| <code>keys()</code>                              |                                                                                                                                                                                                                                                                                                                             |
| <code>maximum(other)</code>                      | Element-wise maximum between this and another matrix.                                                                                                                                                                                                                                                                       |
| <code>mean([axis, dtype, out])</code>            | Compute the arithmetic mean along the specified axis.                                                                                                                                                                                                                                                                       |
| <code>minimum(other)</code>                      | Element-wise minimum between this and another matrix.                                                                                                                                                                                                                                                                       |
| <code>multiply(other)</code>                     | Point-wise multiplication by another matrix                                                                                                                                                                                                                                                                                 |
| <code>nonzero()</code>                           | nonzero indices                                                                                                                                                                                                                                                                                                             |
| <code>pop(k[,d])</code>                          | If key is not found, <i>d</i> is returned if given, otherwise <code>KeyError</code> is raised                                                                                                                                                                                                                               |
| <code>popitem()</code>                           | Remove and return a (key, value) pair as a 2-tuple.                                                                                                                                                                                                                                                                         |
| <code>power(n[, dtype])</code>                   | Element-wise power.                                                                                                                                                                                                                                                                                                         |
| <code>reshape(self, shape[, order, copy])</code> | Gives a new shape to a sparse matrix without changing its data.                                                                                                                                                                                                                                                             |
| <code>resize(*shape)</code>                      | Resize the matrix in-place to dimensions given by <i>shape</i>                                                                                                                                                                                                                                                              |
| <code>set_shape(shape)</code>                    | See <code>reshape</code> .                                                                                                                                                                                                                                                                                                  |
| <code>setdefault(key[, default])</code>          | Insert key with a value of <i>default</i> if key is not in the dictionary.                                                                                                                                                                                                                                                  |
| <code>setdiag(values[, k])</code>                | Set diagonal or off-diagonal elements of the array.                                                                                                                                                                                                                                                                         |
| <code>sum([axis, dtype, out])</code>             | Sum the matrix elements over a given axis.                                                                                                                                                                                                                                                                                  |
| <code>toarray([order, out])</code>               | Return a dense ndarray representation of this matrix.                                                                                                                                                                                                                                                                       |
| <code>tobsr([blocksize, copy])</code>            | Convert this matrix to Block Sparse Row format.                                                                                                                                                                                                                                                                             |
| <code>tocoo([copy])</code>                       | Convert this matrix to COOrdinate format.                                                                                                                                                                                                                                                                                   |
| <code>tocsc([copy])</code>                       | Convert this matrix to Compressed Sparse Column format.                                                                                                                                                                                                                                                                     |
| <code>tocsr([copy])</code>                       | Convert this matrix to Compressed Sparse Row format.                                                                                                                                                                                                                                                                        |
| <code>todense([order, out])</code>               | Return a dense matrix representation of this matrix.                                                                                                                                                                                                                                                                        |
| <code>todia([copy])</code>                       | Convert this matrix to sparse DIAgonal format.                                                                                                                                                                                                                                                                              |
| <code>todok([copy])</code>                       | Convert this matrix to Dictionary Of Keys format.                                                                                                                                                                                                                                                                           |
| <code>tolil([copy])</code>                       | Convert this matrix to List of Lists format.                                                                                                                                                                                                                                                                                |
| <code>transpose([axes, copy])</code>             | Reverses the dimensions of the sparse matrix.                                                                                                                                                                                                                                                                               |
| <code>update([E, ]**F)</code>                    | If <i>E</i> is present and has a <code>.keys()</code> method, then does: for <i>k</i> in <i>E</i> : $D[k] = E[k]$ If <i>E</i> is present and lacks a <code>.keys()</code> method, then does: for <i>k</i> , <i>v</i> in <i>E</i> : $D[k] = v$ In either case, this is followed by: for <i>k</i> in <i>F</i> : $D[k] = F[k]$ |
| <code>values()</code>                            |                                                                                                                                                                                                                                                                                                                             |

**scipy.sparse.dok\_matrix.\_\_len\_\_**

`dok_matrix.__len__()`  
Return `len(self)`.

**scipy.sparse.dok\_matrix.\_\_mul\_\_**

`dok_matrix.__mul__(other)`  
interpret `other` and call one of the following  
`self._mul_scalar()` `self._mul_vector()` `self._mul_multivector()` `self._mul_sparse_matrix()`

**scipy.sparse.dok\_matrix.asformat**

`dok_matrix.asformat(format, copy=False)`  
Return this matrix in the passed format.

**Parameters**

**format** [str, None] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, ...) or None for no conversion.  
**copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

**A** [This matrix in the passed format.]

**scipy.sparse.dok\_matrix.asfptype**

`dok_matrix.asfptype()`  
Upcast matrix to a floating point format (if necessary)

**scipy.sparse.dok\_matrix.astype**

`dok_matrix.astype(dtype, casting='unsafe', copy=True)`  
Cast the matrix elements to a specified type.

**Parameters**

**dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.  
**casting** [{'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same\_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.  
**copy** [bool, optional] If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

### **scipy.sparse.dok\_matrix.clear**

`dok_matrix.clear()` → None. Remove all items from D.

### **scipy.sparse.dok\_matrix.conj**

`dok_matrix.conj(copy=True)`  
Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

#### *Parameters*

**copy** [bool, optional] If True, the result is guaranteed to not share data with self.

#### *Returns*

**A** [The element-wise complex conjugate.]

### **scipy.sparse.dok\_matrix.conjtransp**

`dok_matrix.conjtransp()`  
Return the conjugate transpose.

### **scipy.sparse.dok\_matrix.conjugate**

`dok_matrix.conjugate(copy=True)`  
Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is False, this method does nothing and the data is not copied.

#### *Parameters*

**copy** [bool, optional] If True, the result is guaranteed to not share data with self.

#### *Returns*

**A** [The element-wise complex conjugate.]

### **scipy.sparse.dok\_matrix.copy**

`dok_matrix.copy()`  
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.dok\_matrix.count\_nonzero**

`dok_matrix.count_nonzero()`  
 Number of non-zero entries, equivalent to  
`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.dok\_matrix.diagonal**

`dok_matrix.diagonal(k=0)`  
 Returns the kth diagonal of the matrix.

**Parameters**

**k** [int, optional] Which diagonal to get, corresponding to elements `a[i, i+k]`. Default: 0 (the main diagonal).  
 New in version 1.0.

**See also:*****numpy.diagonal***

Equivalent numpy function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.dok\_matrix.dot**

`dok_matrix.dot(other)`  
 Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([1, -3, -1], dtype=int64)
```

### **scipy.sparse.dok\_matrix.fromkeys**

`dok_matrix.fromkeys` (*iterable*, *value=None*, /)  
Create a new dictionary with keys from *iterable* and values set to *value*.

### **scipy.sparse.dok\_matrix.get**

`dok_matrix.get` (*key*, *default=0.0*)  
This overrides the `dict.get` method, providing type checking but otherwise equivalent functionality.

### **scipy.sparse.dok\_matrix.getH**

`dok_matrix.getH` ()  
Return the Hermitian transpose of this matrix.

**See also:**

*`numpy.matrix.getH`*

NumPy's implementation of *getH* for matrices

### **scipy.sparse.dok\_matrix.get\_shape**

`dok_matrix.get_shape` ()  
Get shape of a matrix.

### **scipy.sparse.dok\_matrix.getcol**

`dok_matrix.getcol` (*j*)  
Returns a copy of column *j* of the matrix, as an (*m* x 1) sparse matrix (column vector).

### **scipy.sparse.dok\_matrix.getformat**

`dok_matrix.getformat` ()  
Format of a matrix representation as a string.

### **scipy.sparse.dok\_matrix.getmaxprint**

`dok_matrix.getmaxprint` ()  
Maximum number of elements to display when printed.

**scipy.sparse.dok\_matrix.getnnz**`dok_matrix.getnnz` (*axis=None*)

Number of stored values, including explicit zeros.

*Parameters*

**axis** [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

**See also:**`count_nonzero`

Number of non-zero entries

**scipy.sparse.dok\_matrix.getrow**`dok_matrix.getrow` (*i*)Returns a copy of row *i* of the matrix, as a (1 x n) sparse matrix (row vector).**scipy.sparse.dok\_matrix.items**`dok_matrix.items` () → a set-like object providing a view on D's items**scipy.sparse.dok\_matrix.keys**`dok_matrix.keys` () → a set-like object providing a view on D's keys**scipy.sparse.dok\_matrix.maximum**`dok_matrix.maximum` (*other*)

Element-wise maximum between this and another matrix.

**scipy.sparse.dok\_matrix.mean**`dok_matrix.mean` (*axis=None, dtype=None, out=None*)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.*Parameters*

**axis** [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis = None*).

**dtype** [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.  
New in version 0.18.0.

**out** [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
New in version 0.18.0.

**Returns**

**m** [np.matrix]

**See also:**

*numpy.matrix.mean*

NumPy's implementation of 'mean' for matrices

**scipy.sparse.dok\_matrix.minimum**

`dok_matrix.minimum` (*other*)  
Element-wise minimum between this and another matrix.

**scipy.sparse.dok\_matrix.multiply**

`dok_matrix.multiply` (*other*)  
Point-wise multiplication by another matrix

**scipy.sparse.dok\_matrix.nonzero**

`dok_matrix.nonzero` ()  
nonzero indices  
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.dok\_matrix.pop**

`dok_matrix.pop` (*k*[, *d*]) → *v*, remove specified key and return the corresponding value.  
If key is not found, *d* is returned if given, otherwise `KeyError` is raised

**scipy.sparse.dok\_matrix.popitem**`dok_matrix.popitem (/)`

Remove and return a (key, value) pair as a 2-tuple.

Pairs are returned in LIFO (last-in, first-out) order. Raises `KeyError` if the dict is empty.**scipy.sparse.dok\_matrix.power**`dok_matrix.power (n, dtype=None)`

Element-wise power.

**scipy.sparse.dok\_matrix.reshape**`dok_matrix.reshape (self, shape, order='C', copy=False)`

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

|              |                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>shape</b> | [length-2 tuple of ints] The new shape should be compatible with the original shape.                                                                                                                                                                                                                                     |
| <b>order</b> | [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc. |
| <b>copy</b>  | [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.                                                                                                                     |

**Returns****reshaped\_matrix**[sparse matrix] A sparse matrix with the given `shape`, not necessarily of the same format as the current object.**See also:**[`numpy.matrix.reshape`](#)

NumPy's implementation of 'reshape' for matrices

**scipy.sparse.dok\_matrix.resize**`dok_matrix.resize (*shape)`Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

**Parameters**

|              |                                                           |
|--------------|-----------------------------------------------------------|
| <b>shape</b> | [(int, int)] number of rows and columns in the new matrix |
|--------------|-----------------------------------------------------------|

## Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In `numpy`, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

### `scipy.sparse.dok_matrix.set_shape`

`dok_matrix.set_shape` (*shape*)  
See *reshape*.

### `scipy.sparse.dok_matrix.setdefault`

`dok_matrix.setdefault` (*key*, *default=None*, /)  
Insert key with a value of default if key is not in the dictionary.  
Return the value for key if key is in the dictionary, else default.

### `scipy.sparse.dok_matrix.setdiag`

`dok_matrix.setdiag` (*values*, *k=0*)  
Set diagonal or off-diagonal elements of the array.

#### Parameters

**values** [array\_like] New values of the diagonal elements.  
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.  
If a scalar value is given, all of the diagonal is set to it.

**k** [int, optional] Which off-diagonal to set, corresponding to elements  $a[i,i+k]$ . Default: 0 (the main diagonal).

### `scipy.sparse.dok_matrix.sum`

`dok_matrix.sum` (*axis=None*, *dtype=None*, *out=None*)  
Sum the matrix elements over a given axis.

#### Parameters

**axis** [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis = None*).

**dtype** [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.  
New in version 0.18.0.

**out** [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
New in version 0.18.0.

**Returns**

**sum\_along\_axis**  
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

*numpy.matrix.sum*

NumPy's implementation of 'sum' for matrices

**scipy.sparse.dok\_matrix.toarray**

`dok_matrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters**

**order** [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.

**out** [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns**

**arr** [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.dok\_matrix.tobsr**

`dok_matrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant *bsr\_matrix*.

When *blocksize=(R, C)* is provided, it will be used for construction of the *bsr\_matrix*.

**scipy.sparse.dok\_matrix.tocoo**

`dok_matrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant *coo\_matrix*.

### scipy.sparse.dok\_matrix.tocsc

`dok_matrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.

### scipy.sparse.dok\_matrix.tocsr

`dok_matrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.

### scipy.sparse.dok\_matrix.todense

`dok_matrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

#### Parameters

- order** [`'C'`, `'F'`], optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is `'None'`, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.
- out** [`ndarray`, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

#### Returns

- arr** [`numpy.matrix`, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

### scipy.sparse.dok\_matrix.todia

`dok_matrix.todia` (*copy=False*)

Convert this matrix to sparse DIAGONAL format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

### scipy.sparse.dok\_matrix.todok

`dok_matrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

**scipy.sparse.dok\_matrix.tolil**`dok_matrix.tolil` (*copy=False*)

Convert this matrix to List of Lists format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `lil_matrix`.**scipy.sparse.dok\_matrix.transpose**`dok_matrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

**Parameters**

- axes** [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.
- copy** [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- p** [*self* with the dimensions reversed.]

**See also:**[\*numpy.matrix.transpose\*](#)

NumPy's implementation of 'transpose' for matrices

**scipy.sparse.dok\_matrix.update**`dok_matrix.update` ( $[E]$ ,  $**F$ )  $\rightarrow$  None. Update D from dict/iterable E and F.If E is present and has a `.keys()` method, then does: for k in E: D[k] = E[k] If E is present and lacks a `.keys()` method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]**scipy.sparse.dok\_matrix.values**`dok_matrix.values` ()  $\rightarrow$  an object providing a view on D's values

|                          |  |
|--------------------------|--|
| <code>__getitem__</code> |  |
|--------------------------|--|

**scipy.sparse.lil\_matrix****class** `scipy.sparse.lil_matrix` (*arg1, shape=None, dtype=None, copy=False*)

Row-based list of lists sparse matrix

This is a structure for constructing sparse matrices incrementally. Note that inserting a single item can take linear time in the worst case; to construct a matrix efficiently, make sure the items are pre-sorted by index, per row.

*This can be instantiated in several ways:*

**`lil_matrix(D)`**

with a dense matrix or rank-2 ndarray D

**`lil_matrix(S)`**

with another sparse matrix S (equivalent to `S.tolil()`)

**`lil_matrix((M, N), [dtype])`**

to construct an empty matrix with shape (M, N) dtype is optional, defaulting to `dtype='d'`.

**Notes**

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

*Advantages of the LIL format*

- supports flexible slicing
- changes to the matrix sparsity structure are efficient

*Disadvantages of the LIL format*

- arithmetic operations LIL + LIL are slow (consider CSR or CSC)
- slow column slicing (consider CSC)
- slow matrix vector products (consider CSR or CSC)

*Intended Usage*

- LIL is a convenient format for constructing sparse matrices
- once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
- consider using the COO format when constructing large matrices

*Data Structure*

- An array (`self.rows`) of rows, each of which is a sorted list of column indices of non-zero elements.
- The corresponding nonzero values are stored in similar fashion in `self.data`.

*Attributes*

|              |                                                    |
|--------------|----------------------------------------------------|
| <b>dtype</b> | [dtype] Data type of the matrix                    |
| <b>shape</b> | [2-tuple] Get shape of a matrix.                   |
| <b>ndim</b>  | [int] Number of dimensions (this is always 2)      |
| <b>nnz</b>   | Number of stored values, including explicit zeros. |
| <b>data</b>  | LIL format data array of the matrix                |
| <b>rows</b>  | LIL format row index array of the matrix           |

## Methods

|                                                  |                                                                                        |
|--------------------------------------------------|----------------------------------------------------------------------------------------|
| <code>__len__()</code>                           |                                                                                        |
| <code>__mul__(other)</code>                      | interpret other and call one of the following                                          |
| <code>asformat(format[, copy])</code>            | Return this matrix in the passed format.                                               |
| <code>asfptype()</code>                          | Upcast matrix to a floating point format (if necessary)                                |
| <code>astype(dtype[, casting, copy])</code>      | Cast the matrix elements to a specified type.                                          |
| <code>conj([copy])</code>                        | Element-wise complex conjugation.                                                      |
| <code>conjugate([copy])</code>                   | Element-wise complex conjugation.                                                      |
| <code>copy()</code>                              | Returns a copy of this matrix.                                                         |
| <code>count_nonzero()</code>                     | Number of non-zero entries, equivalent to                                              |
| <code>diagonal([k])</code>                       | Returns the kth diagonal of the matrix.                                                |
| <code>dot(other)</code>                          | Ordinary dot product                                                                   |
| <code>getH()</code>                              | Return the Hermitian transpose of this matrix.                                         |
| <code>get_shape()</code>                         | Get shape of a matrix.                                                                 |
| <code>getcol(j)</code>                           | Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector). |
| <code>getformat()</code>                         | Format of a matrix representation as a string.                                         |
| <code>getmaxprint()</code>                       | Maximum number of elements to display when printed.                                    |
| <code>getnnz([axis])</code>                      | Number of stored values, including explicit zeros.                                     |
| <code>getrow(i)</code>                           | Returns a copy of the 'i'th row.                                                       |
| <code>getrowview(i)</code>                       | Returns a view of the 'i'th row (without copying).                                     |
| <code>maximum(other)</code>                      | Element-wise maximum between this and another matrix.                                  |
| <code>mean([axis, dtype, out])</code>            | Compute the arithmetic mean along the specified axis.                                  |
| <code>minimum(other)</code>                      | Element-wise minimum between this and another matrix.                                  |
| <code>multiply(other)</code>                     | Point-wise multiplication by another matrix                                            |
| <code>nonzero()</code>                           | nonzero indices                                                                        |
| <code>power(n[, dtype])</code>                   | Element-wise power.                                                                    |
| <code>reshape(self, shape[, order, copy])</code> | Gives a new shape to a sparse matrix without changing its data.                        |
| <code>resize(*shape)</code>                      | Resize the matrix in-place to dimensions given by shape                                |
| <code>set_shape(shape)</code>                    | See <i>reshape</i> .                                                                   |
| <code>setdiag(values[, k])</code>                | Set diagonal or off-diagonal elements of the array.                                    |
| <code>sum([axis, dtype, out])</code>             | Sum the matrix elements over a given axis.                                             |
| <code>toarray([order, out])</code>               | Return a dense ndarray representation of this matrix.                                  |
| <code>tobsr([blocksize, copy])</code>            | Convert this matrix to Block Sparse Row format.                                        |
| <code>tocoo([copy])</code>                       | Convert this matrix to COOrdinate format.                                              |
| <code>tocsc([copy])</code>                       | Convert this matrix to Compressed Sparse Column format.                                |
| <code>tocsr([copy])</code>                       | Convert this matrix to Compressed Sparse Row format.                                   |
| <code>todense([order, out])</code>               | Return a dense matrix representation of this matrix.                                   |
| <code>todia([copy])</code>                       | Convert this matrix to sparse DIAGonal format.                                         |
| <code>todok([copy])</code>                       | Convert this matrix to Dictionary Of Keys format.                                      |
| <code>tolil([copy])</code>                       | Convert this matrix to List of Lists format.                                           |
| <code>transpose([axes, copy])</code>             | Reverses the dimensions of the sparse matrix.                                          |

### scipy.sparse.lil\_matrix.\_\_len\_\_

`lil_matrix.__len__()`

### scipy.sparse.lil\_matrix.\_\_mul\_\_

`lil_matrix.__mul__(other)`

interpret other and call one of the following

`self._mul_scalar()` `self._mul_vector()` `self._mul_multivector()` `self._mul_sparse_matrix()`

### scipy.sparse.lil\_matrix.asformat

`lil_matrix.asformat(format, copy=False)`

Return this matrix in the passed format.

#### Parameters

**format** [{str, None}] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, ...) or None for no conversion.  
**copy** [bool, optional] If True, the result is guaranteed to not share data with self.

#### Returns

**A** [This matrix in the passed format.]

### scipy.sparse.lil\_matrix.asfptype

`lil_matrix.asfptype()`

Upcast matrix to a floating point format (if necessary)

### scipy.sparse.lil\_matrix.astype

`lil_matrix.astype(dtype, casting='unsafe', copy=True)`

Cast the matrix elements to a specified type.

#### Parameters

**dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.  
**casting** [{'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same\_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.  
**copy** [bool, optional] If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.lil\_matrix.conj**`lil_matrix.conj (copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is `False`, this method does nothing and the data is not copied.

**Parameters**

**copy** [bool, optional] If `True`, the result is guaranteed to not share data with self.

**Returns**

**A** [The element-wise complex conjugate.]

**scipy.sparse.lil\_matrix.conjugate**`lil_matrix.conjugate (copy=True)`

Element-wise complex conjugation.

If the matrix is of non-complex data type and `copy` is `False`, this method does nothing and the data is not copied.

**Parameters**

**copy** [bool, optional] If `True`, the result is guaranteed to not share data with self.

**Returns**

**A** [The element-wise complex conjugate.]

**scipy.sparse.lil\_matrix.copy**`lil_matrix.copy ()`

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.lil\_matrix.count\_nonzero**`lil_matrix.count_nonzero ()`

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

### scipy.sparse.lil\_matrix.diagonal

`lil_matrix.diagonal` ( $k=0$ )

Returns the  $k$ th diagonal of the matrix.

#### Parameters

**k** [int, optional] Which diagonal to get, corresponding to elements  $a[i, i+k]$ . Default: 0 (the main diagonal).  
New in version 1.0.

See also:

*numpy.diagonal*

Equivalent numpy function.

#### Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

### scipy.sparse.lil\_matrix.dot

`lil_matrix.dot` (*other*)

Ordinary dot product

#### Examples

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([1, -3, -1], dtype=int64)
```

### scipy.sparse.lil\_matrix.getH

`lil_matrix.getH`()

Return the Hermitian transpose of this matrix.

See also:

*numpy.matrix.getH*

NumPy's implementation of *getH* for matrices

**scipy.sparse.lil\_matrix.get\_shape**

```
lil_matrix.get_shape()
```

Get shape of a matrix.

**scipy.sparse.lil\_matrix.getcol**

```
lil_matrix.getcol(j)
```

Returns a copy of column *j* of the matrix, as an (*m* x 1) sparse matrix (column vector).

**scipy.sparse.lil\_matrix.getformat**

```
lil_matrix.getformat()
```

Format of a matrix representation as a string.

**scipy.sparse.lil\_matrix.getmaxprint**

```
lil_matrix.getmaxprint()
```

Maximum number of elements to display when printed.

**scipy.sparse.lil\_matrix.getnnz**

```
lil_matrix.getnnz(axis=None)
```

Number of stored values, including explicit zeros.

**Parameters**

**axis** [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

**See also:****`count_nonzero`**

Number of non-zero entries

**scipy.sparse.lil\_matrix.getrow**

```
lil_matrix.getrow(i)
```

Returns a copy of the *i*'th row.

**scipy.sparse.lil\_matrix.getrowview**

`lil_matrix.getrowview(i)`  
Returns a view of the *i*'th row (without copying).

**scipy.sparse.lil\_matrix.maximum**

`lil_matrix.maximum(other)`  
Element-wise maximum between this and another matrix.

**scipy.sparse.lil\_matrix.mean**

`lil_matrix.mean(axis=None, dtype=None, out=None)`  
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

**Parameters**

- axis** [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis = None*).
- dtype** [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.  
New in version 0.18.0.
- out** [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
New in version 0.18.0.

**Returns**

- m** [np.matrix]

**See also:**

[\*numpy.matrix.mean\*](#)

NumPy's implementation of 'mean' for matrices

**scipy.sparse.lil\_matrix.minimum**

`lil_matrix.minimum(other)`  
Element-wise minimum between this and another matrix.

**scipy.sparse.lil\_matrix.multiply**

`lil_matrix.multiply` (*other*)  
Point-wise multiplication by another matrix

**scipy.sparse.lil\_matrix.nonzero**

`lil_matrix.nonzero` ()  
nonzero indices  
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**scipy.sparse.lil\_matrix.power**

`lil_matrix.power` (*n*, *dtype=None*)  
Element-wise power.

**scipy.sparse.lil\_matrix.reshape**

`lil_matrix.reshape` (*self*, *shape*, *order='C'*, *copy=False*)  
Gives a new shape to a sparse matrix without changing its data.

**Parameters**

|              |                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>shape</b> | [length-2 tuple of ints] The new shape should be compatible with the original shape.                                                                                                                                                                                                                                     |
| <b>order</b> | [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc. |
| <b>copy</b>  | [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.                                                                                                                     |

**Returns**

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>reshaped_matrix</b> | [sparse matrix] A sparse matrix with the given <i>shape</i> , not necessarily of the same format as the current object. |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|

**See also:**

[\*numpy.matrix.reshape\*](#)

NumPy's implementation of 'reshape' for matrices

### scipy.sparse.lil\_matrix.resize

`lil_matrix.resize(*shape)`

Resize the matrix in-place to dimensions given by `shape`

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

#### Parameters

**shape** [(int, int)] number of rows and columns in the new matrix

#### Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In `numpy`, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

### scipy.sparse.lil\_matrix.set\_shape

`lil_matrix.set_shape(shape)`

See `reshape`.

### scipy.sparse.lil\_matrix.setdiag

`lil_matrix.setdiag(values, k=0)`

Set diagonal or off-diagonal elements of the array.

#### Parameters

**values** [array\_like] New values of the diagonal elements. Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.

**k** [int, optional] Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

### scipy.sparse.lil\_matrix.sum

`lil_matrix.sum(axis=None, dtype=None, out=None)`

Sum the matrix elements over a given axis.

#### Parameters

**axis** [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., `axis = None`).

- dtype** [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.  
New in version 0.18.0.
- out** [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
New in version 0.18.0.

**Returns****sum\_along\_axis**

[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

[\*numpy.matrix.sum\*](#)

NumPy's implementation of 'sum' for matrices

**scipy.sparse.lil\_matrix.toarray**

`lil_matrix.toarray` (*order=None, out=None*)

Return a dense ndarray representation of this matrix.

**Parameters**

- order** [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.
- out** [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- arr** [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.lil\_matrix.tobsr**

`lil_matrix.tobsr` (*blocksize=None, copy=False*)

Convert this matrix to Block Sparse Row format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant *bsr\_matrix*.

When *blocksize=(R, C)* is provided, it will be used for construction of the *bsr\_matrix*.

**scipy.sparse.lil\_matrix.tocoo**`lil_matrix.tocoo (copy=False)`

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.**scipy.sparse.lil\_matrix.tocsc**`lil_matrix.tocsc (copy=False)`

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.**scipy.sparse.lil\_matrix.tocsr**`lil_matrix.tocsr (copy=False)`

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.**scipy.sparse.lil\_matrix.todense**`lil_matrix.todense (order=None, out=None)`

Return a dense matrix representation of this matrix.

**Parameters**

- order** [{"C", "F"}, optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.
- out** [ndarray, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- arr** [numpy.matrix, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

**scipy.sparse.lil\_matrix.todia**`lil_matrix.todia (copy=False)`

Convert this matrix to sparse DIAGONal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

**scipy.sparse.lil\_matrix.todok**`lil_matrix.todok (copy=False)`

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.**scipy.sparse.lil\_matrix.tolil**`lil_matrix.tolil (copy=False)`

Convert this matrix to List of Lists format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.**scipy.sparse.lil\_matrix.transpose**`lil_matrix.transpose (axes=None, copy=False)`

Reverses the dimensions of the sparse matrix.

**Parameters**

- axes** [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.
- copy** [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- p** [*self* with the dimensions reversed.]

**See also:**[\*numpy.matrix.transpose\*](#)

NumPy's implementation of 'transpose' for matrices

|--------------------------|--|
| <code>__getitem__</code> |  |
|--------------------------|--|

**scipy.sparse.spmatrix****class** `scipy.sparse.spmatrix (maxprint=50)`

This class provides a base class for all sparse matrices. It cannot be instantiated. Most of the work is provided by subclasses.

**Attributes**

- nnz** Number of stored values, including explicit zeros.
- shape** Get shape of a matrix.

## Methods

|                                                  |                                                                                        |
|--------------------------------------------------|----------------------------------------------------------------------------------------|
| <code>__len__()</code>                           |                                                                                        |
| <code>__mul__(other)</code>                      | interpret other and call one of the following                                          |
| <code>asformat(format[, copy])</code>            | Return this matrix in the passed format.                                               |
| <code>asfptype()</code>                          | Upcast matrix to a floating point format (if necessary)                                |
| <code>astype(dtype[, casting, copy])</code>      | Cast the matrix elements to a specified type.                                          |
| <code>conj([copy])</code>                        | Element-wise complex conjugation.                                                      |
| <code>conjugate([copy])</code>                   | Element-wise complex conjugation.                                                      |
| <code>copy()</code>                              | Returns a copy of this matrix.                                                         |
| <code>count_nonzero()</code>                     | Number of non-zero entries, equivalent to                                              |
| <code>diagonal([k])</code>                       | Returns the kth diagonal of the matrix.                                                |
| <code>dot(other)</code>                          | Ordinary dot product                                                                   |
| <code>getH()</code>                              | Return the Hermitian transpose of this matrix.                                         |
| <code>get_shape()</code>                         | Get shape of a matrix.                                                                 |
| <code>getcol(j)</code>                           | Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector). |
| <code>getformat()</code>                         | Format of a matrix representation as a string.                                         |
| <code>getmaxprint()</code>                       | Maximum number of elements to display when printed.                                    |
| <code>getnnz([axis])</code>                      | Number of stored values, including explicit zeros.                                     |
| <code>getrow(i)</code>                           | Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).        |
| <code>maximum(other)</code>                      | Element-wise maximum between this and another matrix.                                  |
| <code>mean([axis, dtype, out])</code>            | Compute the arithmetic mean along the specified axis.                                  |
| <code>minimum(other)</code>                      | Element-wise minimum between this and another matrix.                                  |
| <code>multiply(other)</code>                     | Point-wise multiplication by another matrix                                            |
| <code>nonzero()</code>                           | nonzero indices                                                                        |
| <code>power(n[, dtype])</code>                   | Element-wise power.                                                                    |
| <code>reshape(self, shape[, order, copy])</code> | Gives a new shape to a sparse matrix without changing its data.                        |
| <code>resize(shape)</code>                       | Resize the matrix in-place to dimensions given by shape                                |
| <code>set_shape(shape)</code>                    | See <code>reshape</code> .                                                             |
| <code>setdiag(values[, k])</code>                | Set diagonal or off-diagonal elements of the array.                                    |
| <code>sum([axis, dtype, out])</code>             | Sum the matrix elements over a given axis.                                             |
| <code>toarray([order, out])</code>               | Return a dense ndarray representation of this matrix.                                  |
| <code>tobsr([blocksize, copy])</code>            | Convert this matrix to Block Sparse Row format.                                        |
| <code>tocoo([copy])</code>                       | Convert this matrix to COOrdinate format.                                              |
| <code>tocsc([copy])</code>                       | Convert this matrix to Compressed Sparse Column format.                                |
| <code>tocsr([copy])</code>                       | Convert this matrix to Compressed Sparse Row format.                                   |
| <code>todense([order, out])</code>               | Return a dense matrix representation of this matrix.                                   |
| <code>todia([copy])</code>                       | Convert this matrix to sparse DIAGonal format.                                         |
| <code>todok([copy])</code>                       | Convert this matrix to Dictionary Of Keys format.                                      |
| <code>tolil([copy])</code>                       | Convert this matrix to List of Lists format.                                           |
| <code>transpose([axes, copy])</code>             | Reverses the dimensions of the sparse matrix.                                          |

**scipy.sparse.spmatrix.\_\_len\_\_**

`spmatrix.__len__()`

**scipy.sparse.spmatrix.\_\_mul\_\_**

`spmatrix.__mul__(other)`

interpret other and call one of the following

`self._mul_scalar()` `self._mul_vector()` `self._mul_multivector()` `self._mul_sparse_matrix()`

**scipy.sparse.spmatrix.asformat**

`spmatrix.asformat(format, copy=False)`

Return this matrix in the passed format.

**Parameters**

**format** [{str, None}] The desired matrix format (“csr”, “csc”, “lil”, “dok”, “array”, ...) or None for no conversion.

**copy** [bool, optional] If True, the result is guaranteed to not share data with self.

**Returns**

**A** [This matrix in the passed format.]

**scipy.sparse.spmatrix.asfptype**

`spmatrix.asfptype()`

Upcast matrix to a floating point format (if necessary)

**scipy.sparse.spmatrix.astype**

`spmatrix.astype(dtype, casting='unsafe', copy=True)`

Cast the matrix elements to a specified type.

**Parameters**

**dtype** [string or numpy dtype] Typecode or data-type to which to cast the data.

**casting** [{'no', 'equiv', 'safe', 'same\_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same\_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

**copy** [bool, optional] If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

**scipy.sparse.spmatrix.conj**`spmatrix.conj` (*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

**Parameters****copy** [bool, optional] If True, the result is guaranteed to not share data with self.**Returns****A** [The element-wise complex conjugate.]**scipy.sparse.spmatrix.conjugate**`spmatrix.conjugate` (*copy=True*)

Element-wise complex conjugation.

If the matrix is of non-complex data type and *copy* is False, this method does nothing and the data is not copied.

**Parameters****copy** [bool, optional] If True, the result is guaranteed to not share data with self.**Returns****A** [The element-wise complex conjugate.]**scipy.sparse.spmatrix.copy**`spmatrix.copy` ()

Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

**scipy.sparse.spmatrix.count\_nonzero**`spmatrix.count_nonzero` ()

Number of non-zero entries, equivalent to

`np.count_nonzero(a.toarray())`

Unlike `getnnz()` and the `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

**scipy.sparse.spmatrix.diagonal**`spmatrix.diagonal` ( $k=0$ )Returns the  $k$ th diagonal of the matrix.**Parameters**

**k** [int, optional] Which diagonal to get, corresponding to elements  $a[i, i+k]$ . Default: 0 (the main diagonal).  
New in version 1.0.

**See also:***numpy.diagonal*

Equivalent numpy function.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

**scipy.sparse.spmatrix.dot**`spmatrix.dot` (*other*)

Ordinary dot product

**Examples**

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([1, -3, -1], dtype=int64)
```

**scipy.sparse.spmatrix.getH**`spmatrix.getH`()

Return the Hermitian transpose of this matrix.

**See also:***numpy.matrix.getH*NumPy's implementation of *getH* for matrices

### **scipy.sparse.spmatrix.get\_shape**

`spmatrix.get_shape()`  
Get shape of a matrix.

### **scipy.sparse.spmatrix.getcol**

`spmatrix.getcol(j)`  
Returns a copy of column *j* of the matrix, as an (*m* x 1) sparse matrix (column vector).

### **scipy.sparse.spmatrix.getformat**

`spmatrix.getformat()`  
Format of a matrix representation as a string.

### **scipy.sparse.spmatrix.getmaxprint**

`spmatrix.getmaxprint()`  
Maximum number of elements to display when printed.

### **scipy.sparse.spmatrix.getnnz**

`spmatrix.getnnz(axis=None)`  
Number of stored values, including explicit zeros.

#### *Parameters*

**axis** [None, 0, or 1] Select between the number of values across the whole matrix, in each column, or in each row.

#### **See also:**

[`count\_nonzero`](#)

Number of non-zero entries

### **scipy.sparse.spmatrix.getrow**

`spmatrix.getrow(i)`  
Returns a copy of row *i* of the matrix, as a (1 x *n*) sparse matrix (row vector).

**scipy.sparse.spmatrix.maximum**`spmatrix.maximum` (*other*)

Element-wise maximum between this and another matrix.

**scipy.sparse.spmatrix.mean**`spmatrix.mean` (*axis=None, dtype=None, out=None*)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.**Parameters**

- axis** [{-2, -1, 0, 1, None} optional] Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e., *axis = None*).
- dtype** [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.  
New in version 0.18.0.
- out** [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
New in version 0.18.0.

**Returns**

- m** [np.matrix]

**See also:**[\*numpy.matrix.mean\*](#)

NumPy's implementation of 'mean' for matrices

**scipy.sparse.spmatrix.minimum**`spmatrix.minimum` (*other*)

Element-wise minimum between this and another matrix.

**scipy.sparse.spmatrix.multiply**`spmatrix.multiply` (*other*)

Point-wise multiplication by another matrix

### scipy.sparse.spmatrix.nonzero

`spmatrix.nonzero()`  
 nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

#### Examples

```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

### scipy.sparse.spmatrix.power

`spmatrix.power(n, dtype=None)`  
 Element-wise power.

### scipy.sparse.spmatrix.reshape

`spmatrix.reshape(self, shape, order='C', copy=False)`  
 Gives a new shape to a sparse matrix without changing its data.

#### Parameters

- shape** [length-2 tuple of ints] The new shape should be compatible with the original shape.
- order** [{'C', 'F'}, optional] Read the elements using this index order. 'C' means to read and write the elements using C-like index order; e.g., read entire first row, then second row, etc. 'F' means to read and write the elements using Fortran-like index order; e.g., read entire first column, then second column, etc.
- copy** [bool, optional] Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

#### Returns

- reshaped\_matrix** [sparse matrix] A sparse matrix with the given shape, not necessarily of the same format as the current object.

#### See also:

[\*numpy.matrix.reshape\*](#)

NumPy's implementation of 'reshape' for matrices

### scipy.sparse.spmatrix.resize

`spmatrix.resize` (*shape*)

Resize the matrix in-place to dimensions given by *shape*

Any elements that lie within the new shape will remain at the same indices, while non-zero elements lying outside the new shape are removed.

#### Parameters

**shape** [(int, int)] number of rows and columns in the new matrix

#### Notes

The semantics are not identical to `numpy.ndarray.resize` or `numpy.resize`. Here, the same data will be maintained at each index before and after reshape, if that index is within the new bounds. In `numpy`, resizing maintains contiguity of the array, moving elements around in the logical matrix but not within a flattened representation.

We give no guarantees about whether the underlying data attributes (arrays, etc.) will be modified in place or replaced with new objects.

### scipy.sparse.spmatrix.set\_shape

`spmatrix.set_shape` (*shape*)

See `reshape`.

### scipy.sparse.spmatrix.setdiag

`spmatrix.setdiag` (*values*, *k=0*)

Set diagonal or off-diagonal elements of the array.

#### Parameters

**values** [array\_like] New values of the diagonal elements.  
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values are longer than the diagonal, then the remaining values are ignored.

**k** [int, optional] Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

### scipy.sparse.spmatrix.sum

`spmatrix.sum` (*axis=None*, *dtype=None*, *out=None*)

Sum the matrix elements over a given axis.

#### Parameters

**axis** [{-2, -1, 0, 1, None} optional] Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e., *axis = None*).

- dtype** [dtype, optional] The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.  
New in version 0.18.0.
- out** [np.matrix, optional] Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.  
New in version 0.18.0.

**Returns**

- sum\_along\_axis**  
[np.matrix] A matrix with the same shape as *self*, with the specified axis removed.

**See also:**

[\*numpy.matrix.sum\*](#)

NumPy's implementation of 'sum' for matrices

**scipy.sparse.spmatrix.toarray**

`spmatrix.toarray` (*order=None, out=None*)  
Return a dense ndarray representation of this matrix.

**Parameters**

- order** [{'C', 'F'}, optional] Whether to store multidimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the *out* argument.
- out** [ndarray, 2-D, optional] If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, *out* is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- arr** [ndarray, 2-D] An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If *out* was passed, the same object is returned after being modified in-place to contain the appropriate values.

**scipy.sparse.spmatrix.tobsr**

`spmatrix.tobsr` (*blocksize=None, copy=False*)  
Convert this matrix to Block Sparse Row format.  
With *copy=False*, the data/indices may be shared between this matrix and the resultant *bsr\_matrix*.  
When *blocksize=(R, C)* is provided, it will be used for construction of the *bsr\_matrix*.

**scipy.sparse.spmatrix.tocoo**`spmatrix.tocoo` (*copy=False*)

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `coo_matrix`.**scipy.sparse.spmatrix.tocsc**`spmatrix.tocsc` (*copy=False*)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csc_matrix`.**scipy.sparse.spmatrix.tocsr**`spmatrix.tocsr` (*copy=False*)

Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `csr_matrix`.**scipy.sparse.spmatrix.todense**`spmatrix.todense` (*order=None, out=None*)

Return a dense matrix representation of this matrix.

**Parameters**

- order** [`'C'`, `'F'`], optional] Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is `'None'`, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.
- out** [`ndarray`, 2-D, optional] If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- arr** [`numpy.matrix`, 2-D] A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

**scipy.sparse.spmatrix.todia**`spmatrix.todia` (*copy=False*)

Convert this matrix to sparse DIAGONal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

### scipy.sparse.spmatrix.todok

`spmatrix.todok` (*copy=False*)

Convert this matrix to Dictionary Of Keys format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

### scipy.sparse.spmatrix.tolil

`spmatrix.tolil` (*copy=False*)

Convert this matrix to List of Lists format.

With *copy=False*, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

### scipy.sparse.spmatrix.transpose

`spmatrix.transpose` (*axes=None, copy=False*)

Reverses the dimensions of the sparse matrix.

#### Parameters

- axes** [None, optional] This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value.
- copy** [bool, optional] Indicates whether or not attributes of *self* should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

#### Returns

- p** [*self* with the dimensions reversed.]

