((np.linspace(9.5, 10.5, 11),
...                    np.linspace(-100, -50, 3)))
>>> c, low, upp = sigmaclip(a, 1.8, 1.8)
>>> (c == np.linspace(9.5, 10.5, 11)).all()
True
```

## scipy.stats.trimboth

`scipy.stats.trimboth(a, proportiontocut, axis=0)`

Slice off a proportion of items from both ends of an array.

Slice off the passed proportion of items from both ends of the passed array (i.e., with *proportiontocut* = 0.1, slices leftmost 10% **and** rightmost 10% of scores). The trimmed values are the lowest and highest ones. Slice off less if proportion results in a non-integer slice index (i.e. conservatively slices off *proportiontocut*).

### Parameters

**a** [array\_like] Data to trim.  
**proportiontocut** [float] Proportion (in range 0-1) of total data set to trim of each end.  
**axis** [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

### Returns

**out** [ndarray] Trimmed version of array *a*. The order of the trimmed content is undefined.

See also:

[trim\\_mean](#)

## Examples

```
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trimboth(a, 0.1)
>>> b.shape
(16,)
```

## scipy.stats.trim1

`scipy.stats.trim1(a, proportiontocut, tail='right', axis=0)`

Slice off a proportion from ONE end of the passed array distribution.

If *proportiontocut* = 0.1, slices off 'leftmost' or 'rightmost' 10% of scores. The lowest or highest values are trimmed (depending on the tail). Slice off less if proportion results in a non-integer slice index (i.e. conservatively slices off *proportiontocut*).

### Parameters

**a** [array\_like] Input array.  
**proportiontocut** [float] Fraction to cut off of 'left' or 'right' of distribution.  
**tail** [{'left', 'right'}, optional] Defaults to 'right'.  
**axis** [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

### Returns

**trim1** [ndarray] Trimmed version of array *a*. The order of the trimmed content is undefined.

## scipy.stats.zmap

`scipy.stats.zmap` (*scores*, *compare*, *axis=0*, *ddof=0*)

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

### Parameters

<b>scores</b>	[array_like] The input for which z-scores are calculated.
<b>compare</b>	[array_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as <i>scores</i> .
<b>axis</b>	[int or None, optional] Axis over which mean and variance of <i>compare</i> are calculated. Default is 0. If None, compute over the whole array <i>scores</i> .
<b>ddof</b>	[int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

### Returns

<b>zscore</b>	[array_like] Z-scores, in the same shape as <i>scores</i> .
---------------	---

## Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

## Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
```

## scipy.stats.zscore

`scipy.stats.zscore` (*a*, *axis=0*, *ddof=0*, *nan\_policy='propagate'*)

Compute the z score.

Compute the z score of each value in the sample, relative to the sample mean and standard deviation.

### Parameters

<b>a</b>	[array_like] An array like object containing the sample data.
<b>axis</b>	[int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array <i>a</i> .
<b>ddof</b>	[int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.
<b>nan_policy</b>	[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in the input also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

**Returns**

**zscore** [array\_like] The z-scores, standardized by mean and standard deviation of input array *a*.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

**Examples**

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...               0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```
>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...               [ 0.7149,  0.0775,  0.6072,  0.9656],
...               [ 0.6341,  0.1403,  0.9759,  0.4064],
...               [ 0.5918,  0.6948,  0.904 ,  0.3721],
...               [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823, -1.28415119,  1.07259584,  0.40420358],
       [  0.33048416, -1.37380874,  0.04251374,  1.00081084],
       [  0.26796377, -1.12598418,  1.23283094, -0.37481053],
       [ -0.22095197,  0.24468594,  1.19042819, -1.21416216],
       [ -0.82780366,  1.4457416 , -0.43867764, -0.1792603 ]])
```

An example with *nan\_policy='omit'*:

```
>>> x = np.array([[25.11, 30.10, np.nan, 32.02, 43.15],
...               [14.95, 16.06, 121.25, 94.35, 29.81]])
>>> stats.zscore(x, axis=1, nan_policy='omit')
array([[ -1.13490897, -0.37830299,          nan, -0.08718406,  1.60039602],
       [ -0.91611681, -0.89090508,  1.4983032 ,  0.88731639, -0.5785977 ]])
```

**6.29.12 Statistical distances**

<code>wasserstein_distance(u_values, v_values[, ...])</code>	Compute the first Wasserstein distance between two 1D distributions.
<code>energy_distance(u_values, v_values[, ...])</code>	Compute the energy distance between two 1D distributions.

**scipy.stats.wasserstein\_distance**

`scipy.stats.wasserstein_distance` (*u\_values*, *v\_values*, *u\_weights=None*, *v\_weights=None*)

Compute the first Wasserstein distance between two 1D distributions.

This distance is also known as the earth mover’s distance, since it can be seen as the minimum amount of “work” required to transform *u* into *v*, where “work” is measured as the amount of distribution weight that must be moved, multiplied by the distance it has to be moved.

New in version 1.0.0.

**Parameters****u\_values, v\_values**

[array\_like] Values observed in the (empirical) distribution.

**u\_weights, v\_weights**

[array\_like, optional] Weight for each value. If unspecified, each value is assigned the same weight. *u\_weights* (resp. *v\_weights*) must have the same length as *u\_values* (resp. *v\_values*). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

**Returns**

**distance** [float] The computed distance between the distributions.

**Notes**

The first Wasserstein distance between the distributions *u* and *v* is:

$$l_1(u, v) = \inf_{\pi \in \Gamma(u, v)} \int_{\mathbb{R} \times \mathbb{R}} |x - y| d\pi(x, y)$$

where  $\Gamma(u, v)$  is the set of (probability) distributions on  $\mathbb{R} \times \mathbb{R}$  whose marginals are *u* and *v* on the first and second factors respectively.

If *U* and *V* are the respective CDFs of *u* and *v*, this distance also equals to:

$$l_1(u, v) = \int_{-\infty}^{+\infty} |U - V|$$

See [2] for a proof of the equivalence of both definitions.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

## Examples

```
>>> from scipy.stats import wasserstein_distance
>>> wasserstein_distance([0, 1, 3], [5, 6, 8])
5.0
>>> wasserstein_distance([0, 1], [0, 1], [3, 1], [2, 2])
0.25
>>> wasserstein_distance([3.4, 3.9, 7.5, 7.8], [4.5, 1.4],
...                       [1.4, 0.9, 3.1, 7.2], [3.2, 3.5])
4.0781331438047861
```

## scipy.stats.energy\_distance

`scipy.stats.energy_distance` (*u\_values*, *v\_values*, *u\_weights=None*, *v\_weights=None*)

Compute the energy distance between two 1D distributions.

New in version 1.0.0.

### Parameters

#### **u\_values, v\_values**

[array\_like] Values observed in the (empirical) distribution.

#### **u\_weights, v\_weights**

[array\_like, optional] Weight for each value. If unspecified, each value is assigned the same weight. *u\_weights* (resp. *v\_weights*) must have the same length as *u\_values* (resp. *v\_values*). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

### Returns

**distance** [float] The computed distance between the distributions.

## Notes

The energy distance between two distributions  $u$  and  $v$ , whose respective CDFs are  $U$  and  $V$ , equals to:

$$D(u, v) = (2\mathbb{E}|X - Y| - \mathbb{E}|X - X'| - \mathbb{E}|Y - Y'|)^{1/2}$$

where  $X$  and  $X'$  (resp.  $Y$  and  $Y'$ ) are independent random variables whose probability distribution is  $u$  (resp.  $v$ ).

As shown in [2], for one-dimensional real-valued variables, the energy distance is linked to the non-distribution-free version of the Cramér-von Mises distance:

$$D(u, v) = \sqrt{2}l_2(u, v) = \left(2 \int_{-\infty}^{+\infty} (U - V)^2\right)^{1/2}$$

Note that the common Cramér-von Mises criterion uses the distribution-free version of the distance. See [2] (section 2), for more details about both versions of the distance.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

```

### 6.29.13 Random variate generation

---

<code>rvs_ratio_uniforms(pdf, umax, vmin, vmax[, ...])</code>	Generate random samples from a probability density function using the ratio-of-uniforms method.
---	---

---

#### `scipy.stats.rvs_ratio_uniforms`

`scipy.stats.rvs_ratio_uniforms` (*pdf, umax, vmin, vmax, size=1, c=0, random\_state=None*)  
 Generate random samples from a probability density function using the ratio-of-uniforms method.

##### Parameters

<b>pdf</b>	[callable] A function with signature <i>pdf(x)</i> that is proportional to the probability density function of the distribution.
<b>umax</b>	[float] The upper bound of the bounding rectangle in the u-direction.
<b>vmin</b>	[float] The lower bound of the bounding rectangle in the v-direction.
<b>vmax</b>	[float] The upper bound of the bounding rectangle in the v-direction.
<b>size</b>	[int or tuple of ints, optional] Defining number of random variates (default is 1).
<b>c</b>	[float, optional.] Shift parameter of ratio-of-uniforms method, see Notes. Default is 0.
<b>random_state</b>	[{None, int, <i>RandomState</i> , <i>Generator</i> }, optional] If <i>random_state</i> is <i>None</i> the <i>RandomState</i> singleton is used. If <i>random_state</i> is an int, a new <i>RandomState</i> instance is used, seeded with <i>random_state</i> . If <i>random_state</i> is already a <i>RandomState</i> or <i>Generator</i> instance, then that object is used. Default is <i>None</i> .

##### Returns

<b>rvs</b>	[ndarray] The random variates distributed according to the probability distribution defined by the pdf.
------------	---

## Notes

Given a univariate probability density function  $pdf$  and a constant  $c$ , define the set  $A = \{(u, v) : 0 < u \leq \sqrt{pdf(v/u + c)}\}$ . If  $(U, V)$  is a random vector uniformly distributed over  $A$ , then  $V/U + c$  follows a distribution according to  $pdf$ .

The above result (see [1], [2]) can be used to sample random variables using only the pdf, i.e. no inversion of the cdf is required. Typical choices of  $c$  are zero or the mode of  $pdf$ . The set  $A$  is a subset of the rectangle  $R = [0, umax] \times [vmin, vmax]$  where

- $umax = \sup \sqrt{pdf(x)}$
- $vmin = \inf (x - c) \sqrt{pdf(x)}$
- $vmax = \sup (x - c) \sqrt{pdf(x)}$

In particular, these values are finite if  $pdf$  is bounded and  $x^2 * pdf(x)$  is bounded (i.e. subquadratic tails). One can generate  $(U, V)$  uniformly on  $R$  and return  $V/U + c$  if  $(U, V)$  are also in  $A$  which can be directly verified.

The algorithm is not changed if one replaces  $pdf$  by  $k * pdf$  for any constant  $k > 0$ . Thus, it is often convenient to work with a function that is proportional to the probability density function by dropping unnecessary normalization factors.

Intuitively, the method works well if  $A$  fills up most of the enclosing rectangle such that the probability is high that  $(U, V)$  lies in  $A$  whenever it lies in  $R$  as the number of required iterations becomes too large otherwise. To be more precise, note that the expected number of iterations to draw  $(U, V)$  uniformly distributed on  $R$  such that  $(U, V)$  is also in  $A$  is given by the ratio  $area(R) / area(A) = 2 * umax * (vmax - vmin) / area(pdf)$ , where  $area(pdf)$  is the integral of  $pdf$  (which is equal to one if the probability density function is used but can take on other values if a function proportional to the density is used). The equality holds since the area of  $A$  is equal to  $0.5 * area(pdf)$  (Theorem 7.1 in [1]). If the sampling fails to generate a single random variate after 50000 iterations (i.e. not a single draw is in  $A$ ), an exception is raised.

If the bounding rectangle is not correctly specified (i.e. if it does not contain  $A$ ), the algorithm samples from a distribution different from the one given by  $pdf$ . It is therefore recommended to perform a test such as `kstest` as a check.

## References

[1], [2], [3]

## Examples

```
>>> from scipy import stats
```

Simulate normally distributed random variables. It is easy to compute the bounding rectangle explicitly in that case. For simplicity, we drop the normalization factor of the density.

```
>>> f = lambda x: np.exp(-x**2 / 2)
>>> v_bound = np.sqrt(f(np.sqrt(2))) * np.sqrt(2)
>>> umax, vmin, vmax = np.sqrt(f(0)), -v_bound, v_bound
>>> np.random.seed(12345)
>>> rvs = stats.rvs_ratio_uniforms(f, umax, vmin, vmax, size=2500)
```

The K-S test confirms that the random variates are indeed normally distributed (normality is not rejected at 5% significance level):

```
>>> stats.kstest(rvs, 'norm')[1]
0.33783681428365553
```

The exponential distribution provides another example where the bounding rectangle can be determined explicitly.

```
>>> np.random.seed(12345)
>>> rvs = stats.rvs_ratio_uniforms(lambda x: np.exp(-x), umax=1,
...                               vmin=0, vmax=2*np.exp(-1), size=1000)
>>> stats.kstest(rvs, 'expon')[1]
0.928454552559516
```

## 6.29.14 Circular statistical functions

<code>circmean(samples[, high, low, axis, nan_policy])</code>	Compute the circular mean for samples in a range.
<code>circvar(samples[, high, low, axis, nan_policy])</code>	Compute the circular variance for samples assumed to be in a range.
<code>circstd(samples[, high, low, axis, nan_policy])</code>	Compute the circular standard deviation for samples assumed to be in the range [low to high].

### scipy.stats.circmean

```
scipy.stats.circmean(samples, high=6.283185307179586, low=0, axis=None,
nan_policy='propagate')
```

Compute the circular mean for samples in a range.

#### Parameters

- samples** [array\_like] Input array.
- high** [float or int, optional] High boundary for circular mean range. Default is  $2\pi$ .
- low** [float or int, optional] Low boundary for circular mean range. Default is 0.
- axis** [int, optional] Axis along which means are computed. The default is to compute the mean of the flattened array.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

#### Returns

- circmean** [float] Circular mean.