#### See also:

## Functions

Building sparse matrices:

|                                                                |                                                                  |
|----------------------------------------------------------------|------------------------------------------------------------------|
| <code>eye(m[, n, k, dtype, format])</code>                     | Sparse matrix with ones on diagonal                              |
| <code>identity(n[, dtype, format])</code>                      | Identity matrix in sparse format                                 |
| <code>kron(A, B[, format])</code>                              | kronecker product of sparse matrices A and B                     |
| <code>kronsum(A, B[, format])</code>                           | kronecker sum of sparse matrices A and B                         |
| <code>diags(diagonals[, offsets, shape, format, dtype])</code> | Construct a sparse matrix from diagonals.                        |
| <code>spdiags(data, diags, m, n[, format])</code>              | Return a sparse matrix from diagonals.                           |
| <code>block_diag(mats[, format, dtype])</code>                 | Build a block diagonal sparse matrix from provided matrices.     |
| <code>tril(A[, k, format])</code>                              | Return the lower triangular portion of a matrix in sparse format |
| <code>triu(A[, k, format])</code>                              | Return the upper triangular portion of a matrix in sparse format |
| <code>bmat(blocks[, format, dtype])</code>                     | Build a sparse matrix from sparse sub-blocks                     |

Table 183 – continued from previous page

|                                                          |                                                                                            |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------|
| <code>hstack(blocks[, format, dtype])</code>             | Stack sparse matrices horizontally (column wise)                                           |
| <code>vstack(blocks[, format, dtype])</code>             | Stack sparse matrices vertically (row wise)                                                |
| <code>rand(m, n[, density, format, dtype, ...])</code>   | Generate a sparse matrix of the given shape and density with uniformly distributed values. |
| <code>random(m, n[, density, format, dtype, ...])</code> | Generate a sparse matrix of the given shape and density with randomly distributed values.  |

## scipy.sparse.eye

`scipy.sparse.eye` (*m*, *n=None*, *k=0*, *dtype=<class 'float'>*, *format=None*)

Sparse matrix with ones on diagonal

Returns a sparse (*m* x *n*) matrix where the *k*th diagonal is all ones and everything else is zeros.

### Parameters

|               |                                                                                     |
|---------------|-------------------------------------------------------------------------------------|
| <b>m</b>      | [int] Number of rows in the matrix.                                                 |
| <b>n</b>      | [int, optional] Number of columns. Default: <i>m</i> .                              |
| <b>k</b>      | [int, optional] Diagonal to place ones on. Default: 0 (main diagonal).              |
| <b>dtype</b>  | [dtype, optional] Data type of the matrix.                                          |
| <b>format</b> | [str, optional] Sparse format of the result, e.g., <code>format="csr"</code> , etc. |

### Examples

```
>>> from scipy import sparse
>>> sparse.eye(3).toarray()
array([[1., 0., 0.],
 [0., 1., 0.],
 [0., 0., 1.]])
>>> sparse.eye(3, dtype=np.int8)
<3x3 sparse matrix of type '<class 'numpy.int8'>'
 with 3 stored elements (1 diagonals) in DIAGONAL format>
```

## scipy.sparse.identity

`scipy.sparse.identity` (*n*, *dtype='d'*, *format=None*)

Identity matrix in sparse format

Returns an identity matrix with shape (*n*,*n*) using a given sparse format and *dtype*.

### Parameters

|               |                                                                                     |
|---------------|-------------------------------------------------------------------------------------|
| <b>n</b>      | [int] Shape of the identity matrix.                                                 |
| <b>dtype</b>  | [dtype, optional] Data type of the matrix                                           |
| <b>format</b> | [str, optional] Sparse format of the result, e.g., <code>format="csr"</code> , etc. |

## Examples

```
>>> from scipy.sparse import identity
>>> identity(3).toarray()
array([[1., 0., 0.],
 [0., 1., 0.],
 [0., 0., 1.]])
>>> identity(3, dtype='int8', format='dia')
<3x3 sparse matrix of type '<class 'numpy.int8''>'
 with 3 stored elements (1 diagonals) in DIAgonal format>
```

## scipy.sparse.kron

`scipy.sparse.kron(A, B, format=None)`  
 kronecker product of sparse matrices A and B

### Parameters

**A** [sparse or dense matrix] first matrix of the product  
**B** [sparse or dense matrix] second matrix of the product  
**format** [str, optional] format of the result (e.g. “csr”)

### Returns

**kronecker product in a sparse matrix format**

## Examples

```
>>> from scipy import sparse
>>> A = sparse.csr_matrix(np.array([[0, 2], [5, 0]]))
>>> B = sparse.csr_matrix(np.array([[1, 2], [3, 4]]))
>>> sparse.kron(A, B).toarray()
array([[0, 0, 2, 4],
 [0, 0, 6, 8],
 [5, 10, 0, 0],
 [15, 20, 0, 0]])
```

```
>>> sparse.kron(A, [[1, 2], [3, 4]]).toarray()
array([[0, 0, 2, 4],
 [0, 0, 6, 8],
 [5, 10, 0, 0],
 [15, 20, 0, 0]])
```

## scipy.sparse.kronsum

`scipy.sparse.kronsum(A, B, format=None)`

Kronecker sum of sparse matrices A and B

Kronecker sum of two sparse matrices is a sum of two Kronecker products  $\text{kron}(I_n, A) + \text{kron}(B, I_m)$  where A has shape (m,m) and B has shape (n,n) and  $I_m$  and  $I_n$  are identity matrices of shape (m,m) and (n,n), respectively.

### Parameters

|               |                                         |
|---------------|-----------------------------------------|
| <b>A</b>      | square matrix                           |
| <b>B</b>      | square matrix                           |
| <b>format</b> | [str] format of the result (e.g. "csr") |

### Returns

**kronecker sum in a sparse matrix format**

## scipy.sparse.diags

`scipy.sparse.diags(diagonals, offsets=0, shape=None, format=None, dtype=None)`

Construct a sparse matrix from diagonals.

### Parameters

|                          |                                                                                                                                                                                                                    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>diagonals</b>         | [sequence of array_like] Sequence of arrays containing the matrix diagonals, corresponding to <i>offsets</i> .                                                                                                     |
| <b>offsets</b>           | [sequence of int or an int, optional]                                                                                                                                                                              |
| <b>Diagonals to set:</b> |                                                                                                                                                                                                                    |
|                          | <ul style="list-style-type: none"> <li>• <math>k = 0</math> the main diagonal (default)</li> <li>• <math>k &gt; 0</math> the kth upper diagonal</li> <li>• <math>k &lt; 0</math> the kth lower diagonal</li> </ul> |
| <b>shape</b>             | [tuple of int, optional] Shape of the result. If omitted, a square matrix large enough to contain the diagonals is returned.                                                                                       |
| <b>format</b>            | [{"dia", "csr", "csc", "lil", ...}, optional] Matrix format of the result. By default (format=None) an appropriate sparse matrix format is returned. This choice is subject to change.                             |
| <b>dtype</b>             | [dtype, optional] Data type of the matrix.                                                                                                                                                                         |

See also:

### [spdiags](#)

construct matrix from diagonals

### Notes

This function differs from [spdiags](#) in the way it handles off-diagonals.

The result from [diags](#) is the sparse equivalent of:

```
np.diag(diagonals[0], offsets[0])
+ ...
+ np.diag(diagonals[k], offsets[k])
```

Repeated diagonal offsets are disallowed.

New in version 0.11.

## Examples

```
>>> from scipy.sparse import diags
>>> diagonals = [[1, 2, 3, 4], [1, 2, 3], [1, 2]]
>>> diags(diagonals, [0, -1, 2]).toarray()
array([[1, 0, 1, 0],
 [1, 2, 0, 2],
 [0, 2, 3, 0],
 [0, 0, 3, 4]])
```

Broadcasting of scalars is supported (but shape needs to be specified):

```
>>> diags([1, -2, 1], [-1, 0, 1], shape=(4, 4)).toarray()
array([[-2., 1., 0., 0.],
 [1., -2., 1., 0.],
 [0., 1., -2., 1.],
 [0., 0., 1., -2.]])
```

If only one diagonal is wanted (as in `numpy.diag`), the following works as well:

```
>>> diags([1, 2, 3], 1).toarray()
array([[0., 1., 0., 0.],
 [0., 0., 2., 0.],
 [0., 0., 0., 3.],
 [0., 0., 0., 0.]])
```

## scipy.sparse.spdiags

`scipy.sparse.spdiags` (*data*, *diags*, *m*, *n*, *format=None*)

Return a sparse matrix from diagonals.

### Parameters

|               |                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>data</b>   | [array_like] matrix diagonals stored row-wise                                                                                                                                                                                                           |
| <b>diags</b>  | [diagonals to set] <ul style="list-style-type: none"> <li>• <math>k = 0</math> the main diagonal</li> <li>• <math>k &gt; 0</math> the <math>k</math>-th upper diagonal</li> <li>• <math>k &lt; 0</math> the <math>k</math>-th lower diagonal</li> </ul> |
| <b>m, n</b>   | [int] shape of the result                                                                                                                                                                                                                               |
| <b>format</b> | [str, optional] Format of the result. By default ( <i>format=None</i> ) an appropriate sparse matrix format is returned. This choice is subject to change.                                                                                              |

See also:

### `diags`

more convenient form of this function

### `dia_matrix`

the sparse DIAgonal format.

## Examples

```
>>> from scipy.sparse import spdiags
>>> data = np.array([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4]])
>>> diags = np.array([0, -1, 2])
>>> spdiags(data, diags, 4, 4).toarray()
array([[1, 0, 3, 0],
 [1, 2, 0, 4],
 [0, 2, 3, 0],
 [0, 0, 3, 4]])
```

## scipy.sparse.block\_diag

`scipy.sparse.block_diag` (*mats*, *format=None*, *dtype=None*)

Build a block diagonal sparse matrix from provided matrices.

### Parameters

**mats** [sequence of matrices] Input matrices.  
**format** [str, optional] The sparse format of the result (e.g., “csr”). If not given, the matrix is returned in “coo” format.  
**dtype** [dtype specifier, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

### Returns

**res** [sparse matrix]

See also:

[bmat](#), [diags](#)

## Notes

New in version 0.11.0.

## Examples

```
>>> from scipy.sparse import coo_matrix, block_diag
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> block_diag((A, B, C)).toarray()
array([[1, 2, 0, 0],
 [3, 4, 0, 0],
 [0, 0, 5, 0],
 [0, 0, 6, 0],
 [0, 0, 0, 7]])
```

**scipy.sparse.tril**

`scipy.sparse.tril(A, k=0, format=None)`

Return the lower triangular portion of a matrix in sparse format

*Returns the elements on or below the k-th diagonal of the matrix A.*

- $k = 0$  corresponds to the main diagonal
- $k > 0$  is above the main diagonal
- $k < 0$  is below the main diagonal

**Parameters**

- A** [dense or sparse matrix] Matrix whose lower triangular portion is desired.  
**k** [integer] The top-most diagonal of the lower triangle.  
**format** [string] Sparse format of the result, e.g. `format="csr"`, etc.

**Returns**

- L** [sparse matrix] Lower triangular portion of A in sparse format.

See also:

**triu**

upper triangle in sparse format

**Examples**

```
>>> from scipy.sparse import csr_matrix, tril
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
... dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
 [4, 5, 0, 6, 7],
 [0, 0, 8, 9, 0]])
>>> tril(A).toarray()
array([[1, 0, 0, 0, 0],
 [4, 5, 0, 0, 0],
 [0, 0, 8, 0, 0]])
>>> tril(A).nnz
4
>>> tril(A, k=1).toarray()
array([[1, 2, 0, 0, 0],
 [4, 5, 0, 0, 0],
 [0, 0, 8, 9, 0]])
>>> tril(A, k=-1).toarray()
array([[0, 0, 0, 0, 0],
 [4, 0, 0, 0, 0],
 [0, 0, 0, 0, 0]])
>>> tril(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
 with 4 stored elements in Compressed Sparse Column format>
```

**scipy.sparse.triu**

`scipy.sparse.triu(A, k=0, format=None)`

Return the upper triangular portion of a matrix in sparse format

*Returns the elements on or above the k-th diagonal of the matrix A.*

- $k = 0$  corresponds to the main diagonal
- $k > 0$  is above the main diagonal
- $k < 0$  is below the main diagonal

**Parameters**

- |               |                                                                             |
|---------------|-----------------------------------------------------------------------------|
| <b>A</b>      | [dense or sparse matrix] Matrix whose upper triangular portion is desired.  |
| <b>k</b>      | [integer] The bottom-most diagonal of the upper triangle.                   |
| <b>format</b> | [string] Sparse format of the result, e.g. <code>format="csr"</code> , etc. |

**Returns**

- |          |                                                                 |
|----------|-----------------------------------------------------------------|
| <b>L</b> | [sparse matrix] Upper triangular portion of A in sparse format. |
|----------|-----------------------------------------------------------------|

See also:

**tril**

lower triangle in sparse format

**Examples**

```
>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
... dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
 [4, 5, 0, 6, 7],
 [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 2, 0, 0, 3],
 [0, 5, 0, 6, 7],
 [0, 0, 8, 9, 0]])
>>> triu(A).nnz
8
>>> triu(A, k=1).toarray()
array([[0, 2, 0, 0, 3],
 [0, 0, 0, 6, 7],
 [0, 0, 0, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[1, 2, 0, 0, 3],
 [4, 5, 0, 6, 7],
 [0, 0, 8, 9, 0]])
>>> triu(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
 with 8 stored elements in Compressed Sparse Column format>
```

## scipy.sparse.bmat

`scipy.sparse.bmat` (*blocks*, *format=None*, *dtype=None*)

Build a sparse matrix from sparse sub-blocks

### Parameters

- blocks** [array\_like] Grid of sparse matrices with compatible shapes. An entry of `None` implies an all-zero matrix.
- format** [{‘bsr’, ‘coo’, ‘csc’, ‘csr’, ‘dia’, ‘dok’, ‘lil’}, optional] The sparse format of the result (e.g. “csr”). By default an appropriate sparse matrix format is returned. This choice is subject to change.
- dtype** [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

### Returns

- bmat** [sparse matrix]

See also:

[block\\_diag](#), [diags](#)

### Examples

```
>>> from scipy.sparse import coo_matrix, bmat
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> bmat([[A, B], [None, C]]).toarray()
array([[1, 2, 5],
 [3, 4, 6],
 [0, 0, 7]])
```

```
>>> bmat([[A, None], [None, C]]).toarray()
array([[1, 2, 0],
 [3, 4, 0],
 [0, 0, 7]])
```

## scipy.sparse.hstack

`scipy.sparse.hstack` (*blocks*, *format=None*, *dtype=None*)

Stack sparse matrices horizontally (column wise)

### Parameters

- blocks** sequence of sparse matrices with compatible shapes
- format** [str] sparse format of the result (e.g., “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.
- dtype** [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

See also:

**vstack**

stack sparse matrices vertically (row wise)

**Examples**

```
>>> from scipy.sparse import coo_matrix, hstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> hstack([A,B]).toarray()
array([[1, 2, 5],
 [3, 4, 6]])
```

**scipy.sparse.vstack**

`scipy.sparse.vstack` (*blocks, format=None, dtype=None*)

Stack sparse matrices vertically (row wise)

**Parameters**

- blocks** sequence of sparse matrices with compatible shapes
- format** [str, optional] sparse format of the result (e.g., “csr”) by default an appropriate sparse matrix format is returned. This choice is subject to change.
- dtype** [dtype, optional] The data-type of the output matrix. If not given, the dtype is determined from that of *blocks*.

See also:

**hstack**

stack sparse matrices horizontally (column wise)

**Examples**

```
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5, 6]])
>>> vstack([A, B]).toarray()
array([[1, 2],
 [3, 4],
 [5, 6]])
```

**scipy.sparse.rand**

`scipy.sparse.rand` (*m, n, density=0.01, format='coo', dtype=None, random\_state=None*)

Generate a sparse matrix of the given shape and density with uniformly distributed values.

**Parameters**

- m, n** [int] shape of the matrix
- density** [real, optional] density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.

**format** [str, optional] sparse matrix format.  
**dtype** [dtype, optional] type of the returned matrix values.  
**random\_state** [{None, int, `numpy.random.Generator`,  
`numpy.random.RandomState`}, optional  
 If *seed* is None (or `np.random`), the `numpy.random.RandomState` singleton is used.  
 If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already  
 a `Generator` or `RandomState` instance then that instance is used.

**Returns**

**res** [sparse matrix]

**See also:**

`scipy.sparse.random`

Similar function that allows a user-specified random data source.

**Notes**

Only float types are supported for now.

**Examples**

```
>>> from scipy.sparse import rand
>>> matrix = rand(3, 4, density=0.25, format="csr", random_state=42)
>>> matrix
<3x4 sparse matrix of type '<class 'numpy.float64'>'
 with 3 stored elements in Compressed Sparse Row format>
>>> matrix.todense()
matrix([[0.05641158, 0. , 0. , 0.65088847],
 [0. , 0. , 0. , 0.14286682],
 [0. , 0. , 0. , 0.]])
```

**scipy.sparse.random**

`scipy.sparse.random`(*m*, *n*, *density*=0.01, *format*='coo', *dtype*=None, *random\_state*=None,  
*data\_rvs*=None)

Generate a sparse matrix of the given shape and density with randomly distributed values.

**Parameters**

**m, n** [int] shape of the matrix  
**density** [real, optional] density of the generated matrix: density equal to one means a full matrix,  
 density of 0 means a matrix with no non-zero items.  
**format** [str, optional] sparse matrix format.  
**dtype** [dtype, optional] type of the returned matrix values.  
**random\_state** [{None, int, `numpy.random.Generator`,  
`numpy.random.RandomState`}, optional

If *seed* is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used. This random state will be used for sampling the sparsity structure, but not necessarily for sampling the values of the structurally nonzero entries of the matrix.

**data\_rvs** [callable, optional] Samples a requested number of random values. This function should take a single argument specifying the length of the ndarray that it will return. The structurally nonzero entries of the sparse random matrix will be taken from the array sampled by this function. By default, uniform  $[0, 1)$  random values will be sampled using the same random state as is used for sampling the sparsity structure.

#### Returns

**res** [sparse matrix]

#### Notes

Only float types are supported for now.

#### Examples

```
>>> from scipy.sparse import random
>>> from scipy import stats
>>> from numpy.random import default_rng
>>> rng = default_rng()
>>> rvs = stats.poisson(25, loc=10).rvs
>>> S = random(3, 4, density=0.25, random_state=rng, data_rvs=rvs)
>>> S.A
array([[36., 0., 33., 0.], # random
 [0., 0., 0., 0.],
 [0., 0., 36., 0.]])
```

```
>>> from scipy.sparse import random
>>> from scipy.stats import rv_continuous
>>> class CustomDistribution(rv_continuous):
... def _rvs(self, size=None, random_state=None):
... return random_state.standard_normal(size)
>>> X = CustomDistribution(seed=rng)
>>> Y = X() # get a frozen version of the distribution
>>> S = random(3, 4, density=0.25, random_state=rng, data_rvs=Y.rvs)
>>> S.A
array([[0. , 0. , 0. , 0.], # random
 [0.13569738, 1.9467163 , -0.81205367, 0.],
 [0. , 0. , 0. , 0.]])
```

Save and load sparse matrices:

---

`save_npz(file, matrix[, compressed])`

Save a sparse matrix to a file using `.npz` format.

---

`load_npz(file)`

Load a sparse matrix from a file using `.npz` format.

---

## scipy.sparse.save\_npz

`scipy.sparse.save_npz` (*file*, *matrix*, *compressed=True*)

Save a sparse matrix to a file using `.npz` format.

### Parameters

- file** [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be saved. If file is a string, the `.npz` extension will be appended to the file name if it is not already there.
- matrix: spmatrix (format: ```csc```, ```csr```, ```bsr```, ```dia``` or ```coo```)**  
The sparse matrix to save.
- compressed**  
[bool, optional] Allow compressing the file. Default: True

See also:

## `scipy.sparse.load_npz`

Load a sparse matrix from a file using `.npz` format.

## `numpy.savez`

Save several arrays into a `.npz` archive.

## `numpy.savez_compressed`

Save several arrays into a compressed `.npz` archive.

## Examples

Store sparse matrix to disk, and load it again:

```
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0],
→0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
 with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
 [4, 0, 0]], dtype=int64)
```

```
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

```
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
 with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
 [4, 0, 0]], dtype=int64)
```

## scipy.sparse.load\_npz

`scipy.sparse.load_npz` (*file*)

Load a sparse matrix from a file using `.npz` format.

### Parameters

**file** [str or file-like object] Either the file name (string) or an open file (file-like object) where the data will be loaded.

### Returns

**result** [csc\_matrix, csr\_matrix, bsr\_matrix, dia\_matrix or coo\_matrix] A sparse matrix containing the loaded data.

### Raises

**IOError** If the input file does not exist or cannot be read.

**See also:**

### `scipy.sparse.save_npz`

Save a sparse matrix to a file using `.npz` format.

### `numpy.load`

Load several arrays from a `.npz` archive.

## Examples

Store sparse matrix to disk, and load it again:

```
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64''>'
 with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
 [4, 0, 0]], dtype=int64)
```

```
>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)
>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')
```

```
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64''>'
 with 2 stored elements in Compressed Sparse Column format>
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
 [4, 0, 0]], dtype=int64)
```

Sparse matrix tools:

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <code>find(A)</code> | Return the indices and values of the nonzero elements of a matrix |
|----------------------|-------------------------------------------------------------------|

### scipy.sparse.find

`scipy.sparse.find(A)`

Return the indices and values of the nonzero elements of a matrix

**Parameters**

**A** [dense or sparse matrix] Matrix whose nonzero elements are desired.

**Returns**

**(I,J,V)** [tuple of arrays] I,J, and V contain the row indices, column indices, and values of the nonzero matrix entries.

### Examples

```
>>> from scipy.sparse import csr_matrix, find
>>> A = csr_matrix([[7.0, 8.0, 0],[0, 0, 9.0]])
>>> find(A)
(array([0, 0, 1], dtype=int32), array([0, 1, 2], dtype=int32), array([7.,
→ 8., 9.]))
```

Identifying sparse matrices:

|--------------------------------|-------------------------------|
| <code>issparse(x)</code>       | Is x of a sparse matrix type? |
| <code>isspmatrix(x)</code>     | Is x of a sparse matrix type? |
| <code>isspmatrix_csc(x)</code> | Is x of csc_matrix type?      |
| <code>isspmatrix_csr(x)</code> | Is x of csr_matrix type?      |
| <code>isspmatrix_bsr(x)</code> | Is x of a bsr_matrix type?    |
| <code>isspmatrix_lil(x)</code> | Is x of lil_matrix type?      |
| <code>isspmatrix_dok(x)</code> | Is x of dok_matrix type?      |
| <code>isspmatrix_coo(x)</code> | Is x of coo_matrix type?      |
| <code>isspmatrix_dia(x)</code> | Is x of dia_matrix type?      |

### scipy.sparse.issparse

`scipy.sparse.issparse(x)`

Is x of a sparse matrix type?

**Parameters**

**x** object to check for being a sparse matrix

**Returns**

**bool** True if x is a sparse matrix, False otherwise

## Notes

issparse and isspmatrix are aliases for the same function.

## Examples

```
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

## scipy.sparse.isspmatrix

`scipy.sparse.isspmatrix(x)`

Is x of a sparse matrix type?

### Parameters

**x** object to check for being a sparse matrix

### Returns

**bool** True if x is a sparse matrix, False otherwise

## Notes

issparse and isspmatrix are aliases for the same function.

## Examples

```
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

### scipy.sparse.isspmatrix\_csc

scipy.sparse.isspmatrix\_csc(x)

Is x of csc\_matrix type?

**Parameters**

**x** object to check for being a csc matrix

**Returns**

**bool** True if x is a csc matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import csc_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
True
```

```
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csr_matrix([[5]]))
False
```

### scipy.sparse.isspmatrix\_csr

scipy.sparse.isspmatrix\_csr(x)

Is x of csr\_matrix type?

**Parameters**

**x** object to check for being a csr matrix

**Returns**

**bool** True if x is a csr matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import csr_matrix, isspmatrix_csr
>>> isspmatrix_csr(csr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csr(csc_matrix([[5]]))
False
```

### scipy.sparse.isspmatrix\_bsr

scipy.sparse.isspmatrix\_bsr(x)

Is x of a bsr\_matrix type?

#### Parameters

**x** object to check for being a bsr matrix

#### Returns

**bool** True if x is a bsr matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import bsr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(bsr_matrix([[5]]))
True
```

```
>>> from scipy.sparse import bsr_matrix, csr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(csr_matrix([[5]]))
False
```

### scipy.sparse.isspmatrix\_lil

scipy.sparse.isspmatrix\_lil(x)

Is x of lil\_matrix type?

#### Parameters

**x** object to check for being a lil matrix

#### Returns

**bool** True if x is a lil matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import lil_matrix, isspmatrix_lil
>>> isspmatrix_lil(lil_matrix([[5]]))
True
```

```
>>> from scipy.sparse import lil_matrix, csr_matrix, isspmatrix_lil
>>> isspmatrix_lil(csr_matrix([[5]]))
False
```

### scipy.sparse.isspmatrix\_dok

scipy.sparse.isspmatrix\_dok(x)

Is x of dok\_matrix type?

**Parameters**

**x** object to check for being a dok matrix

**Returns**

**bool** True if x is a dok matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import dok_matrix, isspmatrix_dok
>>> isspmatrix_dok(dok_matrix([[5]]))
True
```

```
>>> from scipy.sparse import dok_matrix, csr_matrix, isspmatrix_dok
>>> isspmatrix_dok(csr_matrix([[5]]))
False
```

### scipy.sparse.isspmatrix\_coo

scipy.sparse.isspmatrix\_coo(x)

Is x of coo\_matrix type?

**Parameters**

**x** object to check for being a coo matrix

**Returns**

**bool** True if x is a coo matrix, False otherwise

#### Examples

```
>>> from scipy.sparse import coo_matrix, isspmatrix_coo
>>> isspmatrix_coo(coo_matrix([[5]]))
True
```

```
>>> from scipy.sparse import coo_matrix, csr_matrix, isspmatrix_coo
>>> isspmatrix_coo(csr_matrix([[5]]))
False
```

## scipy.sparse.isspmatrix\_dia

scipy.sparse.isspmatrix\_dia(x)

Is x of dia\_matrix type?

### Parameters

**x** object to check for being a dia matrix

### Returns

**bool** True if x is a dia matrix, False otherwise

### Examples

```
>>> from scipy.sparse import dia_matrix, isspmatrix_dia
>>> isspmatrix_dia(dia_matrix([[5]]))
True
```

```
>>> from scipy.sparse import dia_matrix, csr_matrix, isspmatrix_dia
>>> isspmatrix_dia(csr_matrix([[5]]))
False
```

### Submodules

|                |                                                                  |

### Exceptions

*SparseEfficiencyWarning*

*SparseWarning*

## scipy.sparse.SparseEfficiencyWarning

**exception** scipy.sparse.SparseEfficiencyWarning

**with\_traceback()**

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

## scipy.sparse.SparseWarning

**exception** `scipy.sparse.SparseWarning`

`with_traceback()`

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

## Usage information

There are seven available sparse matrix types:

1. `csc_matrix`: Compressed Sparse Column format
2. `csr_matrix`: Compressed Sparse Row format
3. `bsr_matrix`: Block Sparse Row format
4. `lil_matrix`: List of Lists format
5. `dok_matrix`: Dictionary of Keys format
6. `coo_matrix`: COOrdinate format (aka IJV, triplet format)
7. `dia_matrix`: DIAgonal format

To construct a matrix efficiently, use either `dok_matrix` or `lil_matrix`. The `lil_matrix` class supports basic slicing and fancy indexing with a similar syntax to NumPy arrays. As illustrated below, the COO format may also be used to efficiently construct matrices. Despite their similarity to NumPy arrays, it is **strongly discouraged** to use NumPy functions directly on these matrices because NumPy may not properly convert them for computations, leading to unexpected (and incorrect) results. If you do want to apply a NumPy function to these matrices, first check if SciPy has its own implementation for the given sparse matrix class, or **convert the sparse matrix to a NumPy array** (e.g., using the `toarray()` method of the class) first before applying the method.

To perform manipulations such as multiplication or inversion, first convert the matrix to either CSC or CSR format. The `lil_matrix` format is row-based, so conversion to CSR is efficient, whereas conversion to CSC is less so.

All conversions among the CSR, CSC, and COO formats are efficient, linear-time operations.

## Matrix vector product

To do a vector product between a sparse matrix and a vector simply use the matrix `dot` method, as described in its docstring:

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([1, -3, -1], dtype=int64)
```

**Warning:** As of NumPy 1.7, `np.dot` is not aware of sparse matrices, therefore using it will result on unexpected results or errors. The corresponding dense array should be obtained first instead:

```
>>> np.dot(A.toarray(), v)
array([1, -3, -1], dtype=int64)
```

but then all the performance advantages would be lost.

The CSR format is specially suitable for fast matrix vector products.

### Example 1

Construct a 1000x1000 `lil_matrix` and add some values to it:

```
>>> from scipy.sparse import lil_matrix
>>> from scipy.sparse.linalg import spsolve
>>> from numpy.linalg import solve, norm
>>> from numpy.random import rand
```

```
>>> A = lil_matrix((1000, 1000))
>>> A[0, :100] = rand(100)
>>> A[1, 100:200] = A[0, :100]
>>> A.setdiag(rand(1000))
```

Now convert it to CSR format and solve  $Ax = b$  for  $x$ :

```
>>> A = A.tocsr()
>>> b = rand(1000)
>>> x = spsolve(A, b)
```

Convert it to a dense matrix and solve, and check that the result is the same:

```
>>> x_ = solve(A.toarray(), b)
```

Now we can compute norm of the error with:

```
>>> err = norm(x-x_)
>>> err < 1e-10
True
```

It should be small :)

### Example 2

Construct a matrix in COO format:

```
>>> from scipy import sparse
>>> from numpy import array
>>> I = array([0, 3, 1, 0])
>>> J = array([0, 3, 1, 2])
>>> V = array([4, 5, 7, 9])
>>> A = sparse.coo_matrix((V, (I, J)), shape=(4, 4))
```

Notice that the indices do not need to be sorted.

Duplicate (i,j) entries are summed when converting to CSR or CSC.

```
>>> I = array([0, 0, 1, 3, 1, 0, 0])
>>> J = array([0, 2, 1, 3, 1, 0, 0])
>>> V = array([1, 1, 1, 1, 1, 1, 1])
>>> B = sparse.coo_matrix((V, (I, J)), shape=(4, 4)).tocsr()
```

This is useful for constructing finite-element stiffness and mass matrices.

## Further details

CSR column indices are not necessarily sorted. Likewise for CSC row indices. Use the `.sorted_indices()` and `.sort_indices()` methods when sorted indices are required (e.g., when passing data to other libraries).

### 3.3.24 Sparse linear algebra (`scipy.sparse.linalg`)

#### Abstract linear operators

|                                              |                                                        |
|----------------------------------------------|--------------------------------------------------------|
| <code>LinearOperator(*args, **kwargs)</code> | Common interface for performing matrix vector products |
| <code>aslinearoperator(A)</code>             | Return A as a LinearOperator.                          |

#### `scipy.sparse.linalg.LinearOperator`

**class** `scipy.sparse.linalg.LinearOperator` (*\*args, \*\*kwargs*)

Common interface for performing matrix vector products

Many iterative methods (e.g. `cg`, `gmres`) do not need to know the individual entries of a matrix to solve a linear system  $A*x=b$ . Such solvers only require the computation of matrix vector products,  $A*v$  where  $v$  is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete `LinearOperator`, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods `_matvec` and `_matmat`, and the attributes/properties `shape` (pair of integers) and `dtype` (may be `None`). It may call the `__init__` on this class to have these attributes validated. Implementing `_matvec` automatically implements `_matmat` (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement `_rmatvec` or `_adjoint` to implement the Hermitian adjoint (conjugate transpose). As with `_matvec` and `_matmat`, implementing either `_rmatvec` or `_adjoint` implements the other automatically. Implementing `_adjoint` is preferable; `_rmatvec` is mostly there for backwards compatibility.

#### *Parameters*

|                |                                                                                         |
|----------------|-----------------------------------------------------------------------------------------|
| <b>shape</b>   | [tuple] Matrix dimensions (M, N).                                                       |
| <b>matvec</b>  | [callable f(v)] Returns returns $A * v$ .                                               |
| <b>rmatvec</b> | [callable f(v)] Returns $A^H * v$ , where $A^H$ is the conjugate transpose of $A$ .     |
| <b>matmat</b>  | [callable f(V)] Returns $A * V$ , where $V$ is a dense matrix with dimensions (N, K).   |
| <b>dtype</b>   | [dtype] Data type of the matrix.                                                        |
| <b>rmatmat</b> | [callable f(V)] Returns $A^H * V$ , where $V$ is a dense matrix with dimensions (M, K). |

See also:

#### `aslinearoperator`

Construct `LinearOperators`

## Notes

The user-defined `matvec()` function must properly handle the case where `v` has shape  $(N,)$  as well as the  $(N,1)$  case. The shape of the return type is handled internally by `LinearOperator`.

`LinearOperator` instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite `LinearOperator`, that defers linear operations to the original operators and combines the results.

More details regarding how to subclass a `LinearOperator` and several examples of concrete `LinearOperator` instances can be found in the external project [PyLops](#).

## Examples

```
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
... return np.array([2*v[0], 3*v[1]])
...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([2., 3.])
>>> A * np.ones(2)
array([2., 3.])
```

### Attributes

- args** [tuple] For linear operators describing products etc. of other linear operators, the operands of the binary operation.
- ndim** [int] Number of dimensions (this is always 2)

### Methods

|                          |                                                |
|--------------------------|------------------------------------------------|
| <code>__call__(x)</code> | Call self as a function.                       |
| <code>adjoint()</code>   | Hermitian adjoint.                             |
| <code>dot(x)</code>      | Matrix-matrix or matrix-vector multiplication. |
| <code>matmat(X)</code>   | Matrix-matrix multiplication.                  |
| <code>matvec(x)</code>   | Matrix-vector multiplication.                  |
| <code>rmatmat(X)</code>  | Adjoint matrix-matrix multiplication.          |
| <code>rmatvec(x)</code>  | Adjoint matrix-vector multiplication.          |
| <code>transpose()</code> | Transpose this linear operator.                |

### scipy.sparse.linalg.LinearOperator.\_\_call\_\_

`LinearOperator.__call__(x)`  
 Call self as a function.

### scipy.sparse.linalg.LinearOperator.adjoint

`LinearOperator.adjoint()`  
 Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

**Returns**

**A\_H** [LinearOperator] Hermitian adjoint of self.

### scipy.sparse.linalg.LinearOperator.dot

`LinearOperator.dot(x)`  
 Matrix-matrix or matrix-vector multiplication.

**Parameters**

**x** [array\_like] 1-d or 2-d array, representing a vector or matrix.

**Returns**

**Ax** [array] 1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

### scipy.sparse.linalg.LinearOperator.matmat

`LinearOperator.matmat(X)`  
 Matrix-matrix multiplication.

Performs the operation  $y=A*X$  where A is an  $M \times N$  linear operator and X dense  $N \times K$  matrix or ndarray.

**Parameters**

**X** [{matrix, ndarray}] An array with shape (N,K).

**Returns**

**Y** [{matrix, ndarray}] A matrix or ndarray with shape (M,K) depending on the type of the X argument.

## Notes

This `matmat` wraps any user-specified `matmat` routine or overridden `_matmat` method to ensure that `y` has the correct type.

### `scipy.sparse.linalg.LinearOperator.matvec`

`LinearOperator.matvec(x)`

Matrix-vector multiplication.

Performs the operation  $y=A*x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array.

#### *Parameters*

**x**            `[{matrix, ndarray}]` An array with shape  $(N,)$  or  $(N,1)$ .

#### *Returns*

**y**            `[{matrix, ndarray}]` A matrix or ndarray with shape  $(M,)$  or  $(M,1)$  depending on the type and shape of the `x` argument.

## Notes

This `matvec` wraps the user-specified `matvec` routine or overridden `_matvec` method to ensure that `y` has the correct shape and type.

### `scipy.sparse.linalg.LinearOperator.rmatmat`

`LinearOperator.rmatmat(X)`

Adjoint matrix-matrix multiplication.

Performs the operation  $y = A^H * x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array, or 2-d array. The default implementation defers to the adjoint.

#### *Parameters*

**X**            `[{matrix, ndarray}]` A matrix or 2D array.

#### *Returns*

**Y**            `[{matrix, ndarray}]` A matrix or 2D array depending on the type of the input.

## Notes

This `rmatmat` wraps the user-specified `rmatmat` routine.

### scipy.sparse.linalg.LinearOperator.rmatvec

`LinearOperator.rmatvec(x)`  
 Adjoint matrix-vector multiplication.

Performs the operation  $y = A^H * x$  where  $A$  is an  $M \times N$  linear operator and  $x$  is a column vector or 1-d array.

**Parameters**

**x**            `[{matrix, ndarray}]` An array with shape  $(M,)$  or  $(M,1)$ .

**Returns**

**y**            `[{matrix, ndarray}]` A matrix or ndarray with shape  $(N,)$  or  $(N,1)$  depending on the type and shape of the  $x$  argument.

**Notes**

This `rmatvec` wraps the user-specified `rmatvec` routine or overridden `_rmatvec` method to ensure that  $y$  has the correct shape and type.

### scipy.sparse.linalg.LinearOperator.transpose

`LinearOperator.transpose()`  
 Transpose this linear operator.

Returns a `LinearOperator` that represents the transpose of this one. Can be abbreviated `self.T` instead of `self.transpose()`.

|                      |  |
|----------------------|--|
| <code>__mul__</code> |  |
|----------------------|--|

### scipy.sparse.linalg.aslinearoperator

`scipy.sparse.linalg.aslinearoperator(A)`  
 Return  $A$  as a `LinearOperator`.

*'A' may be any of the following types:*

- ndarray
- matrix
- sparse matrix (e.g. `csr_matrix`, `lil_matrix`, etc.)
- `LinearOperator`
- An object with `.shape` and `.matvec` attributes

See the `LinearOperator` documentation for additional information.

## Notes

If 'A' has no `.dtype` attribute, the data type is determined by calling `LinearOperator.matvec` - set the `.dtype` attribute to prevent this call upon the linear operator creation.

## Examples

```
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1, 2, 3], [4, 5, 6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

## Matrix Operations

|                                                                |                                                          |
|----------------------------------------------------------------|----------------------------------------------------------|
| <code>inv(A)</code>                                            | Compute the inverse of a sparse matrix                   |
| <code>expm(A)</code>                                           | Compute the matrix exponential using Pade approximation. |
| <code>expm_multiply(A, B[, start, stop, num, endpoint])</code> | Compute the action of the matrix exponential of A on B.  |

### scipy.sparse.linalg.inv

`scipy.sparse.linalg.inv(A)`

Compute the inverse of a sparse matrix

#### Parameters

**A** [(M,M) ndarray or sparse matrix] square matrix to be inverted

#### Returns

**Ainv** [(M,M) ndarray or sparse matrix] inverse of A

## Notes

This computes the sparse inverse of A. If the inverse of A is expected to be non-sparse, it will likely be faster to convert A to dense and use `scipy.linalg.inv`.

## Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import inv
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64'>'
 with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64'>'
 with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).todense()
```

(continues on next page)

(continued from previous page)

```
matrix([[1., 0.],
 [0., 1.]])
```

New in version 0.12.0.

### scipy.sparse.linalg.expm

`scipy.sparse.linalg.expm(A)`

Compute the matrix exponential using Pade approximation.

#### Parameters

**A** [(M,M) array\_like or sparse matrix] 2D Array or Matrix (sparse or dense) to be exponentiated

#### Returns

**expA** [(M,M) ndarray] Matrix exponential of A

### Notes

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

### References

[1]

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm
>>> A = csc_matrix([[1, 0, 0], [0, 2, 0], [0, 0, 3]])
>>> A.todense()
matrix([[1, 0, 0],
 [0, 2, 0],
 [0, 0, 3]], dtype=int64)
>>> Aexp = expm(A)
>>> Aexp
<3x3 sparse matrix of type '<class 'numpy.float64''>'
 with 3 stored elements in Compressed Sparse Column format>
>>> Aexp.todense()
matrix([[2.71828183, 0. , 0.],
 [0. , 7.3890561 , 0.],
 [0. , 0. , 20.08553692]])
```

**scipy.sparse.linalg.expm\_multiply**

`scipy.sparse.linalg.expm_multiply` (*A*, *B*, *start=None*, *stop=None*, *num=None*, *endpoint=None*)

Compute the action of the matrix exponential of *A* on *B*.

**Parameters**

|                 |                                                                                                                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A</b>        | [transposable linear operator] The operator whose exponential is of interest.                                                                                                                                                                                                                                                         |
| <b>B</b>        | [ndarray] The matrix or vector to be multiplied by the matrix exponential of <i>A</i> .                                                                                                                                                                                                                                               |
| <b>start</b>    | [scalar, optional] The starting time point of the sequence.                                                                                                                                                                                                                                                                           |
| <b>stop</b>     | [scalar, optional] The end time point of the sequence, unless <i>endpoint</i> is set to <code>False</code> . In that case, the sequence consists of all but the last of <code>num + 1</code> evenly spaced time points, so that <i>stop</i> is excluded. Note that the step size changes when <i>endpoint</i> is <code>False</code> . |
| <b>num</b>      | [int, optional] Number of time points to use.                                                                                                                                                                                                                                                                                         |
| <b>endpoint</b> | [bool, optional] If <code>True</code> , <i>stop</i> is the last time point. Otherwise, it is not included.                                                                                                                                                                                                                            |

**Returns**

|                 |                                                    |
|-----------------|----------------------------------------------------|
| <b>expm_A_B</b> | [ndarray] The result of the action $e^{t_k A} B$ . |
|-----------------|----------------------------------------------------|

**Notes**

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of `numpy.linspace`.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, `expm_A_B[0]` will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply
>>> A = csc_matrix([[1, 0], [0, 1]])
>>> A.todense()
matrix([[1, 0],
 [0, 1]], dtype=int64)
>>> B = np.array([np.exp(-1.), np.exp(-2.)])
>>> B
array([0.36787944, 0.13533528])
>>> expm_multiply(A, B, start=1, stop=2, num=3, endpoint=True)
array([[1. , 0.36787944],
 [1.64872127, 0.60653066],
 [2.71828183, 1.]])
>>> expm(A).dot(B) # Verify 1st timestep
```

(continues on next page)

(continued from previous page)

```
array([1. , 0.36787944])
>>> expm(1.5*A).dot(B) # Verify 2nd timestep
array([1.64872127, 0.60653066])
>>> expm(2*A).dot(B) # Verify 3rd timestep
array([2.71828183, 1.])
```

## Matrix norms

|                                                              |                                                         |
|--------------------------------------------------------------|---------------------------------------------------------|
| <code>norm(x[, ord, axis])</code>                            | Norm of a sparse matrix                                 |
| <code>onenormest(A[, t, itmax, compute_v, compute_w])</code> | Compute a lower bound of the 1-norm of a sparse matrix. |

### scipy.sparse.linalg.norm

`scipy.sparse.linalg.norm(x, ord=None, axis=None)`  
 Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the `ord` parameter.

#### Parameters

- x** [a sparse matrix] Input sparse matrix.
- ord** [{non-zero int, inf, -inf, 'fro'}, optional] Order of the norm (see table under Notes). `inf` means numpy's *inf* object.
- axis** [{int, 2-tuple of ints, None}, optional] If *axis* is an integer, it specifies the axis of *x* along which to compute the vector norms. If *axis* is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If *axis* is None then either a vector norm (when *x* is 1-D) or a matrix norm (when *x* is 2-D) is returned.

#### Returns

- n** [float or ndarray]

#### Notes

Some of the `ord` are not implemented because some associated functions like, `_multi_svd_norm`, are not yet available for sparse matrix.

This docstring is modified based on `numpy.linalg.norm`. <https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py>

The following norms can be calculated:

| ord   | norm for sparse matrices              |
|-------|---------------------------------------|
| None  | Frobenius norm                        |
| 'fro' | Frobenius norm                        |
| inf   | <code>max(sum(abs(x), axis=1))</code> |
| -inf  | <code>min(sum(abs(x), axis=1))</code> |
| 0     | <code>abs(x).sum(axis=axis)</code>    |
| 1     | <code>max(sum(abs(x), axis=0))</code> |
| -1    | <code>min(sum(abs(x), axis=0))</code> |
| 2     | Not implemented                       |
| -2    | Not implemented                       |
| other | Not implemented                       |

The Frobenius norm is given by [1]:

$$\|A\|_F = [\sum_{i,j} \text{abs}(a_{i,j})^2]^{1/2}$$

## References

[1]

## Examples

```
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[-4, -3, -2],
 [-1, 0, 1],
 [2, 3, 4]])
```

```
>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```

### scipy.sparse.linalg.onenormest

`scipy.sparse.linalg.onenormest` (*A*, *t*=2, *itmax*=5, *compute\_v*=False, *compute\_w*=False)

Compute a lower bound of the 1-norm of a sparse matrix.