### Examples

```
>>> from scipy.stats import circmean
>>> circmean([0.1, 2*np.pi+0.2, 6*np.pi+0.3])
0.2
```

```
>>> from scipy.stats import circmean
>>> circmean([0.2, 1.4, 2.6], high = 1, low = 0)
0.4
```

## scipy.stats.circvar

`scipy.stats.circvar` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None, *nan\_policy*='propagate')

Compute the circular variance for samples assumed to be in a range.

### Parameters

**samples** [array\_like] Input array.  
**high** [float or int, optional] High boundary for circular variance range. Default is  $2\pi$ .  
**low** [float or int, optional] Low boundary for circular variance range. Default is 0.  
**axis** [int, optional] Axis along which variances are computed. The default is to compute the variance of the flattened array.  
**nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

**circvar** [float] Circular variance.

### Notes

This uses a definition of circular variance that in the limit of small angles returns a number close to the 'linear' variance.

### Examples

```
>>> from scipy.stats import circvar
>>> circvar([0, 2*np.pi/3, 5*np.pi/3])
2.19722457734
```

## scipy.stats.circstd

`scipy.stats.circstd` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None, *nan\_policy*='propagate')

Compute the circular standard deviation for samples assumed to be in the range [low to high].

### Parameters

**samples** [array\_like] Input array.  
**high** [float or int, optional] High boundary for circular standard deviation range. Default is  $2\pi$ .  
**low** [float or int, optional] Low boundary for circular standard deviation range. Default is 0.  
**axis** [int, optional] Axis along which standard deviations are computed. The default is to compute the standard deviation of the flattened array.  
**nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

**circstd** [float] Circular standard deviation.

## Notes

This uses a definition of circular standard deviation that in the limit of small angles returns a number close to the ‘linear’ standard deviation.

## Examples

```
>>> from scipy.stats import circstd
>>> circstd([0, 0.1*np.pi/2, 0.001*np.pi, 0.03*np.pi/2])
0.063564063306
```

## 6.29.15 Contingency table functions

<code>chi2_contingency(observed[, lambda_])</code>	<code>correction,</code>	Chi-square test of independence of variables in a contingency table.
<code>contingency.expected_freq(observed)</code>		Compute the expected frequencies from a contingency table.
<code>contingency.margins(a)</code>		Return a list of the marginal sums of the array <i>a</i> .
<code>fisher_exact(table[, alternative])</code>		Perform a Fisher exact test on a 2x2 contingency table.

### scipy.stats.chi2\_contingency

`scipy.stats.chi2_contingency(observed, correction=True, lambda_=None)`

Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table [1] *observed*. The expected frequencies are computed based on the marginal sums under the assumption of independence; see `scipy.stats.contingency.expected_freq`. The number of degrees of freedom is (expressed using numpy functions and attributes):

```
dof = observed.size - sum(observed.shape) + observed.ndim - 1
```

#### Parameters

- observed** [array\_like] The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.
- correction** [bool, optional] If True, *and* the degrees of freedom is 1, apply Yates’ correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.
- lambda\_** [float or str, optional.] By default, the statistic computed in this test is Pearson’s chi-squared statistic [2]. *lambda\_* allows a statistic from the Cressie-Read power divergence family [3] to be used instead. See `power_divergence` for details.

#### Returns

- chi2** [float] The test statistic.
- p** [float] The p-value of the test
- dof** [int] Degrees of freedom
- expected** [ndarray, same shape as *observed*] The expected frequencies, based on the marginal sums of the table.

See also:

[contingency.expected\\_freq](#)

[fisher\\_exact](#)

[chisquare](#)

[power\\_divergence](#)

## Notes

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequencies in each cell are at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of *observed* is two or more. Applying the test to a one-dimensional table will always result in *expected* equal to *observed* and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.

Like `stats.chisquare`, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates' correction was not required, one could use `stats.chisquare`. That is, if one calls:

```
chi2, p, dof, ex = chi2_contingency(obs, correction=False)
```

then the following is true:

```
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(),
                             ddof=obs.size - 1 - dof)
```

The `lambda_` argument was added in version 0.13.0 of scipy.

## References

[1], [2], [3]

## Examples

A two-way example (2 x 3):

```
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20], [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777,
 0.24935220877729619,
 2,
 array([[ 12.,  12.,  16.],
        [ 18.,  18.,  24.]])
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```
>>> g, p, dof, expctd = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```
>>> obs = np.array(
...     [[[[12, 17],
...         [11, 16]],
...         [[11, 12],
...         [15, 16]]],
...     [[[[23, 15],
...         [30, 22]],
...         [[14, 17],
...         [15, 16]]]])
>>> chi2_contingency(obs)
(8.7584514426741897,
 0.64417725029295503,
 11,
 array([[[[[ 14.15462386,  14.15462386],
            [ 16.49423111,  16.49423111]],
         [[ 11.2461395 ,  11.2461395 ],
         [ 13.10500554,  13.10500554]]],
        [[ [ 19.5591166 ,  19.5591166 ],
            [ 22.79202844,  22.79202844]],
         [[ 15.54012004,  15.54012004],
         [ 18.10873492,  18.10873492]]]])
```

### scipy.stats.contingency.expected\_freq

scipy.stats.contingency.**expected\_freq**(*observed*)

Compute the expected frequencies from a contingency table.

Given an n-dimensional contingency table of observed frequencies, compute the expected frequencies for the table based on the marginal sums under the assumption that the groups associated with each dimension are independent.

#### Parameters

**observed** [array\_like] The table of observed frequencies. (While this function can handle a 1-D array, that case is trivial. Generally *observed* is at least 2-D.)

#### Returns

**expected** [ndarray of float64] The expected frequencies, based on the marginal sums of the table. Same shape as *observed*.

## Examples

```
>>> observed = np.array([[10, 10, 20],[20, 20, 20]])
>>> from scipy.stats.contingency import expected_freq
>>> expected_freq(observed)
array([[ 12.,  12.,  16.],
       [ 18.,  18.,  24.]])
```

## scipy.stats.contingency.margins

`scipy.stats.contingency.margins(a)`

Return a list of the marginal sums of the array *a*.

### Parameters

**a** [ndarray] The array for which to compute the marginal sums.

### Returns

**margsums** [list of ndarrays] A list of length *a.ndim*. *margsums[k]* is the result of summing *a* over all axes except *k*; it has the same number of dimensions as *a*, but the length of each axis except axis *k* will be 1.

## Examples

```
>>> a = np.arange(12).reshape(2, 6)
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11]])
>>> from scipy.stats.contingency import margins
>>> m0, m1 = margins(a)
>>> m0
array([[15],
       [51]])
>>> m1
array([[ 6,  8, 10, 12, 14, 16]])
```

```
>>> b = np.arange(24).reshape(2, 3, 4)
>>> m0, m1, m2 = margins(b)
>>> m0
array([[[ 66]],
       [[210]])]
>>> m1
array([[[ 60],
       [ 92],
       [124]])]
>>> m2
array([[[60, 66, 72, 78]])]
```

## scipy.stats.fisher\_exact

`scipy.stats.fisher_exact` (*table*, *alternative*='two-sided')

Perform a Fisher exact test on a 2x2 contingency table.

### Parameters

- table** [array\_like of ints] A 2x2 contingency table. Elements should be non-negative integers.
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
- ‘two-sided’
  - ‘less’: one-sided
  - ‘greater’: one-sided

### Returns

- oddsratio** [float] This is prior odds ratio and not a posterior estimate.
- p\_value** [float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

See also:

### [chi2\\_contingency](#)

Chi-square test of independence of variables in a contingency table.

### Notes

The calculated odds ratio is different from the one R uses. This scipy implementation returns the (more common) “unconditional Maximum Likelihood Estimate”, while R uses the “conditional Maximum Likelihood Estimate”.

For tables with large numbers, the (inexact) chi-square test implemented in the function `chi2_contingency` can also be used.

### Examples

Say we spend a few days counting whales and sharks in the Atlantic and Indian oceans. In the Atlantic ocean we find 8 whales and 1 shark, in the Indian ocean 2 whales and 5 sharks. Then our contingency table is:

	Atlantic	Indian
whales	8	2
sharks	1	5

We use this table to find the p-value:

```
>>> import scipy.stats as stats
>>> oddsratio, pvalue = stats.fisher_exact([[8, 2], [1, 5]])
>>> pvalue
0.0349...
```

The probability that we would observe this or an even more imbalanced ratio by chance is about 3.5%. A commonly used significance level is 5%—if we adopt that, we can therefore conclude that our observed imbalance is statistically significant; whales prefer the Atlantic while sharks prefer the Indian ocean.

## 6.29.16 Plot-tests

<code>ppcc_max(x[, brack, dist])</code>	Calculate the shape parameter that maximizes the PPCC.
<code>ppcc_plot(x, a, b[, dist, plot, N])</code>	Calculate and optionally plot probability plot correlation coefficient.
<code>probplot(x[, sparams, dist, fit, plot, rvalue])</code>	Calculate quantiles for a probability plot, and optionally show the plot.
<code>boxcox_normplot(x, la, lb[, plot, N])</code>	Compute parameters for a Box-Cox normality plot, optionally show it.
<code>yeojohnson_normplot(x, la, lb[, plot, N])</code>	Compute parameters for a Yeo-Johnson normality plot, optionally show it.

### scipy.stats.ppcc\_max

`scipy.stats.ppcc_max(x, brack=0.0, 1.0, dist='tukeylambda')`

Calculate the shape parameter that maximizes the PPCC.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. `ppcc_max` returns the shape parameter that would maximize the probability plot correlation coefficient for the given data to a one-parameter family of distributions.

#### Parameters

- x** [array\_like] Input array.
- brack** [tuple, optional] Triple (a,b,c) where (a<b<c). If bracket consists of two numbers (a, c) then they are assumed to be a starting interval for a downhill bracket search (see `scipy.optimize.brent`).
- dist** [str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted. The default is `'tukeylambda'`.

#### Returns

- shape\_value** [float] The shape parameter at which the probability plot correlation coefficient reaches its max value.

#### See also:

`ppcc_plot`, `probplot`, `boxcox`

#### Notes

The `brack` keyword serves as a starting point which is useful in corner cases. One can use a plot to obtain a rough visual estimate of the location for the maximum to start the search near it.

## References

[1], [2]

## Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```
>>> from scipy import stats
>>> x = stats.tukeylambd.rvs(-0.7, loc=2, scale=0.5, size=10000,
...                          random_state=1234567) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(8, 6))
>>> ax = fig.add_subplot(111)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax)
```

We calculate the value where the shape should reach its maximum and a red line is drawn there. The line should coincide with the highest point in the `ppcc_plot`.

```
>>> max = stats.ppcc_max(x)
>>> ax.vlines(max, 0, 1, colors='r', label='Expected shape value')
```

```
>>> plt.show()
```

## scipy.stats.ppcc\_plot

`scipy.stats.ppcc_plot(x, a, b, dist='tukeylambda', plot=None, N=80)`

Calculate and optionally plot probability plot correlation coefficient.

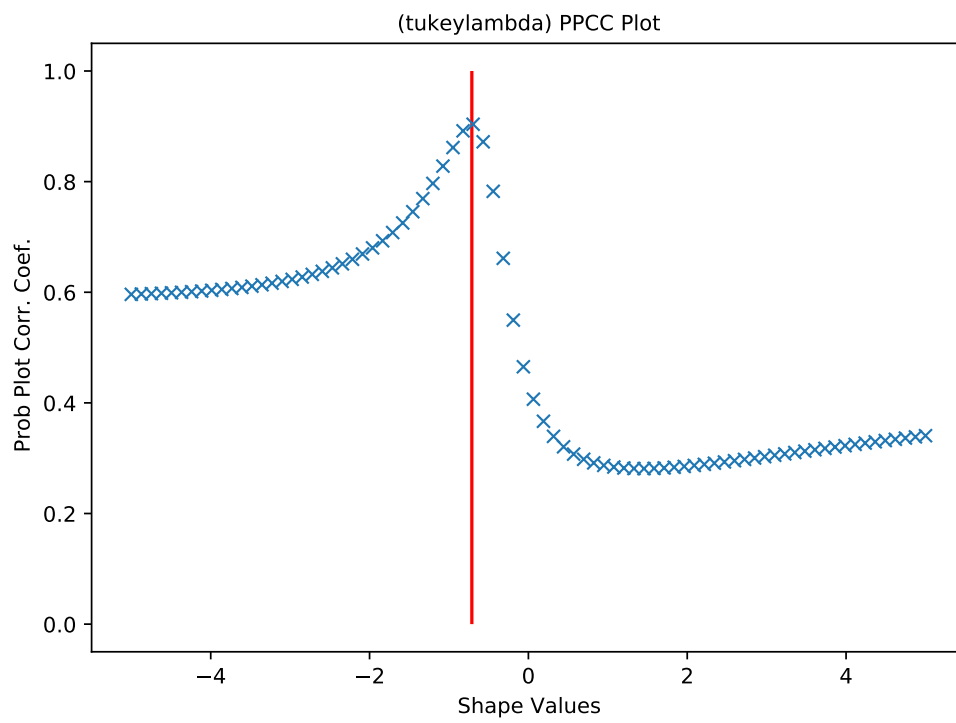

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. It cannot be used for distributions without shape parameters (like the normal distribution) or with multiple shape parameters.

By default a Tukey-Lambda distribution (`stats.tukeylambda`) is used. A Tukey-Lambda PPCC plot interpolates from long-tailed to short-tailed distributions via an approximately normal one, and is therefore particularly useful in practice.

### Parameters

<b>x</b>	[array_like] Input array.
<b>a, b</b>	[scalar] Lower and upper bounds of the shape parameter to use.
<b>dist</b>	[str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a <code>stats.distributions</code> instance (i.e. they have a <code>ppf</code> method) are also accepted. The default is <code>'tukeylambda'</code> .
<b>plot</b>	[object, optional] If given, plots PPCC against the shape parameter. <code>plot</code> is an object that has to have methods “plot” and “text”. The <code>matplotlib.pyplot</code> module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is <code>None</code> , which means that no plot is created.
<b>N</b>	[int, optional] Number of points on the horizontal axis (equally distributed from <code>a</code> to <code>b</code> ).

### Returns

**svals** [ndarray] The shape values for which *ppcc* was calculated.  
**ppcc** [ndarray] The calculated probability plot correlation coefficient values.

## References

J.J. Filliben, “The Probability Plot Correlation Coefficient Test for Normality”, *Technometrics*, Vol. 17, pp. 111-117, 1975.

## Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234567)
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```
>>> fig = plt.figure(figsize=(12, 4))
>>> ax1 = fig.add_subplot(131)
>>> ax2 = fig.add_subplot(132)
>>> ax3 = fig.add_subplot(133)
>>> res = stats.probplot(x, plot=ax1)
>>> res = stats.boxcox_normplot(x, -5, 5, plot=ax2)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax3)
>>> ax3.vlines(-0.7, 0, 1, colors='r', label='Expected shape value')
>>> plt.show()
```

**scipy.stats.probplot**

`scipy.stats.probplot` (*x*, *sparams*=(), *dist*='norm', *fit*=True, *plot*=None, *rvalue*=False)

Calculate quantiles for a probability plot, and optionally show the plot.