#### Parameters

- |                  |                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A</b>         | [ndarray or other linear operator] A linear operator that can be transposed and that can produce matrix products.                                                                         |
| <b>t</b>         | [int, optional] A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output. |
| <b>itmax</b>     | [int, optional] Use at most this many iterations.                                                                                                                                         |
| <b>compute_v</b> | [bool, optional] Request a norm-maximizing linear operator input vector if True.                                                                                                          |
| <b>compute_w</b> | [bool, optional] Request a norm-maximizing linear operator output vector if True.                                                                                                         |

**Returns**

- est** [float] An underestimate of the 1-norm of the sparse matrix.
- v** [ndarray, optional] The vector such that  $\|Av\|_1 == est*\|v\|_1$ . It can be thought of as an input to the linear operator that gives an output with particularly large norm.
- w** [ndarray, optional] The vector  $Av$  which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

**Notes**

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about  $4t$  matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

**References**

- [1], [2]

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest
>>> A = csc_matrix([[1., 0., 0.], [5., 8., 2.], [0., -1., 0.]],
→dtype=float)
>>> A.todense()
matrix([[1., 0., 0.],
 [5., 8., 2.],
 [0., -1., 0.]])
>>> onenormest(A)
9.0
>>> np.linalg.norm(A.todense(), ord=1)
9.0
```

**Solving linear problems**

Direct methods for linear equation systems:

|                                                       |                                                                                |
|-------------------------------------------------------|--------------------------------------------------------------------------------|
| <code>spsolve(A, b[, permc_spec, use_umfpack])</code> | Solve the sparse linear system $Ax=b$ , where $b$ may be a vector or a matrix. |
| <code>spsolve_triangular(A, b[, lower, ...])</code>   | Solve the equation $A x = b$ for $x$ , assuming $A$ is a triangular matrix.    |
| <code>factorized(A)</code>                            | Return a function for solving a sparse linear system, with $A$ pre-factorized. |
| <code>MatrixRankWarning</code>                        |                                                                                |
| <code>use_solver(**kwargs)</code>                     | Select default sparse direct solver to be used.                                |

**scipy.sparse.linalg.spsolve**

`scipy.sparse.linalg.spsolve` (*A*, *b*, *perm\_spec=None*, *use\_umfpack=True*)

Solve the sparse linear system  $Ax=b$ , where *b* may be a vector or a matrix.

**Parameters**

**A** [ndarray or sparse matrix] The square matrix *A* will be converted into CSC or CSR form  
**b** [ndarray or sparse matrix] The matrix or vector representing the right hand side of the equation. If a vector, *b.shape* must be (*n*,) or (*n*, 1).

**perm\_spec**

[str, optional] How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')

- NATURAL: natural ordering.
- MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
- MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T + A$ .
- COLAMD: approximate minimum degree column ordering

**use\_umfpack**

[bool, optional] if True (default) then use umfpack for the solution. This is only referenced if *b* is a vector and `scikit-umfpack` is installed.

**Returns**

**x** [ndarray or sparse matrix] the solution of the sparse linear equation. If *b* is a vector, then *x* is a vector of size *A.shape*[1] If *b* is a matrix, then *x* is a matrix of size (*A.shape*[1], *b.shape*[1])

**Notes**

For solving the matrix expression  $AX = B$ , this solver assumes the resulting matrix *X* is sparse, as is often the case for very sparse inputs. If the resulting *X* is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting *A* to a dense matrix and using `scipy.linalg.solve` or its variants.

**Examples**

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> B = csc_matrix([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve(A, B)
>>> np.allclose(A.dot(x).todense(), B.todense())
True
```

**scipy.sparse.linalg.spsolve\_triangular**

`scipy.sparse.linalg.spsolve_triangular` (*A*, *b*, *lower=True*, *overwrite\_A=False*, *overwrite\_b=False*, *unit\_diagonal=False*)

Solve the equation  $A x = b$  for *x*, assuming *A* is a triangular matrix.

**Parameters**

**A** [(M, M) sparse matrix] A sparse square triangular matrix. Should be in CSR format.  
**b** [(M,) or (M, N) array\_like] Right-hand side matrix in  $A x = b$   
**lower** [bool, optional] Whether *A* is a lower or upper triangular matrix. Default is lower triangular matrix.

**overwrite\_A**

[bool, optional] Allow changing *A*. The indices of *A* are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.

**overwrite\_b**

[bool, optional] Allow overwriting data in *b*. Enabling gives a performance gain. Default is False. If *overwrite\_b* is True, it should be ensured that *b* has an appropriate dtype to be able to store the result.

**unit\_diagonal**

[bool, optional] If True, diagonal elements of *a* are assumed to be 1 and will not be referenced.

New in version 1.4.0.

**Returns**

**x** [(M,) or (M, N) ndarray] Solution to the system  $A \cdot x = b$ . Shape of return matches shape of *b*.

**Raises**

**LinAlgError**

If *A* is singular or not triangular.

**ValueError**

If shape of *A* or shape of *b* do not match the requirements.

**Notes**

New in version 0.19.0.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.linalg import spsolve_triangular
>>> A = csr_matrix([[3, 0, 0], [1, -1, 0], [2, 0, 1]], dtype=float)
>>> B = np.array([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve_triangular(A, B)
>>> np.allclose(A.dot(x), B)
True
```

**scipy.sparse.linalg.factorized**

`scipy.sparse.linalg.factorized(A)`

Return a function for solving a sparse linear system, with *A* pre-factorized.

**Parameters**

**A** [(N, N) array\_like] Input.

**Returns**

**solve** [callable] To solve the linear system of equations given in *A*, the *solve* callable should be passed an ndarray of shape (N,).

## Examples

```
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[3. , 2. , -1.],
... [2. , -2. , 4.],
... [-1. , 0.5, -1.]])
>>> solve = factorized(A) # Makes LU decomposition.
>>> rhs1 = np.array([1, -2, 0])
>>> solve(rhs1) # Uses the LU factors.
array([1., -2., -2.])
```

### scipy.sparse.linalg.MatrixRankWarning

**exception** `scipy.sparse.linalg.MatrixRankWarning`

`with_traceback()`

Exception.`with_traceback(tb)` – set `self.__traceback__` to `tb` and return `self`.

### scipy.sparse.linalg.use\_solver

`scipy.sparse.linalg.use_solver(**kwargs)`

Select default sparse direct solver to be used.

#### Parameters

##### **useUmfpack**

[bool, optional] Use UMFPACK over SuperLU. Has effect only if `scikits.umfpack` is installed. Default: True

##### **assumeSortedIndices**

[bool, optional] Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if `useUmfpack` is True and `scikits.umfpack` is installed. Default: False

## Notes

The default sparse solver is `umfpack` when available (`scikits.umfpack` is installed). This can be changed by passing `useUmfpack = False`, which then causes the always present SuperLU based solver to be used.

`Umfpack` requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass `assumeSortedIndices=True` to gain some speed.

### scipy.sparse.linalg.bicg

`scipy.sparse.linalg.bicg(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None, atol=None)`

Use BiConjugate Gradient iteration to solve  $Ax = b$ .

#### Parameters

- A** `[[sparse matrix, dense matrix, LinearOperator]]` The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce  $Ax$  and  $A^T x$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** `[[array, matrix]]` Right hand side of the linear system. Has shape (N,) or (N,1).

#### Returns

- x** `[[array, matrix]]` The converged solution.
- info** `[integer]`

#### Provides convergence information:

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

#### Other Parameters

- x0** `[[array, matrix]]` Starting guess for the solution.
- tol, atol** `[float, optional]` Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

- maxiter** `[integer]` Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.
- M** `[[sparse matrix, dense matrix, LinearOperator]]` Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** `[function]` User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import bicg
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = bicg(A, b)
>>> print(exitCode) # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

**scipy.sparse.linalg.bicgstab**

`scipy.sparse.linalg.bicgstab` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *atol=None*)

Use BIConjugate Gradient STABILized iteration to solve  $Ax = b$ .

**Parameters**

- A** [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce  $Ax$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- x** [{array, matrix}] The converged solution.
- info** [integer]

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- x0** [{array, matrix}] Starting guess for the solution.
- tol, atol** [float, optional] Tolerances for convergence,  $\text{norm}(\text{residual}) \leq \max(\text{tol} * \text{norm}(b), \text{atol})$ . The default for *atol* is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for *atol* will be changed in a future release. For future compatibility, specify *atol* explicitly.

- maxiter** [integer] Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.
- M** [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** [function] User-supplied function to call after each iteration. It is called as `callback(xk)`, where *xk* is the current solution vector.

**scipy.sparse.linalg.cg**

`scipy.sparse.linalg.cg` (*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *atol=None*)

Use Conjugate Gradient iteration to solve  $Ax = b$ .

**Parameters**

- A** [{sparse matrix, dense matrix, LinearOperator}] The real or complex N-by-N matrix of the linear system. A must represent a hermitian, positive definite matrix. Alternatively, A can be a linear operator which can produce  $Ax$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- x** [{array, matrix}] The converged solution.
- info** [integer]

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

*Other Parameters*

**x0** [{array, matrix}] Starting guess for the solution.  
**tol, atol** [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

**maxiter** [integer] Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.  
**M** [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.  
**callback** [function] User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**scipy.sparse.linalg.cgs**

`scipy.sparse.linalg.cgs(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None, atol=None)`

Use Conjugate Gradient Squared iteration to solve  $Ax = b$ .

*Parameters*

**A** [{sparse matrix, dense matrix, LinearOperator}] The real-valued N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce  $Ax$  using, e.g., `scipy.sparse.linalg.LinearOperator`.  
**b** [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

*Returns*

**x** [{array, matrix}] The converged solution.  
**info** [integer]  
**Provides convergence information:**  
 0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

*Other Parameters*

**x0** [{array, matrix}] Starting guess for the solution.  
**tol, atol** [float, optional] Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

**maxiter** [integer] Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.

|                 |                                                                                                                                                                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>M</b>        | [[sparse matrix, dense matrix, LinearOperator]] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. |
| <b>callback</b> | [function] User-supplied function to call after each iteration. It is called as <code>callback(xk)</code> , where <code>xk</code> is the current solution vector.                                                                                                                       |

### scipy.sparse.linalg.gmres

`scipy.sparse.linalg.gmres` (*A*, *b*, *x0=None*, *tol=1e-05*, *restart=None*, *maxiter=None*, *M=None*, *callback=None*, *restrt=None*, *atol=None*, *callback\_type=None*)

Use Generalized Minimal RESidual iteration to solve  $Ax = b$ .

#### Parameters

|          |                                                                                                                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A</b> | [[sparse matrix, dense matrix, LinearOperator]] The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce $Ax$ using, e.g., <code>scipy.sparse.linalg.LinearOperator</code> . |
| <b>b</b> | [[array, matrix]] Right hand side of the linear system. Has shape (N,) or (N,1).                                                                                                                                                        |

#### Returns

|             |                                           |
|-------------|-------------------------------------------|
| <b>x</b>    | [[array, matrix]] The converged solution. |
| <b>info</b> | [int]                                     |

#### Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

#### Other Parameters

|                  |                                                                                                                                                                                                                               |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x0</b>        | [[array, matrix]] Starting guess for the solution (a vector of zeros by default).                                                                                                                                             |
| <b>tol, atol</b> | [float, optional] Tolerances for convergence, $\text{norm}(\text{residual}) \leq \max(\text{tol} * \text{norm}(b), \text{atol})$ . The default for <code>atol</code> is 'legacy', which emulates a different legacy behavior. |

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

|                      |                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>restart</b>       | [int, optional] Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.                                                                                                                                                                                                               |
| <b>maxiter</b>       | [int, optional] Maximum number of iterations (restart cycles). Iteration will stop after <code>maxiter</code> steps even if the specified tolerance has not been achieved.                                                                                                                                                                                       |
| <b>M</b>             | [[sparse matrix, dense matrix, LinearOperator]] Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used. |
| <b>callback</b>      | [function] User-supplied function to call after each iteration. It is called as <code>callback(args)</code> , where <code>args</code> are selected by <code>callback_type</code> .                                                                                                                                                                               |
| <b>callback_type</b> | [[‘x’, ‘pr_norm’, ‘legacy’], optional]                                                                                                                                                                                                                                                                                                                           |
|                      | <b>Callback function argument requested:</b>                                                                                                                                                                                                                                                                                                                     |
|                      | <ul style="list-style-type: none"> <li>• <code>x</code>: current iterate (ndarray), called on every restart</li> <li>• <code>pr_norm</code>: relative (preconditioned) residual norm (float), called on every inner iteration</li> </ul>                                                                                                                         |

- `legacy` (default): same as `pr_norm`, but also changes the meaning of ‘maxiter’ to count inner iterations instead of restart cycles.

**restrt** [int, optional] DEPRECATED - use `restart` instead.

[LinearOperator](#)

### Notes

A preconditioner,  $P$ , is chosen such that  $P$  is close to  $A$  but easy to solve for. The preconditioner parameter required by this routine is  $M = P^{-1}$ . The inverse should preferably not be calculated explicitly. Rather, use the following template to produce  $M$ :

```
Construct a linear operator that computes $P^{-1} * x$.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
>>> print(exitCode) # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

### scipy.sparse.linalg.lgmres

`scipy.sparse.linalg.lgmres` ( $A$ ,  $b$ ,  $x0=None$ ,  $tol=1e-05$ ,  $maxiter=1000$ ,  $M=None$ ,  $callback=None$ ,  $inner_m=30$ ,  $outer_k=3$ ,  $outer_v=None$ ,  $store_outer_Av=True$ ,  $prepend_outer_v=False$ ,  $atol=None$ )

Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm [1] [2] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

#### Parameters

- A** [{sparse matrix, dense matrix, LinearOperator}] The real or complex  $N$ -by- $N$  matrix of the linear system. Alternatively,  $A$  can be a linear operator which can produce  $Ax$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** [{array, matrix}] Right hand side of the linear system. Has shape  $(N,)$  or  $(N,1)$ .
- x0** [{array, matrix}] Starting guess for the solution.
- tol, atol** [float, optional] Tolerances for convergence,  $\text{norm}(\text{residual}) \leq \max(\text{tol} * \text{norm}(b), \text{atol})$ . The default for `atol` is `tol`.

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>maxiter</b>         | [int, optional] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.                                                                                                                                                                                                                                                                                                         |
| <b>M</b>               | [{sparse matrix, dense matrix, LinearOperator}, optional] Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.                                                                                                                                                    |
| <b>callback</b>        | [function, optional] User-supplied function to call after each iteration. It is called as <code>callback(xk)</code> , where <code>xk</code> is the current solution vector.                                                                                                                                                                                                                                                                          |
| <b>inner_m</b>         | [int, optional] Number of inner GMRES iterations per each outer iteration.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>outer_k</b>         | [int, optional] Number of vectors to carry between inner GMRES iterations. According to [1], good values are in the range of 1...3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.                                                                                                                                                                   |
| <b>outer_v</b>         | [list of tuples, optional] List containing tuples $(v, Av)$ of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element $Av$ can be <i>None</i> if the matrix-vector product should be re-evaluated. This parameter is modified in-place by <i>lgmres</i> , and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems. |
| <b>store_outer_Av</b>  | [bool, optional] Whether LGMRES should store also $A*v$ in addition to vectors $v$ in the <i>outer_v</i> list. Default is True.                                                                                                                                                                                                                                                                                                                      |
| <b>prepend_outer_v</b> | [bool, optional] Whether to put <i>outer_v</i> augmentation vectors before Krylov iterates. In standard LGMRES, <code>prepend_outer_v=False</code> .                                                                                                                                                                                                                                                                                                 |

**Returns**

|             |                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>    | [array or matrix] The converged solution.                                                                                                                                                                                                    |
| <b>info</b> | [int] Provides convergence information: <ul style="list-style-type: none"> <li>• 0 : successful exit</li> <li>• &gt;0 : convergence to tolerance not achieved, number of iterations</li> <li>• &lt;0 : illegal input or breakdown</li> </ul> |

**Notes**

The LGMRES algorithm [1] [2] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the *outer\_v* argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

## Examples

```

>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = lgmres(A, b)
>>> print(exitCode) # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True

```

**scipy.sparse.linalg.minres**

`scipy.sparse.linalg.minres` (*A*, *b*, *x0=None*, *shift=0.0*, *tol=1e-05*, *maxiter=None*, *M=None*, *callback=None*, *show=False*, *check=False*)

Use MINimum RESidual iteration to solve  $Ax=b$

MINRES minimizes  $\text{norm}(A*x - b)$  for a real symmetric matrix *A*. Unlike the Conjugate Gradient method, *A* can be indefinite or singular.

If *shift*  $\neq 0$  then the method solves  $(A - \text{shift}*I)x = b$

**Parameters**

- A** [{sparse matrix, dense matrix, LinearOperator}] The real symmetric N-by-N matrix of the linear system Alternatively, *A* can be a linear operator which can produce  $Ax$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** [{array, matrix}] Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- x** [{array, matrix}] The converged solution.
- info** [integer]

**Provides convergence information:**

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- x0** [{array, matrix}] Starting guess for the solution.
- tol** [float] Tolerance to achieve. The algorithm terminates when the relative residual is below *tol*.
- maxiter** [integer] Maximum number of iterations. Iteration will stop after *maxiter* steps even if the specified tolerance has not been achieved.
- M** [{sparse matrix, dense matrix, LinearOperator}] Preconditioner for *A*. The preconditioner should approximate the inverse of *A*. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- callback** [function] User-supplied function to call after each iteration. It is called as `callback(xk)`, where *xk* is the current solution vector.

True
```

## scipy.sparse.linalg.qmr

`scipy.sparse.linalg.qmr(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, callback=None, atol=None)`

Use Quasi-Minimal Residual iteration to solve  $Ax = b$ .

### Parameters

- A** `[{sparse matrix, dense matrix, LinearOperator}]` The real-valued N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce  $Ax$  and  $A^T x$  using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** `[{array, matrix}]` Right hand side of the linear system. Has shape (N,) or (N,1).

### Returns

- x** `[{array, matrix}]` The converged solution.
- info** `[integer]`

### Provides convergence information:

0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

### Other Parameters

- x0** `[{array, matrix}]` Starting guess for the solution.
- tol, atol** `[float, optional]` Tolerances for convergence, `norm(residual) <= max(tol*norm(b), atol)`. The default for `atol` is 'legacy', which emulates a different legacy behavior.

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

|                 |                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>maxiter</b>  | [integer] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.                                                           |
| <b>M1</b>       | [[sparse matrix, dense matrix, LinearOperator]] Left preconditioner for A.                                                                                                                       |
| <b>M2</b>       | [[sparse matrix, dense matrix, LinearOperator]] Right preconditioner for A. Used together with the left preconditioner M1. The matrix $M1 * A * M2$ should have better conditioned than A alone. |
| <b>callback</b> | [function] User-supplied function to call after each iteration. It is called as <code>callback(xk)</code> , where <code>xk</code> is the current solution vector.                                |

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import qmr
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = qmr(A, b)
>>> print(exitCode) # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

### scipy.sparse.linalg.gcrotmk

`scipy.sparse.linalg.gcrotmk`(*A*, *b*, *x0=None*, *tol=1e-05*, *maxiter=1000*, *M=None*, *callback=None*, *m=20*, *k=None*, *CU=None*, *discard\_C=False*, *truncate='oldest'*, *atol=None*)

Solve a matrix equation using flexible GCROT(*m*,*k*) algorithm.

#### Parameters

|                  |                                                                                                                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A</b>         | [[sparse matrix, dense matrix, LinearOperator]] The real or complex N-by-N matrix of the linear system. Alternatively, A can be a linear operator which can produce $Ax$ using, e.g., <code>scipy.sparse.linalg.LinearOperator</code> . |
| <b>b</b>         | [[array, matrix]] Right hand side of the linear system. Has shape (N,) or (N,1).                                                                                                                                                        |
| <b>x0</b>        | [[array, matrix]] Starting guess for the solution.                                                                                                                                                                                      |
| <b>tol, atol</b> | [float, optional] Tolerances for convergence, <code>norm(residual) &lt;= max(tol*norm(b), atol)</code> . The default for <code>atol</code> is <code>tol</code> .                                                                        |

**Warning:** The default value for `atol` will be changed in a future release. For future compatibility, specify `atol` explicitly.

|                 |                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>maxiter</b>  | [int, optional] Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.                                                                                                                                                                                                                                                                  |
| <b>M</b>        | [[sparse matrix, dense matrix, LinearOperator], optional] Preconditioner for A. The preconditioner should approximate the inverse of A. <code>gcrotmk</code> is a 'flexible' algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. |
| <b>callback</b> | [function, optional] User-supplied function to call after each iteration. It is called as <code>callback(xk)</code> , where <code>xk</code> is the current solution vector.                                                                                                                                                                                                                                   |

- m** [int, optional] Number of inner FGMRES iterations per each outer iteration. Default: 20
- k** [int, optional] Number of vectors to carry between inner FGMRES iterations. According to [2], good values are around m. Default: m
- CU** [list of tuples, optional] List of tuples (c, u) which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [2]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The c elements in the tuples can be None, in which case the vectors are recomputed via  $c = A u$  on start and orthogonalized as described in [3].
- discard\_C** [bool, optional] Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.
- truncate** [{'oldest', 'smallest'}, optional] Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [2] for detailed comparison. Default: 'oldest'

**Returns**

- x** [array or matrix] The solution found.
- info** [int] Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations

| <code>lsqr(A, b[, damp, atol, btol, conlim, ...])</code> | Find the least-squares solution to a large, sparse, linear system of equations. |
| <code>lsmr(A, b[, damp, atol, btol, conlim, ...])</code> | Iterative solver for least-squares problems.                                    |

**scipy.sparse.linalg.lsqr**

`scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=10000000.0, iter_lim=None, show=False, calc_var=False, x0=None)`

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves  $Ax = b$  or  $\min ||Ax - b||^2$  or  $\min ||Ax - b||^2 + d^2 ||x||^2$ .

The matrix A may be square or rectangular (over-determined or under-determined), and may have any rank.

```

1. Unsymmetric equations -- solve A*x = b
2. Linear least squares -- solve A*x = b
 in the least-squares sense
3. Damped least squares -- solve (A) * x = (b)
 (damp*I) (0)
 in the least-squares sense

```

**Parameters**

- A** [{sparse matrix, ndarray, LinearOperator}] Representation of an m-by-n matrix. Alternatively, A can be a linear operator which can produce Ax and A^T x using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** [array\_like, shape (m,)] Right-hand side vector b.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>damp</b>       | [float] Damping coefficient.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>atol, btol</b> | [float, optional] Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final $x$ will usually have fewer correct digits, depending on $\text{cond}(A)$ and the size of $\text{damp}$ .)                                                                                                                                                                                        |
| <b>conlim</b>     | [float, optional] Another stopping tolerance. <code>lsqr</code> terminates if an estimate of $\text{cond}(A)$ exceeds <i>conlim</i> . For compatible systems $Ax = b$ , <i>conlim</i> could be as large as 1.0e+12 (say). For least-squares problems, <i>conlim</i> should be less than 1.0e+8. Maximum precision can be obtained by setting <code>atol = btol = conlim = zero</code> , but the number of iterations may then be excessive. |
| <b>iter_lim</b>   | [int, optional] Explicit limitation on number of iterations (for safety).                                                                                                                                                                                                                                                                                                                                                                   |
| <b>show</b>       | [bool, optional] Display an iteration log.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>calc_var</b>   | [bool, optional] Whether to estimate diagonals of $(A'A + \text{damp}^2 * I)^{-1}$ .                                                                                                                                                                                                                                                                                                                                                        |
| <b>x0</b>         | [array_like, shape (n,), optional] Initial guess of $x$ , if None zeros are used.<br>New in version 1.0.0.                                                                                                                                                                                                                                                                                                                                  |

### Returns

|               |                                                                                                                                                                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>      | [ndarray of float] The final solution.                                                                                                                                                                                                                                                                                                    |
| <b>istop</b>  | [int] Gives the reason for termination. 1 means $x$ is an approximate solution to $Ax = b$ . 2 means $x$ approximately solves the least-squares problem.                                                                                                                                                                                  |
| <b>itn</b>    | [int] Iteration number upon termination.                                                                                                                                                                                                                                                                                                  |
| <b>r1norm</b> | [float] $\text{norm}(r)$ , where $r = b - Ax$ .                                                                                                                                                                                                                                                                                           |
| <b>r2norm</b> | [float] $\sqrt{\text{norm}(r)^2 + \text{damp}^2 * \text{norm}(x)^2}$ . Equal to <i>r1norm</i> if $\text{damp} == 0$ .                                                                                                                                                                                                                     |
| <b>anorm</b>  | [float] Estimate of Frobenius norm of $A_{\text{bar}} = \begin{bmatrix} A \\ \text{damp} * I \end{bmatrix}$ .                                                                                                                                                                                                                             |
| <b>acond</b>  | [float] Estimate of $\text{cond}(A_{\text{bar}})$ .                                                                                                                                                                                                                                                                                       |
| <b>arnorm</b> | [float] Estimate of $\text{norm}(A' * r - \text{damp}^2 * x)$ .                                                                                                                                                                                                                                                                           |
| <b>xnorm</b>  | [float] $\text{norm}(x)$                                                                                                                                                                                                                                                                                                                  |
| <b>var</b>    | [ndarray of float] If <code>calc_var</code> is True, estimates all diagonals of $(A'A)^{-1}$ (if $\text{damp} == 0$ ) or more generally $(A'A + \text{damp}^2 * I)^{-1}$ . This is well defined if $A$ has full column rank or $\text{damp} > 0$ . (Not sure what <code>var</code> means if $\text{rank}(A) < n$ and $\text{damp} = 0$ .) |

### Notes

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of  $A$  should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of  $A$  is very small or large compared to the other rows of  $A$ , the corresponding row of  $(A \ b)$  should be scaled up or down.

In problems 1 and 2, the solution  $x$  is easily recovered following column-scaling. Unless better information is known, the nonzero columns of  $A$  should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if  $\text{damp}$  is nonzero. However, the value of  $\text{damp}$  should be assigned only after attention has been paid to the scaling of  $A$ .

The parameter  $\text{damp}$  is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter `acond`, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate  $x_0$  is known and if  $\text{damp} == 0$ , one could proceed as follows:

1. Compute a residual vector  $r_0 = b - A * x_0$ .
2. Use LSQR to solve the system  $A * dx = r_0$ .

3. Add the correction  $dx$  to obtain a final solution  $x = x_0 + dx$ .

This requires that  $x_0$  be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes  $k_1$  iterations to solve  $A*x = b$  and  $k_2$  iterations to solve  $A*dx = r_0$ . If  $x_0$  is “good”,  $\text{norm}(r_0)$  will be smaller than  $\text{norm}(b)$ . If the same stopping tolerances  $\text{atol}$  and  $\text{btol}$  are used for each system,  $k_1$  and  $k_2$  will be similar, but the final solution  $x_0 + dx$  should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value  $\text{btol}$  is suitable for  $A*x = b$ , the larger value  $\text{btol}*\text{norm}(b)/\text{norm}(r_0)$  should be suitable for  $A*dx = r_0$ .

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system  $M*x = b$  efficiently, where  $M$  approximates  $A$  in some helpful way (e.g.  $M - A$  has low rank or its elements are small relative to those of  $A$ ), LSQR may converge more rapidly on the system  $A*M(\text{inverse})*z = b$ , after which  $x$  can be recovered by solving  $M*x = z$ .

If  $A$  is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (cg) and/or SYMMLQ. SYMMLQ is an implementation of symmetric cg that applies to any symmetric  $A$  and will converge more rapidly than LSQR. If  $A$  is positive definite, there are other implementations of symmetric cg that require slightly less work per iteration than SYMMLQ (but will take the same number of iterations).

## References

## Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution  $[0, 0]$

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
0
>>> x
array([0., 0.]
```

The stopping code  $\text{istop}=0$  returned indicates that a vector of zeros was found as a solution. The returned solution  $x$  indeed contains  $[0., 0.]$ . The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([1., -1.])
>>> itn
1
>>> r1norm
4.440892098500627e-16
```

As indicated by `istop=1`, `lsqr` found a solution obeying the tolerance limits. The given solution `[1., -1.]` obviously solves the equation. The remaining return values include information about the number of iterations (`itn=1`) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([1.00333333, -0.99666667])
>>> A.dot(x)-b
array([0.00333333, -0.00333333, 0.00333333])
>>> r1norm
0.005773502691896255
```

`istop` indicates that the system is inconsistent and thus `x` is rather an approximate solution to the corresponding least-squares problem. `r1norm` contains the norm of the minimal residual that was found.

### scipy.sparse.linalg.lsmr

`scipy.sparse.linalg.lsmr` (`A`, `b`, `damp=0.0`, `atol=1e-06`, `btol=1e-06`, `conlim=100000000.0`, `maxiter=None`, `show=False`, `x0=None`)

Iterative solver for least-squares problems.

`lsmr` solves the system of linear equations  $Ax = b$ . If the system is inconsistent, it solves the least-squares problem  $\min ||b - Ax||_2$ . `A` is a rectangular matrix of dimension `m-by-n`, where all cases are allowed: `m = n`, `m > n`, or `m < n`. `b` is a vector of length `m`. The matrix `A` may be dense or sparse (usually sparse).

#### Parameters

- A** `[[matrix, sparse matrix, ndarray, LinearOperator]]` Matrix `A` in the linear system. Alternatively, `A` can be a linear operator which can produce `Ax` and `AH x` using, e.g., `scipy.sparse.linalg.LinearOperator`.
- b** `[array_like, shape (m,)]` Vector `b` in the linear system.
- damp** `[float]` Damping factor for regularized least-squares. `lsmr` solves the regularized least-squares problem:

$$\min \begin{pmatrix} ||(b) - (A)x|| \\ ||(0) + (damp*I)x|| \end{pmatrix}_2$$

where `damp` is a scalar. If `damp` is `None` or `0`, the system is solved without regularization.

- atol, btol** `[float, optional]` Stopping tolerances. `lsmr` continues iterations until a certain backward error estimate is smaller than some quantity depending on `atol` and `btol`. Let `r = b - Ax` be the residual vector for the current approximate solution `x`. If `Ax = b` seems to be consistent, `lsmr` terminates when `norm(r) <= atol * norm(A) * norm(x) + btol * norm(b)`. Otherwise, `lsmr` terminates when `norm(AH r) <= atol * norm(A) * norm(r)`. If both tolerances are `1.0e-6` (say), the final `norm(r)` should be accurate to about 6 digits. (The final `x` will usually have fewer correct digits, depending on `cond(A)` and the size of `LAMBDA`.) If `atol` or `btol` is `None`, a default value of `1.0e-6` will be used. Ideally, they should be estimates of the relative error in the entries of `A` and `b` respectively. For example, if the entries of `A` have 7 correct digits, set `atol = 1e-7`. This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.
- conlim** `[float, optional]` `lsmr` terminates if an estimate of `cond(A)` exceeds `conlim`. For compatible systems `Ax = b`, `conlim` could be as large as `1.0e+12` (say). For least-squares problems, `conlim` should be less than `1.0e+8`. If `conlim` is `None`, the default value is `1e+8`. Maximum

precision can be obtained by setting `atol = btol = conlim = 0`, but the number of iterations may then be excessive.

**maxiter** [int, optional] *lsqr* terminates if the number of iterations reaches *maxiter*. The default is `maxiter = min(m, n)`. For ill-conditioned systems, a larger value of *maxiter* may be needed.

**show** [bool, optional] Print iterations logs if `show=True`.

**x0** [array\_like, shape (n,), optional] Initial guess of *x*, if None zeros are used.  
New in version 1.0.0.

### Returns

**x** [ndarray of float] Least-square solution returned.

**istop** [int] *istop* gives the reason for stopping:

```
istop = 0 means x=0 is a solution. If x0 was given,
↳then x=x0 is a
 solution.
 = 1 means x is an approximate solution to A*x = B,
 according to atol and btol.
 = 2 means x approximately solves the least-squares
↳problem
 according to atol.
 = 3 means COND(A) seems to be greater than CONLIM.
 = 4 is the same as 1 with atol = btol = eps
↳(machine
 precision)
 = 5 is the same as 2 with atol = eps.
 = 6 is the same as 3 with CONLIM = 1/eps.
 = 7 means ITN reached maxiter before the other
↳stopping
 conditions were satisfied.
```

**itn** [int] Number of iterations used.

**normr** [float]  $\text{norm}(b - Ax)$

**normar** [float]  $\text{norm}(A^H (b - Ax))$

**norma** [float]  $\text{norm}(A)$

**conda** [float] Condition number of *A*.

**normx** [float]  $\text{norm}(x)$

### Notes

New in version 0.11.0.

## Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution  $[0, 0]$

```
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
0
>>> x
array([0., 0.])
```

The stopping code *istop=0* returned indicates that a vector of zeros was found as a solution. The returned solution *x* indeed contains  $[0., 0.]$ . The next example has a non-trivial solution:

```
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
1
>>> x
array([1., -1.])
>>> itn
1
>>> normr
4.440892098500627e-16
```

As indicated by *istop=1*, *lsqr* found a solution obeying the tolerance limits. The given solution  $[1., -1.]$  obviously solves the equation. The remaining return values include information about the number of iterations (*itn=1*) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsqr(A, b)[:4]
>>> istop
2
>>> x
array([1.00333333, -0.99666667])
>>> A.dot(x)-b
array([0.00333333, -0.00333333, 0.00333333])
>>> normr
0.005773502691896255
```

*istop* indicates that the system is inconsistent and thus *x* is rather an approximate solution to the corresponding least-squares problem. *normr* contains the minimal distance that was found.

## Matrix factorizations

Eigenvalue problems:

|                                                           |                                                                                                             |

### scipy.sparse.linalg.eigs

`scipy.sparse.linalg.eigs` ( $A$ ,  $k=6$ ,  $M=None$ ,  $sigma=None$ ,  $which='LM'$ ,  $v0=None$ ,  $ncv=None$ ,  $maxiter=None$ ,  $tol=0$ ,  $return_eigenvectors=True$ ,  $Minv=None$ ,  $OPinv=None$ ,  $OPpart=None$ )

Find  $k$  eigenvalues and eigenvectors of the square matrix  $A$ .

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

If  $M$  is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$

#### Parameters

- A** [ndarray, sparse matrix or LinearOperator] An array, sparse matrix, or LinearOperator representing the operation  $A * x$ , where  $A$  is a real or complex square matrix.
- k** [int, optional] The number of eigenvalues and eigenvectors desired.  $k$  must be smaller than  $N-1$ . It is not possible to compute all eigenvectors of a matrix.
- M** [ndarray, sparse matrix or LinearOperator, optional] An array, sparse matrix, or LinearOperator representing the operation  $M*x$  for the generalized eigenvalue problem  $A * x = w * M * x$ .  
 $M$  must represent a real symmetric matrix if  $A$  is real, and must represent a complex Hermitian matrix if  $A$  is complex. For best results, the data type of  $M$  should be the same as that of  $A$ . Additionally:  
 If  $sigma$  is None,  $M$  is positive definite  
 If  $sigma$  is specified,  $M$  is positive semi-definite
- If  $sigma$  is None, `eigs` requires an operator to compute the solution of the linear equation  $M * x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix  $M$ , or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator `Minv`, which gives  $x = Minv * b = M^{-1} * b$ .
- sigma** [real or complex, optional] Find eigenvalues near  $sigma$  using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - sigma * M] * x = b$ , where  $M$  is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices  $A$  &  $M$ , or via an iterative solver if either  $A$  or  $M$  is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives  $x = OPinv * b = [A - sigma * M]^{-1} * b$ . For a real matrix  $A$ , shift-invert can either be done in imaginary mode or real mode, specified by the parameter `OPpart` ('r' or 'i'). Note that when  $sigma$  is specified, the keyword 'which' (below) refers to the shifted eigenvalues  $w'[i]$  where:

**If  $A$  is real and `OPpart == 'r'` (default),**

$$w'[i] = 1/2 * [1/(w[i]-sigma) + 1/(w[i]-conj(sigma))].$$

**If  $A$  is real and `OPpart == 'i'`,**

$$w'[i] = 1/2i * [1/(w[i]-sigma) - 1/(w[i]-conj(sigma))].$$

If  $A$  is complex,  $w'[i] = 1/(w[i]-sigma)$ .

- v0** [ndarray, optional] Starting vector for iteration. Default: random
- ncv** [int, optional] The number of Lanczos vectors generated *ncv* must be greater than *k*; it is recommended that  $ncv > 2*k$ . Default:  $\min(n, \max(2*k + 1, 20))$
- which** [str, ['LM' | 'SM' | 'LR' | 'SR' | 'LI' | 'SI'], optional] Which *k* eigenvectors and eigenvalues to find:
  - 'LM' : largest magnitude
  - 'SM' : smallest magnitude
  - 'LR' : largest real part
  - 'SR' : smallest real part
  - 'LI' : largest imaginary part
  - 'SI' : smallest imaginary part

When  $\sigma \neq \text{None}$ , 'which' refers to the shifted eigenvalues  $w'[i]$  (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.
- maxiter** [int, optional] Maximum number of Arnoldi update iterations allowed Default:  $n*10$
- tol** [float, optional] Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.
- return\_eigenvectors** [bool, optional] Return eigenvectors (True) in addition to eigenvalues
- Minv** [ndarray, sparse matrix or LinearOperator, optional] See notes in *M*, above.
- OPinv** [ndarray, sparse matrix or LinearOperator, optional] See notes in *sigma*, above.
- OPpart** [{'r' or 'i'}, optional] See notes in *sigma*, above

**Returns**

- w** [ndarray] Array of *k* eigenvalues.
- v** [ndarray] An array of *k* eigenvectors.  $v[:, i]$  is the eigenvector corresponding to the eigenvalue  $w[i]$ .

**Raises**

**ArpackNoConvergence**

When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

**See also:**

**eigsh**

eigenvalues and eigenvectors for symmetric matrix *A*

**svds**

singular value decomposition for a matrix *A*

## Notes

This function is a wrapper to the ARPACK [1] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [2].

## References

[1], [2]

## Examples

Find 6 eigenvectors of the identity matrix:

```
>>> from scipy.sparse.linalg import eigs
>>> id = np.eye(13)
>>> vals, vecs = eigs(id, k=6)
>>> vals
array([1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j])
>>> vecs.shape
(13, 6)
```

## scipy.sparse.linalg.eigsh

`scipy.sparse.linalg.eigsh(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, mode='normal')`

Find  $k$  eigenvalues and eigenvectors of the real symmetric square matrix or complex Hermitian matrix  $A$ .

Solves  $A * x[i] = w[i] * x[i]$ , the standard eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

If  $M$  is specified, solves  $A * x[i] = w[i] * M * x[i]$ , the generalized eigenvalue problem for  $w[i]$  eigenvalues with corresponding eigenvectors  $x[i]$ .

Note that there is no specialized routine for the case when  $A$  is a complex Hermitian matrix. In this case, `eigsh()` will call `eigs()` and return the real parts of the eigenvalues thus obtained.

### Parameters

- A** [ndarray, sparse matrix or LinearOperator] A square operator representing the operation  $A * x$ , where  $A$  is real symmetric or complex Hermitian. For buckling mode (see below)  $A$  must additionally be positive-definite.
- k** [int, optional] The number of eigenvalues and eigenvectors desired.  $k$  must be smaller than  $N$ . It is not possible to compute all eigenvectors of a matrix.

### Returns

- w** [array] Array of  $k$  eigenvalues.
- v** [array] An array representing the  $k$  eigenvectors. The column  $v[:, i]$  is the eigenvector corresponding to the eigenvalue  $w[i]$ .

### Other Parameters

- M** [An  $N \times N$  matrix, array, sparse matrix, or linear operator representing] the operation  $M @ x$  for the generalized eigenvalue problem  $A @ x = w * M @ x$ .

M must represent a real symmetric matrix if A is real, and must represent a complex Hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:

If sigma is None, M is symmetric positive definite.

If sigma is specified, M is symmetric positive semi-definite.

In buckling mode, M is symmetric indefinite.

If sigma is None, eigsh requires an operator to compute the solution of the linear equation  $M @ x = b$ . This is done internally via a (sparse) LU decomposition for an explicit matrix M, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator Minv, which gives  $x = \text{Minv} @ b = M^{-1} @ b$ .

**sigma** [real] Find eigenvalues near sigma using shift-invert mode. This requires an operator to compute the solution of the linear system  $[A - \text{sigma} * M] x = b$ , where M is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices A & M, or via an iterative solver if either A or M is a general linear operator. Alternatively, the user can supply the matrix or operator OPinv, which gives  $x = \text{OPinv} @ b = [A - \text{sigma} * M]^{-1} @ b$ . Note that when sigma is specified, the keyword 'which' refers to the shifted eigenvalues  $w'[i]$  where:

if mode == 'normal',  $w'[i] = 1 / (w[i] - \text{sigma})$ .

if mode == 'cayley',  $w'[i] = (w[i] + \text{sigma}) / (w[i] - \text{sigma})$ .

if mode == 'buckling',  $w'[i] = w[i] / (w[i] - \text{sigma})$ .

(see further discussion in 'mode' below)

**v0** [ndarray, optional] Starting vector for iteration. Default: random

**ncv** [int, optional] The number of Lanczos vectors generated ncv must be greater than k and smaller than n; it is recommended that  $\text{ncv} > 2*k$ . Default:  $\min(n, \max(2*k + 1, 20))$

**which** [str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']] If A is a complex Hermitian matrix, 'BE' is invalid. Which k eigenvectors and eigenvalues to find:

'LM' : Largest (in magnitude) eigenvalues.

'SM' : Smallest (in magnitude) eigenvalues.

'LA' : Largest (algebraic) eigenvalues.

'SA' : Smallest (algebraic) eigenvalues.

'BE' : Half (k/2) from each end of the spectrum.

When k is odd, return one more (k/2+1) from the high end. When sigma != None, 'which' refers to the shifted eigenvalues  $w'[i]$  (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** [int, optional] Maximum number of Arnoldi update iterations allowed. Default:  $n*10$

**tol** [float] Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

**Minv** [N x N matrix, array, sparse matrix, or LinearOperator] See notes in M, above.

**OPinv** [N x N matrix, array, sparse matrix, or LinearOperator] See notes in sigma, above.

**return\_eigenvectors**

[bool] Return eigenvectors (True) in addition to eigenvalues. This value determines the order in which eigenvalues are sorted. The sort order is also dependent on the *which* variable.

**For which = 'LM' or 'SA':**

If *return\_eigenvectors* is True, eigenvalues are sorted by algebraic value.

If *return\_eigenvectors* is False, eigenvalues are sorted by absolute value.

**For which = 'BE' or 'LA':**

eigenvalues are always sorted by algebraic value.

**For which = 'SM':**

If *return\_eigenvectors* is True, eigenvalues are sorted by algebraic value.

If *return\_eigenvectors* is False, eigenvalues are sorted by decreasing absolute value.

**mode** [string ['normal' | 'buckling' | 'cayley']] Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem  $OP * x'[i] = w'[i] * B * x'[i]$  and transforms the resulting Ritz vectors  $x'[i]$  and Ritz values  $w'[i]$  into the desired eigenvectors and eigenvalues of the problem  $A * x[i] = w[i] * M * x[i]$ . The modes are as follows:

**'normal'** :  $OP = [A - \text{sigma} * M]^{-1} @ M$ ,  $B = M$ ,  $w'[i] = 1 / (w[i] - \text{sigma})$

**'buckling'** :

$OP = [A - \text{sigma} * M]^{-1} @ A$ ,  $B = A$ ,  $w'[i] = w[i] / (w[i] - \text{sigma})$

**'cayley'** :  $OP = [A - \text{sigma} * M]^{-1} @ [A + \text{sigma} * M]$ ,  $B = M$ ,  $w'[i] = (w[i] + \text{sigma}) / (w[i] - \text{sigma})$

The choice of mode will affect which eigenvalues are selected by the keyword 'which', and can also impact the stability of convergence (see [2] for a discussion).

### Raises

#### ArpackNoConvergence

When the requested convergence is not obtained.

The currently converged eigenvalues and eigenvectors can be found as `eigenvalues` and `eigenvectors` attributes of the exception object.

See also:

#### eigs

eigenvalues and eigenvectors for a general (nonsymmetric) matrix A

#### svds

singular value decomposition for a matrix A

### Notes

This function is a wrapper to the ARPACK [1] SSEUPD and DSEUPD functions which use the Implicitly Restarted Lanczos Method to find the eigenvalues and eigenvectors [2].

### References

[1], [2]

### Examples

```
>>> from scipy.sparse.linalg import eigsh
>>> identity = np.eye(13)
>>> eigenvalues, eigenvectors = eigsh(identity, k=6)
>>> eigenvalues
array([1., 1., 1., 1., 1., 1.])
>>> eigenvectors.shape
(13, 6)
```

## scipy.sparse.linalg.lobpcg

`scipy.sparse.linalg.lobpcg` (*A*, *X*, *B=None*, *M=None*, *Y=None*, *tol=None*, *maxiter=None*, *largest=True*, *verbosityLevel=0*, *retLambdaHistory=False*, *retResidualNormsHistory=False*)

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

### Parameters

|                                |                                                                                                                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A</b>                       | [[sparse matrix, dense matrix, LinearOperator]] The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.                                                                                                            |
| <b>X</b>                       | [ndarray, float32 or float64] Initial approximation to the <i>k</i> eigenvectors (non-sparse). If <i>A</i> has <code>shape=(n, n)</code> then <i>X</i> should have shape <code>shape=(n, k)</code> .                                                                   |
| <b>B</b>                       | [[dense matrix, sparse matrix, LinearOperator], optional] The right hand side operator in a generalized eigenproblem. By default, <code>B = Identity</code> . Often called the “mass matrix”.                                                                          |
| <b>M</b>                       | [[dense matrix, sparse matrix, LinearOperator], optional] Preconditioner to <i>A</i> ; by default <code>M = Identity</code> . <i>M</i> should approximate the inverse of <i>A</i> .                                                                                    |
| <b>Y</b>                       | [ndarray, float32 or float64, optional] <i>n</i> -by- <i>sizeY</i> matrix of constraints (non-sparse), <code>sizeY &lt; n</code> The iterations will be performed in the <i>B</i> -orthogonal complement of the column-space of <i>Y</i> . <i>Y</i> must be full rank. |
| <b>tol</b>                     | [scalar, optional] Solver tolerance (stopping criterion). The default is <code>tol=n*sqrt(eps)</code> .                                                                                                                                                                |
| <b>maxiter</b>                 | [int, optional] Maximum number of iterations. The default is <code>maxiter = 20</code> .                                                                                                                                                                               |
| <b>largest</b>                 | [bool, optional] When True, solve for the largest eigenvalues, otherwise the smallest.                                                                                                                                                                                 |
| <b>verbosityLevel</b>          | [int, optional] Controls solver output. The default is <code>verbosityLevel=0</code> .                                                                                                                                                                                 |
| <b>retLambdaHistory</b>        | [bool, optional] Whether to return eigenvalue history. Default is False.                                                                                                                                                                                               |
| <b>retResidualNormsHistory</b> | [bool, optional] Whether to return history of residual norms. Default is False.                                                                                                                                                                                        |

### Returns

|                |                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------|
| <b>w</b>       | [ndarray] Array of <i>k</i> eigenvalues                                                                     |
| <b>v</b>       | [ndarray] An array of <i>k</i> eigenvectors. <i>v</i> has the same shape as <i>X</i> .                      |
| <b>lambdas</b> | [list of ndarray, optional] The eigenvalue history, if <code>retLambdaHistory</code> is True.               |
| <b>rnorms</b>  | [list of ndarray, optional] The history of residual norms, if <code>retResidualNormsHistory</code> is True. |

### Notes

If both `retLambdaHistory` and `retResidualNormsHistory` are True, the return tuple has the following format (`lambda`, *V*, `lambda history`, `residual norms history`).

In the following *n* denotes the matrix size and *m* the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size  $3m$  on every iteration by calling the “standard” dense eigensolver, so if *m* is not small enough compared to *n*, it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. `numpy` or `scipy` function in this case. If one calls the LOBPCG algorithm for  $5m > n$ , it will most likely break internally, so the code tries to call the standard function instead.

It is not that *n* should be large for the LOBPCG to work, but rather the ratio  $n / m$  should be large. If you call LOBPCG with  $m=1$  and  $n=10$ , it works though *n* is small. The method is intended for extremely large  $n / m$  [4].

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary *m* to make this better.

- How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large  $n$ , so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for  $A$ , which is easy to code since  $A$  is tridiagonal.

## References

[1], [2], [3], [4]

## Examples

Solve  $A x = \lambda x$  with constraints and preconditioning.

```
>>> import numpy as np
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = np.arange(1, n + 1)
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[1., 0., 0., ..., 0., 0., 0.],
 [0., 2., 0., ..., 0., 0., 0.],
 [0., 0., 3., ..., 0., 0., 0.],
 ...,
 [0., 0., 0., ..., 98., 0., 0.],
 [0., 0., 0., ..., 0., 99., 0.],
 [0., 0., 0., ..., 0., 0., 100.]])
```

Constraints:

```
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```
>>> rng = np.random.default_rng()
>>> X = rng.random((n, 3))
```

Preconditioner in the inverse of  $A$  in this example:

```
>>> invA = spdiags([1./vals], 0, n, n)
```

The preconditioner must be defined by a function:

```
>>> def precondition(x):
... return invA @ x
```

The argument  $x$  of the preconditioner function is a matrix inside `lobpcg`, thus the use of matrix-matrix product `@`.

The preconditioner function is passed to `lobpcg` as a `LinearOperator`:

```
>>> M = LinearOperator(matvec=precond, matmat=precond,
... shape=(n, n), dtype=float)
```

Let us now solve the eigenvalue problem for the matrix A:

```
>>> eigenvalues, _ = lobpcg(A, X, Y=Y, M=M, largest=False)
>>> eigenvalues
array([4., 5., 6.]
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

|                                                              |                                                                                |
|--------------------------------------------------------------|--------------------------------------------------------------------------------|
| <code>svd</code> (A[, k, ncv, tol, which, v0, maxiter, ...]) | Compute the largest or smallest k singular values/vectors for a sparse matrix. |
|--------------------------------------------------------------|--------------------------------------------------------------------------------|

### scipy.sparse.linalg.svds

`scipy.sparse.linalg.svds`(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return\_singular\_vectors=True, solver='arpack')

Compute the largest or smallest k singular values/vectors for a sparse matrix. The order of the singular values is not guaranteed.

#### Parameters

- A** [{sparse matrix, LinearOperator}] Array to compute the SVD on, of shape (M, N)
- k** [int, optional] Number of singular values and vectors to compute. Must be  $1 \leq k < \min(A.shape)$ .
- ncv** [int, optional] The number of Lanczos vectors generated ncv must be greater than k+1 and smaller than n; it is recommended that  $ncv > 2*k$  Default:  $\min(n, \max(2*k + 1, 20))$
- tol** [float, optional] Tolerance for singular values. Zero (default) means machine precision.
- which** [str, ['LM' | 'SM'], optional] Which k singular values to find:
  - 'LM' : largest singular values
  - 'SM' : smallest singular values
 New in version 0.12.0.
- v0** [ndarray, optional] Starting vector for iteration, of length  $\min(A.shape)$ . Should be an (approximate) left singular vector if  $N > M$  and a right singular vector otherwise. Default: random  
New in version 0.12.0.
- maxiter** [int, optional] Maximum number of iterations.  
New in version 0.12.0.
- return\_singular\_vectors** [bool or str, optional]
  - True: return singular vectors (True) in addition to singular values.  
New in version 0.12.0.
  - "u": only return the u matrix, without computing vh (if  $N > M$ ).
  - "vh": only return the vh matrix, without computing u (if  $N \leq M$ ).
 New in version 0.16.0.
- solver** [str, optional] Eigenvalue solver to use. Should be 'arpack' or 'lobpcg'. Default: 'arpack'

#### Returns

- u** [ndarray, shape=(M, k)] Unitary matrix having left singular vectors as columns. If `return_singular_vectors` is "vh", this variable is not computed, and None is returned instead.
- s** [ndarray, shape=(k,)] The singular values.
- vt** [ndarray, shape=(k, N)] Unitary matrix having right singular vectors as rows. If `return_singular_vectors` is "u", this variable is not computed, and None is returned instead.

## Notes

This is a naive implementation using ARPACK or LOBPCG as an eigensolver on  $A.H * A$  or  $A * A.H$ , depending on which one is more efficient.

## Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs
>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]],
→dtype=float)
>>> u, s, vt = svds(A, k=2)
>>> s
array([2.75193379, 5.6059665])
>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([5.6059665 , 2.75193379])
```

Complete or incomplete LU factorizations

|----------------------------------------------------------------|---------------------------------------------------------------------|
| <code>splu(A[, permc_spec, diag_pivot_thresh, ...])</code>     | Compute the LU decomposition of a sparse, square matrix.            |
| <code>spilu(A[, drop_tol, fill_factor, drop_rule, ...])</code> | Compute an incomplete LU decomposition for a sparse, square matrix. |
| <code>SuperLU()</code>                                         | LU factorization of a sparse matrix.                                |

## scipy.sparse.linalg.splu

`scipy.sparse.linalg.splu(A, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options={})`

Compute the LU decomposition of a sparse, square matrix.

### Parameters

- A** [sparse matrix] Sparse matrix to factorize. Should be in CSR or CSC format.
- permc\_spec** [str, optional] How to permute the columns of the matrix for sparsity preservation. (default: 'COLAMD')
- NATURAL: natural ordering.
  - MMD\_ATA: minimum degree ordering on the structure of  $A^T A$ .
  - MMD\_AT\_PLUS\_A: minimum degree ordering on the structure of  $A^T + A$ .
  - COLAMD: approximate minimum degree column ordering
- diag\_pivot\_thresh** [float, optional] Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user's guide for details [1]
- relax** [int, optional] Expert option for customizing the degree of relaxing supernodes. See SuperLU user's guide for details [1]
- panel\_size** [int, optional] Expert option for customizing the panel size. See SuperLU user's guide for details [1]
- options** [dict, optional] Dictionary containing additional expert options to SuperLU. See SuperLU user guide [1] (section 2.4 on the 'Options' argument) for more details. For example, you can specify `options=dict(Equil=False, IterRefine='SINGLE')` to turn equilibration off and perform a single iterative refinement.

### Returns

**invA** [scipy.sparse.linalg.SuperLU] Object, which has a `solve` method.

**See also:**

**spilu**

incomplete LU decomposition

### Notes

This function uses the SuperLU library.

### References

[1]

### Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import splu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
→dtype=float)
>>> B = splu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([1., 2., 3.])
>>> B.solve(A.dot(x))
array([1., 2., 3.])
```

### scipy.sparse.linalg.spilu

`scipy.sparse.linalg.spilu` (*A*, *drop\_tol=None*, *fill\_factor=None*, *drop\_rule=None*, *permc\_spec=None*, *diag\_pivot\_thresh=None*, *relax=None*, *panel\_size=None*, *options=None*)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of *A*.

#### Parameters

- A** [(N, N) array\_like] Sparse matrix to factorize
- drop\_tol** [float, optional] Drop tolerance ( $0 \leq \text{tol} \leq 1$ ) for an incomplete LU decomposition. (default:  $1e-4$ )
- fill\_factor** [float, optional] Specifies the fill ratio upper bound ( $\geq 1.0$ ) for ILU. (default: 10)
- drop\_rule** [str, optional] Comma-separated string of drop rules to use. Available rules: `basic`, `provs`, `column`, `area`, `secondary`, `dynamic`, `interp`. (Default: `basic, area`) See SuperLU documentation for details.

#### Remaining other options

Same as for `splu`

#### Returns

- invA\_approx** [scipy.sparse.linalg.SuperLU] Object, which has a `solve` method.

See also:

`splu`

complete LU decomposition

## Notes

To improve the better approximation to the inverse, you may need to increase *fill\_factor* AND decrease *drop\_tol*. This function uses the SuperLU library.

## Examples

```
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu
>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]],
↳dtype=float)
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([1., 2., 3.])
>>> B.solve(A.dot(x))
array([1., 2., 3.])
```

## scipy.sparse.linalg.SuperLU

**class** `scipy.sparse.linalg.SuperLU`

LU factorization of a sparse matrix.

Factorization is represented as:

$$P_r * A * P_c = L * U$$

To construct these *SuperLU* objects, call the `splu` and `spilu` functions.

## Notes

New in version 0.14.0.

## Examples

The LU decomposition can be used to solve matrix equations. Consider:

```
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla
>>> A = csc_matrix([[1, 2, 0, 4], [1, 0, 0, 1], [1, 0, 2, 1], [2, 2, 1, 0.]])
```

This can be solved for a given right-hand side:

```
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([1., 2., 3., 4.]
```

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The `L` and `U` factors are sparse matrices in CSC format:

```
>>> lu.L.A
array([[1. , 0. , 0. , 0.],
 [0. , 1. , 0. , 0.],
 [0. , 0. , 1. , 0.],
 [1. , 0.5, 0.5, 1.]])
>>> lu.U.A
array([[2., 0., 1., 4.],
 [0., 2., 1., 1.],
 [0., 0., 1., 1.],
 [0., 0., 0., -5.]])
```

The permutation matrices can be constructed:

```
>>> Pr = csc_matrix((np.ones(4), (lu.perm_r, np.arange(4))))
>>> Pc = csc_matrix((np.ones(4), (np.arange(4), lu.perm_c)))
```

We can reassemble the original matrix:

```
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[1., 2., 0., 4.],
 [1., 0., 0., 1.],
 [1., 0., 2., 1.],
 [2., 2., 1., 0.]])
```

### Attributes

|               |                                                                                  |
|---------------|----------------------------------------------------------------------------------|
| <b>shape</b>  | Shape of the original matrix as a tuple of ints.                                 |
| <b>nnz</b>    | Number of nonzero elements in the matrix.                                        |
| <b>perm_c</b> | Permutation <code>Pc</code> represented as an array of indices.                  |
| <b>perm_r</b> | Permutation <code>Pr</code> represented as an array of indices.                  |
| <b>L</b>      | Lower triangular factor with unit diagonal as a <i>scipy.sparse.csc_matrix</i> . |
| <b>U</b>      | Upper triangular factor as a <i>scipy.sparse.csc_matrix</i> .                    |

| <code>solve(rhs[, trans])</code> | Solves linear system of equations with one or several right-hand sides. |
|----------------------------------|-------------------------------------------------------------------------|

---

### scipy.sparse.linalg.SuperLU.solve

SuperLU.**solve** (*rhs* [, *trans* ])

Solves linear system of equations with one or several right-hand sides.

#### Parameters

**rhs** [ndarray, shape (n,) or (n, k)] Right hand side(s) of equation  
**trans** [{'N', 'T', 'H'}, optional] Type of system to solve:

|      |                           |
|------|---------------------------|
| 'N': | A * x == rhs (default)    |
| 'T': | A <sup>T</sup> * x == rhs |
| 'H': | A <sup>H</sup> * x == rhs |

i.e., normal, transposed, and hermitian conjugate.

#### Returns

**x** [ndarray, shape rhs . shape] Solution vector(s)

## Exceptions

### 3.3.25 Compressed sparse graph routines (`scipy.sparse.csgraph`)

Fast graph algorithms based on sparse matrix representations.

#### Contents

|                                                               |                                                                                                                |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>connected_components(csgraph[, directed, ...])</code>   | Analyze the connected components of a sparse graph                                                             |
| <code>laplacian(csgraph[, normed, return_diag, ...])</code>   | Return the Laplacian matrix of a directed graph.                                                               |
| <code>shortest_path(csgraph[, method, directed, ...])</code>  | Perform a shortest-path graph search on a positive directed or undirected graph.                               |
| <code>dijkstra(csgraph[, directed, indices, ...])</code>      | Dijkstra algorithm using Fibonacci Heaps                                                                       |
| <code>floyd_warshall(csgraph[, directed, ...])</code>         | Compute the shortest path lengths using the Floyd-Warshall algorithm                                           |
| <code>bellman_ford(csgraph[, directed, indices, ...])</code>  | Compute the shortest path lengths using the Bellman-Ford algorithm.                                            |
| <code>johnson(csgraph[, directed, indices, ...])</code>       | Compute the shortest path lengths using Johnson's algorithm.                                                   |
| <code>breadth_first_order(csgraph, i_start[, ...])</code>     | Return a breadth-first ordering starting with specified node.                                                  |
| <code>depth_first_order(csgraph, i_start[, ...])</code>       | Return a depth-first ordering starting with specified node.                                                    |
| <code>breadth_first_tree(csgraph, i_start[, directed])</code> | Return the tree generated by a breadth-first search                                                            |
| <code>depth_first_tree(csgraph, i_start[, directed])</code>   | Return a tree generated by a depth-first search.                                                               |
| <code>minimum_spanning_tree(csgraph[, overwrite])</code>      | Return a minimum spanning tree of an undirected graph                                                          |
| <code>reverse_cuthill_mckee(graph[, symmetric_mode])</code>   | Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.        |
| <code>maximum_flow(csgraph, source, sink)</code>              | Maximize the flow between two vertices in a graph.                                                             |
| <code>maximum_bipartite_matching(graph[, perm_type])</code>   | Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph. |
| <code>min_weight_full_bipartite_matching(...[, ...])</code>   | Returns the minimum weight full matching of a bipartite graph.                                                 |
| <code>structural_rank(graph)</code>                           | Compute the structural rank of a graph (matrix) with a given sparsity pattern.                                 |
| <code>NegativeCycleError([message])</code>                    |                                                                                                                |

#### `scipy.sparse.csgraph.connected_components`

`scipy.sparse.csgraph.connected_components` (*csgraph*, *directed=True*, *connection='weak'*, *return\_labels=True*)

Analyze the connected components of a sparse graph

New in version 0.11.0.

#### Parameters

- csgraph** [array\_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**connection**

[str, optional] ['weak'|'strong']. For directed graphs, the type of connection to use. Nodes *i* and *j* are strongly connected if a path exists both from *i* to *j* and from *j* to *i*. A directed graph is weakly connected if replacing all of its directed edges with undirected edges produces a connected (undirected) graph. If directed == False, this keyword is not referenced.

**return\_labels**

[bool, optional] If True (default), then return the labels for each of the connected components.

**Returns****n\_components: int**

The number of connected components.

**labels: ndarray**

The length-N array of labels of the connected components.

**References**

[1]

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import connected_components
```

```
>>> graph = [
... [0, 1, 1, 0, 0],
... [0, 0, 1, 0, 0],
... [0, 0, 0, 0, 0],
... [0, 0, 0, 0, 1],
... [0, 0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 1
(1, 2) 1
(3, 4) 1
```

```
>>> n_components, labels = connected_components(csgraph=graph,
↳directed=False, return_labels=True)
>>> n_components
2
>>> labels
array([0, 0, 0, 1, 1], dtype=int32)
```

**scipy.sparse.csgraph.laplacian**

`scipy.sparse.csgraph.laplacian` (*csgraph*, *normed=False*, *return\_diag=False*,  
*use\_out\_degree=False*)

Return the Laplacian matrix of a directed graph.

**Parameters**

- csgraph** [array\_like or sparse matrix, 2 dimensions] compressed-sparse graph, with shape (N, N).  
**normed** [bool, optional] If True, then compute symmetric normalized Laplacian.  
**return\_diag** [bool, optional] If True, then also return an array related to vertex degrees.  
**use\_out\_degree** [bool, optional] If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns**

- lap** [ndarray or sparse matrix] The N x N laplacian matrix of *csgraph*. It will be a NumPy array (dense) if the input was dense, or a sparse matrix otherwise.  
**diag** [ndarray, optional] The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

**Notes**

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

**Examples**

```
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[0, 0, 0, 0, 0],
 [0, 1, 2, 3, 4],
 [0, 2, 4, 6, 8],
 [0, 3, 6, 9, 12],
 [0, 4, 8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[0, 0, 0, 0, 0],
 [0, 9, -2, -3, -4],
 [0, -2, 16, -6, -8],
 [0, -3, -6, 21, -12],
 [0, -4, -8, -12, 24]])
```

**scipy.sparse.csgraph.shortest\_path**

`scipy.sparse.csgraph.shortest_path` (*csgraph*, *method*='auto', *directed*=True, *return\_predecessors*=False, *unweighted*=False, *overwrite*=False, *indices*=None)

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters**

- csgraph** [array, matrix, or sparse matrix, 2 dimensions] The  $N \times N$  array of distances representing the input graph.
- method** [string ['auto'|'FW'|'D'], optional] Algorithm to use for shortest paths. Options are:  
**'auto'** – (default) select the best among **'FW'**, **'D'**, **'BF'**, or **'J'** based on the input data.  
**'FW'** – **Floyd-Warshall algorithm. Computational cost is** approximately  $O[N^3]$ . The input csgraph will be converted to a dense representation.  
**'D'** – **Dijkstra's algorithm with Fibonacci heaps. Computational cost is** approximately  $O[N(N \cdot k + N \cdot \log(N))]$ , where  $k$  is the average number of connected edges per node. The input csgraph will be converted to a csr representation.  
**'BF'** – **Bellman-Ford algorithm. This algorithm can be used when** weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately  $O[N(N^2 \cdot k)]$ , where  $k$  is the average number of connected edges per node. The input csgraph will be converted to a csr representation.  
**'J'** – **Johnson's algorithm. Like the Bellman-Ford algorithm,** Johnson's algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra's algorithm for faster computation.
- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`
- return\_predecessors** [bool, optional] If True, return the size  $(N, N)$  predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- overwrite** [bool, optional] If True, overwrite `csgraph` with the result. This applies only if `method == 'FW'` and `csgraph` is a dense, c-ordered array with `dtype=float64`.
- indices** [array\_like or int, optional] If specified, only compute the paths from the points at the given indices. Incompatible with `method == 'FW'`.

**Returns**

- dist\_matrix** [ndarray] The  $N \times N$  matrix of distances between graph nodes. `dist_matrix[i, j]` gives the shortest distance from point  $i$  to point  $j$  along the graph.
- predecessors** [ndarray] Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index

of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`

#### Raises

##### NegativeCycleError:

if there are negative cycles in the graph

#### Notes

As currently implemented, Dijkstra's algorithm and Johnson's algorithm do not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are non-equal edges, `method='D'` may yield an incorrect result.

#### Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import shortest_path
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> dist_matrix, predecessors = shortest_path(csgraph=graph,
->directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

### scipy.sparse.csgraph.dijkstra

`scipy.sparse.csgraph.dijkstra` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*, *limit=np.inf*, *min\_only=False*)

Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

#### Parameters

**csgraph** [array, matrix, or sparse matrix, 2 dimensions] The  $N \times N$  array of non-negative distances representing the input graph.

- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]` and from point *j* to *i* along paths `csgraph[j, i]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* or *j* to *i* along either `csgraph[i, j]` or `csgraph[j, i]`.
- indices** [array\_like or int, optional] if specified, only compute the paths from the points at the given indices.
- return\_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- limit** [float, optional] The maximum distance to calculate, must be  $\geq 0$ . Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance  $>$  limit. For such pairs, the distance will be equal to `np.inf` (i.e., not connected). New in version 0.14.0.
- min\_only** [bool, optional] If False (default), for every node in the graph, find the shortest path from every node in indices. If True, for every node in the graph, find the shortest path from any of the nodes in indices (which can be substantially faster). New in version 1.3.0.

**Returns**

- dist\_matrix** [ndarray, shape ([n\_indices, ]n\_nodes,)] The matrix of distances between graph nodes. If `min_only=False`, `dist_matrix` has shape (n\_indices, n\_nodes) and `dist_matrix[i, j]` gives the shortest distance from point *i* to point *j* along the graph. If `min_only=True`, `dist_matrix` has shape (n\_nodes,) and contains for a given node the shortest path to that node from any of the nodes in indices.
- predecessors** [ndarray, shape ([n\_indices, ]n\_nodes,)] If `min_only=False`, this has shape (n\_indices, n\_nodes), otherwise it has shape (n\_nodes,). Returned only if `return_predecessors == True`. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row *i* of the predecessor matrix contains information on the shortest paths from point *i*: each entry `predecessors[i, j]` gives the index of the previous node in the path from point *i* to point *j*. If no path exists between point *i* and *j*, then `predecessors[i, j] = -9999`
- sources** [ndarray, shape (n\_nodes,)] Returned only if `min_only=True` and `return_predecessors=True`. Contains the index of the source which had the shortest path to each target. If no path exists within the limit, this will contain -9999. The value at the indices passed will be equal to that index (i.e. the fastest way to reach node *i*, is to start on node *i*).

**Notes**

As currently implemented, Dijkstra's algorithm does not work for graphs with direction-dependent distances when `directed == False`. i.e., if `csgraph[i,j]` and `csgraph[j,i]` are not equal and both are nonzero, setting `directed=False` will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford's algorithm or Johnson's algorithm.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import dijkstra
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3
```

```
>>> dist_matrix, predecessors = dijkstra(csgraph=graph, directed=False,
→indices=0, return_predecessors=True)
>>> dist_matrix
array([0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

### scipy.sparse.csgraph.floyd\_warshall

`scipy.sparse.csgraph.floyd_warshall` (*csgraph*, *directed=True*, *return\_predecessors=False*, *unweighted=False*, *overwrite=False*)

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

#### Parameters

- csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point *i* to point *j* along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point *i* to *j* along `csgraph[i, j]` or `csgraph[j, i]`
- return\_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- overwrite** [bool, optional] If True, overwrite `csgraph` with the result. This applies only if `csgraph` is a dense, c-ordered array with `dtype=float64`.

#### Returns

- dist\_matrix** [ndarray] The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point *i* to point *j* along the graph.

**predecessors**

[ndarray] Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`

**Raises****NegativeCycleError:**

if there are negative cycles in the graph

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import floyd_warshall
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> dist_matrix, predecessors = floyd_warshall(csgraph=graph,
->directed=False, return_predecessors=True)
>>> dist_matrix
array([[0., 1., 2., 2.],
 [1., 0., 3., 1.],
 [2., 3., 0., 3.],
 [2., 1., 3., 0.]])
>>> predecessors
array([[-9999, 0, 0, 1],
 [1, -9999, 0, 1],
 [2, 0, -9999, 2],
 [1, 3, 3, -9999]], dtype=int32)
```

**scipy.sparse.csgraph.bellman\_ford**

`scipy.sparse.csgraph.bellman_ford` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-Ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, Dijkstra's algorithm may be faster.

New in version 0.11.0.

**Parameters**

- csgraph** [array, matrix, or sparse matrix, 2 dimensions] The N x N array of distances representing the input graph.
- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`
- indices** [array\_like or int, optional] if specified, only compute the paths from the points at the given indices.
- return\_predecessors** [bool, optional] If True, return the size (N, N) predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns**

- dist\_matrix** [ndarray] The N x N matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point i to point j along the graph.
- predecessors** [ndarray] Returned only if `return_predecessors == True`. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

**Raises**

- NegativeCycleError:**  
if there are negative cycles in the graph

**Notes**

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import bellman_ford
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> dist_matrix, predecessors = bellman_ford(csgraph=graph,
->directed=False, indices=0, return_predecessors=True)
>>> dist_matrix
array([0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

### scipy.sparse.csgraph.johnson

`scipy.sparse.csgraph.johnson` (*csgraph*, *directed=True*, *indices=None*, *return\_predecessors=False*, *unweighted=False*)

Compute the shortest path lengths using Johnson's algorithm.

Johnson's algorithm combines the Bellman-Ford algorithm and Dijkstra's algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, `dijkstra` may be faster.

New in version 0.11.0.

#### Parameters

- csgraph** [array, matrix, or sparse matrix, 2 dimensions] The  $N \times N$  array of distances representing the input graph.
- directed** [bool, optional] If True (default), then find the shortest path on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`.
- indices** [array\_like or int, optional] if specified, only compute the paths from the points at the given indices.
- return\_predecessors** [bool, optional] If True, return the size  $(N, N)$  predecessor matrix
- unweighted** [bool, optional] If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

#### Returns

**dist\_matrix**

[ndarray] The  $N \times N$  matrix of distances between graph nodes. `dist_matrix[i,j]` gives the shortest distance from point  $i$  to point  $j$  along the graph.

**predecessors**

[ndarray] Returned only if `return_predecessors == True`. The  $N \times N$  matrix of predecessors, which can be used to reconstruct the shortest paths. Row  $i$  of the predecessor matrix contains information on the shortest paths from point  $i$ : each entry `predecessors[i, j]` gives the index of the previous node in the path from point  $i$  to point  $j$ . If no path exists between point  $i$  and  $j$ , then `predecessors[i, j] = -9999`

**Raises****NegativeCycleError:**

if there are negative cycles in the graph

**Notes**

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra's algorithm is a better choice.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import johnson
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> dist_matrix, predecessors = johnson(csgraph=graph, directed=False,
↳ indices=0, return_predecessors=True)
>>> dist_matrix
array([0., 1., 2., 2.])
>>> predecessors
array([-9999, 0, 0, 1], dtype=int32)
```

**scipy.sparse.csgraph.breadth\_first\_order**

`scipy.sparse.csgraph.breadth_first_order` (*csgraph*, *i\_start*, *directed=True*, *return\_predecessors=True*)

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

**Parameters**

- csgraph** [array\_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** [int] The index of starting node.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- return\_predecessors** [bool, optional] If True (default), then return the predecessor array (see below).

**Returns**

- node\_array** [ndarray, one dimension] The breadth-first list of nodes, starting with specified node. The length of `node_array` is the number of nodes reachable from the specified node.
- predecessors** [ndarray, one dimension] Returned only if `return_predecessors` is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by `predecessors[i]`. If node i is not in the tree (and for the parent node) then `predecessors[i] = -9999`.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_order
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> breadth_first_order(graph, 0)
(array([0, 1, 2, 3], dtype=int32), array([-9999, 0, 0, 1],
dtype=int32))
```

**scipy.sparse.csgraph.depth\_first\_order**

`scipy.sparse.csgraph.depth_first_order` (*csgraph*, *i\_start*, *directed=True*, *return\_predecessors=True*)

Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters**

- csgraph** [array\_like or sparse matrix] The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** [int] The index of starting node.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- return\_predecessors** [bool, optional] If True (default), then return the predecessor array (see below).

**Returns**

- node\_array** [ndarray, one dimension] The depth-first list of nodes, starting with specified node. The length of `node_array` is the number of nodes reachable from the specified node.
- predecessors** [ndarray, one dimension] Returned only if `return_predecessors` is True. The length-N list of predecessors of each node in a depth-first tree. If node i is in the tree, then its parent is given by `predecessors[i]`. If node i is not in the tree (and for the parent node) then `predecessors[i] = -9999`.

**Examples**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_order
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> depth_first_order(graph, 0)
(array([0, 1, 3, 2], dtype=int32), array([-9999, 0, 0, 1],
→dtype=int32))
```

**scipy.sparse.csgraph.breadth\_first\_tree**

`scipy.sparse.csgraph.breadth_first_tree(csgraph, i_start, directed=True)`

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

**Parameters**

- csgraph** [array\_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** [int] The index of starting node.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.

**Returns**

- ctree** [csr matrix] The N x N directed compressed-sparse representation of the breadth-first tree drawn from csgraph, starting at the specified node.

**Examples**

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
... [0, 0, 2, 5],
... [0, 0, 0, 6],
... [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
 [0, 0, 2, 0],
 [0, 0, 0, 0],
 [0, 0, 0, 0]])

```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a given node is unique.

### scipy.sparse.csgraph.depth\_first\_tree

`scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)`

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

#### Parameters

- csgraph** [array\_like or sparse matrix] The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- i\_start** [int] The index of starting node.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.

#### Returns

- cstree** [csr matrix] The N x N directed compressed-sparse representation of the depth- first tree drawn from csgraph, starting at the specified node.

### Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
... [0, 0, 2, 5],
... [0, 0, 0, 6],
... [0, 0, 0, 0]])
>>> Tcsr = depth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
 [0, 0, 2, 0],
 [0, 0, 0, 6],
 [0, 0, 0, 0]])

```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

### scipy.sparse.csgraph.minimum\_spanning\_tree

`scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)`

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

#### Parameters

- csgraph** [array\_like or sparse matrix, 2 dimensions] The N x N matrix representing an undirected graph over N nodes (see notes below).
- overwrite** [bool, optional] if true, then parts of the input graph will be overwritten for efficiency.

#### Returns

- span\_tree** [csr matrix] The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

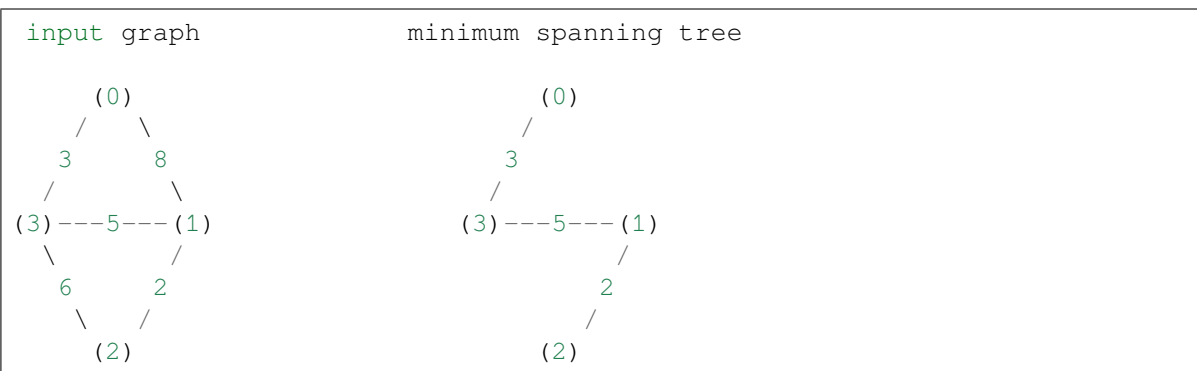

### Notes

This routine uses undirected graphs as input and output. That is, if `graph[i, j]` and `graph[j, i]` are both zero, then nodes `i` and `j` do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

This routine loses precision when users input a dense matrix. Small elements  $< 1\text{E-}8$  of the dense matrix are rounded to zero. All users should input sparse matrices if possible to avoid it.

### Examples

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr_matrix([[0, 8, 0, 3],
```

(continues on next page)

(continued from previous page)

```

... [0, 0, 2, 5],
... [0, 0, 0, 6],
... [0, 0, 0, 0]])
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
 [0, 0, 2, 5],
 [0, 0, 0, 0],
 [0, 0, 0, 0]])

```

### scipy.sparse.csgraph.reverse\_cuthill\_mckee

`scipy.sparse.csgraph.reverse_cuthill_mckee` (*graph*, *symmetric\_mode=False*)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, `symmetric_mode=False`, that the input matrix is not symmetric and works on the matrix  $A+A.T$ . If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set `symmetric_mode=True`.

#### Parameters

**graph** [sparse matrix] Input sparse in CSC or CSR sparse matrix format.  
**symmetric\_mode** [bool, optional] Is input matrix guaranteed to be symmetric.

#### Returns

**perm** [ndarray] Array of permuted row and column indices.

#### Notes

New in version 0.15.0.

#### References

E. Cuthill and J. McKee, "Reducing the Bandwidth of Sparse Symmetric Matrices", ACM '69 Proceedings of the 1969 24th national conference, (1969).

#### Examples

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reverse_cuthill_mckee

```

```

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [2, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1

```

(continues on next page)

(continued from previous page)

```
(0, 2) 2
(1, 3) 1
(2, 0) 2
(2, 3) 3
```

```
>>> reverse_cuthill_mckee(graph)
array([3, 2, 1, 0], dtype=int32)
```

**scipy.sparse.csgraph.maximum\_flow**`scipy.sparse.csgraph.maximum_flow` (*csgraph*, *source*, *sink*)

Maximize the flow between two vertices in a graph.

New in version 1.4.0.

**Parameters**

**csgraph** [*csr\_matrix*] The square matrix representing a directed graph whose (i, j)'th entry is an integer representing the capacity of the edge between vertices i and j.

**source** [*int*] The source vertex from which the flow flows.

**sink** [*int*] The sink vertex to which the flow flows.

**Returns**

**res** [*MaximumFlowResult*] A maximum flow represented by a `MaximumFlowResult` which includes the value of the flow in `flow_value`, and the residual graph in `residual`.

**Raises**

**TypeError:**  
if the input graph is not in CSR format.

**ValueError:**  
if the capacity values are not integers, or the source or sink are out of bounds.

**Notes**

This solves the maximum flow problem on a given directed weighted graph: A flow associates to every edge a value, also called a flow, less than the capacity of the edge, so that for every vertex (apart from the source and the sink vertices), the total incoming flow is equal to the total outgoing flow. The value of a flow is the sum of the flow of all edges leaving the source vertex, and the maximum flow problem consists of finding a flow whose value is maximal.

By the max-flow min-cut theorem, the maximal value of the flow is also the total weight of the edges in a minimum cut.

To solve the problem, we use the Edmonds–Karp algorithm. [1] This particular implementation strives to exploit sparsity. Its time complexity is  $O(VE^2)$  and its space complexity is  $O(E)$ .

The maximum flow problem is usually defined with real valued capacities, but we require that all capacities are integral to ensure convergence. When dealing with rational capacities, or capacities belonging to  $x\mathbb{Q}$  for some fixed  $x \in \mathbb{R}$ , it is possible to reduce the problem to the integral case by scaling all capacities accordingly.

Solving a maximum-flow problem can be used for example for graph cuts optimization in computer vision [3].

## References

[1], [2], [3]

## Examples

Perhaps the simplest flow problem is that of a graph of only two vertices with an edge from source (0) to sink (1):

```
(0) --5--> (1)
```

Here, the maximum flow is simply the capacity of the edge:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_flow
>>> graph = csr_matrix([[0, 5], [0, 0]])
>>> maximum_flow(graph, 0, 1).flow_value
5
```

If, on the other hand, there is a bottleneck between source and sink, that can reduce the maximum flow:

```
(0) --5--> (1) --3--> (2)
```

```
>>> graph = csr_matrix([[0, 5, 0], [0, 0, 3], [0, 0, 0]])
>>> maximum_flow(graph, 0, 2).flow_value
3
```

A less trivial example is given in [2], Chapter 26.1:

```
>>> graph = csr_matrix([[0, 16, 13, 0, 0, 0],
... [0, 10, 0, 12, 0, 0],
... [0, 4, 0, 0, 14, 0],
... [0, 0, 9, 0, 0, 20],
... [0, 0, 0, 7, 0, 4],
... [0, 0, 0, 0, 0, 0]])
>>> maximum_flow(graph, 0, 5).flow_value
23
```

It is possible to reduce the problem of finding a maximum matching in a bipartite graph to a maximum flow problem: Let  $G = ((U, V), E)$  be a bipartite graph. Then, add to the graph a source vertex with edges to every vertex in  $U$  and a sink vertex with edges from every vertex in  $V$ . Finally, give every edge in the resulting graph a capacity of 1. Then, a maximum flow in the new graph gives a maximum matching in the original graph consisting of the edges in  $E$  whose flow is positive.