Generates a probability plot of sample data against the quantiles of a specified theoretical distribution (the normal distribution by default). `probplot` optionally calculates a best-fit line for the data and plots the results using Matplotlib or a given plot function.

**Parameters**

<b>x</b>	[array_like] Sample/response data from which <code>probplot</code> creates the plot.
<b>sparams</b>	[tuple, optional] Distribution-specific shape parameters (shape parameters plus location and scale).
<b>dist</b>	[str or stats.distributions instance, optional] Distribution or distribution function name. The default is 'norm' for a normal probability plot. Objects that look enough like a stats.distributions instance (i.e. they have a <code>ppf</code> method) are also accepted.
<b>fit</b>	[bool, optional] Fit a least-squares regression (best-fit) line to the sample data if True (default).
<b>plot</b>	[object, optional] If given, plots the quantiles and least squares fit. <code>plot</code> is an object that has to have methods "plot" and "text". The <code>matplotlib.pyplot</code> module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

**Returns**

<b>(osm, osr)</b>	[tuple of ndarrays] Tuple of theoretical quantiles ( <code>osm</code> , or order statistic medians) and ordered responses ( <code>osr</code> ). <code>osr</code> is simply sorted input <code>x</code> . For details on how <code>osm</code> is calculated see the Notes section.
<b>(slope, intercept, r)</b>	[tuple of floats, optional] Tuple containing the result of the least-squares fit, if that is performed by <code>probplot</code> . <code>r</code> is the square root of the coefficient of determination. If <code>fit=False</code> and <code>plot=None</code> , this tuple is not returned.

**Notes**

Even if `plot` is given, the figure is not shown or saved by `probplot`; `plt.show()` or `plt.savefig('filename.png')` should be used after calling `probplot`.

`probplot` generates a probability plot, which should not be confused with a Q-Q or a P-P plot. Statsmodels has more extensive functionality of this type, see `statsmodels.api.ProbPlot`.

The formula used for the theoretical quantiles (horizontal axis of the probability plot) is Filliben's estimate:

```
quantiles = dist.ppf(val), for
    0.5**(1/n), for i = n
val = (i - 0.3175) / (n + 0.365), for i = 2, ..., n-1
    1 - 0.5**(1/n), for i = 1
```

where `i` indicates the `i`-th ordered value and `n` is the total number of values.

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> nsample = 100
>>> np.random.seed(7654321)
```

A t distribution with small degrees of freedom:

```
>>> ax1 = plt.subplot(221)
>>> x = stats.t.rvs(3, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A t distribution with larger degrees of freedom:

```
>>> ax2 = plt.subplot(222)
>>> x = stats.t.rvs(25, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A mixture of two normal distributions with broadcasting:

```
>>> ax3 = plt.subplot(223)
>>> x = stats.norm.rvs(loc=[0,5], scale=[1,1.5],
...                   size=(nsample//2,2)).ravel()
>>> res = stats.probplot(x, plot=plt)
```

A standard normal distribution:

```
>>> ax4 = plt.subplot(224)
>>> x = stats.norm.rvs(loc=0, scale=1, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

Produce a new figure with a loggamma distribution, using the `dist` and `sparams` keywords:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = stats.loggamma.rvs(c=2.5, size=500)
>>> res = stats.probplot(x, dist=stats.loggamma, sparams=(2.5,), plot=ax)
>>> ax.set_title("Probplot for loggamma dist with shape parameter 2.5")
```

Show the results with Matplotlib:

```
>>> plt.show()
```

## scipy.stats.boxcox\_normplot

`scipy.stats.boxcox_normplot` (*x*, *la*, *lb*, *plot=None*, *N=80*)

Compute parameters for a Box-Cox normality plot, optionally show it.

A Box-Cox normality plot shows graphically what the best transformation parameter is to use in `boxcox` to obtain a distribution that is close to normal.

### Parameters

**x** [array\_like] Input array.

<b>la, lb</b>	[scalar] The lower and upper bounds for the <code>lambda</code> values to pass to <code>boxcox</code> for Box-Cox transformations. These are also the limits of the horizontal axis of the plot if that is generated.
<b>plot</b>	[object, optional] If given, plots the quantiles and least squares fit. <code>plot</code> is an object that has to have methods “plot” and “text”. The <code>matplotlib.pyplot</code> module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is <code>None</code> , which means that no plot is created.
<b>N</b>	[int, optional] Number of points on the horizontal axis (equally distributed from <code>la</code> to <code>lb</code> ).

**Returns**

<b>lmbdas</b>	[ndarray] The <code>lambda</code> values for which a Box-Cox transform was done.
<b>ppcc</b>	[ndarray] Probability Plot Correlation Coefficient, as obtained from <code>probplot</code> when fitting the Box-Cox transformed input <code>x</code> against a normal distribution.

**See also:**

`probplot`, `boxcox`, `boxcox_normmax`, `boxcox_llf`, `ppcc_max`

**Notes**

Even if `plot` is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('filename.png')` should be used after calling `probplot`.

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some non-normally distributed data, and create a Box-Cox plot:

```
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal `lambda` to transform `x` and plot it in the same plot:

```
>>> _, maxlog = stats.boxcox(x)
>>> ax.axvline(maxlog, color='r')
```

```
>>> plt.show()
```

**scipy.stats.yeojohnson\_normplot**

`scipy.stats.yeojohnson_normplot(x, la, lb, plot=None, N=80)`

Compute parameters for a Yeo-Johnson normality plot, optionally show it.

A Yeo-Johnson normality plot shows graphically what the best transformation parameter is to use in `yeojohnson` to obtain a distribution that is close to normal.

**Parameters**

**x** [array\_like] Input array.

- la, lb** [scalar] The lower and upper bounds for the `lambda` values to pass to `yeojohnson` for Yeo-Johnson transformations. These are also the limits of the horizontal axis of the plot if that is generated.
- plot** [object, optional] If given, plots the quantiles and least squares fit. `plot` is an object that has to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is `None`, which means that no plot is created.
- N** [int, optional] Number of points on the horizontal axis (equally distributed from `la` to `lb`).
- Returns**
- lmbdas** [ndarray] The `lambda` values for which a Yeo-Johnson transform was done.
- ppcc** [ndarray] Probability Plot Correlation Coefficient, as obtained from `probplot` when fitting the Box-Cox transformed input `x` against a normal distribution.

See also:

`probplot`, `yeojohnson`, `yeojohnson_normmax`, `yeojohnson_llf`, `ppcc_max`

## Notes

Even if `plot` is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('figname.png')` should be used after calling `probplot`.

New in version 1.2.0.

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some non-normally distributed data, and create a Yeo-Johnson plot:

```
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.yeojohnson_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal `lambda` to transform `x` and plot it in the same plot:

```
>>> _, maxlog = stats.yeojohnson(x)
>>> ax.axvline(maxlog, color='r')
```

```
>>> plt.show()
```

## 6.29.17 Masked statistics functions

### Statistical functions for masked arrays (`scipy.stats.mstats`)

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in `scipy.stats` but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

#### Summary statistics

<code>describe(a[, axis, ddof, bias])</code>	Computes several descriptive statistics of the passed array.
<code>gmean(a[, axis, dtype])</code>	Compute the geometric mean along the specified axis.
<code>hmean(a[, axis, dtype])</code>	Calculate the harmonic mean along the specified axis.
<code>kurtosis(a[, axis, fisher, bias])</code>	Computes the kurtosis (Fisher or Pearson) of a dataset.
<code>mode(a[, axis])</code>	Returns an array of the modal (most common) value in the passed array.
<code>mquantiles(a[, prob, alphap, betap, axis, limit])</code>	Computes empirical quantiles for a data array.
<code>hdmedian(data[, axis, var])</code>	Returns the Harrell-Davis estimate of the median along the given axis.
<code>hdquantiles(data[, prob, axis, var])</code>	Computes quantile estimates with the Harrell-Davis method.
<code>hdquantiles_sd(data[, prob, axis])</code>	The standard error of the Harrell-Davis quantile estimates by jackknife.
<code>idealfourths(data[, axis])</code>	Returns an estimate of the lower and upper quartiles.
<code>plotting_positions(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>meppf(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>moment(a[, moment, axis])</code>	Calculates the nth moment about the mean for a sample.
<code>skew(a[, axis, bias])</code>	Computes the skewness of a data set.
<code>tmean(a[, limits, inclusive, axis])</code>	Compute the trimmed mean.
<code>tvar(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed variance
<code>tmin(a[, lowerlimit, axis, inclusive])</code>	Compute the trimmed minimum
<code>tmax(a[, upperlimit, axis, inclusive])</code>	Compute the trimmed maximum
<code>tsem(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed standard error of the mean.
<code>variation(a[, axis])</code>	Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.
<code>find_repeats(arr)</code>	Find repeats in arr and return a tuple (repeats, repeat_count).
<code>sem(a[, axis, ddof])</code>	Calculates the standard error of the mean of the input array.
<code>trimmed_mean(a[, limits, inclusive, ...])</code>	Returns the trimmed mean of the data along the given axis.
<code>trimmed_mean_ci(data[, limits, inclusive, ...])</code>	Selected confidence interval of the trimmed mean along the given axis.
<code>trimmed_std(a[, limits, inclusive, ...])</code>	Returns the trimmed standard deviation of the data along the given axis.
<code>trimmed_var(a[, limits, inclusive, ...])</code>	Returns the trimmed variance of the data along the given axis.

**scipy.stats.mstats.describe**

`scipy.stats.mstats.describe` (*a*, *axis*=0, *ddof*=0, *bias*=True)

Computes several descriptive statistics of the passed array.

**Parameters**

<b>a</b>	[array_like] Data array
<b>axis</b>	[int or None, optional] Axis along which to calculate statistics. Default 0. If None, compute over the whole array <i>a</i> .
<b>ddof</b>	[int, optional] degree of freedom (default 0); note that default ddof is different from the same routine in <code>stats.describe</code>
<b>bias</b>	[bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.

**Returns**

<b>nobs</b>	[int] (size of the data (discarding missing values))
<b>minmax</b>	[(int, int)] min, max
<b>mean</b>	[float] arithmetic mean
<b>variance</b>	[float] unbiased variance
<b>skewness</b>	[float] biased skewness
<b>kurtosis</b>	[float] biased kurtosis

**Examples**

```
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult(nobs=3, minmax=(masked_array(data=0,
      mask=False,
      fill_value=999999), masked_array(data=2,
      mask=False,
      fill_value=999999)), mean=1.0, variance=0.6666666666666666,
skewness=masked_array(data=0., mask=False, fill_value=1e+20),
kurtosis=-1.5)
```

**scipy.stats.mstats.gmean**

`scipy.stats.mstats.gmean` (*a*, *axis*=0, *dtype*=None)

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is:  $n$ -th root of  $(x_1 * x_2 * \dots * x_n)$

**Parameters**

<b>a</b>	[array_like] Input array or object that can be converted to an array.
<b>axis</b>	[int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array <i>a</i> .
<b>dtype</b>	[dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of <i>a</i> , unless <i>a</i> has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

**gmean** [ndarray] See *dtype* parameter above.

See also:

*numpy.mean*

Arithmetic average

*numpy.average*

Weighted average

**hmean**

Harmonic mean

## Notes

The geometric average is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

## Examples

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

## scipy.stats.mstats.hmean

`scipy.stats.mstats.hmean` (*a*, *axis=0*, *dtype=None*)

Calculate the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

### Parameters

- a** [array\_like] Input array, masked array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

### Returns

**hmean** [ndarray] See *dtype* parameter above.

See also:

*numpy.mean*

Arithmetic average

***numpy.average***

Weighted average

***gmean***

Geometric mean

**Notes**

The harmonic mean is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

**Examples**

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

**`scipy.stats.mstats.kurtosis`**

`scipy.stats.mstats.kurtosis` (*a*, *axis=0*, *fisher=True*, *bias=True*)

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If `bias` is `False` then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

***Parameters***

- a** [array] data for which the kurtosis is calculated
- axis** [int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array *a*.
- fisher** [bool, optional] If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
- bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

***Returns***

- kurtosis** [array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.

## Notes

For more details about *kurtosis*, see *stats.kurtosis*.

## scipy.stats.mstats.mode

`scipy.stats.mstats.mode(a, axis=0)`

Returns an array of the modal (most common) value in the passed array.

### Parameters

**a** [array\_like] n-dimensional array of which to find mode(s).  
**axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

### Returns

**mode** [ndarray] Array of modal values.  
**count** [ndarray] Array of counts for each mode.

## Notes

For more details, see *stats.mode*.

## Examples