Assume that the edges are represented by a  $|U| \times |V|$  matrix in CSR format whose  $(i, j)$ 'th entry is 1 if there is an edge from  $i \in U$  to  $j \in V$  and 0 otherwise; that is, the input is of the form required by `maximum_bipartite_matching`. Then the CSR representation of the graph constructed above contains this matrix as a block. Here's an example:

```
>>> graph = csr_matrix([[0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 1, 0]])
>>> print(graph.toarray())
[[0 1 0 1]
 [1 0 1 0]
 [0 1 1 0]]
```

(continues on next page)

(continued from previous page)

```

>>> i, j = graph.shape
>>> n = graph.nnz
>>> indptr = np.concatenate([[0],
... graph.indptr + i,
... np.arange(n + i + 1, n + i + j + 1),
... [n + i + j]])
>>> indices = np.concatenate([np.arange(1, i + 1),
... graph.indices + i + 1,
... np.repeat(i + j + 1, j)])
>>> data = np.ones(n + i + j, dtype=int)
>>>
>>> graph_flow = csr_matrix((data, indices, indptr))
>>> print(graph_flow.toarray())
[[0 1 1 1 0 0 0 0 0]
 [0 0 0 0 0 1 0 1 0]
 [0 0 0 0 1 0 1 0 0]
 [0 0 0 0 0 1 1 0 0]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 1]
 [0 0 0 0 0 0 0 0 0]]

```

At this point, we can find the maximum flow between the added sink and the added source and the desired matching can be obtained by restricting the residual graph to the block corresponding to the original graph:

```

>>> flow = maximum_flow(graph_flow, 0, i+j+1)
>>> matching = flow.residual[1:i+1, i+1:i+j+1]
>>> print(matching.toarray())
[[0 1 0 0]
 [1 0 0 0]
 [0 0 1 0]]

```

This tells us that the first, second, and third vertex in  $U$  are matched with the second, first, and third vertex in  $V$  respectively.

While this solves the maximum bipartite matching problem in general, note that algorithms specialized to that problem, such as `maximum_bipartite_matching`, will generally perform better.

This approach can also be used to solve various common generalizations of the maximum bipartite matching problem. If, for instance, some vertices can be matched with more than one other vertex, this may be handled by modifying the capacities of the new graph appropriately.

### scipy.sparse.csgraph.maximum\_bipartite\_matching

`scipy.sparse.csgraph.maximum_bipartite_matching` (*graph*, *perm\_type*='row')

Returns a matching of a bipartite graph whose cardinality is as least that of any given matching of the graph.

#### Parameters

**graph** [sparse matrix] Input sparse in CSR format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix existing in its sparse representation.

**perm\_type** [str, {'row', 'column'}] Which partition to return the matching in terms of: If 'row', the function produces an array whose length is the number of columns in the input, and whose

$j$ 'th element is the row matched to the  $j$ 'th column. Conversely, if `perm_type` is 'column', this returns the columns matched to each row.

### Returns

**perm** [ndarray] A matching of the vertices in one of the two partitions. Unmatched vertices are represented by a  $-1$  in the result.

### Notes

This function implements the Hopcroft–Karp algorithm [1]. Its time complexity is  $O(|E|\sqrt{|V|})$ , and its space complexity is linear in the number of rows. In practice, this asymmetry between rows and columns means that it can be more efficient to transpose the input if it contains more columns than rows.

By König's theorem, the cardinality of the matching is also the number of vertices appearing in a minimum vertex cover of the graph.

Note that if the sparse representation contains explicit zeros, these are still counted as edges.

The implementation was changed in SciPy 1.4.0 to allow matching of general bipartite graphs, where previous versions would assume that a perfect matching existed. As such, code written against 1.4.0 will not necessarily work on older versions.

[1]

### Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
```

As a simple example, consider a bipartite graph in which the partitions contain 2 and 3 elements respectively. Suppose that one partition contains vertices labelled 0 and 1, and that the other partition contains vertices labelled A, B, and C. Suppose that there are edges connecting 0 and C, 1 and A, and 1 and B. This graph would then be represented by the following sparse matrix:

```
>>> graph = csr_matrix([[0, 0, 1], [1, 1, 0]])
```

Here, the 1s could be anything, as long as they end up being stored as elements in the sparse matrix. We can now calculate maximum matchings as follows:

```
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[1 -1 0]
```

The first output tells us that 1 and 2 are matched with C and A respectively, and the second output tells us that A, B, and C are matched with 1, nothing, and 0 respectively.

Note that explicit zeros are still converted to edges. This means that a different way to represent the above graph is by using the CSR structure directly as follows:

```

>>> data = [0, 0, 0]
>>> indices = [2, 0, 1]
>>> indptr = [0, 1, 3]
>>> graph = csr_matrix((data, indices, indptr))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[2 0]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[1 -1 0]

```

When one or both of the partitions are empty, the matching is empty as well:

```

>>> graph = csr_matrix((2, 0))
>>> print(maximum_bipartite_matching(graph, perm_type='column'))
[-1 -1]
>>> print(maximum_bipartite_matching(graph, perm_type='row'))
[]

```

When the input matrix is square, and the graph is known to admit a perfect matching, i.e. a matching with the property that every vertex in the graph belongs to some edge in the matching, then one can view the output as the permutation of rows (or columns) turning the input matrix into one with the property that all diagonal elements are non-empty:

```

>>> a = [[0, 1, 2, 0], [1, 0, 0, 1], [2, 0, 0, 3], [0, 1, 3, 0]]
>>> graph = csr_matrix(a)
>>> perm = maximum_bipartite_matching(graph, perm_type='row')
>>> print(graph[perm].toarray())
[[1 0 0 1]
 [0 1 2 0]
 [0 1 3 0]
 [2 0 0 3]]

```

### scipy.sparse.csgraph.min\_weight\_full\_bipartite\_matching

`scipy.sparse.csgraph.min_weight_full_bipartite_matching` (*biadjacency\_matrix*, *maximize=False*)

Returns the minimum weight full matching of a bipartite graph.

New in version 1.6.0.

#### Parameters

##### **biadjacency\_matrix**

[sparse matrix] Biadjacency matrix of the bipartite graph: A sparse matrix in CSR, CSC, or COO format whose rows represent one partition of the graph and whose columns represent the other partition. An edge between two vertices is indicated by the corresponding entry in the matrix, and the weight of the edge is given by the value of that entry. This should not be confused with the full adjacency matrix of the graph, as we only need the submatrix defining the bipartite structure.

**maximize** [bool (default: False)] Calculates a maximum weight matching if true.

#### Returns

##### **row\_ind, col\_ind**

[array] An array of row indices and one of corresponding column indices giving the optimal matching. The total weight of the matching can be computed as `graph[row_ind, col_ind].sum()`. The row indices will be sorted; in the case of a square matrix they will be equal to `numpy.arange(graph.shape[0])`.

## Notes

Let  $G = ((U, V), E)$  be a weighted bipartite graph with non-zero weights  $w : E \rightarrow \mathbb{R} \setminus \{0\}$ . This function then produces a matching  $M \subseteq E$  with cardinality

$$|M| = \min(|U|, |V|),$$

which minimizes the sum of the weights of the edges included in the matching,  $\sum_{e \in M} w(e)$ , or raises an error if no such matching exists.

When  $|U| = |V|$ , this is commonly referred to as a perfect matching; here, since we allow  $|U|$  and  $|V|$  to differ, we follow Karp [1] and refer to the matching as *full*.

This function implements the LAPJVsp algorithm [2], short for “Linear assignment problem, Jonker–Volgenant, sparse”.

The problem it solves is equivalent to the rectangular linear assignment problem. [3] As such, this function can be used to solve the same problems as `scipy.optimize.linear_sum_assignment`. That function may perform better when the input is dense, or for certain particular types of inputs, such as those for which the  $(i, j)$ ’th entry is the distance between two points in Euclidean space.

If no full matching exists, this function raises a `ValueError`. For determining the size of the largest matching in the graph, see `maximum_bipartite_matching`.

We require that weights are non-zero only to avoid issues with the handling of explicit zeros when converting between different sparse representations. Zero weights can be handled by adding a constant to all weights, so that the resulting matrix contains no zeros.

## References

[1], [2], [3]

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import min_weight_full_bipartite_matching
```

Let us first consider an example in which all weights are equal:

```
>>> biadjacency_matrix = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
```

Here, all we get is a perfect matching of the graph:

```
>>> print(min_weight_full_bipartite_matching(biadjacency_matrix)[1])
[2 0 1]
```

That is, the first, second, and third rows are matched with the third, first, and second column respectively. Note that in this example, the 0 in the input matrix does *not* correspond to an edge with weight 0, but rather a pair of vertices not paired by an edge.

Note also that in this case, the output matches the result of applying `maximum_bipartite_matching`:

```
>>> from scipy.sparse.csgraph import maximum_bipartite_matching
>>> biadjacency = csr_matrix([[1, 1, 1], [1, 0, 0], [0, 1, 0]])
>>> print(maximum_bipartite_matching(biadjacency, perm_type='column'))
[2 0 1]
```

When multiple edges are available, the ones with lowest weights are preferred:

```
>>> biadjacency = csr_matrix([[3, 3, 6], [4, 3, 5], [10, 1, 8]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(col_ind)
[0 2 1]
```

The total weight in this case is  $3 + 5 + 1 = 9$ :

```
>>> print(biadjacency[row_ind, col_ind].sum())
9
```

When the matrix is not square, i.e. when the two partitions have different cardinalities, the matching is as large as the smaller of the two partitions:

```
>>> biadjacency = csr_matrix([[0, 1, 1], [0, 2, 3]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[0 1] [2 1]
>>> biadjacency = csr_matrix([[0, 1], [3, 1], [1, 4]])
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[0 2] [1 0]
```

When one or both of the partitions are empty, the matching is empty as well:

```
>>> biadjacency = csr_matrix((2, 0))
>>> row_ind, col_ind = min_weight_full_bipartite_matching(biadjacency)
>>> print(row_ind, col_ind)
[] []
```

In general, we will always reach the same sum of weights as if we had used `scipy.optimize.linear_sum_assignment` but note that for that one, missing edges are represented by a matrix entry of `float('inf')`. Let us generate a random sparse matrix with integer entries between 1 and 10:

```
>>> import numpy as np
>>> from scipy.sparse import random
>>> from scipy.optimize import linear_sum_assignment
>>> sparse = random(10, 10, random_state=42, density=.5, format='coo') * 10
→10
>>> sparse.data = np.ceil(sparse.data)
>>> dense = sparse.toarray()
>>> dense = np.full(sparse.shape, np.inf)
>>> dense[sparse.row, sparse.col] = sparse.data
>>> sparse = sparse.tocsr()
>>> row_ind, col_ind = linear_sum_assignment(dense)
>>> print(dense[row_ind, col_ind].sum())
28.0
>>> row_ind, col_ind = min_weight_full_bipartite_matching(sparse)
>>> print(sparse[row_ind, col_ind].sum())
28.0
```

### scipy.sparse.csgraph.structural\_rank

scipy.sparse.csgraph.**structural\_rank** (*graph*)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

New in version 0.19.0.

#### *Parameters*

**graph** [sparse matrix] Input sparse matrix.

#### *Returns*

**rank** [int] The structural rank of the sparse graph.

**scipy.sparse.csgraph.construct\_dist\_matrix**

`scipy.sparse.csgraph.construct_dist_matrix` (*graph*, *predecessors*, *directed=True*, *null\_value=np.inf*)

Construct distance matrix from a predecessor matrix

New in version 0.11.0.

**Parameters**

- graph** [array\_like or sparse] The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.
- predecessors** [array\_like] The N x N matrix of predecessors of each node (see Notes below).
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.
- null\_value** [bool, optional] value to use for distances between unconnected nodes. Default is `np.inf`

**Returns**

- dist\_matrix** [ndarray] The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

**Notes**

The predecessor matrix is of the form returned by `shortest_path`. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry `predecessors[i, j]` gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then `predecessors[i, j] = -9999`

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import construct_dist_matrix
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3
```

```
>>> pred = np.array([[-9999, 0, 0, 2],
... [1, -9999, 0, 1],
... [2, 0, -9999, 2],
... [1, 3, 3, -9999]], dtype=np.int32)
```

```
>>> construct_dist_matrix(graph=graph, predecessors=pred, directed=False)
array([[0., 1., 2., 5.],
 [1., 0., 3., 1.],
 [2., 3., 0., 3.],
 [2., 1., 3., 0.]])
```

**scipy.sparse.csgraph.csgraph\_from\_dense**

`scipy.sparse.csgraph.csgraph_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*)

Construct a CSR-format sparse graph from a dense matrix.

New in version 0.11.0.

**Parameters**

- graph** [array\_like] Input graph. Shape should be (n\_nodes, n\_nodes).
- null\_value** [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.
- infinity\_null** [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.
- nan\_null** [bool] If True (default), then NaN entries are treated as non-edges

**Returns**

- csgraph** [csr\_matrix] Compressed sparse representation of graph,

## Examples

```
>>> from scipy.sparse.csgraph import csgraph_from_dense
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...]
```

```
>>> csgraph_from_dense(graph)
<4x4 sparse matrix of type '<class 'numpy.float64''>'
 with 4 stored elements in Compressed Sparse Row format>
```

### scipy.sparse.csgraph.csgraph\_from\_masked

scipy.sparse.csgraph.**csgraph\_from\_masked**(*graph*)

Construct a CSR-format graph from a masked array.

New in version 0.11.0.

#### Parameters

**graph** [MaskedArray] Input graph. Shape should be (n\_nodes, n\_nodes).

#### Returns

**csgraph** [csr\_matrix] Compressed sparse representation of graph,

## Examples

```
>>> import numpy as np
>>> from scipy.sparse.csgraph import csgraph_from_masked
```

```
>>> graph_masked = np.ma.masked_array(data = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...],
... mask=[[True, False, False, True],
... [True, True, True, False],
... [True, True, True, False],
... [True, True, True, True]],
... fill_value = 0)
```

```
>>> csgraph_from_masked(graph_masked)
<4x4 sparse matrix of type '<class 'numpy.float64''>'
 with 4 stored elements in Compressed Sparse Row format>
```

**scipy.sparse.csgraph.csgraph\_masked\_from\_dense**

`scipy.sparse.csgraph.csgraph_masked_from_dense` (*graph*, *null\_value=0*, *nan\_null=True*, *infinity\_null=True*, *copy=True*)

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

**Parameters**

- graph** [array\_like] Input graph. Shape should be (n\_nodes, n\_nodes).
- null\_value** [float or None (optional)] Value that denotes non-edges in the graph. Default is zero.
- infinity\_null** [bool] If True (default), then infinite entries (both positive and negative) are treated as null edges.
- nan\_null** [bool] If True (default), then NaN entries are treated as non-edges

**Returns**

- csgraph** [MaskedArray] masked array representation of graph

**Examples**

```
>>> from scipy.sparse.csgraph import csgraph_masked_from_dense
```

```
>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...]
```

```
>>> csgraph_masked_from_dense(graph)
masked_array(
 data=[[--, 1, 2, --],
 [--, --, --, 1],
 [--, --, --, 3],
 [--, --, --, --]],
 mask=[[True, False, False, True],
 [True, True, True, False],
 [True, True, True, False],
 [True, True, True, True]],
 fill_value=0)
```

**scipy.sparse.csgraph.csgraph\_to\_dense**

`scipy.sparse.csgraph.csgraph_to_dense` (*csgraph*, *null\_value=0*)

Convert a sparse graph representation to a dense representation

New in version 0.11.0.

**Parameters**

- csgraph** [csr\_matrix, csc\_matrix, or lil\_matrix] Sparse representation of a graph.
- null\_value** [float, optional] The value used to indicate null edges in the dense representation. Default is 0.

**Returns**

**graph** [ndarray] The dense representation of the sparse graph.

## Notes

For normal sparse graph representations, calling `csgraph_to_dense` with `null_value=0` produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in `scipy.sparse` will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we'll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
 [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
 [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default `scipy.sparse` behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let's look at the example of a two-node directed graph, connected by an edge of weight zero:

```
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 0],
 [0, 0]])
>>> csgraph.csgraph_to_dense(M, np.inf)
array([[inf, 0.],
 [inf, inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_dense
```

```
>>> graph = csr_matrix([
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...])
>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64''>'
with 4 stored elements in Compressed Sparse Row format>
```

```
>>> csgraph_to_dense(graph)
array([[0., 1., 2., 0.],
 [0., 0., 0., 1.],
 [0., 0., 0., 3.],
 [0., 0., 0., 0.]])
```

**scipy.sparse.csgraph.csgraph\_to\_masked**

`scipy.sparse.csgraph.csgraph_to_masked` (*csgraph*)

Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

**Parameters**

**csgraph** [csr\_matrix, csc\_matrix, or lil\_matrix] Sparse representation of a graph.

**Returns**

**graph** [MaskedArray] The masked dense representation of the sparse graph.

## Examples

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import csgraph_to_masked
```

```
>>> graph = csr_matrix([
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...])
>>> graph
<4x4 sparse matrix of type '<class 'numpy.int64''>'
with 4 stored elements in Compressed Sparse Row format>
```

```
>>> csgraph_to_masked(graph)
masked_array(
```

(continues on next page)

(continued from previous page)

```

data=[[--, 1.0, 2.0, --],
 [--, --, --, 1.0],
 [--, --, --, 3.0],
 [--, --, --, --]],
mask=[[True, False, False, True],
 [True, True, True, False],
 [True, True, True, False],
 [True, True, True, True]],
fill_value=1e+20)

```

### scipy.sparse.csgraph.reconstruct\_path

`scipy.sparse.csgraph.reconstruct_path` (*csgraph*, *predecessors*, *directed=True*)

Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

#### Parameters

- csgraph** [array\_like or sparse matrix] The  $N \times N$  matrix representing the directed or undirected graph from which the predecessors are drawn.
- predecessors** [array\_like, one dimension] The length- $N$  array of indices of predecessors for the tree. The index of the parent of node  $i$  is given by `predecessors[i]`.
- directed** [bool, optional] If True (default), then operate on a directed graph: only move from point  $i$  to point  $j$  along paths `csgraph[i, j]`. If False, then operate on an undirected graph: the algorithm can progress from point  $i$  to  $j$  along `csgraph[i, j]` or `csgraph[j, i]`.

#### Returns

- ctree** [csr matrix] The  $N \times N$  directed compressed-sparse representation of the tree drawn from `csgraph` which is encoded by the predecessor list.

### Examples

```

>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import reconstruct_path

```

```

>>> graph = [
... [0, 1, 2, 0],
... [0, 0, 0, 1],
... [0, 0, 0, 3],
... [0, 0, 0, 0]
...]
>>> graph = csr_matrix(graph)
>>> print(graph)
(0, 1) 1
(0, 2) 2
(1, 3) 1
(2, 3) 3

```

```

>>> pred = np.array([-9999, 0, 0, 1], dtype=np.int32)

```

```

>>> cstree = reconstruct_path(csgraph=graph, predecessors=pred,
→directed=False)
>>> cstree.todense()
matrix([[0., 1., 2., 0.],
 [0., 0., 0., 1.],
 [0., 0., 0., 0.],
 [0., 0., 0., 0.]])

```

## Graph Representations

This module uses graphs which are stored in a matrix format. A graph with  $N$  nodes can be represented by an  $(N \times N)$  adjacency matrix  $G$ . If there is a connection from node  $i$  to node  $j$ , then  $G[i, j] = w$ , where  $w$  is the weight of the connection. For nodes  $i$  and  $j$  which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by  $G[i, j] = 0$ , infinity, or NaN.
- for dense masked representations (of type `np.ma.MaskedArray`), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```

>>> G_dense = np.array([[0, 2, 1],
... [2, 0, 0],
... [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)

```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```
>>> G2_data = np.array([[np.inf, 2, 0],
... [2, np.inf, np.inf],
... [0, np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> # G2_sparse = csr_matrix(G2_data) would give the wrong result
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([2., 0., 2., 0.]
```

Here we have used a utility routine from the `csgraph` submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

### Directed vs. undirected

Matrices may represent either directed or undirected graphs. This is specified throughout the `csgraph` module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node  $i$  to node  $j$  can be accomplished over the edge  $G[i, j]$ , but not the edge  $G[j, i]$ . Consider the following dense graph:

```
>>> G_dense = np.array([[0, 1, 0],
... [2, 0, 3],
... [0, 4, 0]])
```

When `directed=True` we get the graph:

```
 ---1--> ---3-->
(0) (1) (2)
 <--2--- <--4---
```

In a non-directed graph, traversal from node  $i$  to node  $j$  can be accomplished over either  $G[i, j]$  or  $G[j, i]$ . If both edges are not null, and the two have unequal weights, then the smaller of the two is used.

So for the same graph, when `directed=False` we get the graph:

```
(0) --1-- (1) --2-- (2)
```

Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to True or False. In this case, using `directed=True` generally leads to more efficient computation.

The routines in this module accept as input either `scipy.sparse` representations (`csr`, `csc`, or `lil` format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

### 3.3.26 Spatial algorithms and data structures (`scipy.spatial`)

#### Spatial transformations

These are contained in the `scipy.spatial.transform` submodule.

#### Nearest-neighbor queries

|                                                             |                                            |
|-------------------------------------------------------------|--------------------------------------------|
| <code>KDTree</code> (data[, leafsize, compact_nodes, ...])  | kd-tree for quick nearest-neighbor lookup. |
| <code>cKDTree</code> (data[, leafsize, compact_nodes, ...]) | kd-tree for quick nearest-neighbor lookup  |
| <code>Rectangle</code> (maxes, mins)                        | Hyperrectangle class.                      |

#### `scipy.spatial.KDTree`

**class** `scipy.spatial.KDTree` (*data*, *leafsize=10*, *compact\_nodes=True*, *copy\_data=False*, *balanced\_tree=True*, *boxsize=None*)  
kd-tree for quick nearest-neighbor lookup.

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

##### *Parameters*

- data** [array\_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with `copy_data=True`.
- leafsize** [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 10.
- compact\_nodes** [bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.
- copy\_data** [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.
- balanced\_tree** [bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.
- boxsize** [array\_like or scalar, optional] Apply a m-d toroidal topology to the KDTree.. The topology is generated by  $x_i + n_i L_i$  where  $n_i$  are integers and  $L_i$  is the boxsize along i-th dimension. The input data shall be wrapped into  $[0, L_i)$ . A `ValueError` is raised if any of the data is outside of this bound.

## Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the  $r$  closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the  $r$  approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

### Attributes

|                 |                                                                                                                                                                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>data</b>     | [ndarray, shape (n,m)] The $n$ data points of dimension $m$ to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with <code>copy_data=True</code> . |
| <b>leafsize</b> | [positive int] The number of points at which the algorithm switches over to brute-force.                                                                                                                                                                   |
| <b>m</b>        | [int] The dimension of a single data-point.                                                                                                                                                                                                                |
| <b>n</b>        | [int] The number of data points.                                                                                                                                                                                                                           |
| <b>maxes</b>    | [ndarray, shape (m,)] The maximum value in each dimension of the $n$ data points.                                                                                                                                                                          |
| <b>mins</b>     | [ndarray, shape (m,)] The minimum value in each dimension of the $n$ data points.                                                                                                                                                                          |
| <b>size</b>     | [int] The number of nodes in the tree.                                                                                                                                                                                                                     |

## Methods

|                                                               |                                                                                               |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <code>count_neighbors(other, r[, p, weights, ...])</code>     | Count how many nearby pairs can be formed.                                                    |
| <code>query(x[, k, eps, p, distance_upper_bound, ...])</code> | Query the kd-tree for nearest neighbors.                                                      |
| <code>query_ball_point(x, r[, p, eps, workers, ...])</code>   | Find all points within distance $r$ of point(s) $x$ .                                         |
| <code>query_ball_tree(other, r[, p, eps])</code>              | Find all pairs of points between <i>self</i> and <i>other</i> whose distance is at most $r$ . |
| <code>query_pairs(r[, p, eps, output_type])</code>            | Find all pairs of points in <i>self</i> whose distance is at most $r$ .                       |
| <code>sparse_distance_matrix(other, max_distance)</code>      | Compute a sparse distance matrix.                                                             |

### scipy.spatial.KDTree.count\_neighbors

`KDTree.count_neighbors` (*other*,  $r$ ,  $p=2.0$ , *weights=None*, *cumulative=True*)

Count how many nearby pairs can be formed.

Count the number of pairs ( $x_1$ ,  $x_2$ ) can be formed, with  $x_1$  drawn from *self* and  $x_2$  drawn from *other*, and where `distance(x1, x2, p) <= r`.

Data points on *self* and *other* are optionally weighted by the `weights` argument. (See below)

This is adapted from the “two-point correlation” algorithm described by Gray and Moore [1]. See notes for further discussion.

#### Parameters

**other** [KDTree] The other tree to draw points from, can be the same tree as *self*.

- r** [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative (`cumulative=False`), `r` defines the edges of the bins, and must be non-decreasing.
- p** [float, optional]  $1 \leq p \leq \infty$ . Which Minkowski  $p$ -norm to use. Default 2.0. A finite large  $p$  may cause a `ValueError` if overflow can occur.
- weights** [tuple, array\_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, `weights[0]` is the weights of points in `self`, and `weights[1]` is the weights of points in `other`; either can be None to indicate the points are unweighted. If given as an array\_like, `weights` is the weights of points in `self` and `other`. For this to make sense, `self` and `other` must be the same tree. If `self` and `other` are two different trees, a `ValueError` is raised. Default: None  
New in version 1.6.0.
- cumulative** [bool, optional] Whether the returned counts are cumulative. When `cumulative` is set to `False` the algorithm is optimized to work with a large number of bins ( $>10$ ) specified by `r`. When `cumulative` is set to `True`, the algorithm is optimized to work with a small number of `r`. Default: `True`  
New in version 1.6.0.

#### Returns

- result** [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If `cumulative` is `False`, `result[i]` contains the counts with  $(-\infty \text{ if } i == 0 \text{ else } r[i-1]) < R \leq r[i]$

#### Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of  $D$  measures the clustering signal in  $D$ . [2]

For example, given the position of two sets of objects,

- objects  $D$  (data) contains the clustering signal, and
- objects  $R$  (random) that contains no signal,

$$\xi(r) = \frac{\langle D, D \rangle - 2f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},$$

where the brackets represents counting pairs between two data sets in a finite bin around  $r$  (distance), corresponding to setting `cumulative=False`, and  $f = \text{float}(\text{len}(D)) / \text{float}(\text{len}(R))$  is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

## Examples

You can count neighbors number between two kd-trees within a distance:

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
1
```

This number is same as the total pair number calculated by `query_ball_tree`:

```
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
1
```

## scipy.spatial.KDTree.query

`KDTree.query(x, k=1, eps=0, p=2, distance_upper_bound=inf, workers=1)`

Query the kd-tree for nearest neighbors.

### Parameters

- x** [array\_like, last dimension self.m] An array of points to query.
- k** [int or Sequence[int], optional] Either the number of nearest neighbors to return, or a list of the k-th nearest neighbors to return, starting from 1.
- eps** [nonnegative float, optional] Return approximate nearest neighbors; the kth returned value is guaranteed to be no further than  $(1+eps)$  times the distance to the real kth nearest neighbor.
- p** [float,  $1 \leq p \leq \text{infinity}$ , optional] Which Minkowski p-norm to use. 1 is the sum-of-absolute-values distance (“Manhattan” distance). 2 is the usual Euclidean distance. infinity is the maximum-coordinate-difference distance. A large, finite p may cause a `ValueError` if overflow can occur.
- distance\_upper\_bound** [nonnegative float, optional] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.
- workers** [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.  
New in version 1.6.0.

### Returns

- d** [float or array of floats] The distances to the nearest neighbors. If `x` has shape `tuple+(self.m,)`, then `d` has shape `tuple+(k,)`. When `k == 1`, the last dimen-

sion of the output is squeezed. Missing neighbors are indicated with infinite distances. Hits are sorted by distance (nearest first).

Deprecated since version 1.6.0: If `k=None`, then `d` is an object array of shape `tuple`, containing lists of distances. This behavior is deprecated and will be removed in SciPy 1.8.0, use `query_ball_point` instead.

**i** [integer or array of integers] The index of each neighbor in `self.data`. `i` is the same shape as `d`. Missing neighbors are indicated with `self.n`.

## Examples

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = KDTree(np.c_[x.ravel(), y.ravel()])
```

To query the nearest neighbours and return squeezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[2. 0.14142136] [0 13]
```

To query the nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[2.]
 [0.14142136]] [[0]
 [13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[2.23606798]
 [0.90553851]] [[6]
 [12]]
```

To query the first and second nearest neighbours, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[2. 2.23606798]
 [0.14142136 0.90553851]] [[0 6]
 [13 12]]
```

or, be more specific

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[2. 2.23606798]
 [0.14142136 0.90553851]] [[0 6]
 [13 12]]
```

**scipy.spatial.KDTree.query\_ball\_point**

`KDTree.query_ball_point(x, r, p=2.0, eps=0, workers=1, return_sorted=None, return_length=False)`

Find all points within distance  $r$  of point(s)  $x$ .

**Parameters**

- x** [array\_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
- r** [array\_like, float] The radius of points to return, must broadcast to the length of  $x$ .
- p** [float, optional] Which Minkowski  $p$ -norm to use. Should be in the range  $[1, \text{inf}]$ . A finite large  $p$  may cause a `ValueError` if overflow can occur.
- eps** [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .
- workers** [int, optional] Number of jobs to schedule for parallel processing. If  $-1$  is given all processors are used. Default: 1.  
New in version 1.6.0.
- return\_sorted** [bool, optional] Sorts returned indicies if `True` and does not sort them if `False`. If `None`, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added.  
New in version 1.6.0.
- return\_length: bool, optional**  
Return the number of points inside the radius instead of a list of the indices.  
New in version 1.6.0.

**Returns**

- results** [list or array of lists] If  $x$  is a single point, returns a list of the indices of the neighbors of  $x$ . If  $x$  is an array of points, returns an object array of shape tuple containing lists of neighbors.

**Notes**

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a `KDTree` and using `query_ball_tree`.

**Examples**

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.KDTree(points)
>>> sorted(tree.query_ball_point([2, 0], 1))
[5, 10, 11, 15]
```

Query multiple points and plot the results:

```
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point([2, 0], [3, 3]), 1):
```

(continues on next page)

(continued from previous page)

```

... nearby_points = points[results]
... plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()

```

### scipy.spatial.KDTree.query\_ball\_tree

`KDTree.query_ball_tree` (*other*, *r*, *p*=2.0, *eps*=0)

Find all pairs of points between *self* and *other* whose distance is at most *r*.

#### Parameters

- other** [KDTree instance] The tree containing points to search against.
- r** [float] The maximum distance, has to be positive.
- p** [float, optional] Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ .
- eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

#### Returns

- results** [list of lists] For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

## Examples

You can search all pairs of points between two kd-trees within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((15, 2))
>>> points2 = rng.random((15, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
... for j in indexes[i]:
... plt.plot([points1[i, 0], points2[j, 0]],
... [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()
```

### scipy.spatial.KDTree.query\_pairs

`KDTree.query_pairs` (*r*, *p*=2.0, *eps*=0, *output\_type*='set')

Find all pairs of points in *self* whose distance is at most *r*.

#### Parameters

- r** [positive float] The maximum distance.
- p** [float, optional] Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ .
- eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.
- output\_type** [string, optional] Choose the output container, 'set' or 'ndarray'. Default: 'set' New in version 1.6.0.

#### Returns

- results** [set or ndarray] Set of pairs (*i*, *j*), with  $i < j$ , for which the corresponding positions are close. If *output\_type* is 'ndarray', an ndarray is returned instead of a set.

## Examples

You can search all pairs of points in a kd-tree within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points = rng.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = KDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
... plt.plot([points[i, 0], points[j, 0]],
... [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

### scipy.spatial.KDTree.sparse\_distance\_matrix

`KDTree.sparse_distance_matrix` (*other*, *max\_distance*, *p=2.0*, *output\_type='dok\_matrix'*)

Compute a sparse distance matrix.

Computes a distance matrix between two KDTrees, leaving as zero any distance greater than *max\_distance*.

#### Parameters

**other** [KDTree]  
**max\_distance** [positive float]  
**p** [float, 1<=p<=infinity] Which Minkowski p-norm to use. A finite large p may cause a ValueError if overflow can occur.  
**output\_type** [string, optional] Which container to use for output data. Options: 'dok\_matrix', 'coo\_matrix', 'dict', or 'ndarray'. Default: 'dok\_matrix'.  
 New in version 1.6.0.

#### Returns

**result** [dok\_matrix, coo\_matrix, dict or ndarray] Sparse matrix representing the results in “dictionary of keys” format. If a dict is returned the keys are (i,j) tuples of indices. If output\_type is 'ndarray' a record array with fields 'i', 'j', and 'v' is returned,

## Examples

You can compute a sparse distance matrix between two kd-trees:

```
>>> import numpy as np
>>> from scipy.spatial import KDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = KDTree(points1)
>>> kd_tree2 = KDTree(points2)
```

(continues on next page)

(continued from previous page)

```
>>> sdm = kd_tree1.sparse_distance_matrix(kd_tree2, 0.3)
>>> sdm.toarray()
array([[0. , 0. , 0.12295571, 0. , 0.],
 [0. , 0. , 0. , 0. , 0.],
 [0.28942611, 0. , 0. , 0.2333084 , 0.],
 [0. , 0. , 0. , 0. , 0.],
 [0.24617575, 0.29571802, 0.26836782, 0. , 0.]])
```

You can check distances above the *max\_distance* are zeros:

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.56906522, 0.39923701, 0.12295571, 0.8658745 , 0.79428925],
 [0.37327919, 0.7225693 , 0.87665969, 0.32580855, 0.75679479],
 [0.28942611, 0.30088013, 0.6395831 , 0.2333084 , 0.33630734],
 [0.31994999, 0.72658602, 0.71124834, 0.55396483, 0.90785663],
 [0.24617575, 0.29571802, 0.26836782, 0.57714465, 0.6473269]])
```

### scipy.spatial.cKDTree

**class** `scipy.spatial.cKDTree` (*data*, *leafsize=16*, *compact\_nodes=True*, *copy\_data=False*, *balanced\_tree=True*, *boxsize=None*)  
 kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

---

**Note:** `cKDTree` is functionally identical to `KDTree`. Prior to SciPy v1.6.0, `cKDTree` had better performance and slightly different functionality but now the two names exist only for backward-compatibility reasons. If compatibility with SciPy < 1.6 is not a concern, prefer `KDTree`.

---

#### Parameters

- data** [array\_like, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with `copy_data=True`.
- leafsize** [positive int, optional] The number of points at which the algorithm switches over to brute-force. Default: 16.
- compact\_nodes** [bool, optional] If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.
- copy\_data** [bool, optional] If True the data is always copied to protect the kd-tree against data corruption. Default: False.
- balanced\_tree**

[bool, optional] If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

**boxsize** [array\_like or scalar, optional] Apply a m-d toroidal topology to the KDTree.. The topology is generated by  $x_i + n_i L_i$  where  $n_i$  are integers and  $L_i$  is the boxsize along i-th dimension. The input data shall be wrapped into  $[0, L_i)$ . A ValueError is raised if any of the data is outside of this bound.

## Notes

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the r closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the r approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

### Attributes

**data** [ndarray, shape (n,m)] The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles. The data are also copied if the kd-tree is built with *copy\_data=True*.

**leafsize** [positive int] The number of points at which the algorithm switches over to brute-force.

**m** [int] The dimension of a single data-point.

**n** [int] The number of data points.

**maxes** [ndarray, shape (m,)] The maximum value in each dimension of the n data points.

**mins** [ndarray, shape (m,)] The minimum value in each dimension of the n data points.

**tree** [object, class cKDTreeNode] This attribute exposes a Python view of the root node in the cKDTree object. A full Python view of the kd-tree is created dynamically on the first access. This attribute allows you to create your own query functions in Python.

**size** [int] The number of nodes in the tree.

## Methods

|                                                                |                                                                                           |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <code>count_neighbors(self, other, r[, p, ...])</code>         | Count how many nearby pairs can be formed.                                                |
| <code>query(self, x[, k, eps, p, ...])</code>                  | Query the kd-tree for nearest neighbors                                                   |
| <code>query_ball_point(self, x, r[, p, eps, ...])</code>       | Find all points within distance r of point(s) x.                                          |
| <code>query_ball_tree(self, other, r[, p, eps])</code>         | Find all pairs of points between <i>self</i> and <i>other</i> whose distance is at most r |
| <code>query_pairs(self, r[, p, eps])</code>                    | Find all pairs of points in <i>self</i> whose distance is at most r.                      |
| <code>sparse_distance_matrix(self, other, max_distance)</code> | Compute a sparse distance matrix                                                          |

**scipy.spatial.cKDTree.count\_neighbors**

`cKDTree.count_neighbors` (*self*, *other*, *r*, *p=2.*, *weights=None*, *cumulative=True*)

Count how many nearby pairs can be formed.

Count the number of pairs ( $x_1, x_2$ ) can be formed, with  $x_1$  drawn from *self* and  $x_2$  drawn from *other*, and where  $\text{distance}(x_1, x_2, p) \leq r$ .

Data points on *self* and *other* are optionally weighted by the *weights* argument. (See below)

This is adapted from the “two-point correlation” algorithm described by Gray and Moore [1]. See notes for further discussion.

**Parameters**

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>other</b>      | [cKDTree instance] The other tree to draw points from, can be the same tree as <i>self</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>r</b>          | [float or one-dimensional array of floats] The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative ( <i>cumulative=False</i> ), <i>r</i> defines the edges of the bins, and must be non-decreasing.                                                                                                                                                                                                                                                                                                                           |
| <b>p</b>          | [float, optional] $1 \leq p \leq \text{infinity}$ . Which Minkowski <i>p</i> -norm to use. Default 2.0. A finite large <i>p</i> may cause a <code>ValueError</code> if overflow can occur.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>weights</b>    | [tuple, array_like, or None, optional] If None, the pair-counting is unweighted. If given as a tuple, <i>weights[0]</i> is the weights of points in <i>self</i> , and <i>weights[1]</i> is the weights of points in <i>other</i> ; either can be None to indicate the points are unweighted. If given as an <i>array_like</i> , <i>weights</i> is the weights of points in <i>self</i> and <i>other</i> . For this to make sense, <i>self</i> and <i>other</i> must be the same tree. If <i>self</i> and <i>other</i> are two different trees, a <code>ValueError</code> is raised. Default: None |
| <b>cumulative</b> | [bool, optional] Whether the returned counts are cumulative. When <i>cumulative</i> is set to <code>False</code> the algorithm is optimized to work with a large number of bins (>10) specified by <i>r</i> . When <i>cumulative</i> is set to <code>True</code> , the algorithm is optimized to work with a small number of <i>r</i> . Default: <code>True</code>                                                                                                                                                                                                                                |

**Returns**

|               |                                                                                                                                                                                                                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>result</b> | [scalar or 1-D array] The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If <i>cumulative</i> is <code>False</code> , <i>result[i]</i> contains the counts with $(-\text{inf} \text{ if } i == 0 \text{ else } r[i-1]) < R \leq r[i]$ |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Notes**

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of *D* measures the clustering signal in *D*. [2]

For example, given the position of two sets of objects,

- objects *D* (data) contains the clustering signal, and
- objects *R* (random) that contains no signal,

$$\xi(r) = \frac{\langle D, D \rangle - 2f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},$$

where the brackets represents counting pairs between two data sets in a finite bin around  $r$  (distance), corresponding to setting `cumulative=False`, and  $f = \text{float}(\text{len}(D)) / \text{float}(\text{len}(R))$  is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in [1]. We switch between two different pair-cumulation scheme depending on the setting of `cumulative`. The computing time of the method we use when for `cumulative == False` does not scale with the total number of bins. The algorithm for `cumulative == True` scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. [5].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions ([3], section 2.2), or to properly calculate the average of data per distance bin (e.g. [4], section 2.1 on redshift).

## Examples

You can count neighbors number between two kd-trees within a distance:

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> kd_tree1.count_neighbors(kd_tree2, 0.2)
1
```

This number is same as the total pair number calculated by `query_ball_tree`:

```
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> sum([len(i) for i in indexes])
1
```

## scipy.spatial.cKDTree.query

`cKDTree.query` (*self*, *x*, *k=1*, *eps=0*, *p=2*, *distance\_upper\_bound=np.inf*, *workers=1*)

Query the kd-tree for nearest neighbors

### Parameters

- x** [array\_like, last dimension self.m] An array of points to query.
- k** [list of integer or integer] The list of k-th nearest neighbors to return. If *k* is an integer it is treated as a list of [1, ... *k*] (range(1, *k*+1)). Note that the counting starts from 1.
- eps** [non-negative float] Return approximate nearest neighbors; the *k*-th returned value is guaranteed to be no further than (1+eps) times the distance to the real *k*-th nearest neighbor.
- p** [float, 1<=p<=infinity] Which Minkowski *p*-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance A finite large *p* may cause a `ValueError` if overflow can occur.

**distance\_upper\_bound**

[nonnegative float] Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

**workers**

[int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default: 1.

Changed in version 1.6.0: The “n\_jobs” argument was renamed “workers”. The old name “n\_jobs” is deprecated and will stop working in SciPy 1.8.0.

**Returns**

**d** [array of floats] The distances to the nearest neighbors. If `x` has shape `tuple+(self.m,)`, then `d` has shape `tuple+(k,)`. When `k == 1`, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.