```
>>> from scipy import stats
>>> from scipy.stats import mstats
>>> m_arr = np.ma.array([1, 1, 0, 0, 0, 0], mask=[0, 0, 1, 1, 1, 0])
>>> stats.mode(m_arr)
ModeResult(mode=array([0]), count=array([4]))
>>> mstats.mode(m_arr)
ModeResult(mode=array([1.]), count=array([2.]))
```

## scipy.stats.mstats.mquantiles

`scipy.stats.mstats.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())`

Computes empirical quantiles for a data array.

Samples quantile are defined by  $Q(p) = (1-\gamma)*x[j] + \gamma*x[j+1]$ , where  $x[j]$  is the  $j$ -th order statistic, and  $\gamma$  is a function of  $j = \text{floor}(n*p + m)$ ,  $m = \text{alphap} + p*(1 - \text{alphap} - \text{betap})$  and  $g = n*p + m - j$ .

Rinterpreting the above equations to compare to **R** lead to the equation:  $p(k) = (k - \text{alphap}) / (n + 1 - \text{alphap} - \text{betap})$

**Typical values of (alphap,betap) are:**

- (0,1):  $p(k) = k/n$ : linear interpolation of cdf (**R** type 4)
- (.5,.5):  $p(k) = (k - 1/2.) / n$ : piecewise linear function (**R** type 5)
- (0,0):  $p(k) = k / (n+1)$ : (**R** type 6)

- (1,1):  $p(k) = (k-1) / (n-1)$ :  $p(k) = \text{mode}[F(x[k])]$ . (**R** type 7, **R** default)
- (1/3,1/3):  $p(k) = (k-1/3) / (n+1/3)$ : Then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (**R** type 8)
- (3/8,3/8):  $p(k) = (k-3/8) / (n+1/4)$ : Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (**R** type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM

**Parameters**

<b>a</b>	[array_like] Input data, as a sequence or array of dimension at most 2.
<b>prob</b>	[array_like, optional] List of quantiles to compute.
<b>alphap</b>	[float, optional] Plotting positions parameter, default is 0.4.
<b>betap</b>	[float, optional] Plotting positions parameter, default is 0.4.
<b>axis</b>	[int, optional] Axis along which to perform the trimming. If None (default), the input array is first flattened.
<b>limit</b>	[tuple, optional] Tuple of (lower, upper) values. Values of $a$ outside this open interval are ignored.

**Returns**

<b>mquantiles</b>	[MaskedArray] An array containing the calculated quantiles.
-------------------	---

**Notes**

This formulation is very similar to **R** except the calculation of  $m$  from `alphap` and `betap`, where in **R**  $m$  is defined with each type.

**References**

[1], [2]

**Examples**

```
>>> from scipy.stats.mstats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([ 19.2,  40. ,  42.8])
```

Using a 2D array, specifying axis and limit.

```
>>> data = np.array([[ 6.,  7.,  1.],
...                 [ 47., 15.,  2.],
...                 [ 49., 36.,  3.],
...                 [ 15., 39.,  4.],
...                 [ 42., 40., -999.],
...                 [ 41., 41., -999.],
...                 [  7., -999., -999.],
...                 [ 39., -999., -999.]])
```

(continues on next page)

(continued from previous page)

```

...           [ 43., -999., -999.],
...           [ 40., -999., -999.],
...           [ 36., -999., -999.]]
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.2  14.6  1.45]
 [40.   37.5  2.5 ]
 [42.8  40.05  3.55]]

```

```

>>> data[:, 2] = -999.
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]

```

### scipy.stats.mstats.hdmedian

`scipy.stats.mstats.hdmedian` (*data*, *axis=-1*, *var=False*)

Returns the Harrell-Davis estimate of the median along the given axis.

#### Parameters

**data** [ndarray] Data array.  
**axis** [int, optional] Axis along which to compute the quantiles. If None, use a flattened array.  
**var** [bool, optional] Whether to return the variance of the estimate.

#### Returns

**hdmedian** [MaskedArray] The median values. If *var=True*, the variance is returned inside the masked array. E.g. for a 1-D array the shape change from (1,) to (2,).

### scipy.stats.mstats.hdquantiles

`scipy.stats.mstats.hdquantiles` (*data*, *prob=[0.25, 0.5, 0.75]*, *axis=None*, *var=False*)

Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

#### Parameters

**data** [array\_like] Data array.  
**prob** [sequence, optional] Sequence of quantiles to compute.  
**axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.  
**var** [bool, optional] Whether to return the variance of the estimate.

#### Returns

**hdquantiles** [MaskedArray] A (p,) array of quantiles (if *var* is False), or a (2,p) array of quantiles and variances (if *var* is True), where p is the number of quantiles.

See also:

[hdquantiles\\_sd](#)

**scipy.stats.mstats.hdquantiles\_sd**

`scipy.stats.mstats.hdquantiles_sd` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

The standard error of the Harrell-Davis quantile estimates by jackknife.

**Parameters**

**data** [array\_like] Data array.  
**prob** [sequence, optional] Sequence of quantiles to compute.  
**axis** [int, optional] Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

**hdquantiles\_sd**  
 [MaskedArray] Standard error of the Harrell-Davis quantile estimates.

See also:

[hdquantiles](#)

**scipy.stats.mstats.idealfourths**

`scipy.stats.mstats.idealfourths` (*data*, *axis*=None)

Returns an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

**Parameters**

**data** [array\_like] Input array.  
**axis** [int, optional] Axis along which the quartiles are estimated. If None, the arrays are flattened.

**Returns**

**idealfourths**  
 [{list of floats, masked array}] Returns the two internal values that divide *data* into four parts using the ideal fourths algorithm either along the flattened array (if *axis* is None) or along *axis* of *data*.

**scipy.stats.mstats.plotting\_positions**

`scipy.stats.mstats.plotting_positions` (*data*, *alpha*=0.4, *beta*=0.4)

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as  $(i - \alpha) / (n + 1 - \alpha - \beta)$ , where:*

- *i* is the rank order statistics
- *n* is the number of unmasked values along the given axis
- *alpha* and *beta* are two parameters.

*Typical values for alpha and beta are:*

- (0,1) :  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5) :  $p(k) = (k - 1/2) / n$ , piecewise linear function (R, type 5)
- (0,0) :  $p(k) = k / (n + 1)$ , Weibull (R type 6)

- (1,1):  $p(k) = (k-1)/(n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3)/(n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8)/(n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (R type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

- data** [array\_like] Input data, as a sequence or array of dimension at most 2.
- alpha** [float, optional] Plotting positions parameter. Default is 0.4.
- beta** [float, optional] Plotting positions parameter. Default is 0.4.

**Returns**

- positions** [MaskedArray] The calculated plotting positions.

**scipy.stats.mstats.meppf**

`scipy.stats.mstats.meppf(data, alpha=0.4, beta=0.4)`

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as  $(i-\alpha)/(n+1-\alpha-\beta)$ , where:*

- $i$  is the rank order statistics
- $n$  is the number of unmasked values along the given axis
- $\alpha$  and  $\beta$  are two parameters.

*Typical values for alpha and beta are:*

- (0,1):  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5):  $p(k) = (k-1/2)/n$ , piecewise linear function (R, type 5)
- (0,0):  $p(k) = k/(n+1)$ , Weibull (R type 6)
- (1,1):  $p(k) = (k-1)/(n-1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k-1/3)/(n+1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (R type 8)
- (3/8,3/8):  $p(k) = (k-3/8)/(n+1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (R type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

**Parameters**

**data** [array\_like] Input data, as a sequence or array of dimension at most 2.  
**alpha** [float, optional] Plotting positions parameter. Default is 0.4.  
**beta** [float, optional] Plotting positions parameter. Default is 0.4.

**Returns**

**positions** [MaskedArray] The calculated plotting positions.

**scipy.stats.mstats.moment**

`scipy.stats.mstats.moment(a, moment=1, axis=0)`

Calculates the nth moment about the mean for a sample.

**Parameters**

**a** [array\_like] data  
**moment** [int, optional] order of central moment that is returned  
**axis** [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.

**Returns****n-th central moment**

[ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**Notes**

For more details about *moment*, see *stats.moment*.

**scipy.stats.mstats.skew**

`scipy.stats.mstats.skew(a, axis=0, bias=True)`

Computes the skewness of a data set.

**Parameters**

**a** [ndarray] data  
**axis** [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.  
**bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

**Returns**

**skewness** [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

## Notes

For more details about *skew*, see *stats.skew*.

## scipy.stats.mstats.tmean

`scipy.stats.mstats.tmean` (*a*, *limits=None*, *inclusive=True*, *True*, *axis=None*)

Compute the trimmed mean.

### Parameters

<b>a</b>	[array_like] Array of values.
<b>limits</b>	[None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
<b>inclusive</b>	[(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
<b>axis</b>	[int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is None.

### Returns

<b>tmean</b>	[float]
--------------	---------

## Notes

For more details on *tmean*, see *stats.tmean*.

## Examples

```
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...              [3, 9, 1, 2],
...              [8, 7, 8, 2],
...              [5, 6, 0, 2],
...              [4, 5, 5, 2]])
...
...
>>> mstats.tmean(a, (2,5))
3.3
>>> mstats.tmean(a, (2,5), axis=0)
masked_array(data=[4.0, 5.0, 4.0, 2.0],
             mask=[False, False, False, False],
             fill_value=1e+20)
```

**scipy.stats.mstats.tvar**

`scipy.stats.mstats.tvar` (*a*, *limits=None*, *inclusive=True*, *True*, *axis=0*, *ddof=1*)

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

**Parameters**

- a** [array\_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is *None*, then all values are used. Either of the limit values in the tuple can also be *None* representing a half-open interval. The default value is *None*.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to operate. If *None*, compute over the whole array. Default is zero.
- ddof** [int, optional] Delta degrees of freedom. Default is 1.

**Returns**

- tvar** [float] Trimmed variance.

**Notes**

For more details on *tvar*, see *stats.tvar*.

**scipy.stats.mstats.tmin**

`scipy.stats.mstats.tmin` (*a*, *lowerlimit=None*, *axis=0*, *inclusive=True*)

Compute the trimmed minimum

**Parameters**

- a** [array\_like] array of values
- lowerlimit** [None or float, optional] Values in the input array less than the given limit will be ignored. When *lowerlimit* is *None*, then all values are used. The default value is *None*.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If *None*, compute over the whole array *a*.
- inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the lower limit are included. The default value is *True*.

**Returns**

- tmin** [float, int or ndarray]

## Notes

For more details on `tmin`, see `stats.tmin`.

## Examples

```
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...              [3, 2, 1, 2],
...              [8, 1, 8, 2],
...              [5, 3, 0, 2],
...              [4, 7, 5, 2]])
...
>>> mstats.tmin(a, 5)
masked_array(data=[5, 7, 5, --],
             mask=[False, False, False,  True],
             fill_value=999999)
```

## `scipy.stats.mstats.tmax`

`scipy.stats.mstats.tmax(a, upperlimit=None, axis=0, inclusive=True)`

Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

### Parameters

- a** [array\_like] array of values
- upperlimit** [None or float, optional] Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

### Returns

- tmax** [float, int or ndarray]

## Notes

For more details on `tmax`, see `stats.tmax`.

## Examples

```
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...              [3, 9, 1, 2],
...              [8, 7, 8, 2],
...              [5, 6, 0, 2],
...              [4, 5, 5, 2]])
...
...
>>> mstats.tmax(a, 4)
masked_array(data=[4, --, 3, 2],
             mask=[False,  True, False, False],
             fill_value=999999)
```

### scipy.stats.mstats.tsem

`scipy.stats.mstats.tsem(a, limits=None, inclusive=True, True, axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

#### Parameters

<b>a</b>	[array_like] array of values
<b>limits</b>	[None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When <i>limits</i> is <i>None</i> , then all values are used. Either of the limit values in the tuple can also be <i>None</i> representing a half-open interval. The default value is <i>None</i> .
<b>inclusive</b>	[(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
<b>axis</b>	[int or None, optional] Axis along which to operate. If <i>None</i> , compute over the whole array. Default is zero.
<b>ddof</b>	[int, optional] Delta degrees of freedom. Default is 1.

#### Returns

<b>tsem</b>	[float]
-------------	---------

## Notes

For more details on *tsem*, see *stats.tsem*.

## scipy.stats.mstats.variation

scipy.stats.mstats.**variation**(*a*, *axis=0*)

Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.

### Parameters

**a** [array\_like] Input array.  
**axis** [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.

### Returns

**variation** [ndarray] The calculated variation along the requested axis.

## Notes

For more details about *variation*, see *stats.variation*.

## Examples

```
>>> from scipy.stats.mstats import variation
>>> a = np.array([2, 8, 4])
>>> variation(a)
0.5345224838248487
>>> b = np.array([2, 8, 3, 4])
>>> c = np.ma.masked_array(b, mask=[0, 0, 1, 0])
>>> variation(c)
0.5345224838248487
```

In the example above, it can be seen that this works the same as *stats.variation* except 'stats.mstats.variation' ignores masked array elements.

## scipy.stats.mstats.find\_repeats

scipy.stats.mstats.**find\_repeats**(*arr*)

Find repeats in *arr* and return a tuple (repeats, repeat\_count).

The input is cast to float64. Masked values are discarded.

### Parameters

**arr** [sequence] Input array. The array is flattened if it is not 1D.

### Returns

**repeats** [ndarray] Array of repeated values.  
**counts** [ndarray] Array of counts.

**scipy.stats.mstats.sem**

`scipy.stats.mstats.sem(a, axis=0, ddof=1)`

Calculates the standard error of the mean of the input array.

Also sometimes called standard error of measurement.

**Parameters**

- a** [array\_like] An array containing the values for which the standard error is returned.
- axis** [int or None, optional] If axis is None, ravel *a* first. If axis is an integer, this will be the axis over which to operate. Defaults to 0.
- ddof** [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

**Returns**

- s** [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

**Notes**

The default value for *ddof* changed in scipy 0.15.0 to be consistent with *stats.sem* as well as with the most common definition used (like in the R documentation).

**Examples**

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903 2.8284271247461903 2.8284271247461903
 2.8284271247461903]
```

Find standard error across the whole array, using n degrees of freedom:

```
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

**scipy.stats.mstats.trimmed\_mean**

`scipy.stats.mstats.trimmed_mean(a, limits=0.1, 0.1, inclusive=1, 1, relative=True, axis=None)`

Returns the trimmed mean of the data along the given axis.

**Parameters**

- a** [sequence] Input array
- limits** [{None, tuple}, optional] If *relative* is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If *relative* is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting *n* the number of unmasked data before trimming, the (*n*\*limits[0])th smallest data and the (*n*\*limits[1])th largest data are masked, and the total number of unmasked data after

trimming is  $n*(1-\text{sum}(\text{limits}))$ . In each case, the value of one limit can be set to `None` to indicate an open interval.

If `limits` is `None`, no trimming is performed

- inclusive** [(bool, bool) tuple], optional] If *relative* is `False`, tuple indicating whether values exactly equal to the absolute limits are allowed. If *relative* is `True`, tuple indicating whether the number of data being masked on each side should be rounded (`True`) or truncated (`False`).
- relative** [bool, optional] Whether to consider the limits as absolute values (`False`) or proportions to cut (`True`).
- axis** [int, optional] Axis along which to trim.

### scipy.stats.mstats.trimmed\_mean\_ci

`scipy.stats.mstats.trimmed_mean_ci` (*data*, *limits*=0.2, 0.2, *inclusive*=`True`, `True`, *alpha*=0.05, *axis*=`None`)

Selected confidence interval of the trimmed mean along the given axis.

#### Parameters

- data** [array\_like] Input data.
- limits** [(None, tuple), optional] `None` or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If *n* is the number of unmasked data before trimming, then  $(n * \text{limits}[0])$ th smallest data and  $(n * \text{limits}[1])$ th largest data are masked. The total number of unmasked data after trimming is  $n * (1. - \text{sum}(\text{limits}))$ . The value of one limit can be set to `None` to indicate an open interval. Defaults to (0.2, 0.2).
- inclusive** [(2,) tuple of boolean, optional] If *relative*==`False`, tuple indicating whether values exactly equal to the absolute limits are allowed. If *relative*==`True`, tuple indicating whether the number of data being masked on each side should be rounded (`True`) or truncated (`False`). Defaults to (`True`, `True`).
- alpha** [float, optional] Confidence level of the intervals. Defaults to 0.05.
- axis** [int, optional] Axis along which to cut. If `None`, uses a flattened version of *data*. Defaults to `None`.

#### Returns

- trimmed\_mean\_ci** [(2,) ndarray] The lower and upper confidence intervals of the trimmed data.

### scipy.stats.mstats.trimmed\_std

`scipy.stats.mstats.trimmed_std` (*a*, *limits*=0.1, 0.1, *inclusive*=`1`, `1`, *relative*=`True`, *axis*=`None`, *ddof*=0)

Returns the trimmed standard deviation of the data along the given axis.

#### Parameters

- a** [sequence] Input array
- limits** [(None, tuple), optional] If *relative* is `False`, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If *relative* is `True`, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting *n* the number of unmasked data before trimming, the  $(n*\text{limits}[0])$ th smallest data and the  $(n*\text{limits}[1])$ th largest data are masked, and the total number of unmasked data after

trimming is  $n*(1-\text{sum}(\text{limits}))$  In each case, the value of one limit can be set to None to indicate an open interval.  
 If limits is None, no trimming is performed

<b>inclusive</b>	[(bool, bool) tuple], optional] If <i>relative</i> is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If <i>relative</i> is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
<b>relative</b>	[bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
<b>axis</b>	[int, optional] Axis along which to trim.
<b>ddof</b>	[[0,integer], optional] Means Delta Degrees of Freedom. The denominator used during computations is (n-ddof). DDOF=0 corresponds to a biased estimate, DDOF=1 to an unbiased estimate of the variance.

### scipy.stats.mstats.trimmed\_var

`scipy.stats.mstats.trimmed_var(a, limits=0.1, 0.1, inclusive=1, 1, relative=True, axis=None, ddof=0)`

Returns the trimmed variance of the data along the given axis.

#### Parameters

<b>a</b>	[sequence] Input array
<b>limits</b>	[[None, tuple], optional] If <i>relative</i> is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If <i>relative</i> is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting n the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked data after trimming is $n*(1-\text{sum}(\text{limits}))$ In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed
<b>inclusive</b>	[(bool, bool) tuple], optional] If <i>relative</i> is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If <i>relative</i> is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
<b>relative</b>	[bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
<b>axis</b>	[int, optional] Axis along which to trim.
<b>ddof</b>	[[0,integer], optional] Means Delta Degrees of Freedom. The denominator used during computations is (n-ddof). DDOF=0 corresponds to a biased estimate, DDOF=1 to an unbiased estimate of the variance.

### Frequency statistics

---

<code>scoreatpercentile(data, per[, limit, ...])</code>	Calculate the score at the given 'per' percentile of the sequence a.
---	--

---

### scipy.stats.mstats.scoreatpercentile

`scipy.stats.mstats.scoreatpercentile` (*data*, *per*, *limit=()*, *alphap=0.4*, *betap=0.4*)

Calculate the score at the given 'per' percentile of the sequence a. For example, the score at per=50 is the median.

This function is a shortcut to `mquantile`

### Correlation functions

<code>f_oneway(*args)</code>	Performs a 1-way ANOVA, returning an F-value and probability given any number of groups.
<code>pearsonr(x, y)</code>	Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.
<code>spearmanr(x[, y, use_ties, axis, nan_policy])</code>	Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.
<code>pointbiserialr(x, y)</code>	Calculates a point biserial correlation coefficient and its p-value.
<code>kendalltau(x, y[, use_ties, use_missing, method])</code>	Computes Kendall's rank correlation tau on two variables <i>x</i> and <i>y</i> .
<code>kendalltau_seasonal(x)</code>	Computes a multivariate Kendall's rank correlation tau, for seasonal data.
<code>linregress(x[, y])</code>	Linear regression calculation
<code>siegelslopes(y[, x, method])</code>	Computes the Siegel estimator for a set of points ( <i>x</i> , <i>y</i> ).
<code>theilslopes(y[, x, alpha])</code>	Computes the Theil-Sen estimator for a set of points ( <i>x</i> , <i>y</i> ).
<code>sen_seasonal_slopes(x)</code>	

### scipy.stats.mstats.f\_oneway

`scipy.stats.mstats.f_oneway` (*\*args*)

Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

Usage: `f_oneway(*args)`, where *\*args* is 2 or more arrays, one per treatment group.

#### Returns

**statistic** [float] The computed F-value of the test.  
**pvalue** [float] The associated p-value from the F-distribution.

### scipy.stats.mstats.pearsonr

`scipy.stats.mstats.pearsonr` (*x*, *y*)

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson's correlation requires that each dataset be normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

**x** [1-D array\_like] Input  
**y** [1-D array\_like] Input

**Returns**

**pearsonr** [float] Pearson's correlation coefficient, 2-tailed p-value.

**References**

<http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation>

**scipy.stats.mstats.spearmanr**

`scipy.stats.mstats.spearmanr(x, y=None, use_ties=True, axis=None, nan_policy='propagate')`

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a monotonic relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

Missing values are discarded pair-wise: if a value is missing in  $x$ , the corresponding value in  $y$  is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

**x, y** [1D or 2D array\_like, y is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under `axis`, below.

**use\_ties** [bool, optional] DO NOT USE. Does not do anything, keyword is only left in place for backwards compatibility reasons.

**axis** [int or None, optional] If `axis=0` (default), then each column represents a variable, with observations in the rows. If `axis=1`, the relationship is transposed: each row represents a variable, while the columns contain observations. If `axis=None`, then both arrays will be raveled.

**nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**correlation** [float] Spearman correlation coefficient  
**pvalue** [float] 2-tailed p-value.

## References

[CRCProbStat2000] section 14.7

### scipy.stats.mstats.pointbiserialr

`scipy.stats.mstats.pointbiserialr(x, y)`

Calculates a point biserial correlation coefficient and its p-value.

#### Parameters

**x** [array\_like of bools] Input array.  
**y** [array\_like] Input array.

#### Returns

**correlation** [float] R value  
**pvalue** [float] 2-tailed p-value

## Notes

Missing values are considered pair-wise: if a value is missing in x, the corresponding value in y is masked.

For more details on *pointbiserialr*, see *stats.pointbiserialr*.

### scipy.stats.mstats.kendalltau

`scipy.stats.mstats.kendalltau(x, y, use_ties=True, use_missing=False, method='auto')`

Computes Kendall's rank correlation tau on two variables x and y.

#### Parameters

**x** [sequence] First data list (for example, time).  
**y** [sequence] Second data list.  
**use\_ties** [{True, False}, optional] Whether ties correction should be performed.  
**use\_missing** [{False, True}, optional] Whether missing data should be allocated a rank of 0 (False) or the average rank (True)

**method: {'auto', 'asymptotic', 'exact'}, optional**

Defines which method is used to calculate the p-value [1]. 'asymptotic' uses a normal approximation valid for large samples. 'exact' computes the exact p-value, but can only be used if no ties are present. As the sample size increases, the 'exact' computation time may grow and the result may lose some precision. 'auto' is the default and selects the appropriate method based on a trade-off between speed and accuracy.

#### Returns

**correlation** [float] Kendall tau  
**pvalue** [float] Approximate 2-side p-value.

## References

[1]

### `scipy.stats.mstats.kendalltau_seasonal`

`scipy.stats.mstats.kendalltau_seasonal` (*x*)

Computes a multivariate Kendall's rank correlation tau, for seasonal data.

#### *Parameters*

**x** [2-D ndarray] Array of seasonal data, with seasons in columns.

### `scipy.stats.mstats.linregress`

`scipy.stats.mstats.linregress` (*x*, *y=None*)

Linear regression calculation

Note that the non-masked version is used, and that this docstring is replaced by the non-masked docstring + some info on missing data.

### `scipy.stats.mstats.siegelslopes`

`scipy.stats.mstats.siegelslopes` (*y*, *x=None*, *method='hierarchical'*)

Computes the Siegel estimator for a set of points (*x*, *y*).

*siegelslopes* implements a method for robust linear regression using repeated medians to fit a line to the points (*x*, *y*). The method is robust to outliers with an asymptotic breakdown point of 50%.

#### *Parameters*

**y** [array\_like] Dependent variable.

**x** [array\_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.

**method** [{'hierarchical', 'separate'}] If 'hierarchical', estimate the intercept using the estimated slope `medslope` (default option). If 'separate', estimate the intercept independent of the estimated slope. See Notes for details.

#### *Returns*

**medslope** [float] Estimate of the slope of the regression line.

**medintercept**

[float] Estimate of the intercept of the regression line.

See also:

#### `theilslopes`

a similar technique without repeated medians

## Notes

For more details on *siegelslopes*, see `scipy.stats.siegelslopes`.

## scipy.stats.mstats.theilslopes

`scipy.stats.mstats.theilslopes` (*y*, *x=None*, *alpha=0.95*)

Computes the Theil-Sen estimator for a set of points (*x*, *y*).

*theilslopes* implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

### Parameters

- y** [array\_like] Dependent variable.
- x** [array\_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- alpha** [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that *alpha* is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

### Returns

- medslope** [float] Theil slope.
- medintercept** [float] Intercept of the Theil line, as `median(y) - medslope*median(x)`.
- lo\_slope** [float] Lower bound of the confidence interval on *medslope*.
- up\_slope** [float] Upper bound of the confidence interval on *medslope*.

See also:

### *siegelslopes*

a similar technique with repeated medians

## Notes

For more details on *theilslopes*, see `stats.theilslopes`.

## scipy.stats.mstats.sen\_seasonal\_slopes

`scipy.stats.mstats.sen_seasonal_slopes` (*x*)

### Statistical tests

<code>ttest_1samp(a, popmean[, axis])</code>	Calculates the T-test for the mean of ONE group of scores.
<code>ttest_onesamp(a, popmean[, axis])</code>	Calculates the T-test for the mean of ONE group of scores.
<code>ttest_ind(a, b[, axis, equal_var])</code>	Calculates the T-test for the means of TWO INDEPENDENT samples of scores.
<code>ttest_rel(a, b[, axis])</code>	Calculates the T-test on TWO RELATED samples of scores, a and b.

continues on next page

Table 276 – continued from previous page

<code>chisquare(f_obs[, f_exp, ddof, axis])</code>	Calculate a one-way chi-square test.
<code>kstest(data1, data2[, args, alternative, mode])</code>	
<i>Parameters</i>	
<code>ks_2samp(data1, data2[, alternative, mode])</code>	Computes the Kolmogorov-Smirnov test on two samples.
<code>ks_1samp(x, cdf[, args, alternative, mode])</code>	Computes the Kolmogorov-Smirnov test on one sample of masked values.
<code>ks_twosamp(data1, data2[, alternative, mode])</code>	Computes the Kolmogorov-Smirnov test on two samples.
<code>mannwhitneyu(x, y[, use_continuity])</code>	Computes the Mann-Whitney statistic
<code>rankdata(data[, axis, use_missing])</code>	Returns the rank (also known as order statistics) of each data point along the given axis.
<code>kruskal(*args)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>kruskalwallis(*args)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>friedmanchisquare(*args)</code>	Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA.
<code>brunnermunzel(x, y[, alternative, distribution])</code>	Computes the Brunner-Munzel test on samples x and y
<code>skewtest(a[, axis])</code>	Tests whether the skew is different from the normal distribution.
<code>kurtosistest(a[, axis])</code>	Tests whether a dataset has normal kurtosis
<code>normaltest(a[, axis])</code>	Tests whether a sample differs from a normal distribution.

### scipy.stats.mstats.ttest\_1samp

`scipy.stats.mstats.ttest_1samp(a, popmean, axis=0)`

Calculates the T-test for the mean of ONE group of scores.

#### Parameters

<b>a</b>	[array_like] sample observation
<b>popmean</b>	[float or array_like] expected value in null hypothesis, if array_like than it must have the same shape as <i>a</i> excluding the axis dimension
<b>axis</b>	[int or None, optional] Axis along which to compute test. If None, compute over the whole array <i>a</i> .

#### Returns

<b>statistic</b>	[float or array] t-statistic
<b>pvalue</b>	[float or array] two-tailed p-value

#### Notes

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

**scipy.stats.mstats.ttest\_onesamp**`scipy.stats.mstats.ttest_onesamp(a, popmean, axis=0)`

Calculates the T-test for the mean of ONE group of scores.

**Parameters**

- a** [array\_like] sample observation
- popmean** [float or array\_like] expected value in null hypothesis, if array\_like then it must have the same shape as *a* excluding the axis dimension
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole array *a*.

**Returns**

- statistic** [float or array] t-statistic
- pvalue** [float or array] two-tailed p-value

**Notes**For more details on `ttest_1samp`, see `stats.ttest_1samp`.**scipy.stats.mstats.ttest\_ind**`scipy.stats.mstats.ttest_ind(a, b, axis=0, equal_var=True)`

Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

**Parameters**

- a, b** [array\_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.
- equal\_var** [bool, optional] If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch's t-test, which does not assume equal population variance.  
New in version 0.17.0.

**Returns**

- statistic** [float or array] The calculated t-statistic.
- pvalue** [float or array] The two-tailed p-value.

**Notes**For more details on `ttest_ind`, see `stats.ttest_ind`.

**scipy.stats.mstats.ttest\_rel**

`scipy.stats.mstats.ttest_rel` (*a*, *b*, *axis*=0)

Calculates the T-test on TWO RELATED samples of scores, *a* and *b*.

**Parameters**

**a, b** [array\_like] The arrays must have the same shape.  
**axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

**Returns**

**statistic** [float or array] t-statistic  
**pvalue** [float or array] two-tailed p-value

**Notes**

For more details on `ttest_rel`, see `stats.ttest_rel`.

**scipy.stats.mstats.chisquare**

`scipy.stats.mstats.chisquare` (*f\_obs*, *f\_exp*=None, *ddof*=0, *axis*=0)

Calculate a one-way chi-square test.

The chi-square test tests the null hypothesis that the categorical data has the given frequencies.

**Parameters**

**f\_obs** [array\_like] Observed frequencies in each category.  
**f\_exp** [array\_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.  
**ddof** [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where *k* is the number of observed frequencies. The default value of *ddof* is 0.  
**axis** [int or None, optional] The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If *axis* is None, all values in *f\_obs* are treated as a single data set. Default is 0.

**Returns**

**chisq** [float or ndarray] The chi-squared test statistic. The value is a float if *axis* is None or *f\_obs* and *f\_exp* are 1-D.  
**p** [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

See also:

`scipy.stats.power_divergence`

## Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom,  $k-1$ , are for the case when no parameters of the distribution are estimated. If  $p$  parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are  $k-1-p$ . If the parameters are estimated in a different way, then the dof can be between  $k-1-p$  and  $k-1$ . However, it is also possible that the asymptotic distribution is not chi-square, in which case this test is not appropriate.

## References

[1], [2]

## Examples

When just  $f_{obs}$  is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With  $f_{exp}$  the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When  $f_{obs}$  is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting  $axis=None$ , the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

$ddof$  is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with  $ddof$ .

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

$f_{obs}$  and  $f_{exp}$  are also broadcast. In the following,  $f_{obs}$  has shape (6,) and  $f_{exp}$  has shape (2, 6), so the result of broadcasting  $f_{obs}$  and  $f_{exp}$  has shape (2, 6). To compute the desired chi-squared statistics, we use `axis=1`:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...           f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...           axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

### scipy.stats.mstats.kstest

`scipy.stats.mstats.kstest` (*data1*, *data2*, *args*=(), *alternative*='two-sided', *mode*='auto')

#### Parameters

**data1** [array\_like]  
**data2** [str, callable or array\_like]  
**args** [tuple, sequence, optional] Distribution parameters, used if *data1* or *data2* are strings.  
**alternative** [str, as documented in `stats.kstest`]  
**mode** [str, as documented in `stats.kstest`]

#### Returns

tuple of (K-S statistic, probability)

### scipy.stats.mstats.ks\_2samp

`scipy.stats.mstats.ks_2samp` (*data1*, *data2*, *alternative*='two-sided', *mode*='auto')

Computes the Kolmogorov-Smirnov test on two samples.

Missing values in *x* and/or *y* are discarded.

#### Parameters

**data1** [array\_like] First data set  
**data2** [array\_like] Second data set  
**alternative** [{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.  
**mode** [{'auto', 'exact', 'asympt'}, optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'):

- 'auto': use 'exact' for small size arrays, 'asympt' for large
- 'exact': use approximation to exact distribution of test statistic
- 'asympt': use asymptotic distribution of test statistic

#### Returns

**d** [float] Value of the Kolmogorov Smirnov test  
**p** [float] Corresponding p-value.

**scipy.stats.mstats.ks\_1samp**

`scipy.stats.mstats.ks_1samp(x, cdf, args=(), alternative='two-sided', mode='auto')`

Computes the Kolmogorov-Smirnov test on one sample of masked values.

Missing values in *x* are discarded.

**Parameters**

<b>x</b>	[array_like] a 1-D array of observations of random variables.
<b>cdf</b>	[str or callable] If a string, it should be the name of a distribution in <code>scipy.stats</code> . If a callable, that callable is used to calculate the cdf.
<b>args</b>	[tuple, sequence, optional] Distribution parameters, used if <i>cdf</i> is a string.
<b>alternative</b>	[{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.
<b>mode</b>	[{'auto', 'exact', 'asympt'}, optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'): <ul style="list-style-type: none"><li>• 'auto': use 'exact' for small size arrays, 'asympt' for large</li><li>• 'exact': use approximation to exact distribution of test statistic</li><li>• 'asympt': use asymptotic distribution of test statistic</li></ul>

**Returns**

<b>d</b>	[float] Value of the Kolmogorov Smirnov test
<b>p</b>	[float] Corresponding p-value.

**scipy.stats.mstats.ks\_twosamp**

`scipy.stats.mstats.ks_twosamp(data1, data2, alternative='two-sided', mode='auto')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values in *x* and/or *y* are discarded.

**Parameters**

<b>data1</b>	[array_like] First data set
<b>data2</b>	[array_like] Second data set
<b>alternative</b>	[{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.
<b>mode</b>	[{'auto', 'exact', 'asympt'}, optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'): <ul style="list-style-type: none"><li>• 'auto': use 'exact' for small size arrays, 'asympt' for large</li><li>• 'exact': use approximation to exact distribution of test statistic</li><li>• 'asympt': use asymptotic distribution of test statistic</li></ul>

**Returns**

<b>d</b>	[float] Value of the Kolmogorov Smirnov test
<b>p</b>	[float] Corresponding p-value.

**scipy.stats.mstats.mannwhitneyu**

`scipy.stats.mstats.mannwhitneyu(x, y, use_continuity=True)`

Computes the Mann-Whitney statistic

Missing values in *x* and/or *y* are discarded.

**Parameters**

**x** [sequence] Input  
**y** [sequence] Input  
**use\_continuity** [{True, False}, optional] Whether a continuity correction (1/2.) should be taken into account.

**Returns**

**statistic** [float] The Mann-Whitney statistics  
**pvalue** [float] Approximate p-value assuming a normal distribution.

**scipy.stats.mstats.rankdata**

`scipy.stats.mstats.rankdata(data, axis=None, use_missing=False)`

Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if `use_missing` is False, or set to the average rank of the unmasked values if `use_missing` is True.

**Parameters**

**data** [sequence] Input data. The data is transformed to a masked array  
**axis** [{None,int}, optional] Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2  
**use\_missing** [bool, optional] Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

**scipy.stats.mstats.kruskal**

`scipy.stats.mstats.kruskal(*args)`

Compute the Kruskal-Wallis H-test for independent samples

**Parameters**

**sample1, sample2, ...**  
 [array\_like] Two or more arrays with the sample measurements can be given as arguments.

**Returns**

**statistic** [float] The Kruskal-Wallis H statistic, corrected for ties  
**pvalue** [float] The p-value for the test using the assumption that H has a chi square distribution

## Notes

For more details on `kruskal`, see `stats.kruskal`.

## Examples