**i** [ndarray of ints] The index of each neighbor in `self.data`. If `x` has shape `tuple+(self.m,)`, then `i` has shape `tuple+(k,)`. When `k == 1`, the last dimension of the output is squeezed. Missing neighbors are indicated with `self.n`.

**Notes**

If the KD-Tree is periodic, the position `x` is wrapped into the box.

When the input `k` is a list, a query for `arange(max(k))` is performed, but only columns that store the requested values of `k` are preserved. This is implemented in a manner that reduces memory usage.

**Examples**

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = cKDTree(np.c_[x.ravel(), y.ravel()])
```

To query the nearest neighbours and return squeezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=1)
>>> print(dd, ii)
[2. 0.14142136] [0 13]
```

To query the nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1])
>>> print(dd, ii)
[[2.]
 [0.14142136]] [[0]
 [13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[2])
>>> print(dd, ii)
[[2.23606798]
 [0.90553851]] [[6]
 [12]]
```

To query the first and second nearest neighbours, use

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[2. 2.23606798]
 [0.14142136 0.90553851]] [[0 6]
 [13 12]]
```

or, be more specific

```
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[2. 2.23606798]
 [0.14142136 0.90553851]] [[0 6]
 [13 12]]
```

### scipy.spatial.cKDTree.query\_ball\_point

`cKDTree.query_ball_point` (*self*, *x*, *r*, *p=2.*, *eps=0*, *workers=1*, *return\_sorted=None*, *return\_length=False*)

Find all points within distance *r* of point(s) *x*.

#### Parameters

- x** [array\_like, shape tuple + (self.m,)] The point or points to search for neighbors of.
- r** [array\_like, float] The radius of points to return, shall broadcast to the length of *x*.
- p** [float, optional] Which Minkowski *p*-norm to use. Should be in the range [1, inf]. A finite large *p* may cause a `ValueError` if overflow can occur.
- eps** [nonnegative float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ .
- workers** [int, optional] Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.  
Changed in version 1.6.0: The “`n_jobs`” argument was renamed “`workers`”. The old name “`n_jobs`” is deprecated and will stop working in SciPy 1.8.0.
- return\_sorted** [bool, optional] Sorts returned indicies if True and does not sort them if False. If None, does not sort single point queries, but does sort multi-point queries which was the behavior before this option was added.  
New in version 1.2.0.
- return\_length: bool, optional**  
Return the number of points inside the radius instead of a list of the indices. .. version-added:: 1.3.0

#### Returns

- results** [list or array of lists] If *x* is a single point, returns a list of the indices of the neighbors of *x*. If *x* is an array of points, returns an object array of shape tuple containing lists of neighbors.

## Notes

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a `cKDTree` and using `query_ball_tree`.

## Examples

```
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[4, 8, 9, 12]
```

Query multiple points and plot the results:

```
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.')
>>> for results in tree.query_ball_point([2, 0], [3, 3], 1):
... nearby_points = points[results]
... plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```

**scipy.spatial.cKDTree.query\_ball\_tree**

`cKDTree.query_ball_tree` (*self*, *other*, *r*, *p*=2., *eps*=0)

Find all pairs of points between *self* and *other* whose distance is at most *r*

**Parameters**

- other** [cKDTree instance] The tree containing points to search against.
- r** [float] The maximum distance, has to be positive.
- p** [float, optional] Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ . A finite large *p* may cause a `ValueError` if overflow can occur.
- eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**Returns**

- results** [list of lists] For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

**Examples**

You can search all pairs of points between two kd-trees within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((15, 2))
>>> points2 = rng.random((15, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points1[:, 0], points1[:, 1], "xk", markersize=14)
>>> plt.plot(points2[:, 0], points2[:, 1], "og", markersize=14)
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> indexes = kd_tree1.query_ball_tree(kd_tree2, r=0.2)
>>> for i in range(len(indexes)):
... for j in indexes[i]:
... plt.plot([points1[i, 0], points2[j, 0]],
... [points1[i, 1], points2[j, 1]], "-r")
>>> plt.show()
```

**scipy.spatial.cKDTree.query\_pairs**

`cKDTree.query_pairs` (*self*, *r*, *p*=2., *eps*=0)

Find all pairs of points in *self* whose distance is at most *r*.

**Parameters**

- r** [positive float] The maximum distance.
- p** [float, optional] Which Minkowski norm to use. *p* has to meet the condition  $1 \leq p \leq \text{infinity}$ . A finite large *p* may cause a `ValueError` if overflow can occur.
- eps** [float, optional] Approximate search. Branches of the tree are not explored if their nearest points are further than  $r / (1 + \text{eps})$ , and branches are added in bulk if their furthest points are nearer than  $r * (1 + \text{eps})$ . *eps* has to be non-negative.

**output\_type**

[string, optional] Choose the output container, 'set' or 'ndarray'. Default: 'set'

**Returns**

**results** [set or ndarray] Set of pairs  $(i, j)$ , with  $i < j$ , for which the corresponding positions are close. If `output_type` is 'ndarray', an ndarray is returned instead of a set.

## Examples

You can search all pairs of points in a kd-tree within a distance:

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points = rng.random((20, 2))
>>> plt.figure(figsize=(6, 6))
>>> plt.plot(points[:, 0], points[:, 1], "xk", markersize=14)
>>> kd_tree = cKDTree(points)
>>> pairs = kd_tree.query_pairs(r=0.2)
>>> for (i, j) in pairs:
... plt.plot([points[i, 0], points[j, 0]],
... [points[i, 1], points[j, 1]], "-r")
>>> plt.show()
```

## scipy.spatial.cKDTree.sparse\_distance\_matrix

`cKDTree.sparse_distance_matrix` (*self, other, max\_distance, p=2.*)

Compute a sparse distance matrix

Computes a distance matrix between two `cKDTree`s, leaving as zero any distance greater than `max_distance`.

**Parameters**

**other** [cKDTree]

**max\_distance**

[positive float]

**p** [float,  $1 \leq p \leq \text{infinity}$ ] Which Minkowski  $p$ -norm to use. A finite large  $p$  may cause a `ValueError` if overflow can occur.

**output\_type**

[string, optional] Which container to use for output data. Options: 'dok\_matrix', 'coo\_matrix', 'dict', or 'ndarray'. Default: 'dok\_matrix'.

**Returns**

**result** [dok\_matrix, coo\_matrix, dict or ndarray] Sparse matrix representing the results in “dictionary of keys” format. If a dict is returned the keys are  $(i, j)$  tuples of indices. If `output_type` is 'ndarray' a record array with fields 'i', 'j', and 'v' is returned,

## Examples

You can compute a sparse distance matrix between two kd-trees:

```
>>> import numpy as np
>>> from scipy.spatial import cKDTree
>>> rng = np.random.default_rng()
>>> points1 = rng.random((5, 2))
>>> points2 = rng.random((5, 2))
>>> kd_tree1 = cKDTree(points1)
>>> kd_tree2 = cKDTree(points2)
>>> sdm = kd_tree1.sparse_distance_matrix(kd_tree2, 0.3)
>>> sdm.toarray()
array([[0. , 0. , 0.12295571, 0. , 0.],
 [0. , 0. , 0. , 0. , 0.],
 [0.28942611, 0. , 0. , 0.2333084 , 0.],
 [0. , 0. , 0. , 0. , 0.],
 [0.24617575, 0.29571802, 0.26836782, 0. , 0.]])
```

You can check distances above the *max\_distance* are zeros:

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix(points1, points2)
array([[0.56906522, 0.39923701, 0.12295571, 0.8658745 , 0.79428925],
 [0.37327919, 0.7225693 , 0.87665969, 0.32580855, 0.75679479],
 [0.28942611, 0.30088013, 0.6395831 , 0.2333084 , 0.33630734],
 [0.31994999, 0.72658602, 0.71124834, 0.55396483, 0.90785663],
 [0.24617575, 0.29571802, 0.26836782, 0.57714465, 0.6473269]])
```

## scipy.spatial.Rectangle

**class** `scipy.spatial.Rectangle` (*maxes, mins*)

Hyperrectangle class.

Represents a Cartesian product of intervals.

### Methods

|                                                 |                                                                             |
|-------------------------------------------------|-----------------------------------------------------------------------------|
| <code>max_distance_point(x[, p])</code>         | Return the maximum distance between input and points in the hyperrectangle. |
| <code>max_distance_rectangle(other[, p])</code> | Compute the maximum distance between points in the two hyperrectangles.     |
| <code>min_distance_point(x[, p])</code>         | Return the minimum distance between input and points in the hyperrectangle. |
| <code>min_distance_rectangle(other[, p])</code> | Compute the minimum distance between points in the two hyperrectangles.     |
| <code>split(d, split)</code>                    | Produce two hyperrectangles by splitting.                                   |
| <code>volume()</code>                           | Total volume.                                                               |

**scipy.spatial.Rectangle.max\_distance\_point**

`Rectangle.max_distance_point` (*x*, *p*=2.0)

Return the maximum distance between input and points in the hyperrectangle.

*Parameters*

**x** [array\_like] Input array.  
**p** [float, optional] Input.

**scipy.spatial.Rectangle.max\_distance\_rectangle**

`Rectangle.max_distance_rectangle` (*other*, *p*=2.0)

Compute the maximum distance between points in the two hyperrectangles.

*Parameters*

**other** [hyperrectangle] Input.  
**p** [float, optional] Input.

**scipy.spatial.Rectangle.min\_distance\_point**

`Rectangle.min_distance_point` (*x*, *p*=2.0)

Return the minimum distance between input and points in the hyperrectangle.

*Parameters*

**x** [array\_like] Input.  
**p** [float, optional] Input.

**scipy.spatial.Rectangle.min\_distance\_rectangle**

`Rectangle.min_distance_rectangle` (*other*, *p*=2.0)

Compute the minimum distance between points in the two hyperrectangles.

*Parameters*

**other** [hyperrectangle] Input.  
**p** [float] Input.

**scipy.spatial.Rectangle.split**

`Rectangle.split` (*d*, *split*)

Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

*Parameters*

**d** [int] Axis to split hyperrectangle along.  
**split** [float] Position along axis *d* to split at.

### scipy.spatial.Rectangle.volume

`Rectangle.volume()`  
 Total volume.

Distance metrics are contained in the `scipy.spatial.distance` submodule.

### Delaunay triangulation, convex hulls, and Voronoi diagrams

|                                                                |                                              |
|----------------------------------------------------------------|----------------------------------------------|
| <code>Delaunay(points[, furthest_site, ...])</code>            | Delaunay tessellation in N dimensions.       |
| <code>ConvexHull(points[, incremental, qhull_options])</code>  | Convex hulls in N dimensions.                |
| <code>Voronoi(points[, furthest_site, ...])</code>             | Voronoi diagrams in N dimensions.            |
| <code>SphericalVoronoi(points[, radius, center, ...])</code>   | Voronoi diagrams on the surface of a sphere. |
| <code>HalfspaceIntersection(halfspaces, interior_point)</code> | Halfspace intersections in N dimensions.     |

### scipy.spatial.Delaunay

**class** `scipy.spatial.Delaunay` (*points, furthest\_site=False, incremental=False, qhull\_options=None*)  
 Delaunay tessellation in N dimensions.

New in version 0.9.

#### Parameters

- points** [ndarray of floats, shape (npoints, ndim)] Coordinates of points to triangulate
- furthest\_site** [bool, optional] Whether to compute a furthest-site Delaunay triangulation. Default: False  
 New in version 0.12.0.
- incremental** [bool, optional] Allow adding new points incrementally. This takes up some additional resources.
- qhull\_options** [str, optional] Additional options to pass to Qhull. See Qhull manual for details. Option “Qt” is always enabled. Default: “Qbb Qc Qz Qx Q12” for ndim > 4 and “Qbb Qc Qz Q12” otherwise. Incremental mode omits “Qz”.  
 New in version 0.12.0.

#### Raises

- QhullError**  
 Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- ValueError**  
 Raised if an incompatible array is given as input.

## Notes

The tessellation is computed using the Qhull library [Qhull library](#).

**Note:** Unless you pass in the Qhull option “QJ”, Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the *coplanar* attribute.

## Examples

Triangulation of a set of points:

```
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices)
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```

Point indices and coordinates for the two triangles forming the triangulation:

```
>>> tri.simplices
array([[2, 3, 0],
 [3, 1, 0]], dtype=int32) # may vary
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```
>>> points[tri.simplices]
array([[1. , 0.],
 [1. , 1.]], dtype=float64) # may vary
```

(continues on next page)

(continued from previous page)

```
[1. , 1.],
 [0. , 0.]],
 [[1. , 1.],
 [0. , 1.1],
 [0. , 0.]]])
```

Triangle 0 is the only neighbor of triangle 1, and it's opposite to vertex 1 of triangle 1:

```
>>> tri.neighbors[1]
array([-1, 0, -1], dtype=int32)
>>> points[tri.simplices[1,1]]
array([0. , 1.1])
```

We can find out which triangle points are in:

```
>>> p = np.array([(0.1, 0.2), (1.5, 0.5), (0.5, 1.05)])
>>> tri.find_simplex(p)
array([1, -1, 1], dtype=int32)
```

The returned integers in the array are the indices of the simplex the corresponding point is in. If -1 is returned, the point is in no simplex. Be aware that the shortcut in the following example only works correctly for valid points as invalid points result in -1 which is itself a valid index for the last simplex in the list.

```
>>> p_valids = np.array([(0.1, 0.2), (0.5, 1.05)])
>>> tri.simplices[tri.find_simplex(p_valids)]
array([[3, 1, 0],
 [3, 1, 0]], dtype=int32) # may vary
```

We can also compute barycentric coordinates in triangle 1 for these points:

```
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[0.1 , 0.09090909, 0.80909091],
 [1.5 , -0.90909091, 0.40909091],
 [0.5 , 0.5 , 0.]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

#### Attributes

- points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- simplices** [ndarray of ints, shape (nsimplex, ndim+1)] Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.
- neighbors** [ndarray of ints, shape (nsimplex, ndim+1)] Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.
- equations** [ndarray of double, shape (nsimplex, ndim+2)] [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see [Qhull documentation](#) for more).
- paraboloid\_scale, paraboloid\_shift** [float] Scale and shift for the extra paraboloid dimension (see [Qhull documentation](#) for more).
- transform** [ndarray of double, shape (nsimplex, ndim+1, ndim)] Affine transform from  $x$  to the barycentric coordinates  $c$ .

**vertex\_to\_simplex**  
[ndarray of int, shape (npoints,)] Lookup array, from a vertex, to some simplex which it is a part of.

**convex\_hull**  
[ndarray of int, shape (nfaces, ndim)] Vertices of facets forming the convex hull of the point set.

**coplanar** [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were *not* included in the triangulation due to numerical precision issues.  
If option “Qc” is not specified, this list is not computed.  
New in version 0.12.0.

**vertices** Same as *simplices*, but deprecated.

**vertex\_neighbor\_vertices**  
[tuple of two ndarrays of int; (indptr, indices)] Neighboring vertices of vertices.

**furthest\_site**  
True if this was a furthest site triangulation and False if not.  
New in version 1.4.0.

## Methods

|                                                        |                                                                         |
|--------------------------------------------------------|-------------------------------------------------------------------------|
| <code>add_points(points[, restart])</code>             | Process a set of additional new points.                                 |
| <code>close()</code>                                   | Finish incremental processing.                                          |
| <code>find_simplex(self, xi[, bruteforce, tol])</code> | Find the simplices containing the given points.                         |
| <code>lift_points(self, x)</code>                      | Lift points to the Qhull paraboloid.                                    |
| <code>plane_distance(self, xi)</code>                  | Compute hyperplane distances to the point <i>xi</i> from all simplices. |

## scipy.spatial.Delaunay.add\_points

`Delaunay.add_points(points, restart=False)`

Process a set of additional new points.

### Parameters

**points** [ndarray] New points to add. The dimensionality should match that of the initial points.  
**restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

### Raises

#### QhullError

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

`close`

## Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

### `scipy.spatial.Delaunay.close`

`Delaunay.close()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

### `scipy.spatial.Delaunay.find_simplex`

`Delaunay.find_simplex(self, xi, bruteforce=False, tol=None)`

Find the simplices containing the given points.

#### Parameters

|                   |                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------|
| <b>tri</b>        | [DelaunayInfo] Delaunay triangulation                                                             |
| <b>xi</b>         | [ndarray of double, shape (... , ndim)] Points to locate                                          |
| <b>bruteforce</b> | [bool, optional] Whether to only perform a brute-force search                                     |
| <b>tol</b>        | [float, optional] Tolerance allowed in the inside-triangle check. Default is $100 * \text{eps}$ . |

#### Returns

|          |                                                                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>i</b> | [ndarray of int, same shape as <code>xi</code> ] Indices of simplices containing each point. Points outside the triangulation get the value -1. |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|

## Notes

This uses an algorithm adapted from Qhull's `qh_findbestfacet`, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in  $N+1$  dimensions, the algorithm falls back to directed search in  $N$  dimensions.

### `scipy.spatial.Delaunay.lift_points`

`Delaunay.lift_points(self, x)`

Lift points to the Qhull paraboloid.

### `scipy.spatial.Delaunay.plane_distance`

`Delaunay.plane_distance(self, xi)`

Compute hyperplane distances to the point `xi` from all simplices.

**scipy.spatial.ConvexHull**

**class** `scipy.spatial.ConvexHull` (*points*, *incremental=False*, *qhull\_options=None*)  
Convex hulls in N dimensions.

New in version 0.12.0.

**Parameters**

**points** [ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a convex hull from

**incremental** [bool, optional] Allow adding new points incrementally. This takes up some additional resources.

**qhull\_options** [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qx” for `ndim > 4` and “” otherwise) Option “Qt” is always enabled.

**Raises**

**QhullError**  
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**ValueError**  
Raised if an incompatible array is given as input.

**Notes**

The convex hull is computed using the [Qhull library](#).

**References**

[Qhull]

**Examples**

Convex hull of a random set of points:

```
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2)) # 30 random points in 2-D
>>> hull = ConvexHull(points)
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> for simplex in hull.simplices:
... plt.plot(points[simplex, 0], points[simplex, 1], 'k-')
```

We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:

```
>>> plt.plot(points[hull.vertices,0], points[hull.vertices,1], 'r--', lw=2)
>>> plt.plot(points[hull.vertices[0],0], points[hull.vertices[0],1], 'ro')
>>> plt.show()
```

Facets visible from a point:

Create a square and add a point above the square.

```
>>> generators = np.array([[0.2, 0.2],
... [0.2, 0.4],
... [0.4, 0.4],
... [0.4, 0.2],
... [0.3, 0.6]])
```

Call ConvexHull with the QG option. QG4 means compute the portions of the hull not including point 4, indicating the facets that are visible from point 4.

```
>>> hull = ConvexHull(points=generators,
... qhull_options='QG4')
```

The “good” array indicates which facets are visible from point 4.

```
>>> print(hull.simplices)
[[1 0]
 [1 2]
 [3 0]
 [3 2]]
>>> print(hull.good)
[False True False False]
```

Now plot it, highlighting the visible facets.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1,1,1)
```

(continues on next page)

(continued from previous page)

```

>>> for visible_facet in hull.simplices[hull.good]:
... ax.plot(hull.points[visible_facet, 0],
... hull.points[visible_facet, 1],
... color='violet',
... lw=6)
>>> convex_hull_plot_2d(hull, ax=ax)
<Figure size 640x480 with 1 Axes> # may vary
>>> plt.show()

```

### Attributes

- points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- vertices** [ndarray of ints, shape (nvertices,)] Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.
- simplices** [ndarray of ints, shape (nfacet, ndim)] Indices of points forming the simplicial facets of the convex hull.
- neighbors** [ndarray of ints, shape (nfacet, ndim)] Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.
- equations** [ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the facet (see [Qhull documentation](#) for more).
- coplanar** [ndarray of int, shape (ncoplanar, 3)] Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were *not* included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed.
- good** [ndarray of bool or None] A one-dimensional Boolean array indicating which facets are good. Used with options that compute good facets, e.g. QGn and QG-n. Good facets are defined as those that are visible (n) or invisible (-n) from point n, where n is the nth point in ‘points’. The ‘good’ attribute may be used as an index into ‘simplices’ to return the good (visible) facets: simplices[good]. A facet is visible from the outside of the hull only, and neither coplanarity nor degeneracy count as cases of visibility. If a “QGn” or “QG-n” option is not specified, None is returned. New in version 1.3.0.

- area** [float] Surface area of the convex hull when input dimension > 2. When input `points` are 2-dimensional, this is the perimeter of the convex hull.  
New in version 0.17.0.
- volume** [float] Volume of the convex hull when input dimension > 2. When input `points` are 2-dimensional, this is the area of the convex hull.  
New in version 0.17.0.

## Methods

|                                            |                                         |
|--------------------------------------------|-----------------------------------------|
| <code>add_points(points[, restart])</code> | Process a set of additional new points. |
| <code>close()</code>                       | Finish incremental processing.          |

### `scipy.spatial.ConvexHull.add_points`

`ConvexHull.add_points(points, restart=False)`

Process a set of additional new points.

#### Parameters

- points** [ndarray] New points to add. The dimensionality should match that of the initial points.
- restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

#### Raises

##### **QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

#### See also:

`close`

## Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

### `scipy.spatial.ConvexHull.close`

`ConvexHull.close()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**scipy.spatial.Voronoi**

**class** `scipy.spatial.Voronoi` (*points*, *furthest\_site=False*, *incremental=False*, *qhull\_options=None*)  
 Voronoi diagrams in N dimensions.

New in version 0.12.0.

**Parameters**

- points** [ndarray of floats, shape (npoints, ndim)] Coordinates of points to construct a Voronoi diagram from
- furthest\_site** [bool, optional] Whether to compute a furthest-site Voronoi diagram. Default: False
- incremental** [bool, optional] Allow adding new points incrementally. This takes up some additional resources.
- qhull\_options** [str, optional] Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qbb Qc Qz Qx” for  $\text{ndim} > 4$  and “Qbb Qc QZ” otherwise. Incremental mode omits “QZ”.)

**Raises**

- QhullError**  
 Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- ValueError**  
 Raised if an incompatible array is given as input.

**Notes**

The Voronoi diagram is computed using the [Qhull library](#).

**Examples**

Voronoi diagram for a set of point:

```
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2],
... [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

Plot it:

```
>>> import matplotlib.pyplot as plt
>>> fig = voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:

```
>>> vor.vertices
array([[0.5, 0.5],
 [0.5, 1.5],
 [1.5, 0.5],
 [1.5, 1.5]])
```

There is a single finite Voronoi region, and four finite Voronoi ridges:

```
>>> vor.regions
[[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [0, 1, 3,
→ 2], [2, -1, 0], [3, -1, 1]]
>>> vor.ridge_vertices
[[-1, 0], [-1, 0], [-1, 1], [-1, 1], [0, 1], [-1, 3], [-1, 2], [2, 3], [-
→ 1, 3], [-1, 2], [1, 3], [0, 2]]
```

The ridges are perpendicular between lines drawn between the following input points:

```
>>> vor.ridge_points
array([[0, 3],
 [0, 1],
 [2, 5],
 [2, 1],
 [1, 4],
 [7, 8],
 [7, 6],
 [7, 4],
 [8, 5],
 [6, 3],
 [4, 5],
 [4, 3]], dtype=int32)
```

### Attributes

- points** [ndarray of double, shape (npoints, ndim)] Coordinates of input points.
- vertices** [ndarray of double, shape (nvertices, ndim)] Coordinates of the Voronoi vertices.
- ridge\_points** [ndarray of ints, shape (nridges, 2)] Indices of the points between which each Voronoi ridge lies.
- ridge\_vertices** [list of list of ints, shape (nridges, \*)] Indices of the Voronoi vertices forming each Voronoi ridge.

- regions** [list of list of ints, shape (nregions, \*)] Indices of the Voronoi vertices forming each Voronoi region. -1 indicates vertex outside the Voronoi diagram.
- point\_region** [list of ints, shape (npoints)] Index of the Voronoi region for each input point. If qhull option “Qc” was not specified, the list will contain -1 for points that are not associated with a Voronoi region.
- furthest\_site** True if this was a furthest site triangulation and False if not. New in version 1.4.0.

## Methods

|                                            |                                         |
|--------------------------------------------|-----------------------------------------|
| <code>add_points(points[, restart])</code> | Process a set of additional new points. |
| <code>close()</code>                       | Finish incremental processing.          |

### `scipy.spatial.Voronoi.add_points`

`Voronoi.add_points(points, restart=False)`

Process a set of additional new points.

#### *Parameters*

- points** [ndarray] New points to add. The dimensionality should match that of the initial points.
- restart** [bool, optional] Whether to restart processing from scratch, rather than adding points incrementally.

#### *Raises*

##### **QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

`close`

## Notes

You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

### `scipy.spatial.Voronoi.close`

`Voronoi.close()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**scipy.spatial.SphericalVoronoi**

**class** `scipy.spatial.SphericalVoronoi` (*points*, *radius=1*, *center=None*, *threshold=1e-06*)  
 Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

**Parameters**

**points** [ndarray of floats, shape (npoints, ndim)] Coordinates of points from which to construct a spherical Voronoi diagram.  
**radius** [float, optional] Radius of the sphere (Default: 1)  
**center** [ndarray of floats, shape (ndim,)] Center of sphere (Default: origin)  
**threshold** [float] Threshold for detecting duplicate points and mismatches between points and sphere parameters. (Default: 1e-06)

**Raises****ValueError**

If there are duplicates in *points*. If the provided *radius* is not consistent with *points*.

See also:

**Voronoi**

Conventional Voronoi diagrams in N dimensions.

**Notes**

The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [Caroli]. The Convex Hull neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement).

**References**

[Caroli], [VanOosterom]

**Examples**

Do some imports and take some points on a cube:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import SphericalVoronoi, geometric_slerp
>>> from mpl_toolkits.mplot3d import proj3d
>>> # set input data
>>> points = np.array([[0, 0, 1], [0, 0, -1], [1, 0, 0],
... [0, 1, 0], [0, -1, 0], [-1, 0, 0],])
```

Calculate the spherical Voronoi diagram:

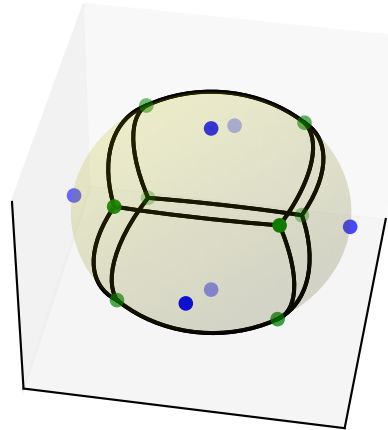

```
>>> radius = 1
>>> center = np.array([0, 0, 0])
>>> sv = SphericalVoronoi(points, radius, center)
```

Generate plot:

```
>>> # sort vertices (optional, helpful for plotting)
>>> sv.sort_vertices_of_regions()
>>> t_vals = np.linspace(0, 1, 2000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> # plot the unit sphere for reference (optional)
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
>>> # plot generator points
>>> ax.scatter(points[:, 0], points[:, 1], points[:, 2], c='b')
>>> # plot Voronoi vertices
>>> ax.scatter(sv.vertices[:, 0], sv.vertices[:, 1], sv.vertices[:, 2],
... c='g')
>>> # indicate Voronoi regions (as Euclidean polygons)
>>> for region in sv.regions:
... n = len(region)
... for i in range(n):
... start = sv.vertices[region][i]
... end = sv.vertices[region][(i + 1) % n]
... result = geometric_slerp(start, end, t_vals)
... ax.plot(result[..., 0],
... result[..., 1],
... result[..., 2],
... c='k')
>>> ax.azim = 10
>>> ax.elev = 40
>>> _ = ax.set_xticks([])
>>> _ = ax.set_yticks([])
>>> _ = ax.set_zticks([])
>>> fig.set_size_inches(4, 4)
>>> plt.show()
```

| <b>regions</b>  | [list of list of integers of shape (npoints, _)] the n-th entry is a list consisting of the indices of the vertices belonging to the n-th point in points |

## Methods

---

`calculate_areas()`

Calculates the areas of the Voronoi regions.

---

### `scipy.spatial.SphericalVoronoi.calculate_areas`

`SphericalVoronoi.calculate_areas()`

Calculates the areas of the Voronoi regions.

For 2D point sets, the regions are circular arcs. The sum of the areas is  $2 * \pi * radius$ .

For 3D point sets, the regions are spherical polygons. The sum of the areas is  $4 * \pi * radius^2$ .

New in version 1.5.0.

#### *Returns*

**areas** [double array of shape (npoints,)] The areas of the Voronoi regions.

### `scipy.spatial.HalfspaceIntersection`

**class** `scipy.spatial.HalfspaceIntersection` (*halfspaces*, *interior\_point*, *incremental=False*, *qhull\_options=None*)

Halfspace intersections in N dimensions.

New in version 0.19.0.

#### *Parameters*

**halfspaces** [ndarray of floats, shape (nineq, ndim+1)] Stacked Inequalities of the form  $Ax + b \leq 0$  in format [A; b]

**interior\_point**

[ndarray of floats, shape (ndim,)] Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming. **Chapter 3. SciPy API**

1918

**incremental**

[bool, optional] Allow adding new halfspaces incrementally. This takes up some additional resources.

**qhull\_options**

## Notes

The intersections are computed using the [Qhull library](#). This reproduces the “qhalf” functionality of Qhull.

## References

[Qhull], [1]

## Examples

Halfspace intersection of planes forming some polygon

```
>>> from scipy.spatial import HalfspaceIntersection
>>> halfspaces = np.array([[-1, 0., 0.],
... [0., -1., 0.],
... [2., 1., -4.],
... [-0.5, 1., -2.]])
>>> feasible_point = np.array([0.5, 0.5])
>>> hs = HalfspaceIntersection(halfspaces, feasible_point)
```

Plot halfspaces as filled regions and intersection points:

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(1, 1, 1, aspect='equal')
>>> xlim, ylim = (-1, 3), (-1, 3)
>>> ax.set_xlim(xlim)
>>> ax.set_ylim(ylim)
>>> x = np.linspace(-1, 3, 100)
>>> symbols = ['-', '+', 'x', '*']
>>> signs = [0, 0, -1, -1]
>>> fmt = {"color": None, "edgecolor": "b", "alpha": 0.5}
>>> for h, sym, sign in zip(halfspaces, symbols, signs):
... hlist = h.tolist()
... fmt["hatch"] = sym
... if h[1]== 0:
... ax.axvline(-h[2]/h[0], label='{}x+{}y+{}=0'.format(*hlist))
... xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
... ax.fill_between(xi, ylim[0], ylim[1], **fmt)
... else:
... ax.plot(x, (-h[2]-h[0]*x)/h[1], label='{}x+{}y+{}=0'.
... ↪format(*hlist))
... ax.fill_between(x, (-h[2]-h[0]*x)/h[1], ylim[sign], **fmt)
>>> x, y = zip(*hs.intersections)
>>> ax.plot(x, y, 'o', markersize=8)
```

By default, qhull does not provide with a way to compute an interior point. This can easily be computed using linear programming. Considering halfspaces of the form  $Ax + b \leq 0$ , solving the linear program:

$$\begin{aligned} & \max y \\ & \text{s.t. } Ax + y||A_i|| \leq -b \end{aligned}$$

With  $A_i$  being the rows of A, i.e. the normals to each plane.

Will yield a point  $x$  that is furthest inside the convex polyhedron. To be precise, it is the center of the largest hypersphere of radius  $y$  inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron (see [1] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

```
>>> from scipy.optimize import linprog
>>> from matplotlib.patches import Circle
>>> norm_vector = np.reshape(np.linalg.norm(halfspaces[:, :-1], axis=1),
... (halfspaces.shape[0], 1))
>>> c = np.zeros((halfspaces.shape[1],))
>>> c[-1] = -1
>>> A = np.hstack((halfspaces[:, :-1], norm_vector))
>>> b = - halfspaces[:, -1:]
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=(None, None))
>>> x = res.x[:-1]
>>> y = res.x[-1]
>>> circle = Circle(x, radius=y, alpha=0.3)
>>> ax.add_patch(circle)
>>> plt.legend(bbox_to_anchor=(1.6, 1.0))
>>> plt.show()
```

### Attributes

**halfspaces** [ndarray of double, shape (nineq, ndim+1)] Input halfspaces.

**interior\_point** :ndarray of floats, shape (ndim,)

Input interior point.

**intersections**

[ndarray of double, shape (ninter, ndim)] Intersections of all halfspaces.

**dual\_points**

[ndarray of double, shape (nineq, ndim)] Dual points of the input halfspaces.

**dual\_facets**

[list of lists of ints] Indices of points forming the (non necessarily simplicial) facets of the dual convex hull.

**dual\_vertices**

[ndarray of ints, shape (nvertices,)] Indices of halfspaces forming the vertices of the dual convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.

**dual\_equations**

[ndarray of double, shape (nfacet, ndim+1)] [normal, offset] forming the hyperplane equation of the dual facet (see [Qhull documentation](#) for more).

**dual\_area** [float] Area of the dual convex hull

**dual\_volume**

[float] Volume of the dual convex hull

**Methods**

|                                                    |                                             |
|----------------------------------------------------|---------------------------------------------|
| <code>add_halfspaces(halfspaces[, restart])</code> | Process a set of additional new halfspaces. |
| <code>close()</code>                               | Finish incremental processing.              |

**scipy.spatial.HalfspaceIntersection.add\_halfspaces**

`HalfspaceIntersection.add_halfspaces(halfspaces, restart=False)`

Process a set of additional new halfspaces.

**Parameters**

**halfspaces** [ndarray] New halfspaces to add. The dimensionality should match that of the initial halfspaces.

**restart** [bool, optional] Whether to restart processing from scratch, rather than adding halfspaces incrementally.

**Raises****QhullError**

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

[close](#)

**Notes**

You need to specify `incremental=True` when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after `close` has been called.

**scipy.spatial.HalfspaceIntersection.close**

`HalfspaceIntersection.close()`

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

## Plotting helpers

|                                              |                                              |
|----------------------------------------------|----------------------------------------------|
| <code>delaunay_plot_2d(tri[, ax])</code>     | Plot the given Delaunay triangulation in 2-D |
| <code>convex_hull_plot_2d(hull[, ax])</code> | Plot the given convex hull diagram in 2-D    |
| <code>voronoi_plot_2d(vor[, ax])</code>      | Plot the given Voronoi diagram in 2-D        |

### `scipy.spatial.delaunay_plot_2d`

`scipy.spatial.delaunay_plot_2d` (*tri*, *ax=None*)

Plot the given Delaunay triangulation in 2-D

#### Parameters

**tri** [scipy.spatial.Delaunay instance] Triangulation to plot  
**ax** [matplotlib.axes.Axes instance, optional] Axes to plot on

#### Returns

**fig** [matplotlib.figure.Figure instance] Figure for the plot

See also:

[Delaunay](#)

`matplotlib.pyplot.triplot`

#### Notes

Requires Matplotlib.

#### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d
```

The Delaunay triangulation of a set of random points:

```
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))
>>> tri = Delaunay(points)
```

Plot it:

```
>>> _ = delaunay_plot_2d(tri)
>>> plt.show()
```

### scipy.spatial.convex\_hull\_plot\_2d

`scipy.spatial.convex_hull_plot_2d(hull, ax=None)`

Plot the given convex hull diagram in 2-D

#### Parameters

**hull** [scipy.spatial.ConvexHull instance] Convex hull to plot  
**ax** [matplotlib.axes.Axes instance, optional] Axes to plot on

#### Returns

**fig** [matplotlib.figure.Figure instance] Figure for the plot

See also:

[ConvexHull](#)

#### Notes

Requires Matplotlib.

#### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import ConvexHull, convex_hull_plot_2d
```

The convex hull of a random set of points:

```
>>> rng = np.random.default_rng()
>>> points = rng.random((30, 2))
>>> hull = ConvexHull(points)
```

Plot it:

```
>>> _ = convex_hull_plot_2d(hull)
>>> plt.show()
```

### scipy.spatial.voronoi\_plot\_2d

`scipy.spatial.voronoi_plot_2d(vor, ax=None, **kw)`

Plot the given Voronoi diagram in 2-D

#### Parameters

- vor** [scipy.spatial.Voronoi instance] Diagram to plot
- ax** [matplotlib.axes.Axes instance, optional] Axes to plot on
- show\_points: bool, optional**  
Add the Voronoi points to the plot.
- show\_vertices**  
[bool, optional] Add the Voronoi vertices to the plot.
- line\_colors**  
[string, optional] Specifies the line color for polygon boundaries
- line\_width** [float, optional] Specifies the line width for polygon boundaries
- line\_alpha: float, optional**  
Specifies the line alpha for polygon boundaries
- point\_size: float, optional**  
Specifies the size of points

#### Returns

- fig** [matplotlib.figure.Figure instance] Figure for the plot

See also:

[Voronoi](#)

## Notes

Requires Matplotlib.

## Examples

Set of point:

```
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> points = rng.random((10,2))
```

Voronoi diagram of the points:

```
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)
```

using `voronoi_plot_2d` for visualisation:

```
>>> fig = voronoi_plot_2d(vor)
```

using `voronoi_plot_2d` for visualisation with enhancements:

```
>>> fig = voronoi_plot_2d(vor, show_vertices=False, line_colors='orange',
... line_width=2, line_alpha=0.6, point_size=2)
>>> plt.show()
```

### Simplex representation

The simplices (triangles, tetrahedra, etc.) appearing in the Delaunay tessellation (N-D simplices), convex hull facets, and Voronoi ridges (N-1-D simplices) are represented in the following scheme:

```
tess = Delaunay(points)
hull = ConvexHull(points)
voro = Voronoi(points)

coordinates of the jth vertex of the ith simplex
tess.points[tess.simplices[i, j], :] # tessellation element
hull.points[hull.simplices[i, j], :] # convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :] # ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition: `tess.neighbors[i, j]` is the neighboring simplex of the `i`th simplex, opposite to the `j`-vertex. It is -1 in case of no neighbor.

Convex hull facets also define a hyperplane equation:

```
(hull.equations[i, :-1] * coord).sum() + hull.equations[i, -1] == 0
```

Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding N+1-D paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.

## Functions

|                                                    |                                                                |
|----------------------------------------------------|----------------------------------------------------------------|
| <code>tsearch(tri, xi)</code>                      | Find simplices containing the given points.                    |
| <code>distance_matrix(x, y[, p, threshold])</code> | Compute the distance matrix.                                   |

| <code>minkowski_distance_p(x, y[, p])</code>       | Compute the pth power of the L**p distance between two arrays. |
| <code>procrustes(data1, data2)</code>              | Procrustes analysis, a similarity test for two data sets.      |
| <code>geometric_slerp(start, end, t[, tol])</code> | Geometric spherical linear interpolation.                      |

## scipy.spatial.tsearch

`scipy.spatial.tsearch(tri, xi)`

Find simplices containing the given points. This function does the same thing as `Delaunay.find_simplex`.

New in version 0.9.

**See also:**

[`Delaunay.find\_simplex`](#)

## Examples

```
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.spatial import Delaunay, delaunay_plot_2d, tsearch
>>> rng = np.random.default_rng()
```

The Delaunay triangulation of a set of random points:

```
>>> pts = rng.random((20, 2))
>>> tri = Delaunay(pts)
>>> _ = delaunay_plot_2d(tri)
```

Find the simplices containing a given set of points:

```
>>> loc = rng.uniform(0.2, 0.8, (5, 2))
>>> s = tsearch(tri, loc)
>>> plt.triplot(pts[:, 0], pts[:, 1], tri.simplices[s], 'b-', mask=s==-1)
>>> plt.scatter(loc[:, 0], loc[:, 1], c='r', marker='x')
>>> plt.show()
```

### scipy.spatial.distance\_matrix

`scipy.spatial.distance_matrix(x, y, p=2, threshold=1000000)`

Compute the distance matrix.

Returns the matrix of all pair-wise distances.

#### Parameters

- x** [(M, K) array\_like] Matrix of M vectors in K dimensions.
- y** [(N, K) array\_like] Matrix of N vectors in K dimensions.
- p** [float, 1 <= p <= infinity] Which Minkowski p-norm to use.
- threshold** [positive int] If  $M * N * K > threshold$ , algorithm uses a Python loop instead of large temporary arrays.

#### Returns

- result** [(M, N) ndarray] Matrix containing the distance from every vector in *x* to every vector in *y*.

### Examples

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0,0],[0,1]], [[1,0],[1,1]])
array([[1. , 1.41421356],
 [1.41421356, 1.]])
```

### scipy.spatial.minkowski\_distance

`scipy.spatial.minkowski_distance(x, y, p=2)`

Compute the  $L^p$  distance between two arrays.

#### Parameters

|          |                                                            |
|----------|------------------------------------------------------------|
| <b>x</b> | [(M, K) array_like] Input array.                           |
| <b>y</b> | [(N, K) array_like] Input array.                           |
| <b>p</b> | [float, 1 <= p <= infinity] Which Minkowski p-norm to use. |

#### Examples

```
>>> from scipy.spatial import minkowski_distance
>>> minkowski_distance([[0, 0], [0, 0]], [[1, 1], [0, 1]])
array([1.41421356, 1.])
```

### scipy.spatial.minkowski\_distance\_p

`scipy.spatial.minkowski_distance_p(x, y, p=2)`

Compute the  $p$ th power of the  $L^p$  distance between two arrays.

For efficiency, this function computes the  $L^p$  distance but does not extract the  $p$ th root. If  $p$  is 1 or infinity, this is equal to the actual  $L^p$  distance.

#### Parameters

|          |                                                            |
|----------|------------------------------------------------------------|
| <b>x</b> | [(M, K) array_like] Input array.                           |
| <b>y</b> | [(N, K) array_like] Input array.                           |
| <b>p</b> | [float, 1 <= p <= infinity] Which Minkowski p-norm to use. |

#### Examples

```
>>> from scipy.spatial import minkowski_distance_p
>>> minkowski_distance_p([[0, 0], [0, 0]], [[1, 1], [0, 1]])
array([2, 1])
```

### scipy.spatial.procrustes

`scipy.spatial.procrustes(data1, data2)`

Procrustes analysis, a similarity test for two data sets.

Each input matrix is a set of points or vectors (the rows of the matrix). The dimension of the space is the number of columns of each matrix. Given two identically sized matrices, procrustes standardizes both such that:

- $tr(AA^T) = 1$ .
- Both sets of points are centered around the origin.

Procrustes ([1], [2]) then applies the optimal transform to the second matrix (including scaling/dilation, rotations, and reflections) to minimize  $M^2 = \sum (data1 - data2)^2$ , or the sum of the squares of the pointwise differences between the two input datasets.

This function was not designed to handle datasets with different numbers of datapoints (rows). If two data sets have different dimensionality (different number of columns), simply add columns of zeros to the smaller of the two.

**Parameters**

- data1** [array\_like] Matrix, n rows represent points in k (columns) space *data1* is the reference data, after it is standardised, the data from *data2* will be transformed to fit the pattern in *data1* (must have >1 unique points).
- data2** [array\_like] n rows of data in k space to be fit to *data1*. Must be the same shape (numrows, numcols) as data1 (must have >1 unique points).

**Returns**

- mtx1** [array\_like] A standardized version of *data1*.
- mtx2** [array\_like] The orientation of *data2* that best fits *data1*. Centered, but not necessarily  $tr(AA^T) = 1$ .
- disparity** [float]  $M^2$  as defined above.

**Raises**

- ValueError** If the input arrays are not two-dimensional. If the shape of the input arrays is different. If the input arrays have zero columns or zero rows.

See also:

- [scipy.linalg.orthogonal\\_procrustes](#)
- [scipy.spatial.distance.directed\\_hausdorff](#)

Another similarity test for two data sets

**Notes**

- The disparity should not depend on the order of the input matrices, but the output matrices will, as only the first output matrix is guaranteed to be scaled such that  $tr(AA^T) = 1$ .
- Duplicate data points are generally ok, duplicating a data point will increase its effect on the procrustes fit.
- The disparity scales as the number of points per input matrix.

**References**

- [1], [2]

**Examples**

```
>>> from scipy.spatial import procrustes
```

The matrix b is a rotated, shifted, scaled and mirrored version of a here:

```
>>> a = np.array([[1, 3], [1, 2], [1, 1], [2, 1]], 'd')
>>> b = np.array([[4, -2], [4, -4], [4, -6], [2, -6]], 'd')
>>> mtx1, mtx2, disparity = procrustes(a, b)
>>> round(disparity)
0.0
```

**scipy.spatial.geometric\_slerp**

`scipy.spatial.geometric_slerp` (*start, end, t, tol=1e-07*)

Geometric spherical linear interpolation.

The interpolation occurs along a unit-radius great circle arc in arbitrary dimensional space.

**Parameters**

- start** [(n\_dimensions, ) array-like] Single n-dimensional input coordinate in a 1-D array-like object. *n* must be greater than 1.
- end** [(n\_dimensions, ) array-like] Single n-dimensional input coordinate in a 1-D array-like object. *n* must be greater than 1.
- t: float or (n\_points,) array-like**  
A float or array-like of doubles representing interpolation parameters, with values required in the inclusive interval between 0 and 1. A common approach is to generate the array with `np.linspace(0, 1, n_pts)` for linearly spaced points. Ascending, descending, and scrambled orders are permitted.
- tol: float** The absolute tolerance for determining if the start and end coordinates are antipodes.

**Returns**

- result** [(t.size, D)] An array of doubles containing the interpolated spherical path and including start and end when 0 and 1 *t* are used. The interpolated values should correspond to the same sort order provided in the *t* array. The result may be 1-dimensional if *t* is a float.

**Raises****ValueError**

If *start* and *end* are antipodes, not on the unit *n*-sphere, or for a variety of degenerate conditions.

See also:

***scipy.spatial.transform.Slerp***

3-D Slerp that works with quaternions

**Notes**

The implementation is based on the mathematical formula provided in [1], and the first known presentation of this algorithm, derived from study of 4-D geometry, is credited to Glenn Davis in a footnote of the original quaternion Slerp publication by Ken Shoemake [2].

New in version 1.5.0.

**References**

[1], [2]

## Examples

Interpolate four linearly-spaced values on the circumference of a circle spanning 90 degrees:

```
>>> from scipy.spatial import geometric_slerp
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> start = np.array([1, 0])
>>> end = np.array([0, 1])
>>> t_vals = np.linspace(0, 1, 4)
>>> result = geometric_slerp(start,
... end,
... t_vals)
```

The interpolated results should be at 30 degree intervals recognizable on the unit circle:

```
>>> ax.scatter(result[...,0], result[...,1], c='k')
>>> circle = plt.Circle((0, 0), 1, color='grey')
>>> ax.add_artist(circle)
>>> ax.set_aspect('equal')
>>> plt.show()
```

Attempting to interpolate between antipodes on a circle is ambiguous because there are two possible paths, and on a sphere there are infinite possible paths on the geodesic surface. Nonetheless, one of the ambiguous paths is returned along with a warning:

```
>>> opposite_pole = np.array([-1, 0])
>>> with np.testing.suppress_warnings() as sup:
... sup.filter(UserWarning)
... geometric_slerp(start,
... opposite_pole,
... t_vals)
array([[1.00000000e+00, 0.00000000e+00],
```

(continues on next page)

(continued from previous page)

```
[5.00000000e-01, 8.66025404e-01],
 [-5.00000000e-01, 8.66025404e-01],
 [-1.00000000e+00, 1.22464680e-16]]
```

Extend the original example to a sphere and plot interpolation points in 3D:

```
>>> from mpl_toolkits.mplot3d import proj3d
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
```

Plot the unit sphere for reference (optional):

```
>>> u = np.linspace(0, 2 * np.pi, 100)
>>> v = np.linspace(0, np.pi, 100)
>>> x = np.outer(np.cos(u), np.sin(v))
>>> y = np.outer(np.sin(u), np.sin(v))
>>> z = np.outer(np.ones(np.size(u)), np.cos(v))
>>> ax.plot_surface(x, y, z, color='y', alpha=0.1)
```

Interpolating over a larger number of points may provide the appearance of a smooth curve on the surface of the sphere, which is also useful for discretized integration calculations on a sphere surface:

```
>>> start = np.array([1, 0, 0])
>>> end = np.array([0, 0, 1])
>>> t_vals = np.linspace(0, 1, 200)
>>> result = geometric_slerp(start,
... end,
... t_vals)
>>> ax.plot(result[...,0],
... result[...,1],
... result[...,2],
... c='k')
>>> plt.show()
```

### 3.3.27 Distance computations (`scipy.spatial.distance`)

#### Function reference

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

|                                               |                                                                                         |
|-----------------------------------------------|-----------------------------------------------------------------------------------------|
| <code>pdist(X[, metric, out])</code>          | Pairwise distances between observations in n-dimensional space.                         |

| <code>squareform(X[, force, checks])</code>   | Convert a vector-form distance vector to a square-form distance matrix, and vice-versa. |
| <code>directed_hausdorff(u, v[, seed])</code> | Compute the directed Hausdorff distance between two N-D arrays.                         |

#### `scipy.spatial.distance.pdist`

`scipy.spatial.distance.pdist` (*X*, *metric*='euclidean', \*, *out*=None, *\*\*kwargs*)  
 Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

##### Parameters

- X** [array\_like] An m by n array of m original observations in an n-dimensional space.
- metric** [str or function, optional] The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.
- \*\*kwargs** [dict, optional] Extra arguments to *metric*: refer to each metric documentation for a list of all possible arguments.  
 Some possible arguments:  
*p* : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.  
*w* : ndarray The weight vector for metrics that support weights (e.g., Minkowski).  
*V* : ndarray The variance vector for standardized Euclidean. Default: var(X, axis=0, ddof=1)  
*VI* : ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(X.T)).T  
*out* : ndarray. The output array If not None, condensed distance matrix Y is stored in this array.

##### Returns

- Y** [ndarray] Returns a condensed distance matrix Y. For each *i* and *j* (where  $i < j < m$ ), where *m* is the number of original observations. The metric `dist(u=X[i], v=X[j])` is computed and stored in entry  $m * i + j - ((i + 2) * (i + 1)) // 2$ .

See also:

#### `squareform`

converts between condensed distance matrices and square distance matrices.

## Notes

See `squareform` for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. `Y = pdist(X, 'euclidean')`

Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix  $X$ .

2. `Y = pdist(X, 'minkowski', p=2.)`

Computes the distances using the Minkowski distance  $\|u - v\|_p$  (p-norm) where  $p \geq 1$ .

3. `Y = pdist(X, 'cityblock')`

Computes the city block or Manhattan distance between the points.

4. `Y = pdist(X, 'seuclidean', V=None)`

Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}$$

$V$  is the variance vector;  $V[i]$  is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5. `Y = pdist(X, 'sqeuclidean')`

Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.

6. `Y = pdist(X, 'cosine')`

Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|*\|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7. `Y = pdist(X, 'correlation')`

Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8. `Y = pdist(X, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9. `Y = pdist(X, 'jaccard')`

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree.

10. `Y = pdist(X, 'jensenshannon')`

Computes the Jensen-Shannon distance between two probability arrays. Given two probability vectors,  $p$  and  $q$ , the Jensen-Shannon distance is

$$\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}$$

where  $m$  is the pointwise mean of  $p$  and  $q$  and  $D$  is the Kullback-Leibler divergence.

11. `Y = pdist(X, 'chebyshev')`

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|$$

12. `Y = pdist(X, 'canberra')`

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

13. `Y = pdist(X, 'braycurtis')`

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}$$

14. `Y = pdist(X, 'mahalanobis', VI=None)`

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the `VI` variable) is the inverse covariance. If `VI` is not `None`, `VI` will be used as the inverse covariance matrix.

15. `Y = pdist(X, 'yule')`

Computes the Yule distance between each pair of boolean vectors. (see `yule` function documentation)

16. `Y = pdist(X, 'matching')`

Synonym for 'hamming'.

17. `Y = pdist(X, 'dice')`

Computes the Dice distance between each pair of boolean vectors. (see `dice` function documentation)

18. `Y = pdist(X, 'kulsinski')`

Computes the Kulsinski distance between each pair of boolean vectors. (see `kulsinski` function documentation)

19. `Y = pdist(X, 'rogerstanimoto')`

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see `rogerstanimoto` function documentation)

20. `Y = pdist(X, 'russellrao')`

Computes the Russell-Rao distance between each pair of boolean vectors. (see `russellrao` function documentation)

21. `Y = pdist(X, 'sokalmichener')`

Computes the Sokal-Michener distance between each pair of boolean vectors. (see `sokalmichener` function documentation)

22. `Y = pdist(X, 'sokalsneath')`

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see `sokalsneath` function documentation)

23. `Y = pdist(X, 'wminkowski', p=2, w=w)`

Computes the weighted Minkowski distance between each pair of vectors. (see `wminkowski` function documentation)

'wminkowski' is deprecated and will be removed in SciPy 1.8.0. Use 'minkowski' instead.

24. `Y = pdist(X, f)`

Computes the distance between all pairs of vectors in `X` using the user supplied 2-arity function `f`. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = pdist(X, lambda u, v: np.sqrt((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = pdist(X, sokalsneath)
```

would calculate the pair-wise distances between the vectors in `X` using the Python function `sokalsneath`. This would result in `sokalsneath` being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

```
dm = pdist(X, 'sokalsneath')
```

### scipy.spatial.distance.cdist

`scipy.spatial.distance.cdist(XA, XB, metric='euclidean', *, out=None, **kwargs)`

Compute distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

#### Parameters

- XA** [array\_like] An  $m_A$  by  $n$  array of  $m_A$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.
- XB** [array\_like] An  $m_B$  by  $n$  array of  $m_B$  original observations in an  $n$ -dimensional space. Inputs are converted to float type.
- metric** [str or callable, optional] The distance metric to use. If a string, the distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'euclidean', 'hamming', 'jaccard', 'jensenshannon', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'wminkowski', 'yule'.
- \*\*kwargs** [dict, optional] Extra arguments to `metric`: refer to each metric documentation for a list of all possible arguments.  
Some possible arguments:  
  - `p` : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
  - `w` : array\_like The weight vector for metrics that support weights (e.g., Minkowski).
  - `V` : array\_like The variance vector for standardized Euclidean. Default: `var(vstack([XA, XB]), axis=0, ddof=1)`

**VI** : array\_like The inverse of the covariance matrix for Mahalanobis. Default: `inv(cov(vstack([XA, XB].T))).T`  
**out** : ndarray The output array If not None, the distance matrix Y is stored in this array.

**Returns**

**Y** [ndarray] A  $m_A$  by  $m_B$  distance matrix is returned. For each  $i$  and  $j$ , the metric `dist(u=XA[i], v=XB[j])` is computed and stored in the  $ij$  th entry.

**Raises**

**ValueError**  
 An exception is thrown if XA and XB do not have the same number of columns.

**Notes**

The following are common calling conventions:

1. `Y = cdist(XA, XB, 'euclidean')`  
 Computes the distance between  $m$  points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as  $m$   $n$ -dimensional row vectors in the matrix X.
2. `Y = cdist(XA, XB, 'minkowski', p=2.)`  
 Computes the distances using the Minkowski distance  $\|u - v\|_p$  ( $p$ -norm) where  $p \geq 1$ .
3. `Y = cdist(XA, XB, 'cityblock')`  
 Computes the city block or Manhattan distance between the points.
4. `Y = cdist(XA, XB, 'seuclidean', V=None)`  
 Computes the standardized Euclidean distance. The standardized Euclidean distance between two  $n$ -vectors  $u$  and  $v$  is

$$\sqrt{\sum (u_i - v_i)^2 / V[x_i]}.$$

V is the variance vector; V[i] is the variance computed over all the  $i$ 'th components of the points. If not passed, it is automatically computed.

5. `Y = cdist(XA, XB, 'sqeuclidean')`  
 Computes the squared Euclidean distance  $\|u - v\|_2^2$  between the vectors.
6. `Y = cdist(XA, XB, 'cosine')`  
 Computes the cosine distance between vectors  $u$  and  $v$ ,

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $\|*\|_2$  is the 2-norm of its argument  $*$ , and  $u \cdot v$  is the dot product of  $u$  and  $v$ .

7. `Y = cdist(XA, XB, 'correlation')`  
 Computes the correlation distance between vectors  $u$  and  $v$ . This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\|(u - \bar{u})\|_2 \|(v - \bar{v})\|_2}$$

where  $\bar{v}$  is the mean of the elements of vector  $v$ , and  $x \cdot y$  is the dot product of  $x$  and  $y$ .

8. `Y = cdist(XA, XB, 'hamming')`

Computes the normalized Hamming distance, or the proportion of those vector elements between two  $n$ -vectors  $u$  and  $v$  which disagree. To save memory, the matrix  $X$  can be of type boolean.

9. `Y = cdist(XA, XB, 'jaccard')`

Computes the Jaccard distance between the points. Given two vectors,  $u$  and  $v$ , the Jaccard distance is the proportion of those elements  $u[i]$  and  $v[i]$  that disagree where at least one of them is non-zero.

10. `Y = cdist(XA, XB, 'jensenshannon')`

Computes the Jensen-Shannon distance between two probability arrays. Given two probability vectors,  $p$  and  $q$ , the Jensen-Shannon distance is

$$\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}$$

where  $m$  is the pointwise mean of  $p$  and  $q$  and  $D$  is the Kullback-Leibler divergence.

11. `Y = cdist(XA, XB, 'chebyshev')`

Computes the Chebyshev distance between the points. The Chebyshev distance between two  $n$ -vectors  $u$  and  $v$  is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|.$$

12. `Y = cdist(XA, XB, 'canberra')`

Computes the Canberra distance between the points. The Canberra distance between two points  $u$  and  $v$  is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

13. `Y = cdist(XA, XB, 'braycurtis')`

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points  $u$  and  $v$  is

$$d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}$$

14. `Y = cdist(XA, XB, 'mahalanobis', VI=None)`

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points  $u$  and  $v$  is  $\sqrt{(u - v)(1/V)(u - v)^T}$  where  $(1/V)$  (the `VI` variable) is the inverse covariance. If `VI` is not `None`, `VI` will be used as the inverse covariance matrix.

15. `Y = cdist(XA, XB, 'yule')`

Computes the Yule distance between the boolean vectors. (see [yule](#) function documentation)

16. `Y = cdist(XA, XB, 'matching')`

Synonym for 'hamming'.

17. `Y = cdist(XA, XB, 'dice')`

Computes the Dice distance between the boolean vectors. (see [dice](#) function documentation)

18. `Y = cdist(XA, XB, 'kulsinski')`

Computes the Kulsinski distance between the boolean vectors. (see [kulsinski](#) function documentation)

19. `Y = cdist(XA, XB, 'rogerstanimoto')`

Computes the Rogers-Tanimoto distance between the boolean vectors. (see [rogerstanimoto](#) function documentation)

20. `Y = cdist(XA, XB, 'russellrao')`

Computes the Russell-Rao distance between the boolean vectors. (see [russellrao](#) function documentation)

21. `Y = cdist(XA, XB, 'sokalmichener')`

Computes the Sokal-Michener distance between the boolean vectors. (see [sokalmichener](#) function documentation)

22. `Y = cdist(XA, XB, 'sokalsneath')`

Computes the Sokal-Sneath distance between the vectors. (see [sokalsneath](#) function documentation)

23. `Y = cdist(XA, XB, 'wminkowski', p=2., w=w)`

Computes the weighted Minkowski distance between the vectors. (see [wminkowski](#) function documentation)

'wminkowski' is deprecated and will be removed in SciPy 1.8.0. Use 'minkowski' instead.

24. `Y = cdist(XA, XB, f)`

Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

```
dm = cdist(XA, XB, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

```
dm = cdist(XA, XB, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function [sokalsneath](#). This would result in [sokalsneath](#) being called  $\binom{n}{2}$  times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

```
dm = cdist(XA, XB, 'sokalsneath')
```

## Examples

Find the Euclidean distances between four 2-D coordinates:

```
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
... (35.1174, -89.9711),
... (35.9728, -83.9422),
... (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[0. , 4.7044, 1.6172, 1.8856],
 [4.7044, 0. , 6.0893, 3.3561],
 [1.6172, 6.0893, 0. , 2.8477],
 [1.8856, 3.3561, 2.8477, 0.]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```
>>> a = np.array([[0, 0, 0],
... [0, 0, 1],
... [0, 1, 0],
... [0, 1, 1],
... [1, 0, 0],
... [1, 0, 1],
... [1, 1, 0],
... [1, 1, 1]])
>>> b = np.array([[0.1, 0.2, 0.4]])
>>> distance.cdist(a, b, 'cityblock')
array([[0.7],
 [0.9],
 [1.3],
 [1.5],
 [1.5],
 [1.7],
 [2.1],
 [2.3]])
```

### scipy.spatial.distance.squareform

`scipy.spatial.distance.squareform(X, force='no', checks=True)`

Convert a vector-form distance vector to a square-form distance matrix, and vice-versa.

#### Parameters

- X** [array\_like] Either a condensed or redundant distance matrix.
- force** [str, optional] As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.
- checks** [bool, optional] If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that  $X - X.T$  is small and  $\text{diag}(X)$  is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

#### Returns

- Y** [ndarray] If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

### Notes

1.  $v = \text{squareform}(X)$

Given a square  $n$ -by- $n$  symmetric distance matrix  $X$ ,  $v = \text{squareform}(X)$  returns a  $n * (n-1) / 2$  (i.e. binomial coefficient  $n$  choose 2) sized vector  $v$  where  $v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  is the distance between distinct points  $i$  and  $j$ . If  $X$  is non-square or asymmetric, an error is raised.

2.  $X = \text{squareform}(v)$

Given a  $n * (n-1) / 2$  sized vector  $v$  for some integer  $n \geq 1$  encoding distances as described,  $X = \text{squareform}(v)$  returns a  $n$ -by- $n$  distance matrix  $X$ . The  $X[i, j]$  and  $X[j, i]$  values are set to  $v[\binom{n}{2} - \binom{n-i}{2} + (j-i-1)]$  and all diagonal elements are zero.

In SciPy 0.19.0, `squareform` stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

**scipy.spatial.distance.directed\_hausdorff**

`scipy.spatial.distance.directed_hausdorff` (*u*, *v*, *seed*=0)

Compute the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

**Parameters**

**u** [(M,N) array\_like] Input array.  
**v** [(O,N) array\_like] Input array.  
**seed** [int or None] Local `numpy.random.RandomState` seed. Default is 0, a random shuffling of *u* and *v* that guarantees reproducibility.

**Returns**

**d** [double] The directed Hausdorff distance between arrays *u* and *v*,  
**index\_1** [int] index of point contributing to Hausdorff pair in *u*  
**index\_2** [int] index of point contributing to Hausdorff pair in *v*

**Raises****ValueError**

An exception is thrown if *u* and *v* do not have the same number of columns.

See also:

**scipy.spatial.procrustes**

Another similarity test for two data sets

**Notes**

Uses the early break technique and the random sampling approach described by [1]. Although worst-case performance is  $O(m * o)$  (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is  $O(m)$ , which is satisfied by selecting an inner loop distance that is less than `cmx` and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to  $O(m)$ .

New in version 0.19.0.

**References**

[1]

**Examples**

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
... (0.0, 1.0),
... (-1.0, 0.0),
... (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
```

(continues on next page)

(continued from previous page)

```
... (0.0, 2.0),
... (-2.0, 0.0),
... (0.0, -4.0)]])
```

```
>>> directed_hausdorff(u, v)[0]
2.23606797749979
>>> directed_hausdorff(v, u)[0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

|                                                          |                                                                                                    |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>is_valid_dm(D[, tol, throw, name, warning])</code> | Return True if input array is a valid distance matrix.                                             |
| <code>is_valid_y(y[, warning, throw, name])</code>       | Return True if the input array is a valid condensed distance matrix.                               |
| <code>num_obs_dm(d)</code>                               | Return the number of original observations that correspond to a square, redundant distance matrix. |
| <code>num_obs_y(Y)</code>                                | Return the number of original observations that correspond to a condensed distance matrix.         |

### scipy.spatial.distance.is\_valid\_dm

`scipy.spatial.distance.is_valid_dm(D, tol=0.0, throw=False, name='D', warning=False)`

Return True if input array is a valid distance matrix.

Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

#### Parameters

|                |                                                                                                                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>D</b>       | [array_like] The candidate object to test for validity.                                                                                                                                              |
| <b>tol</b>     | [float, optional] The distance matrix should be symmetric. <i>tol</i> is the maximum difference between entries $i j$ and $j i$ for the distance metric to be considered symmetric.                  |
| <b>throw</b>   | [bool, optional] An exception is thrown if the distance matrix passed is not valid.                                                                                                                  |
| <b>name</b>    | [str, optional] The name of the variable to checked. This is useful if <i>throw</i> is set to True so the offending variable can be identified in the exception message when an exception is thrown. |
| <b>warning</b> | [bool, optional] Instead of throwing an exception, a warning message is raised.                                                                                                                      |

#### Returns

|              |                                                                         |
|--------------|-------------------------------------------------------------------------|
| <b>valid</b> | [bool] True if the variable <i>D</i> passed is a valid distance matrix. |
|--------------|-------------------------------------------------------------------------|

## Notes

Small numerical differences in  $D$  and  $D.T$  and non-zerosness of the diagonal are ignored if they are within the tolerance specified by *tol*.

### scipy.spatial.distance.is\_valid\_y

`scipy.spatial.distance.is_valid_y(y, warning=False, throw=False, name=None)`

Return True if the input array is a valid condensed distance matrix.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient  $\binom{n}{2}$  for some positive integer  $n$ .

#### Parameters

|                |                                                                                                                                                                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>       | [array_like] The condensed distance matrix.                                                                                                                                                                                         |
| <b>warning</b> | [bool, optional] Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. <i>name</i> is used when referencing the offending variable. |
| <b>throw</b>   | [bool, optional] Throws an exception if the variable passed is not a valid condensed distance matrix.                                                                                                                               |
| <b>name</b>    | [bool, optional] Used when referencing the offending variable in the warning or exception message.                                                                                                                                  |

### scipy.spatial.distance.num\_obs\_dm

`scipy.spatial.distance.num_obs_dm(d)`

Return the number of original observations that correspond to a square, redundant distance matrix.

#### Parameters

|          |                                          |
|----------|------------------------------------------|
| <b>d</b> | [array_like] The target distance matrix. |
|----------|------------------------------------------|

#### Returns

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| <b>num_obs_dm</b> | [int] The number of observations in the redundant distance matrix. |
|-------------------|--------------------------------------------------------------------|

### scipy.spatial.distance.num\_obs\_y

`scipy.spatial.distance.num_obs_y(Y)`

Return the number of original observations that correspond to a condensed distance matrix.

#### Parameters

|          |                                         |
|----------|-----------------------------------------|
| <b>Y</b> | [array_like] Condensed distance matrix. |
|----------|-----------------------------------------|

#### Returns

|          |                                                                         |
|----------|-------------------------------------------------------------------------|
| <b>n</b> | [int] The number of observations in the condensed distance matrix $Y$ . |
|----------|-------------------------------------------------------------------------|

Distance functions between two numeric vectors  $u$  and  $v$ . Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

---

|                                    |                                                          |
|------------------------------------|----------------------------------------------------------|
| <code>braycurtis(u, v[, w])</code> | Compute the Bray-Curtis distance between two 1-D arrays. |
| <code>canberra(u, v[, w])</code>   | Compute the Canberra distance between two 1-D arrays.    |
| <code>chebyshev(u, v[, w])</code>  | Compute the Chebyshev distance.                          |
| <code>cityblock(u, v[, w])</code>  | Compute the City Block (Manhattan) distance.             |

Table 217 – continued from previous page

|                                                          |                                                                              |
|----------------------------------------------------------|------------------------------------------------------------------------------|
| <code>correlation(u, v[, w, centered])</code>            | Compute the correlation distance between two 1-D arrays.                     |
| <code>cosine(u, v[, w])</code>                           | Compute the Cosine distance between 1-D arrays.                              |
| <code>euclidean(u, v[, w])</code>                        | Computes the Euclidean distance between two 1-D arrays.                      |
| <code>jensenshannon(p, q[, base, axis, keepdims])</code> | Compute the Jensen-Shannon distance (metric) between two probability arrays. |
| <code>mahalanobis(u, v, VI)</code>                       | Compute the Mahalanobis distance between two 1-D arrays.                     |
| <code>minkowski(u, v[, p, w])</code>                     | Compute the Minkowski distance between two 1-D arrays.                       |
| <code>seuclidean(u, v, V)</code>                         | Return the standardized Euclidean distance between two 1-D arrays.           |
| <code>squclidean(u, v[, w])</code>                       | Compute the squared Euclidean distance between two 1-D arrays.               |
| <code>wminkowski(u, v, p, w)</code>                      | Compute the weighted Minkowski distance between two 1-D arrays.              |

**scipy.spatial.distance.braycurtis**

`scipy.spatial.distance.braycurtis(u, v, w=None)`

Compute the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

$$\sum |u_i - v_i| / \sum |u_i + v_i|$$

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

**Parameters**

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- braycurtis** [double] The Bray-Curtis distance between 1-D arrays *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.braycurtis([1, 0, 0], [0, 1, 0])
1.0
>>> distance.braycurtis([1, 1, 0], [0, 1, 0])
0.33333333333333331
```

**scipy.spatial.distance.canberra**`scipy.spatial.distance.canberra` (*u*, *v*, *w=None*)

Compute the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.$$

**Parameters**

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- canberra** [double] The Canberra distance between vectors *u* and *v*.

**Notes**When *u*[*i*] and *v*[*i*] are 0 for given *i*, then the fraction 0/0 = 0 is used in the calculation.**Examples**

```
>>> from scipy.spatial import distance
>>> distance.canberra([1, 0, 0], [0, 1, 0])
2.0
>>> distance.canberra([1, 1, 0], [0, 1, 0])
1.0
```

**scipy.spatial.distance.chebyshev**`scipy.spatial.distance.chebyshev` (*u*, *v*, *w=None*)

Compute the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays *u* and *v*, which is defined as

$$\max_i |u_i - v_i|.$$

**Parameters**

- u** [(N,) array\_like] Input vector.
- v** [(N,) array\_like] Input vector.
- w** [(N,) array\_like, optional] Unused, as ‘max’ is a weightless operation. Here for API consistency.

**Returns**

- chebyshev** [double] The Chebyshev distance between vectors *u* and *v*.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.chebyshev([1, 0, 0], [0, 1, 0])
1
>>> distance.chebyshev([1, 1, 0], [0, 1, 0])
1
```

### scipy.spatial.distance.cityblock

`scipy.spatial.distance.cityblock` (*u*, *v*, *w=None*)

Compute the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays *u* and *v*, which is defined as

$$\sum_i |u_i - v_i|.$$

#### Parameters

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

#### Returns

- cityblock** [double] The City Block (Manhattan) distance between vectors *u* and *v*.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.cityblock([1, 0, 0], [0, 1, 0])
2
>>> distance.cityblock([1, 0, 0], [0, 2, 0])
3
>>> distance.cityblock([1, 0, 0], [1, 1, 0])
1
```

### scipy.spatial.distance.correlation

`scipy.spatial.distance.correlation` (*u*, *v*, *w=None*, *centered=True*)

Compute the correlation distance between two 1-D arrays.

The correlation distance between *u* and *v*, is defined as

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\| (u - \bar{u}) \|_2 \| (v - \bar{v}) \|_2}$$

where  $\bar{u}$  is the mean of the elements of *u* and  $x \cdot y$  is the dot product of *x* and *y*.

#### Parameters

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**centered** [bool, optional] If True,  $u$  and  $v$  will be centered. Default is True.

**Returns**

**correlation** [double] The correlation distance between 1-D array  $u$  and  $v$ .

**scipy.spatial.distance.cosine**

`scipy.spatial.distance.cosine` ( $u, v, w=None$ )  
 Compute the Cosine distance between 1-D arrays.

The Cosine distance between  $u$  and  $v$ , is defined as

$$1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}$$

where  $u \cdot v$  is the dot product of  $u$  and  $v$ .

**Parameters**

**u** [(N,) array\_like] Input array.  
**v** [(N,) array\_like] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns**

**cosine** [double] The Cosine distance between vectors  $u$  and  $v$ .

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.cosine([1, 0, 0], [0, 1, 0])
1.0
>>> distance.cosine([100, 0, 0], [0, 1, 0])
1.0
>>> distance.cosine([1, 1, 0], [0, 1, 0])
0.29289321881345254
```

**scipy.spatial.distance.euclidean**

`scipy.spatial.distance.euclidean` ( $u, v, w=None$ )  
 Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays  $u$  and  $v$ , is defined as

$$\|u - v\|_2 = \left( \sum (w_i |(u_i - v_i)|^2) \right)^{1/2}$$

**Parameters**

**u** [(N,) array\_like] Input array.  
**v** [(N,) array\_like] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns**

**euclidean** [double] The Euclidean distance between vectors  $u$  and  $v$ .

## Examples

```
>>> from scipy.spatial import distance
>>> distance.euclidean([1, 0, 0], [0, 1, 0])
1.4142135623730951
>>> distance.euclidean([1, 1, 0], [0, 1, 0])
1.0
```

## scipy.spatial.distance.jensenshannon

`scipy.spatial.distance.jensenshannon` (*p*, *q*, *base=None*, \*, *axis=0*, *keepdims=False*)

Compute the Jensen-Shannon distance (metric) between two probability arrays. This is the square root of the Jensen-Shannon divergence.

The Jensen-Shannon distance between two probability vectors *p* and *q* is defined as,

$$\sqrt{\frac{D(p \parallel m) + D(q \parallel m)}{2}}$$

where *m* is the pointwise mean of *p* and *q* and *D* is the Kullback-Leibler divergence.

This routine will normalize *p* and *q* if they don't sum to 1.0.

### Parameters

|                 |                                                                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>p</b>        | [(N,) array_like] left probability vector                                                                                                                                                                                                                           |
| <b>q</b>        | [(N,) array_like] right probability vector                                                                                                                                                                                                                          |
| <b>base</b>     | [double, optional] the base of the logarithm used to compute the output if not given, then the routine uses the default base of <code>scipy.stats.entropy</code> .                                                                                                  |
| <b>axis</b>     | [int, optional] Axis along which the Jensen-Shannon distances are computed. The default is 0.<br>New in version 1.7.0.                                                                                                                                              |
| <b>keepdims</b> | [bool, optional] If this is set to <code>True</code> , the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array. Default is <code>False</code> .<br>New in version 1.7.0. |

### Returns

**js** [double or ndarray] The Jensen-Shannon distances between *p* and *q* along the *axis*.

## Notes

New in version 1.2.0.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.jensenshannon([1.0, 0.0, 0.0], [0.0, 1.0, 0.0], 2.0)
1.0
>>> distance.jensenshannon([1.0, 0.0], [0.5, 0.5])
0.46450140402245893
>>> distance.jensenshannon([1.0, 0.0, 0.0], [1.0, 0.0, 0.0])
0.0
>>> a = np.array([[1, 2, 3, 4],
```

(continues on next page)

(continued from previous page)

```

... [5, 6, 7, 8],
... [9, 10, 11, 12]])
>>> b = np.array([[13, 14, 15, 16],
... [17, 18, 19, 20],
... [21, 22, 23, 24]])
>>> distance.jensenshannon(a, b, axis=0)
array([0.1954288, 0.1447697, 0.1138377, 0.0927636])
>>> distance.jensenshannon(a, b, axis=1)
array([0.1402339, 0.0399106, 0.0201815])

```

**scipy.spatial.distance.mahalanobis**

`scipy.spatial.distance.mahalanobis` (*u*, *v*, *VI*)

Compute the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays *u* and *v*, is defined as

$$\sqrt{(u - v)V^{-1}(u - v)^T}$$

where *V* is the covariance matrix. Note that the argument *VI* is the inverse of *V*.

**Parameters**

**u** [(N,) array\_like] Input array.  
**v** [(N,) array\_like] Input array.  
**VI** [array\_like] The inverse of the covariance matrix.

**Returns**

**mahalanobis**  
 [double] The Mahalanobis distance between vectors *u* and *v*.

**Examples**

```

>>> from scipy.spatial import distance
>>> iv = [[1, 0.5, 0.5], [0.5, 1, 0.5], [0.5, 0.5, 1]]
>>> distance.mahalanobis([1, 0, 0], [0, 1, 0], iv)
1.0
>>> distance.mahalanobis([0, 2, 0], [0, 1, 0], iv)
1.0
>>> distance.mahalanobis([2, 0, 0], [0, 1, 0], iv)
1.7320508075688772

```

**scipy.spatial.distance.minkowski**

`scipy.spatial.distance.minkowski` (*u*, *v*, *p=2*, *w=None*)

Compute the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays *u* and *v*, is defined as

$$\|u - v\|_p = \left( \sum |u_i - v_i|^p \right)^{1/p}.$$

$$\left( \sum w_i (|u_i - v_i|^p) \right)^{1/p}.$$

**Parameters**

**u** [(N,) array\_like] Input array.  
**v** [(N,) array\_like] Input array.  
**p** [scalar] The order of the norm of the difference  $\|u - v\|_p$ .  
**w** [(N,) array\_like, optional] The weights for each value in  $u$  and  $v$ . Default is None, which gives each value a weight of 1.0

**Returns****minkowski**

[double] The Minkowski distance between vectors  $u$  and  $v$ .

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 1)
2.0
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 2)
1.4142135623730951
>>> distance.minkowski([1, 0, 0], [0, 1, 0], 3)
1.2599210498948732
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 1)
1.0
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 2)
1.0
>>> distance.minkowski([1, 1, 0], [0, 1, 0], 3)
1.0
```

**scipy.spatial.distance.seuclidean**

`scipy.spatial.distance.seuclidean` ( $u, v, V$ )

Return the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between  $u$  and  $v$ .

**Parameters**

**u** [(N,) array\_like] Input array.  
**v** [(N,) array\_like] Input array.  
**V** [(N,) array\_like]  $V$  is an 1-D array of component variances. It is usually computed among a larger collection vectors.

**Returns**

**seuclidean** [double] The standardized Euclidean distance between vectors  $u$  and  $v$ .

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [0.1, 0.1, 0.1])
4.4721359549995796
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [1, 0.1, 0.1])
3.3166247903553998
>>> distance.seuclidean([1, 0, 0], [0, 1, 0], [10, 0.1, 0.1])
3.1780497164141406
```

### scipy.spatial.distance.sqeuclidean

scipy.spatial.distance.**sqeuclidean** (*u*, *v*, *w=None*)

Compute the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between *u* and *v* is defined as

$$\|u - v\|_2^2$$

$$\left( \sum (w_i |u_i - v_i|^2) \right)$$

#### Parameters

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

#### Returns

- sqeuclidean**  
[double] The squared Euclidean distance between vectors *u* and *v*.

#### Examples

```
>>> from scipy.spatial import distance
>>> distance.sqeuclidean([1, 0, 0], [0, 1, 0])
2.0
>>> distance.sqeuclidean([1, 1, 0], [0, 1, 0])
1.0
```

### scipy.spatial.distance.wminkowski

scipy.spatial.distance.**wminkowski** (*u*, *v*, *p*, *w*)

Compute the weighted Minkowski distance between two 1-D arrays.

The weighted Minkowski distance between *u* and *v*, defined as

$$\left( \sum (w_i |u_i - v_i|^p) \right)^{1/p} .$$

#### Parameters

- u** [(N,) array\_like] Input array.
- v** [(N,) array\_like] Input array.
- p** [scalar] The order of the norm of the difference  $\|u - v\|_p$ .
- w** [(N,) array\_like] The weight vector.

#### Returns

- wminkowski**  
[double] The weighted Minkowski distance between vectors *u* and *v*.

## Notes

`wminkowski` is deprecated and will be removed in SciPy 1.8.0. Use `minkowski` with the `w` argument instead.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 1, np.ones(3))
2.0
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 2, np.ones(3))
1.4142135623730951
>>> distance.wminkowski([1, 0, 0], [0, 1, 0], 3, np.ones(3))
1.2599210498948732
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 1, np.ones(3))
1.0
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 2, np.ones(3))
1.0
>>> distance.wminkowski([1, 1, 0], [0, 1, 0], 3, np.ones(3))
1.0
```

Distance functions between two boolean vectors (representing sets)  $u$  and  $v$ . As in the case of numerical vectors, `pdist` is more efficient for computing the distances between all pairs.

|                                        |                                                                           |
|----------------------------------------|---------------------------------------------------------------------------|
| <code>dice(u, v[, w])</code>           | Compute the Dice dissimilarity between two boolean 1-D arrays.            |
| <code>hamming(u, v[, w])</code>        | Compute the Hamming distance between two 1-D arrays.                      |
| <code>jaccard(u, v[, w])</code>        | Compute the Jaccard-Needham dissimilarity between two boolean 1-D arrays. |

| <code>sokalsneath(u, v[, w])</code>    | Compute the Sokal-Sneath dissimilarity between two boolean 1-D arrays.    |
| <code>yule(u, v[, w])</code>           | Compute the Yule dissimilarity between two boolean 1-D arrays.            |

### scipy.spatial.distance.dice

`scipy.spatial.distance.dice(u, v, w=None)`

Compute the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between  $u$  and  $v$ , is

$$\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

#### Parameters

**u** [(N,) array\_like, bool] Input 1-D array.  
**v** [(N,) array\_like, bool] Input 1-D array.  
**w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**dice** [double] The Dice dissimilarity between 1-D arrays *u* and *v*.

**Examples**

```

>>> from scipy.spatial import distance
>>> distance.dice([1, 0, 0], [0, 1, 0])
1.0
>>> distance.dice([1, 0, 0], [1, 1, 0])
0.3333333333333333
>>> distance.dice([1, 0, 0], [2, 0, 0])
-0.3333333333333333

```

**scipy.spatial.distance.hamming**

scipy.spatial.distance.hamming(*u*, *v*, *w=None*)

Compute the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays *u* and *v*, is simply the proportion of disagreeing components in *u* and *v*. If *u* and *v* are boolean vectors, the Hamming distance is

$$\frac{c_{01} + c_{10}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

**u** [(N,) array\_like] Input array.  
**v** [(N,) array\_like] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**hamming** [double] The Hamming distance between vectors *u* and *v*.

**Examples**

```

>>> from scipy.spatial import distance
>>> distance.hamming([1, 0, 0], [0, 1, 0])
0.6666666666666666
>>> distance.hamming([1, 0, 0], [1, 1, 0])
0.3333333333333333
>>> distance.hamming([1, 0, 0], [2, 0, 0])
0.3333333333333333
>>> distance.hamming([1, 0, 0], [3, 0, 0])
0.3333333333333333

```

**scipy.spatial.distance.jaccard**

`scipy.spatial.distance.jaccard` (*u*, *v*, *w=None*)

Compute the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays *u* and *v*, is defined as

$$\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

**Parameters**

- u** [(N,) array\_like, bool] Input array.
- v** [(N,) array\_like, bool] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- jaccard** [double] The Jaccard distance between vectors *u* and *v*.

**Notes**

When both *u* and *v* lead to a  $0/0$  division i.e. there is no overlap between the items in the vectors the returned distance is 0. See the Wikipedia page on the Jaccard index [1], and this paper [2].

Changed in version 1.2.0: Previously, when *u* and *v* lead to a  $0/0$  division, the function would return NaN. This was changed to return 0 instead.