```
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

```
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands' durations are identical. Use 5% level of significance.

```
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

## `scipy.stats.mstats.kruskalwallis`

`scipy.stats.mstats.kruskalwallis(*args)`

Compute the Kruskal-Wallis H-test for independent samples

### Parameters

**sample1, sample2, ...**

[array\_like] Two or more arrays with the sample measurements can be given as arguments.

### Returns

**statistic** [float] The Kruskal-Wallis H statistic, corrected for ties

**pvalue** [float] The p-value for the test using the assumption that H has a chi square distribution

## Notes

For more details on `kruskal`, see `stats.kruskal`.

## Examples

```
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

```
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands' durations are identical. Use 5% level of significance.

```
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

### scipy.stats.mstats.friedmanchisquare

`scipy.stats.mstats.friedmanchisquare(*args)`

Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first n treatments are taken into account, where n is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.

#### Returns

**statistic** [float] the test statistic.  
**pvalue** [float] the associated p-value.

### scipy.stats.mstats.brunnermunzel

`scipy.stats.mstats.brunnermunzel(x, y, alternative='two-sided', distribution='t')`

Computes the Brunner-Munzel test on samples x and y

Missing values in x and/or y are discarded.

#### Parameters

**x, y** [array\_like] Array of samples, should be one-dimensional.  
**alternative** ['less', 'two-sided', or 'greater', optional] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults value is 'two-sided'.

#### distribution: 't' or 'normal', optional

Whether to get the p-value by t-distribution or by standard normal distribution. Defaults value is 't'.

#### Returns

**statistic** [float] The Brunner-Munzer W statistic.  
**pvalue** [float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of *alternative* and *distribution*.

See also:

### `mannwhitneyu`

Mann-Whitney rank test on two samples.

### Notes

For more details on `brunnermunzel`, see `stats.brunnermunzel`.

### `scipy.stats.mstats.skewtest`

`scipy.stats.mstats.skewtest` (*a*, *axis=0*)

Tests whether the skew is different from the normal distribution.

#### Parameters

**a** [array] The data to be tested  
**axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.

#### Returns

**statistic** [float] The computed z-score for this test.  
**pvalue** [float] a 2-sided p-value for the hypothesis test

### Notes

For more details about `skewtest`, see `stats.skewtest`.

### `scipy.stats.mstats.kurtosistest`

`scipy.stats.mstats.kurtosistest` (*a*, *axis=0*)

Tests whether a dataset has normal kurtosis

#### Parameters

**a** [array] array of the sample data  
**axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

#### Returns

**statistic** [float] The computed z-score for this test.  
**pvalue** [float] The 2-sided p-value for the hypothesis test

### Notes

For more details about `kurtosistest`, see `stats.kurtosistest`.

**scipy.stats.mstats.normaltest**

`scipy.stats.mstats.normaltest(a, axis=0)`

Tests whether a sample differs from a normal distribution.

**Parameters**

**a** [array\_like] The array containing the data to be tested.  
**axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

**Returns**

**statistic** [float or array]  $s^2 + k^2$ , where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.  
**pvalue** [float or array] A 2-sided chi squared probability for the hypothesis test.

**Notes**

For more details about `normaltest`, see `stats.normaltest`.

**Transformations**

<code>obrientransform(*args)</code>	Computes a transform on input data (any number of columns).
<code>trim(a[, limits, inclusive, relative, axis])</code>	Trims an array by masking the data outside some given limits.
<code>trima(a[, limits, inclusive])</code>	Trims an array by masking the data outside some given limits.
<code>trimmed_stde(a[, limits, inclusive, axis])</code>	Returns the standard error of the trimmed mean along the given axis.
<code>trimr(a[, limits, inclusive, axis])</code>	Trims an array by masking some proportion of the data on each end.
<code>trimtail(data[, proportiontocut, tail, ...])</code>	Trims the data by masking values from one tail.
<code>trimboth(data[, proportiontocut, inclusive, ...])</code>	Trims the smallest and largest data values.
<code>winsorize(a[, limits, inclusive, inplace, ...])</code>	Returns a Winsorized version of the input array.
<code>zmap(scores, compare[, axis, ddof])</code>	Calculate the relative z-scores.
<code>zscore(a[, axis, ddof, nan_policy])</code>	Compute the z score.

**scipy.stats.mstats.obrientransform**

`scipy.stats.mstats.obrientransform(*args)`

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in `*args` is one level of a factor. If an `f_oneway()` run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA

## scipy.stats.mstats.trim

`scipy.stats.mstats.trim(a, limits=None, inclusive=True, True, relative=False, axis=None)`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

### Parameters

<b>a</b>	[sequence] Input array
<b>limits</b>	[[None, tuple], optional] If <i>relative</i> is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If <i>relative</i> is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting <i>n</i> the number of unmasked data before trimming, the ( <i>n</i> *limits[0])th smallest data and the ( <i>n</i> *limits[1])th largest data are masked, and the total number of unmasked data after trimming is <i>n</i> *(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed
<b>inclusive</b>	[(bool, bool) tuple], optional] If <i>relative</i> is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If <i>relative</i> is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
<b>relative</b>	[bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
<b>axis</b>	[int, optional] Axis along which to trim.

### Examples

```
>>> from scipy.stats.mstats import trim
>>> z = [ 1, 2, 3, 4, 5, 6, 7, 8, 9,10]
>>> print(trim(z, (3,8)))
[-- -- 3 4 5 6 7 8 -- --]
>>> print(trim(z, (0.1,0.2), relative=True))
[-- 2 3 4 5 6 7 8 -- --]
```

## scipy.stats.mstats.trima

`scipy.stats.mstats.trima(a, limits=None, inclusive=True, True)`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

### Parameters

<b>a</b>	[array_like] Input array.
<b>limits</b>	[[None, tuple], optional] Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.
<b>inclusive</b>	[(bool, bool) tuple, optional] Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.

## Examples

```
>>> from scipy.stats.mstats import trima
```

```
>>> a = np.arange(10)
```

The interval is left-closed and right-open, i.e.,  $[2, 8)$ . Trim the array by keeping only values in the interval.

```
>>> trima(a, limits=(2, 8), inclusive=(True, False))
masked_array(data=[--, --, 2, 3, 4, 5, 6, 7, --, --],
             mask=[ True,  True, False, False, False, False, False, False,
                   True,  True],
             fill_value=999999)
```

## scipy.stats.mstats.trimmed\_stde

`scipy.stats.mstats.trimmed_stde` (*a*, *limits*=0.1, 0.1, *inclusive*=1, 1, *axis*=None)

Returns the standard error of the trimmed mean along the given axis.

### Parameters

- a** [sequence] Input array
- limits** [{(0.1,0.1), tuple of float}, optional] tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.  
If *n* is the number of unmasked data before trimming, the values smaller than  $n * \text{limits}[0]$  and the values larger than  $n * \text{limits}[1]$  are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . In each case, the value of one limit can be set to None to indicate an open interval. If *limits* is None, no trimming is performed.
- inclusive** [{(bool, bool) tuple} optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- axis** [int, optional] Axis along which to trim.

### Returns

- trimmed\_stde** [scalar or ndarray]

## scipy.stats.mstats.trimr

`scipy.stats.mstats.trimr` (*a*, *limits*=None, *inclusive*=True, True, *axis*=None)

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

### Parameters

- a** [sequence] Input array.
- limits** [{None, tuple}, optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting *n* the number of unmasked data before trimming, the ( $n * \text{limits}[0]$ )th smallest data and the ( $n * \text{limits}[1]$ )th largest data are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . The value of one limit can be set to None to indicate an open interval.
- inclusive** [{(True, True) tuple}, optional] Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.

**axis** [None,int], optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

### scipy.stats.mstats.trimtail

`scipy.stats.mstats.trimtail` (*data*, *proportiontocut*=0.2, *tail*='left', *inclusive*=True, *True*, *axis*=None)  
Trims the data by masking values from one tail.

#### Parameters

**data** [array\_like] Data to trim.  
**proportiontocut** [float, optional] Percentage of trimming. If *n* is the number of unmasked values before trimming, the number of values after trimming is  $(1 - \text{proportiontocut}) * n$ . Default is 0.2.  
**tail** [{'left','right'}, optional] If 'left' the *proportiontocut* lowest values will be masked. If 'right' the *proportiontocut* highest values will be masked. Default is 'left'.  
**inclusive** [(bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).  
**axis** [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

#### Returns

**trimtail** [ndarray] Returned array of same shape as *data* with masked tail values.

### scipy.stats.mstats.trimboth

`scipy.stats.mstats.trimboth` (*data*, *proportiontocut*=0.2, *inclusive*=True, *True*, *axis*=None)  
Trims the smallest and largest data values.

Trims the *data* by masking the  $\text{int}(\text{proportiontocut} * n)$  smallest and  $\text{int}(\text{proportiontocut} * n)$  largest values of data along the given axis, where *n* is the number of unmasked values before trimming.

#### Parameters

**data** [ndarray] Data to trim.  
**proportiontocut** [float, optional] Percentage of trimming (as a float between 0 and 1). If *n* is the number of unmasked values before trimming, the number of values after trimming is  $(1 - 2 * \text{proportiontocut}) * n$ . Default is 0.2.  
**inclusive** [(bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).  
**axis** [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened.

**scipy.stats.mstats.winsorize**

`scipy.stats.mstats.winsorize` (*a*, *limits=None*, *inclusive=True*, *True*, *inplace=False*, *axis=None*, *nan\_policy='propagate'*)

Returns a Winsorized version of the input array.

The (`limits[0]`)th lowest values are set to the (`limits[0]`)th percentile, and the (`limits[1]`)th highest values are set to the  $(1 - \text{limits}[1])$ th percentile. Masked values are skipped.

**Parameters**

- a** [sequence] Input array.
- limits** [{None, tuple of float}, optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting *n* the number of unmasked data before trimming, the  $(n * \text{limits}[0])$ th smallest data and the  $(n * \text{limits}[1])$ th largest data are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . The value of one limit can be set to None to indicate an open interval.
- inclusive** [{(True, True) tuple}, optional] Tuple indicating whether the number of data being masked on each side should be truncated (True) or rounded (False).
- inplace** [{False, True}, optional] Whether to winsorize in place (True) or to use a copy (False)
- axis** [{None, int}, optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': allows nan values and may overwrite or propagate them
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

**Notes**

This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

**Examples**

```
>>> from scipy.stats.mstats import winsorize
```

A shuffled array contains integers from 1 to 10.

```
>>> a = np.array([10, 4, 9, 8, 5, 3, 7, 2, 1, 6])
```

The 10% of the lowest value (i.e., 1) and the 20% of the highest values (i.e., 9 and 10) are replaced.

```
>>> winsorize(a, limits=[0.1, 0.2])
masked_array(data=[8, 4, 8, 8, 5, 3, 7, 2, 2, 6],
              mask=False,
              fill_value=999999)
```

## scipy.stats.mstats.zmap

`scipy.stats.mstats.zmap(scores, compare, axis=0, ddof=0)`

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

### Parameters

- scores** [array\_like] The input for which z-scores are calculated.
- compare** [array\_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as *scores*.
- axis** [int or None, optional] Axis over which mean and variance of *compare* are calculated. Default is 0. If None, compute over the whole array *scores*.
- ddof** [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

### Returns

- zscore** [array\_like] Z-scores, in the same shape as *scores*.

## Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

## Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
```

## scipy.stats.mstats.zscore

`scipy.stats.mstats.zscore(a, axis=0, ddof=0, nan_policy='propagate')`

Compute the z score.

Compute the z score of each value in the sample, relative to the sample mean and standard deviation.

### Parameters

- a** [array\_like] An array like object containing the sample data.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’. Note that when the value is ‘omit’, nans in the input also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

**Returns**

**zscore** [array\_like] The z-scores, standardized by mean and standard deviation of input array *a*.

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

**Examples**

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...               0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```
>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...               [ 0.7149,  0.0775,  0.6072,  0.9656],
...               [ 0.6341,  0.1403,  0.9759,  0.4064],
...               [ 0.5918,  0.6948,  0.904 ,  0.3721],
...               [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823, -1.28415119,  1.07259584,  0.40420358],
       [  0.33048416, -1.37380874,  0.04251374,  1.00081084],
       [  0.26796377, -1.12598418,  1.23283094, -0.37481053],
       [ -0.22095197,  0.24468594,  1.19042819, -1.21416216],
       [ -0.82780366,  1.4457416 , -0.43867764, -0.1792603 ]])
```

An example with *nan\_policy='omit'*:

```
>>> x = np.array([[25.11, 30.10, np.nan, 32.02, 43.15],
...               [14.95, 16.06, 121.25, 94.35, 29.81]])
>>> stats.zscore(x, axis=1, nan_policy='omit')
array([[ -1.13490897, -0.37830299,          nan, -0.08718406,  1.60039602],
       [ -0.91611681, -0.89090508,  1.4983032 ,  0.88731639, -0.5785977 ]])
```

**Other**

<i>argstoarray</i> (*args)	Constructs a 2D array from a group of sequences.
<i>count_tied_groups</i> (x[, use_missing])	Counts the number of tied values.
<i>msign</i> (x)	Returns the sign of x, or 0 if x is masked.
<i>compare_medians_ms</i> (group_1, group_2[, axis])	Compares the medians from two independent groups along the given axis.
<i>median_cihs</i> (data[, alpha, axis])	Computes the alpha-level confidence interval for the median of the data.
<i>mjci</i> (data[, prob, axis])	Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

continues on next page

Table 278 – continued from previous page

<code>mquantiles_cimj(data[, prob, alpha, axis])</code>	Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.
<code>rsh(data[, points])</code>	Evaluates Rosenblatt's shifted histogram estimators for each data point.

### scipy.stats.mstats.argstoarray

`scipy.stats.mstats.argstoarray(*args)`

Constructs a 2D array from a group of sequences.

Sequences are filled with missing values to match the length of the longest sequence.

#### Parameters

**args** [sequences] Group of sequences.

#### Returns

##### argstoarray

[MaskedArray] A ( $m \times n$ ) masked array, where  $m$  is the number of arguments and  $n$  the length of the longest argument.

#### Notes

`numpy.ma.row_stack` has identical behavior, but is called with a sequence of sequences.

#### Examples

A 2D masked array constructed from a group of sequences is returned.

```
>>> from scipy.stats.mstats import argstoarray
>>> argstoarray([1, 2, 3], [4, 5, 6])
masked_array(
  data=[[1.0, 2.0, 3.0],
        [4.0, 5.0, 6.0]],
  mask=[[False, False, False],
        [False, False, False]],
  fill_value=1e+20)
```

The returned masked array filled with missing values when the lengths of sequences are different.

```
>>> argstoarray([1, 3], [4, 5, 6])
masked_array(
  data=[[1.0, 3.0, --],
        [4.0, 5.0, 6.0]],
  mask=[[False, False, True],
        [False, False, False]],
  fill_value=1e+20)
```

**scipy.stats.mstats.count\_tied\_groups**

`scipy.stats.mstats.count_tied_groups(x, use_missing=False)`

Counts the number of tied values.

**Parameters**

**x** [sequence] Sequence of data on which to counts the ties  
**use\_missing** [bool, optional] Whether to consider missing values as tied.

**Returns**

**count\_tied\_groups**  
 [dict] Returns a dictionary (nb of ties: nb of groups).

**Examples**

```
>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}
```

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

```
>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 2, 3: 1}
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}
```

**scipy.stats.mstats.msign**

`scipy.stats.mstats.msign(x)`

Returns the sign of  $x$ , or 0 if  $x$  is masked.

**scipy.stats.mstats.compare\_medians\_ms**

`scipy.stats.mstats.compare_medians_ms(group_1, group_2, axis=None)`

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

**Parameters**

**group\_1** [array\_like] First dataset. Has to be of size  $\geq 7$ .  
**group\_2** [array\_like] Second dataset. Has to be of size  $\geq 7$ .  
**axis** [int, optional] Axis along which the medians are estimated. If `None`, the arrays are flattened. If `axis` is not `None`, then `group_1` and `group_2` should have the same shape.

**Returns**

**compare\_medians\_ms**

[[float, ndarray]] If *axis* is None, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of *group\_1* along *axis*.

**scipy.stats.mstats.median\_cihs**

`scipy.stats.mstats.median_cihs` (*data*, *alpha*=0.05, *axis*=None)

Computes the alpha-level confidence interval for the median of the data.

Uses the Hettmasperger-Sheather method.

*Parameters*

**data** [array\_like] Input data. Masked values are discarded. The input should be 1D only, or *axis* should be set to None.  
**alpha** [float, optional] Confidence level of the intervals.  
**axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

*Returns*

**median\_cihs**  
 Alpha level confidence interval.

**scipy.stats.mstats.mjci**

`scipy.stats.mstats.mjci` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

*Parameters*

**data** [ndarray] Data array.  
**prob** [sequence, optional] Sequence of quantiles to compute.  
**axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

**scipy.stats.mstats.mquantiles\_cimj**

`scipy.stats.mstats.mquantiles_cimj` (*data*, *prob*=[0.25, 0.5, 0.75], *alpha*=0.05, *axis*=None)

Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

*Parameters*

**data** [ndarray] Data array.  
**prob** [sequence, optional] Sequence of quantiles to compute.  
**alpha** [float, optional] Confidence level of the intervals.  
**axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

*Returns*

**ci\_lower** [ndarray] The lower boundaries of the confidence interval. Of the same length as *prob*.  
**ci\_upper** [ndarray] The upper boundaries of the confidence interval. Of the same length as *prob*.

**scipy.stats.mstats.rsh**

`scipy.stats.mstats.rsh` (*data*, *points=None*)

Evaluates Rosenblatt's shifted histogram estimators for each data point.

Rosenblatt's estimator is a centered finite-difference approximation to the derivative of the empirical cumulative distribution function.

**Parameters**

**data** [sequence] Input data, should be 1-D. Masked values are ignored.  
**points** [sequence or None, optional] Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.

**6.29.18 Univariate and multivariate kernel density estimation**

---

<code>gaussian_kde</code> ( <i>dataset</i> [, <i>bw_method</i> , <i>weights</i> ])	Representation of a kernel-density estimate using Gaussian kernels.
--	---

---

**scipy.stats.gaussian\_kde**

**class** `scipy.stats.gaussian_kde` (*dataset*, *bw\_method=None*, *weights=None*)

Representation of a kernel-density estimate using Gaussian kernels.

Kernel density estimation is a way to estimate the probability density function (PDF) of a random variable in a non-parametric way. `gaussian_kde` works for both uni-variate and multi-variate data. It includes automatic bandwidth determination. The estimation works best for a unimodal distribution; bimodal or multi-modal distributions tend to be oversmoothed.

**Parameters**

**dataset** [array\_like] Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).  
**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as *kde.factor*. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), 'scott' is used. See Notes for more details.  
**weights** [array\_like, optional] weights of datapoints. This must be the same shape as dataset. If None (default), the samples are assumed to be equally weighted

**Notes**

Bandwidth selection strongly influences the estimate obtained from the KDE (much more so than the actual shape of the kernel). Bandwidth selection can be done by a "rule of thumb", by cross-validation, by "plug-in methods" or by other means; see [3], [4] for reviews. `gaussian_kde` uses a rule of thumb, the default is Scott's Rule.

Scott's Rule [1], implemented as `scotts_factor`, is:

$$n^{**(-1./(d+4))},$$

with *n* the number of data points and *d* the number of dimensions. In the case of unequally weighted points, `scotts_factor` becomes:

```
neff**(-1./(d+4)),
```

with `neff` the effective number of datapoints. Silverman's Rule [2], implemented as `silverman_factor`, is:

```
(n * (d + 2) / 4.)**(-1. / (d + 4)).
```

or in the case of unequally weighted points:

```
(neff * (d + 2) / 4.)**(-1. / (d + 4)).
```

Good general descriptions of kernel density estimation can be found in [1] and [2], the mathematics for this multi-dimensional implementation can be found in [1].

With a set of weighted samples, the effective number of datapoints `neff` is defined by:

```
neff = sum(weights)^2 / sum(weights^2)
```

as detailed in [5].

## References

[1], [2], [3], [4], [5]

## Examples

Generate some random two-dimensional data:

```
>>> from scipy import stats
>>> def measure(n):
...     "Measurement model, return two coupled measurements."
...     m1 = np.random.normal(size=n)
...     m2 = np.random.normal(scale=0.5, size=n)
...     return m1+m2, m1-m2
```

```
>>> m1, m2 = measure(2000)
>>> xmin = m1.min()
>>> xmax = m1.max()
>>> ymin = m2.min()
>>> ymax = m2.max()
```

Perform a kernel density estimate on the data:

```
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel(positions).T, X.shape)
```

Plot the results:

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
```

(continues on next page)

(continued from previous page)

```

>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
...           extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()

```

### Attributes

<b>dataset</b>	[ndarray] The dataset with which <i>gaussian_kde</i> was initialized.
<b>d</b>	[int] Number of dimensions.
<b>n</b>	[int] Number of datapoints.
<b>neff</b>	[int] Effective number of datapoints. New in version 1.2.0.
<b>factor</b>	[float] The bandwidth factor, obtained from <i>kde.covariance_factor</i> , with which the covariance matrix is multiplied.
<b>covariance</b>	[ndarray] The covariance matrix of <i>dataset</i> , scaled by the calculated bandwidth ( <i>kde.factor</i> ).
<b>inv_cov</b>	[ndarray] The inverse of <i>covariance</i> .

### Methods

<i>evaluate</i> (self, points)	Evaluate the estimated pdf on a set of points.
<i>__call__</i> (self, points)	Evaluate the estimated pdf on a set of points.
<i>integrate_gaussian</i> (self, mean, cov)	Multiply estimated density by a multivariate Gaussian and integrate over the whole space.
<i>integrate_box_1d</i> (self, low, high)	Computes the integral of a 1D pdf between two bounds.
<i>integrate_box</i> (self, low_bounds, high_bounds)	Computes the integral of a pdf over a rectangular interval.
<i>integrate_kde</i> (self, other)	Computes the integral of the product of this kernel density estimate with another.

continues on next page

Table 280 – continued from previous page

<code>pdf(self, x)</code>	Evaluate the estimated pdf on a provided set of points.
<code>logpdf(self, x)</code>	Evaluate the log of the estimated pdf on a provided set of points.
<code>resample(self[, size, seed])</code>	Randomly sample a dataset from the estimated pdf.
<code>set_bandwidth(self[, bw_method])</code>	Compute the estimator bandwidth with given method.
<code>covariance_factor(self)</code>	Computes the coefficient ( <i>kde.factor</i> ) that multiplies the data covariance matrix to obtain the kernel covariance matrix.

### scipy.stats.gaussian\_kde.evaluate

`gaussian_kde.evaluate(self, points)`

Evaluate the estimated pdf on a set of points.

#### Parameters

**points** [(# of dimensions, # of points)-array] Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

#### Returns

**values** [(# of points,)-array] The values at each point.

#### Raises

##### ValueError

[if the dimensionality of the input points is different than] the dimensionality of the KDE.

### scipy.stats.gaussian\_kde.\_\_call\_\_

`gaussian_kde.__call__(self, points)`

Evaluate the estimated pdf on a set of points.

#### Parameters

**points** [(# of dimensions, # of points)-array] Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

#### Returns

**values** [(# of points,)-array] The values at each point.

#### Raises

##### ValueError

[if the dimensionality of the input points is different than] the dimensionality of the KDE.

### scipy.stats.gaussian\_kde.integrate\_gaussian

`gaussian_kde.integrate_gaussian(self, mean, cov)`

Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

#### Parameters

**mean** [array\_like] A 1-D array, specifying the mean of the Gaussian.

**cov** [array\_like] A 2-D array, specifying the covariance matrix of the Gaussian.

#### Returns

**result** [scalar] The value of the integral.

**Raises****ValueError**

If the mean or covariance of the input Gaussian differs from the KDE's dimensionality.

**scipy.stats.gaussian\_kde.integrate\_box\_1d**

`gaussian_kde.integrate_box_1d` (*self*, *low*, *high*)

Computes the integral of a 1D pdf between two bounds.

**Parameters**

**low** [scalar] Lower bound of integration.

**high** [scalar] Upper bound of integration.

**Returns**

**value** [scalar] The result of the integral.

**Raises****ValueError**

If the KDE is over more than one dimension.

**scipy.stats.gaussian\_kde.integrate\_box**

`gaussian_kde.integrate_box` (*self*, *low\_bounds*, *high\_bounds*, *maxpts=None*)

Computes the integral of a pdf over a rectangular interval.

**Parameters**

**low\_bounds** [array\_like] A 1-D array containing the lower bounds of integration.

**high\_bounds** [array\_like] A 1-D array containing the upper bounds of integration.

**maxpts** [int, optional] The maximum number of points to use for integration.

**Returns**

**value** [scalar] The result of the integral.

**scipy.stats.gaussian\_kde.integrate\_kde**

`gaussian_kde.integrate_kde` (*self*, *other*)

Computes the integral of the product of this kernel density estimate with another.

**Parameters**

**other** [gaussian\_kde instance] The other kde.

**Returns**

**value** [scalar] The result of the integral.

**Raises****ValueError**

If the KDEs have different dimensionality.

**scipy.stats.gaussian\_kde.pdf**`gaussian_kde.pdf` (*self*, *x*)

Evaluate the estimated pdf on a provided set of points.

**Notes**

This is an alias for `gaussian_kde.evaluate`. See the `evaluate` docstring for more details.

**scipy.stats.gaussian\_kde.logpdf**`gaussian_kde.logpdf` (*self*, *x*)

Evaluate the log of the estimated pdf on a provided set of points.

**scipy.stats.gaussian\_kde.resample**`gaussian_kde.resample` (*self*, *size=None*, *seed=None*)

Randomly sample a dataset from the estimated pdf.

**Parameters**

- size** [int, optional] The number of samples to draw. If not provided, then the size is the same as the effective number of samples in the underlying dataset.
- seed** [{None, int, *RandomState*, *Generator*}, optional] This parameter defines the object to use for drawing random variates. If *seed* is *None* the *RandomState* singleton is used. If *seed* is an int, a new *RandomState* instance is used, seeded with *seed*. If *seed* is already a *RandomState* or *Generator* instance, then that object is used. Default is *None*. Specify *seed* for reproducible drawing of random variates.

**Returns**

- resample** [(*self.d*, *size*) ndarray] The sampled dataset.

**scipy.stats.gaussian\_kde.set\_bandwidth**`gaussian_kde.set_bandwidth` (*self*, *bw\_method=None*)

Compute the estimator bandwidth with given method.

The new bandwidth calculated after a call to `set_bandwidth` is used for subsequent evaluations of the estimated density.

**Parameters**

- bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as *kde.factor*. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If *None* (default), nothing happens; the current *kde.covariance\_factor* method is kept.

## Notes

New in version 0.11.

## Examples

```
>>> import scipy.stats as stats
>>> x1 = np.array([-7, -5, 1, 4, 5.])
>>> kde = stats.gaussian_kde(x1)
>>> xs = np.linspace(-10, 10, num=50)
>>> y1 = kde(xs)
>>> kde.set_bandwidth(bw_method='silverman')
>>> y2 = kde(xs)
>>> kde.set_bandwidth(bw_method=kde.factor / 3.)
>>> y3 = kde(xs)
```

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.plot(x1, np.full(x1.shape, 1 / (4. * x1.size)), 'bo',
...        label='Data points (rescaled)')
>>> ax.plot(xs, y1, label='Scott (default)')
>>> ax.plot(xs, y2, label='Silverman')
>>> ax.plot(xs, y3, label='Const (1/3 * Silverman)')
>>> ax.legend()
>>> plt.show()
```

### scipy.stats.gaussian\_kde.covariance\_factor

`gaussian_kde.covariance_factor` (*self*)

Computes the coefficient (*kde.factor*) that multiplies the data covariance matrix to obtain the kernel covariance matrix. The default is `scotts_factor`. A subclass can overwrite this method to provide a different method, or set it through a call to `kde.set_bandwidth`.

## 6.29.19 Warnings used in `scipy.stats`

<code>F_onewayConstantInputWarning([msg])</code>	Warning generated by <code>f_oneway</code> when an input is constant, e.g.
<code>F_onewayBadInputSizesWarning</code>	Warning generated by <code>f_oneway</code> when an input has length 0, or if all the inputs have length 1.
<code>PearsonRConstantInputWarning([msg])</code>	Warning generated by <code>pearsonr</code> when an input is constant.
<code>PearsonRNearConstantInputWarning([msg])</code>	Warning generated by <code>pearsonr</code> when an input is nearly constant.
<code>SpearmanRConstantInputWarning([msg])</code>	Warning generated by <code>spearmanr</code> when an input is constant.

### scipy.stats.F\_onewayConstantInputWarning

**exception** `scipy.stats.F_onewayConstantInputWarning` (*msg=None*)

Warning generated by `f_oneway` when an input is constant, e.g. each of the samples provided is a constant array.

**with\_traceback** ()

Exception.with\_traceback(tb) – set `self.__traceback__` to `tb` and return `self`.

### scipy.stats.F\_onewayBadInputSizesWarning

**exception** `scipy.stats.F_onewayBadInputSizesWarning`

Warning generated by `f_oneway` when an input has length 0, or if all the inputs have length 1.

**with\_traceback** ()

Exception.with\_traceback(tb) – set `self.__traceback__` to `tb` and return `self`.

### scipy.stats.PearsonRConstantInputWarning

**exception** `scipy.stats.PearsonRConstantInputWarning` (*msg=None*)

Warning generated by `pearsonr` when an input is constant.

**with\_traceback** ()

Exception.with\_traceback(tb) – set `self.__traceback__` to `tb` and return `self`.

### scipy.stats.PearsonRNearConstantInputWarning

**exception** `scipy.stats.PearsonRNearConstantInputWarning` (*msg=None*)  
Warning generated by `pearsonr` when an input is nearly constant.

**with\_traceback** ()  
Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### scipy.stats.SpearmanRConstantInputWarning

**exception** `scipy.stats.SpearmanRConstantInputWarning` (*msg=None*)  
Warning generated by `spearmanr` when an input is constant.

**with\_traceback** ()  
Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

For many more stat related functions install the software R and the interface package rpy.

## 6.30 Low-level callback functions

Some functions in SciPy take as arguments callback functions, which can either be python callables or low-level compiled functions. Using compiled callback functions can improve performance somewhat by avoiding wrapping data in Python objects.

Such low-level functions in SciPy are wrapped in `LowLevelCallable` objects, which can be constructed from function pointers obtained from ctypes, cffi, Cython, or contained in Python `PyCapsule` objects.

---

<code>LowLevelCallable(function[, user_data, ...])</code>	Low-level callback function.
---	------------------------------

---

### 6.30.1 scipy.LowLevelCallable

**class** `scipy.LowLevelCallable` (*function, user\_data=None, signature=None*)  
Low-level callback function.

#### Parameters

**function** `[[PyCapsule, ctypes function pointer, cffi function pointer]]` Low-level callback function.  
**user\_data** `[[PyCapsule, ctypes void pointer, cffi void pointer]]` User data to pass on to the callback function.  
**signature** `[str, optional]` Signature of the function. If omitted, determined from *function*, if possible.

#### Notes

The argument *function* can be one of:

- PyCapsule, whose name contains the C function signature
- ctypes function pointer
- cffi function pointer

The signature of the low-level callback must match one of those expected by the routine it is passed to.

If constructing low-level functions from a PyCapsule, the name of the capsule must be the corresponding signature, in the format:

```
return_type (arg1_type, arg2_type, ...)
```

For example:

```
"void (double)"
"double (double, int *, void *)"
```

The context of a PyCapsule passed in as `function` is used as `user_data`, if an explicit value for `user_data` was not given.

#### Attributes

**function**    Callback function given.  
**user\_data**    User data given.  
**signature**    Signature of the function.

#### Methods

---

<code>from_cython(module, name[, user_data, signature])</code>	Create a low-level callback function from an exported Cython function.
--	--

---

### scipy.LowLevelCallable.from\_cython

**classmethod** `LowLevelCallable.from_cython(module, name, user_data=None, signature=None)`  
 Create a low-level callback function from an exported Cython function.

#### Parameters

**module**    [module] Cython module where the exported function resides  
**name**        [str] Name of the exported function  
**user\_data**    [{PyCapsule, ctypes void pointer, cffi void pointer}, optional] User data to pass on to the callback function.  
**signature**    [str, optional] Signature of the function. If omitted, determined from *function*.

#### See also:

Functions accepting low-level callables:

`scipy.integrate.quad`,                    `scipy.ndimage.generic_filter`,                    `scipy.ndimage.generic_filter1d`, `scipy.ndimage.geometric_transform`

Usage examples:

*Extending scipy.ndimage in C, Faster integration using low-level callback functions*