**References**

[1], [2]

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.jaccard([1, 0, 0], [0, 1, 0])
1.0
>>> distance.jaccard([1, 0, 0], [1, 1, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 2, 0])
0.5
>>> distance.jaccard([1, 0, 0], [1, 1, 1])
0.6666666666666666
```

### scipy.spatial.distance.kulsinski

scipy.spatial.distance.**kulsinski** (*u*, *v*, *w=None*)

Compute the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays *u* and *v*, is defined as

$$\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

#### Parameters

- u** [(N,) array\_like, bool] Input array.
- v** [(N,) array\_like, bool] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

#### Returns

- kulsinski** [double] The Kulsinski distance between vectors *u* and *v*.

### Examples

```
>>> from scipy.spatial import distance
>>> distance.kulsinski([1, 0, 0], [0, 1, 0])
1.0
>>> distance.kulsinski([1, 0, 0], [1, 1, 0])
0.75
>>> distance.kulsinski([1, 0, 0], [2, 1, 0])
0.33333333333333331
>>> distance.kulsinski([1, 0, 0], [3, 1, 0])
-0.5
```

### scipy.spatial.distance.rogerstanimoto

scipy.spatial.distance.**rogerstanimoto** (*u*, *v*, *w=None*)

Compute the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays *u* and *v*, is defined as

$$\frac{R}{c_{TT} + c_{FF} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

#### Parameters

- u** [(N,) array\_like, bool] Input array.
- v** [(N,) array\_like, bool] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

#### Returns

- rogerstanimoto** [double] The Rogers-Tanimoto dissimilarity between vectors *u* and *v*.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.rogerstanimoto([1, 0, 0], [0, 1, 0])
0.8
>>> distance.rogerstanimoto([1, 0, 0], [1, 1, 0])
0.5
>>> distance.rogerstanimoto([1, 0, 0], [2, 0, 0])
-1.0
```

### scipy.spatial.distance.russellrao

scipy.spatial.distance.**russellrao** (*u*, *v*, *w=None*)

Compute the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays, *u* and *v*, is defined as

$$\frac{n - c_{TT}}{n}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ .

#### Parameters

**u** [(N,) array\_like, bool] Input array.  
**v** [(N,) array\_like, bool] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

#### Returns

**russellrao** [double] The Russell-Rao dissimilarity between vectors *u* and *v*.

## Examples

```
>>> from scipy.spatial import distance
>>> distance.russellrao([1, 0, 0], [0, 1, 0])
1.0
>>> distance.russellrao([1, 0, 0], [1, 1, 0])
0.6666666666666666
>>> distance.russellrao([1, 0, 0], [2, 0, 0])
0.3333333333333333
```

### scipy.spatial.distance.sokalmichener

scipy.spatial.distance.**sokalmichener** (*u*, *v*, *w=None*)

Compute the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays *u* and *v*, is defined as

$$\frac{R}{S + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$ ,  $R = 2 * (c_{TF} + c_{FT})$  and  $S = c_{FF} + c_{TT}$ .

#### Parameters

**u** [(N,) array\_like, bool] Input array.  
**v** [(N,) array\_like, bool] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**sokalmichener**  
 [double] The Sokal-Michener dissimilarity between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.sokalmichener([1, 0, 0], [0, 1, 0])
0.8
>>> distance.sokalmichener([1, 0, 0], [1, 1, 0])
0.5
>>> distance.sokalmichener([1, 0, 0], [2, 0, 0])
-1.0
```

**scipy.spatial.distance.sokalsneath**

`scipy.spatial.distance.sokalsneath(u, v, w=None)`  
 Compute the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between *u* and *v*,

$$\frac{R}{c_{TT} + R}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2(c_{TF} + c_{FT})$ .

**Parameters**

**u** [(N,) array\_like, bool] Input array.  
**v** [(N,) array\_like, bool] Input array.  
**w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

**sokalsneath**  
 [double] The Sokal-Sneath dissimilarity between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.sokalsneath([1, 0, 0], [0, 1, 0])
1.0
>>> distance.sokalsneath([1, 0, 0], [1, 1, 0])
0.6666666666666666
>>> distance.sokalsneath([1, 0, 0], [2, 1, 0])
0.0
>>> distance.sokalsneath([1, 0, 0], [3, 1, 0])
-2.0
```

**scipy.spatial.distance.yule**

`scipy.spatial.distance.yule` (*u*, *v*, *w=None*)

Compute the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

$$\frac{R}{c_{TT} * c_{FF} + \frac{R}{2}}$$

where  $c_{ij}$  is the number of occurrences of  $u[k] = i$  and  $v[k] = j$  for  $k < n$  and  $R = 2.0 * c_{TF} * c_{FT}$ .

**Parameters**

- u** [(N,) array\_like, bool] Input array.
- v** [(N,) array\_like, bool] Input array.
- w** [(N,) array\_like, optional] The weights for each value in *u* and *v*. Default is None, which gives each value a weight of 1.0

**Returns**

- yule** [double] The Yule dissimilarity between vectors *u* and *v*.

**Examples**

```
>>> from scipy.spatial import distance
>>> distance.yule([1, 0, 0], [0, 1, 0])
2.0
>>> distance.yule([1, 1, 0], [0, 1, 0])
0.0
```

*hamming* also operates over discrete numerical vectors.

**3.3.28 Special functions (scipy.special)**

Nearly all of the functions below are universal functions and follow broadcasting and automatic array-looping rules.

**See also:**

`scipy.special.cython_special` – Typed Cython versions of special functions

**Error handling**

Errors are handled by returning NaNs or other appropriate values. Some of the special function routines can emit warnings or raise exceptions when an error occurs. By default this is disabled; to query and control the current error handling state the following functions are provided.

|                                     |                                                          |
|-------------------------------------|----------------------------------------------------------|
| <code>geterr</code>                 | Get the current way of handling special-function errors. |
| <code>seterr</code>                 | Set how special-function errors are handled.             |
| <code>errstate(**kwargs)</code>     | Context manager for special-function error handling.     |
| <code>SpecialFunctionWarning</code> | Warning that can be emitted by special functions.        |
| <code>SpecialFunctionError</code>   | Exception that can be raised by special functions.       |

## scipy.special.geterr

`scipy.special.geterr()`

Get the current way of handling special-function errors.

### Returns

**err** [dict] A dictionary with keys “singular”, “underflow”, “overflow”, “slow”, “loss”, “no\_result”, “domain”, “arg”, and “other”, whose values are from the strings “ignore”, “warn”, and “raise”. The keys represent possible special-function errors, and the values define how these errors are handled.

### See also:

#### [seterr](#)

set how special-function errors are handled

#### [errstate](#)

context manager for special-function error handling

#### [numpy.geterr](#)

similar numpy function for floating-point errors

### Notes

For complete documentation of the types of special-function errors and treatment options, see [seterr](#).

### Examples

By default all errors are ignored.

```
>>> import scipy.special as sc
>>> for key, value in sorted(sc.geterr().items()):
... print("{}: {}".format(key, value))
...
arg: ignore
domain: ignore
loss: ignore
no_result: ignore
other: ignore
overflow: ignore
singular: ignore
slow: ignore
underflow: ignore
```

## scipy.special.seterr

`scipy.special.seterr()`

Set how special-function errors are handled.

### Parameters

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>all</b>       | [[‘ignore’, ‘warn’, ‘raise’], optional] Set treatment for all type of special-function errors at once. The options are: <ul style="list-style-type: none"> <li>• ‘ignore’ Take no action when the error occurs</li> <li>• ‘warn’ Print a <i>SpecialFunctionWarning</i> when the error occurs (via the Python <code>warnings</code> module)</li> <li>• ‘raise’ Raise a <i>SpecialFunctionError</i> when the error occurs.</li> </ul> The default is to not change the current behavior. If behaviors for additional categories of special-function errors are specified, then <code>all</code> is applied first, followed by the additional categories. |
| <b>singular</b>  | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for singularities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>underflow</b> | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for underflow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>overflow</b>  | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for overflow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>slow</b>      | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for slow convergence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>loss</b>      | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for loss of accuracy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>no_result</b> | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for failing to find a result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>domain</b>    | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for an invalid argument to a function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>arg</b>       | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for an invalid parameter to a function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>other</b>     | [[‘ignore’, ‘warn’, ‘raise’], optional] Treatment for an unknown error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Returns

**olderr** [dict] Dictionary containing the old settings.

See also:

[`geterr`](#)

get the current way of handling special-function errors

[`errstate`](#)

context manager for special-function error handling

[`numpy.seterr`](#)

similar numpy function for floating-point errors

### Examples

```

>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> olderr = sc.seterr(singular='raise')
>>> with raises(sc.SpecialFunctionError):
... sc.gammaln(0)
...
>>> _ = sc.seterr(**olderr)

```

We can also raise for every category except one.

```

>>> olderr = sc.seterr(all='raise', singular='ignore')
>>> sc.gammaln(0)
inf
>>> with raises(sc.SpecialFunctionError):
... sc.spence(-1)
...
>>> _ = sc.seterr(**olderr)

```

### scipy.special.errstate

**class** `scipy.special.errstate` (\*\*kwargs)

Context manager for special-function error handling.

Using an instance of `errstate` as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with `seterr`, and upon exiting it is restored to what it was before.

#### Parameters

**kwargs** [{all, singular, underflow, overflow, slow, loss, no\_result, domain, arg, other}] Keyword arguments. The valid keywords are possible special-function errors. Each keyword should have a string value that defines the treatment for the particular type of error. Values must be 'ignore', 'warn', or 'other'. See `seterr` for details.

**See also:**

#### `geterr`

get the current way of handling special-function errors

#### `seterr`

set how special-function errors are handled

#### `numpy.errstate`

similar numpy function for floating-point errors

### Examples

```

>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> with sc.errstate(singular='raise'):
... with raises(sc.SpecialFunctionError):
... sc.gammaln(0)
...
>>> sc.gammaln(0)
inf

```

We can also raise on every category except one.

```

>>> with sc.errstate(all='raise', singular='ignore'):
... sc.gammaln(0)
... with raises(sc.SpecialFunctionError):

```

(continues on next page)

(continued from previous page)

```

... sc.spence(-1)
...
inf

```

**scipy.special.SpecialFunctionWarning****exception** `scipy.special.SpecialFunctionWarning`

Warning that can be emitted by special functions.

**with\_traceback()**

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

**scipy.special.SpecialFunctionError****exception** `scipy.special.SpecialFunctionError`

Exception that can be raised by special functions.

**with\_traceback()**

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

**Available functions****Airy functions**

|                           |                                                                                |

**scipy.special.airy**`scipy.special.airy(z) = <ufunc 'airy'>`

Airy functions and their derivatives.

**Parameters****z** [array\_like] Real or complex argument.**Returns****Ai, Aip, Bi, Bip**

[ndarrays] Airy functions Ai and Bi, and their derivatives Aip and Bip.

**See also:****airyex**

exponentially scaled Airy functions.

## Notes

The Airy functions  $Ai$  and  $Bi$  are two independent solutions of

$$y''(x) = xy(x).$$

For real  $z$  in  $[-10, 10]$ , the computation is carried out by calling the Cephes [1] `airy` routine, which uses power series summation for small  $z$  and rational minimax approximations for large  $z$ .

Outside this range, the AMOS [2] `zairy` and `zbiry` routines are employed. They are computed using power series for  $|z| < 1$  and the following relations to modified Bessel functions for larger  $z$  (where  $t \equiv 2z^{3/2}/3$ ):

$$\begin{aligned} Ai(z) &= \frac{1}{\pi\sqrt{3}} K_{1/3}(t) \\ Ai'(z) &= -\frac{z}{\pi\sqrt{3}} K_{2/3}(t) \\ Bi(z) &= \sqrt{\frac{z}{3}} (I_{-1/3}(t) + I_{1/3}(t)) \\ Bi'(z) &= \frac{z}{\sqrt{3}} (I_{-2/3}(t) + I_{2/3}(t)) \end{aligned}$$

## References

[1], [2]

## Examples

Compute the Airy functions on the interval  $[-15, 5]$ .

```
>>> from scipy import special
>>> x = np.linspace(-15, 5, 201)
>>> ai, aip, bi, bip = special.airy(x)
```

Plot  $Ai(x)$  and  $Bi(x)$ .

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, ai, 'r', label='Ai(x)')
>>> plt.plot(x, bi, 'b--', label='Bi(x)')
>>> plt.ylim(-0.5, 1.0)
>>> plt.grid()
>>> plt.legend(loc='upper left')
>>> plt.show()
```

## scipy.special.airy

`scipy.special.airy(z) = <ufunc 'airy'>`  
Exponentially scaled Airy functions and their derivatives.

Scaling:

```
eAi = Ai * exp(2.0/3.0*z*sqrt(z))
eAip = Aip * exp(2.0/3.0*z*sqrt(z))
eBi = Bi * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
eBip = Bip * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
```

#### Parameters

**z** [array\_like] Real or complex argument.

#### Returns

**eAi, eAip, eBi, eBip**

[array\_like] Exponentially scaled Airy functions eAi and eBi, and their derivatives eAip and eBip

#### See also:

[airy](#)

#### Notes

Wrapper for the AMOS [1] routines *zairy* and *zbiry*.

#### References

[1]

## Examples

We can compute exponentially scaled Airy functions and their derivatives:

```
>>> from scipy.special import airye
>>> import matplotlib.pyplot as plt
>>> z = np.linspace(0, 50, 500)
>>> eAi, eAip, eBi, eBip = airye(z)
>>> f, ax = plt.subplots(2, 1, sharex=True)
>>> for ind, data in enumerate([[eAi, eAip, ["eAi", "eAip"]],
... [eBi, eBip, ["eBi", "eBip"]]]):
... ax[ind].plot(z, data[0], "-r", z, data[1], "-b")
... ax[ind].legend(data[2])
... ax[ind].grid(True)
>>> plt.show()
```

We can compute these using usual non-scaled Airy functions by:

```
>>> from scipy.special import airy
>>> Ai, Aip, Bi, Bip = airy(z)
>>> np.allclose(eAi, Ai * np.exp(2.0 / 3.0 * z * np.sqrt(z)))
True
>>> np.allclose(eAip, Aip * np.exp(2.0 / 3.0 * z * np.sqrt(z)))
True
>>> np.allclose(eBi, Bi * np.exp(-abs(np.real(2.0 / 3.0 * z * np.
->sqrt(z))))))
True
>>> np.allclose(eBip, Bip * np.exp(-abs(np.real(2.0 / 3.0 * z * np.
->sqrt(z))))))
True
```

Comparing non-scaled and exponentially scaled ones, the usual non-scaled function quickly underflows for large values, whereas the exponentially scaled function does not.

```

>>> airy(200)
(0.0, 0.0, nan, nan)
>>> airye(200)
(0.07501041684381093, -1.0609012305109042, 0.15003188417418148, 2.
 →1215836725571093)

```

### scipy.special.ai\_zeros

`scipy.special.ai_zeros` (*nt*)

Compute *nt* zeros and values of the Airy function  $Ai$  and its derivative.

Computes the first *nt* zeros, *a*, of the Airy function  $Ai(x)$ ; first *nt* zeros, *ap*, of the derivative of the Airy function  $Ai'(x)$ ; the corresponding values  $Ai(a')$ ; and the corresponding values  $Ai'(a)$ .

#### Parameters

**nt** [int] Number of zeros to compute

#### Returns

**a** [ndarray] First *nt* zeros of  $Ai(x)$   
**ap** [ndarray] First *nt* zeros of  $Ai'(x)$   
**ai** [ndarray] Values of  $Ai(x)$  evaluated at first *nt* zeros of  $Ai'(x)$   
**aip** [ndarray] Values of  $Ai'(x)$  evaluated at first *nt* zeros of  $Ai(x)$

## scipy.special.ellipj

`scipy.special.ellipj(u, m) = <ufunc 'ellipj'>`

Jacobian elliptic functions

Calculates the Jacobian elliptic functions of parameter  $m$  between 0 and 1, and real argument  $u$ .

### Parameters

**m** [array\_like] Parameter.  
**u** [array\_like] Argument.

### Returns

**sn, cn, dn, ph**

[ndarrays] The returned functions:

|                             |
|-----------------------------|
| $sn(u m), cn(u m), dn(u m)$ |
|-----------------------------|

The value  $ph$  is such that if  $u = ellipkinc(ph, m)$ , then  $sn(u|m) = sin(ph)$  and  $cn(u|m) = cos(ph)$ .

See also:

**ellipk**

Complete elliptic integral of the first kind

**ellipkinc**

Incomplete elliptic integral of the first kind

## Notes

Wrapper for the Cephes [1] routine *ellpj*.

These functions are periodic, with quarter-period on the real axis equal to the complete elliptic integral *ellipk(m)*.

Relation to incomplete elliptic integral: If  $u = \text{ellipkinc}(\phi, m)$ , then  $\text{sn}(u|m) = \sin(\phi)$ , and  $\text{cn}(u|m) = \cos(\phi)$ . The  $\phi$  is called the amplitude of  $u$ .

Computation is by means of the arithmetic-geometric mean algorithm, except when  $m$  is within  $1e-9$  of 0 or 1. In the latter case with  $m$  close to 1, the approximation applies only for  $\phi < \pi/2$ .

## References

[1]

## scipy.special.ellipk

`scipy.special.ellipk(m) = <ufunc 'ellipk'>`

Complete elliptic integral of the first kind.

This function is defined as

$$K(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

### Parameters

**m** [array\_like] The parameter of the elliptic integral.

### Returns

**K** [array\_like] Value of the elliptic integral.

See also:

### `ellipkm1`

Complete elliptic integral of the first kind around  $m = 1$

### `ellipkinc`

Incomplete elliptic integral of the first kind

### `ellipe`

Complete elliptic integral of the second kind

### `ellipeinc`

Incomplete elliptic integral of the second kind

## Notes

For more precision around point  $m = 1$ , use `ellipkm1`, which this function calls.

The parameterization in terms of  $m$  follows that of section 17.2 in [1]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

## References

[1]

## scipy.special.ellipkm1

`scipy.special.ellipkm1(p) = <ufunc 'ellipkm1'>`  
Complete elliptic integral of the first kind around  $m = 1$

This function is defined as

$$K(p) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{-1/2} dt$$

where  $m = 1 - p$ .

### Parameters

**p** [array\_like] Defines the parameter of the elliptic integral as  $m = 1 - p$ .

### Returns

**K** [ndarray] Value of the elliptic integral.

See also:

### `ellipk`

Complete elliptic integral of the first kind

### `ellipkinc`

Incomplete elliptic integral of the first kind

### `ellipe`

Complete elliptic integral of the second kind

### `ellipeinc`

Incomplete elliptic integral of the second kind

## Notes

Wrapper for the Cephes [1] routine *ellpk*.

For  $p \leq 1$ , computation uses the approximation,

$$K(p) \approx P(p) - \log(p)Q(p),$$

where  $P$  and  $Q$  are tenth-order polynomials. The argument  $p$  is used internally rather than  $m$  so that the logarithmic singularity at  $m = 1$  will be shifted to the origin; this preserves maximum accuracy. For  $p > 1$ , the identity

$$K(p) = K(1/p)/\sqrt{p}$$

is used.

## References

[1]

## scipy.special.ellipkinc

`scipy.special.ellipkinc(phi, m) = <ufunc 'ellipkinc'>`

Incomplete elliptic integral of the first kind

This function is defined as

$$K(\phi, m) = \int_0^\phi [1 - m \sin(t)^2]^{-1/2} dt$$

This function is also called  $F(\phi, m)$ .

### Parameters

**phi** [array\_like] amplitude of the elliptic integral  
**m** [array\_like] parameter of the elliptic integral

### Returns

**K** [ndarray] Value of the elliptic integral

See also:

[ellipkm1](#)

Complete elliptic integral of the first kind, near  $m = 1$

## scipy.special.ellipe

`scipy.special.ellipe(m) = <ufunc 'ellipe'>`

Complete elliptic integral of the second kind

This function is defined as

$$E(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{1/2} dt$$

### Parameters

**m** [array\_like] Defines the parameter of the elliptic integral.

### Returns

**E** [ndarray] Value of the elliptic integral.

**See also:**

### `ellipkm1`

Complete elliptic integral of the first kind, near  $m = 1$

### `ellipk`

Complete elliptic integral of the first kind

### `ellipkinc`

Incomplete elliptic integral of the first kind

### `ellipeinc`

Incomplete elliptic integral of the second kind

## Notes

Wrapper for the Cephes [1] routine *ellpe*.

For  $m > 0$  the computation uses the approximation,

$$E(m) \approx P(1 - m) - (1 - m) \log(1 - m) Q(1 - m),$$

where  $P$  and  $Q$  are tenth-order polynomials. For  $m < 0$ , the relation

$$E(m) = E(m/(m - 1)) \sqrt{1 - m}$$

is used.

The parameterization in terms of  $m$  follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

## References

[1], [2]

## Examples

This function is used in finding the circumference of an ellipse with semi-major axis  $a$  and semi-minor axis  $b$ .

```
>>> from scipy import special
```

```
>>> a = 3.5
>>> b = 2.1
>>> e_sq = 1.0 - b**2/a**2 # eccentricity squared
```

Then the circumference is found using the following:

```
>>> C = 4*a*special.ellipse(e_sq) # circumference formula
>>> C
17.868899204378693
```

When  $a$  and  $b$  are the same (meaning eccentricity is 0), this reduces to the circumference of a circle.

```
>>> 4*a*special.ellipse(0.0) # formula for ellipse with a = b
21.991148575128552
>>> 2*np.pi*a # formula for circle of radius a
21.991148575128552
```

## scipy.special.ellipeinc

`scipy.special.ellipeinc(phi, m) = <ufunc 'ellipeinc'>`

Incomplete elliptic integral of the second kind

This function is defined as

$$E(\phi, m) = \int_0^\phi [1 - m \sin(t)^2]^{1/2} dt$$

### Parameters

**phi** [array\_like] amplitude of the elliptic integral.  
**m** [array\_like] parameter of the elliptic integral.

### Returns

**E** [ndarray] Value of the elliptic integral.

See also:

**ellipkm1**

Complete elliptic integral of the first kind, near  $m = 1$

**ellipk**

Complete elliptic integral of the first kind

**ellipkinc**

Incomplete elliptic integral of the first kind

**ellipe**

Complete elliptic integral of the second kind

**Notes**

Wrapper for the Cephes [1] routine *ellie*.

Computation uses arithmetic-geometric means algorithm.

The parameterization in terms of  $m$  follows that of section 17.2 in [2]. Other parameterizations in terms of the complementary parameter  $1 - m$ , modular angle  $\sin^2(\alpha) = m$ , or modulus  $k^2 = m$  are also used, so be careful that you choose the correct parameter.

**scipy.special.jv**

`scipy.special.jv(v, z) = <ufunc 'jv'>`

Bessel function of the first kind of real order and complex argument.

**Parameters**

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

**Returns**

**J** [ndarray] Value of the Bessel function,  $J_v(z)$ .

See also:

**jve**

$J_v$  with leading exponential behavior stripped off.

**spherical\_jn**

spherical Bessel functions.

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [1] `zbesj` routine, which exploits the connection to the modified Bessel function  $I_\nu$ ,

$$\begin{aligned} J_\nu(z) &= \exp(v\pi i/2) I_\nu(-iz) & (\Im z > 0) \\ J_\nu(z) &= \exp(-v\pi i/2) I_\nu(iz) & (\Im z < 0) \end{aligned}$$

For negative  $\nu$  values the formula,

$$J_{-\nu}(z) = J_\nu(z) \cos(\pi\nu) - Y_\nu(z) \sin(\pi\nu)$$

is used, where  $Y_\nu(z)$  is the Bessel function of the second kind, computed using the AMOS routine `zbesy`. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

Not to be confused with the spherical Bessel functions (see `spherical_jn`).

**References**

[1]

**scipy.special.jve**

`scipy.special.jve(v, z) = <ufunc 'jve'>`

Exponentially scaled Bessel function of order  $\nu$ .

Defined as:

```
jve(v, z) = jv(v, z) * exp(-abs(z.imag))
```

**Parameters**

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

**Returns**

**J** [ndarray] Value of the exponentially scaled Bessel function.

**Notes**

For positive  $\nu$  values, the computation is carried out using the AMOS [1] *zbesj* routine, which exploits the connection to the modified Bessel function  $I_\nu$ ,

$$\begin{aligned} J_\nu(z) &= \exp(v\pi i/2) I_\nu(-iz) & (\Im z > 0) \\ J_\nu(z) &= \exp(-v\pi i/2) I_\nu(iz) & (\Im z < 0) \end{aligned}$$

For negative  $\nu$  values the formula,

$$J_{-\nu}(z) = J_\nu(z) \cos(\pi\nu) - Y_\nu(z) \sin(\pi\nu)$$

is used, where  $Y_\nu(z)$  is the Bessel function of the second kind, computed using the AMOS routine *zbesy*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

**References**

[1]

**scipy.special.yn**

`scipy.special.yn(n, x) = <ufunc 'yn'>`

Bessel function of the second kind of integer order and real argument.

**Parameters**

**n** [array\_like] Order (integer).  
**z** [array\_like] Argument (float).

**Returns**

**Y** [ndarray] Value of the Bessel function,  $Y_n(x)$ .

**See also:**

**yv**

For real order and real or complex argument.

## Notes

Wrapper for the Cephes [1] routine `yn`.

The function is evaluated by forward recurrence on  $n$ , starting with values computed by the Cephes routines `y0` and `y1`. If  $n = 0$  or 1, the routine for `y0` or `y1` is called directly.

## References

[1]

## scipy.special.yv

`scipy.special.yv(v, z) = <ufunc 'yv'>`

Bessel function of the second kind of real order and complex argument.

### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

### Returns

**Y** [ndarray] Value of the Bessel function of the second kind,  $Y_v(x)$ .

**See also:**

### `yve`

$Y_v$  with leading exponential behavior stripped off.

## Notes

For positive  $\nu$  values, the computation is carried out using the AMOS [1] `zbesy` routine, which exploits the connection to the Hankel Bessel functions  $H_v^{(1)}$  and  $H_v^{(2)}$ ,

$$Y_\nu(z) = \frac{1}{2i}(H_\nu^{(1)} - H_\nu^{(2)}).$$

For negative  $\nu$  values the formula,

$$Y_{-\nu}(z) = Y_\nu(z) \cos(\pi\nu) + J_\nu(z) \sin(\pi\nu)$$

is used, where  $J_\nu(z)$  is the Bessel function of the first kind, computed using the AMOS routine `zbesj`. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

## References

[1]

### scipy.special.yve

`scipy.special.yve(v, z) = <ufunc 'yve'>`

Exponentially scaled Bessel function of the second kind of real order.

Returns the exponentially scaled Bessel function of the second kind of real order  $\nu$  at complex  $z$ :

$$yve(v, z) = yv(v, z) * \exp(-abs(z.imag))$$

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**Y** [ndarray] Value of the exponentially scaled Bessel function.

## Notes

For positive  $\nu$  values, the computation is carried out using the AMOS [1] *zbesy* routine, which exploits the connection to the Hankel Bessel functions  $H_\nu^{(1)}$  and  $H_\nu^{(2)}$ ,

$$Y_\nu(z) = \frac{1}{2i}(H_\nu^{(1)} - H_\nu^{(2)}).$$

For negative  $\nu$  values the formula,

$$Y_{-\nu}(z) = Y_\nu(z) \cos(\pi\nu) + J_\nu(z) \sin(\pi\nu)$$

is used, where  $J_\nu(z)$  is the Bessel function of the first kind, computed using the AMOS routine *zbesj*. Note that the second term is exactly zero for integer  $\nu$ ; to improve accuracy the second term is explicitly omitted for  $\nu$  values such that  $\nu = \text{floor}(\nu)$ .

## References

[1]

### scipy.special.kn

`scipy.special.kn(n, x) = <ufunc 'kn'>`

Modified Bessel function of the second kind of integer order  $n$

Returns the modified Bessel function of the second kind for integer order  $n$  at real  $z$ .

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions.

#### Parameters

**n** [array\_like of int] Order of Bessel functions (floats will truncate with a warning)  
**z** [array\_like of float] Argument at which to evaluate the Bessel functions

**Returns****out** [ndarray] The results**See also:****kv**

Same function, but accepts real order and complex argument

**kvp**

Derivative of this function

**Notes**Wrapper for AMOS [1] routine *zbesk*. For a discussion of the algorithm used, see [2] and the references therein.**References**

[1], [2]

**Examples**

Plot the function of several orders for real input:

```

>>> from scipy.special import kn
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in range(6):
... plt.plot(x, kn(N, x), label='$K_{%d}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_n(x)$')
>>> plt.show()

```

Calculate for a single value at multiple orders:

```
>>> kn([4, 5, 6], 1)
array([44.23241585, 360.9605896 , 3653.83831186])
```

## scipy.special.kv

`scipy.special.kv(v, z) = <ufunc 'kv'>`

Modified Bessel function of the second kind of real order  $\nu$

Returns the modified Bessel function of the second kind for real order  $\nu$  at complex  $z$ .

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions. They are defined as those solutions of the modified Bessel equation for which,

$$K_\nu(x) \sim \sqrt{\pi/(2x)} \exp(-x)$$

as  $x \rightarrow \infty$  [3].

### Parameters

**v** [array\_like of float] Order of Bessel functions  
**z** [array\_like of complex] Argument at which to evaluate the Bessel functions

### Returns

**out** [ndarray] The results. Note that input must be of complex type to get complex output, e.g. `kv(3, -2+0j)` instead of `kv(3, -2)`.

**See also:**

[kve](#)

This function with leading exponential behavior stripped off.

[kvp](#)

Derivative of this function

## Notes

Wrapper for AMOS [1] routine `zbesk`. For a discussion of the algorithm used, see [2] and the references therein.

## References

[1], [2], [3]

## Examples

Plot the function of several orders for real input:

```
>>> from scipy.special import kv
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in np.linspace(0, 6, 5):
... plt.plot(x, kv(N, x), label='$K_{\{\}\}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_{\nu}(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:

```
>>> kv([4, 4.5, 5], 1+2j)
array([0.1992+2.3892j, 2.3493+3.6j, 7.2827+3.8104j])
```

## scipy.special.kve

`scipy.special.kve(v, z) = <ufunc 'kve'>`

Exponentially scaled modified Bessel function of the second kind.

Returns the exponentially scaled, modified Bessel function of the second kind (sometimes called the third kind) for real order  $\nu$  at complex  $z$ :

```
kve(v, z) = kv(v, z) * exp(z)
```

### Parameters

- v** [array\_like of float] Order of Bessel functions
- z** [array\_like of complex] Argument at which to evaluate the Bessel functions

### Returns

**out** [ndarray] The exponentially scaled modified Bessel function of the second kind.

### Notes

Wrapper for AMOS [1] routine *zbesk*. For a discussion of the algorithm used, see [2] and the references therein.

### References

[1], [2]

## scipy.special.iv

`scipy.special.iv(v, z) = <ufunc 'iv'>`

Modified Bessel function of the first kind of real order.

#### Parameters

**v** [array\_like] Order. If *z* is of real type and negative, *v* must be integer valued.  
**z** [array\_like of float or complex] Argument.

#### Returns

**out** [ndarray] Values of the modified Bessel function.

#### See also:

#### [kve](#)

This function with leading exponential behavior stripped off.

### Notes

For real *z* and  $v \in [-50, 50]$ , the evaluation is carried out using Temme's method [1]. For larger orders, uniform asymptotic expansions are applied.

For complex *z* and positive *v*, the AMOS [2] *zbesi* routine is called. It uses a power series for small *z*, the asymptotic expansion for large  $\text{abs}(z)$ , the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for  $I_\nu(z)$  and  $J_\nu(z)$  for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_\nu(z \exp(\pm i\pi)) = \exp(\pm \nu\pi) I_\nu(z)$$

(valid when the real part of *z* is positive). For negative *v*, the formula

$$I_{-\nu}(z) = I_\nu(z) + \frac{2}{\pi} \sin(\pi\nu) K_\nu(z)$$

is used, where  $K_\nu(z)$  is the modified Bessel function of the second kind, evaluated using the AMOS routine *zbesk*.

## References

[1], [2]

### scipy.special.ive

`scipy.special.ive(v, z) = <ufunc 'ive'>`  
Exponentially scaled modified Bessel function of the first kind

Defined as:

```
ive(v, z) = iv(v, z) * exp(-abs(z.real))
```

#### Parameters

**v** [array\_like of float] Order.  
**z** [array\_like of float or complex] Argument.

#### Returns

**out** [ndarray] Values of the exponentially scaled modified Bessel function.

## Notes

For positive  $\nu$ , the AMOS [1] `zbesi` routine is called. It uses a power series for small  $z$ , the asymptotic expansion for large  $\text{abs}(z)$ , the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for  $I_\nu(z)$  and  $J_\nu(z)$  for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_\nu(z \exp(\pm i\pi)) = \exp(\pm \pi\nu) I_\nu(z)$$

(valid when the real part of  $z$  is positive). For negative  $\nu$ , the formula

$$I_{-\nu}(z) = I_\nu(z) + \frac{2}{\pi} \sin(\pi\nu) K_\nu(z)$$

is used, where  $K_\nu(z)$  is the modified Bessel function of the second kind, evaluated using the AMOS routine `zbesk`.

## References

[1]

### scipy.special.hankel1

`scipy.special.hankel1(v, z) = <ufunc 'hankel1'>`  
Hankel function of the first kind

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**out** [Values of the Hankel function of the first kind.]

**See also:**

`hankel1e`

this function with leading exponential behavior stripped off.

### Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(1)}(z) = \frac{2}{i\pi} \exp(-i\pi v/2) K_v(z \exp(-i\pi/2))$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(1)}(z) = H_v^{(1)}(z) \exp(i\pi v)$$

is used.

### References

[1]

### `scipy.special.hankel1e`

`scipy.special.hankel1e(v, z) = <ufunc 'hankel1e'>`

Exponentially scaled Hankel function of the first kind

Defined as:

```
hankel1e(v, z) = hankel1(v, z) * exp(-1j * z)
```

#### *Parameters*

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### *Returns*

**out** [Values of the exponentially scaled Hankel function.]

### Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(1)}(z) = \frac{2}{i\pi} \exp(-i\pi v/2) K_v(z \exp(-i\pi/2))$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(1)}(z) = H_v^{(1)}(z) \exp(i\pi v)$$

is used.

## References

[1]

### scipy.special.hankel2

`scipy.special.hankel2(v, z) = <ufunc 'hankel2'>`  
Hankel function of the second kind

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**out** [Values of the Hankel function of the second kind.]

See also:

#### [hankel2e](#)

this function with leading exponential behavior stripped off.

## Notes

A wrapper for the AMOS [1] routine *zbesh*, which carries out the computation using the relation,

$$H_v^{(2)}(z) = -\frac{2}{i\pi} \exp(i\pi v/2) K_v(z \exp(i\pi/2))$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(2)}(z) = H_v^{(2)}(z) \exp(-i\pi v)$$

is used.

## References

[1]

### scipy.special.hankel2e

`scipy.special.hankel2e(v, z) = <ufunc 'hankel2e'>`  
Exponentially scaled Hankel function of the second kind

Defined as:

```
hankel2e(v, z) = hankel2(v, z) * exp(1j * z)
```

#### Parameters

**v** [array\_like] Order (float).  
**z** [array\_like] Argument (float or complex).

#### Returns

**out** [Values of the exponentially scaled Hankel function of the second kind.]

## Notes

A wrapper for the AMOS [1] routine *zbes*, which carries out the computation using the relation,

$$H_v^{(2)}(z) = -\frac{2}{i\pi} \exp\left(\frac{i\pi v}{2}\right) K_v\left(z \exp\left(\frac{i\pi}{2}\right)\right)$$

where  $K_v$  is the modified Bessel function of the second kind. For negative orders, the relation

$$H_{-v}^{(2)}(z) = H_v^{(2)}(z) \exp(-i\pi v)$$

is used.

## References

[1]

## scipy.special.wright\_bessel

`scipy.special.wright_bessel(a, b, x) = <ufunc 'wright_bessel'>`  
Wright's generalized Bessel function.

Wright's generalized Bessel function is an entire function and defined as

$$\Phi(a, b; x) = \sum_{k=0}^{\infty} \frac{x^k}{k! \Gamma(ak + b)}$$

See also [1].

### Parameters

**a** [array\_like of float]  $a \geq 0$   
**b** [array\_like of float]  $b \geq 0$   
**x** [array\_like of float]  $x \geq 0$

## Notes

Due to the complexity of the function with its three parameters, only non-negative arguments are implemented.

## References

[1]

## Examples

```
>>> from scipy.special import wright_bessel
>>> a, b, x = 1.5, 1.1, 2.5
>>> wright_bessel(a, b-1, x)
4.5314465939443025
```

Now, let us verify the relation

$$\Phi(a, b - 1; x) = ax\Phi(a, b + a; x) + (b - 1)\Phi(a, b; x)$$

```
>>> a * x * wright_bessel(a, b+a, x) + (b-1) * wright_bessel(a, b, x)
4.53144465939443025
```

The following is not a universal function:

| <code>lmbda(v, x)</code> | Jahnke-Emden Lambda function, <code>Lambdav(x)</code> . |
|--------------------------|---------------------------------------------------------|

### scipy.special.lmbda

`scipy.special.lmbda(v, x)`  
 Jahnke-Emden Lambda function, `Lambdav(x)`.

This function is defined as [2],

$$\Lambda_v(x) = \Gamma(v + 1) \frac{J_v(x)}{(x/2)^v},$$

where  $\Gamma$  is the gamma function and  $J_v$  is the Bessel function of the first kind.

#### Parameters

- v** [float] Order of the Lambda function
- x** [float] Value at which to evaluate the function and derivatives

#### Returns

- vl** [ndarray] Values of `Lambda_vi(x)`, for  $vi=v-int(v)$ ,  $vi=1+v-int(v)$ , ...,  $vi=v$ .
- dl** [ndarray] Derivatives `Lambda_vi'(x)`, for  $vi=v-int(v)$ ,  $vi=1+v-int(v)$ , ...,  $vi=v$ .

**scipy.special.jnjnp\_zeros**`scipy.special.jnjnp_zeros` ( $nt$ )Compute zeros of integer-order Bessel functions  $J_n$  and  $J_n'$ .

Results are arranged in order of the magnitudes of the zeros.

**Parameters****nt** [int] Number ( $\leq 1200$ ) of zeros to compute**Returns****zo[l-1]** [ndarray] Value of the  $l$ th zero of  $J_n(x)$  and  $J_n'(x)$ . Of length  $nt$ .**n[l-1]** [ndarray] Order of the  $J_n(x)$  or  $J_n'(x)$  associated with  $l$ th zero. Of length  $nt$ .**m[l-1]** [ndarray] Serial number of the zeros of  $J_n(x)$  or  $J_n'(x)$  associated with  $l$ th zero. Of length  $nt$ .**t[l-1]** [ndarray] 0 if  $l$ th zero in  $zo$  is zero of  $J_n(x)$ , 1 if it is a zero of  $J_n'(x)$ . Of length  $nt$ .

## `scipy.special.jn_zeros`

`scipy.special.jn_zeros` (*n*, *nt*)

Compute zeros of integer-order Bessel functions  $J_n$ .

Compute *nt* zeros of the Bessel functions  $J_n(x)$  on the interval  $(0, \infty)$ . The zeros are returned in ascending order. Note that this interval excludes the zero at  $x = 0$  that exists for  $n > 0$ .

### Parameters

**n** [int] Order of Bessel function  
**nt** [int] Number of zeros to return

### Returns

**ndarray** First *n* zeros of the Bessel function.

See also:

`jv`

## References

[1]

## Examples

```
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with `jv`.

```
>>> n = 1
>>> x = sc.jn_zeros(n, 3)
>>> x
array([3.83170597, 7.01558667, 10.17346814])
>>> sc.jv(n, x)
array([-0.00000000e+00, 1.72975330e-16, 2.89157291e-16])
```

Note that the zero at  $x = 0$  for  $n > 0$  is not included.

```
>>> sc.jv(1, 0)
0.0
```

## scipy.special.jnp\_zeros

`scipy.special.jnp_zeros` ( $n$ ,  $nt$ )

Compute zeros of integer-order Bessel function derivatives  $J_n'$ .

Compute  $nt$  zeros of the functions  $J_n'(x)$  on the interval  $(0, \infty)$ . The zeros are returned in ascending order. Note that this interval excludes the zero at  $x = 0$  that exists for  $n > 1$ .

### Parameters

|           |                                 |
|-----------|---------------------------------|
| <b>n</b>  | [int] Order of Bessel function  |
| <b>nt</b> | [int] Number of zeros to return |

### Returns

**ndarray** First  $n$  zeros of the Bessel function.

## Examples

```
>>> import scipy.special as sc
```

We can check that we are getting approximations of the zeros by evaluating them with `jvp`.

```
>>> n = 2
>>> x = sc.jnp_zeros(n, 3)
>>> x
array([3.05423693, 6.70613319, 9.96946782])
>>> sc.jvp(n, x)
array([2.77555756e-17, 2.08166817e-16, -3.01841885e-16])
```

Note that the zero at  $x = 0$  for  $n > 1$  is not included.

```
>>> sc.jvp(n, 0)
0.0
```

## scipy.special.yn\_zeros

`scipy.special.yn_zeros` ( $n$ ,  $nt$ )

Compute zeros of integer-order Bessel function  $Y_n(x)$ .

Compute  $nt$  zeros of the functions  $Y_n(x)$  on the interval  $(0, \infty)$ . The zeros are returned in ascending order.

### Parameters

|           |                                 |
|-----------|---------------------------------|
| <b>n</b>  | [int] Order of Bessel function  |
| <b>nt</b> | [int] Number of zeros to return |

### Returns

**ndarray** First  $n$  zeros of the Bessel function.

**See also:**

>>> x = sc.ynp_zeros(n, 3)
>>> x
array([5.00258293, 8.3507247 , 11.57419547])
>>> sc.yvp(n, x)
array([2.220444605e-16, -3.33066907e-16, 2.94902991e-16])
```

## scipy.special.y0\_zeros

`scipy.special.y0_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel function  $Y_0(z)$ , and derivative at each zero.

The derivatives are given by  $Y_0'(z_0) = -Y_1(z_0)$  at each zero  $z_0$ .

### Parameters

**nt** [int] Number of zeros to return

**complex** [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

### Returns

**z0n** [ndarray] Location of *nth* zero of  $Y_0(z)$

**y0pz0n** [ndarray] Value of derivative  $Y_0'(z_0)$  for *nth* zero

## References

[1]

## scipy.special.y1\_zeros

`scipy.special.y1_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel function  $Y_1(z)$ , and derivative at each zero.

The derivatives are given by  $Y_1'(z_1) = Y_0(z_1)$  at each zero  $z_1$ .

### Parameters

**nt** [int] Number of zeros to return

**complex** [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

### Returns

**z1n** [ndarray] Location of *nth* zero of  $Y_1(z)$

**y1pz1n** [ndarray] Value of derivative  $Y_1'(z_1)$  for *nth* zero

## References

[1]

### scipy.special.y1p\_zeros

`scipy.special.y1p_zeros` (*nt*, *complex=False*)

Compute *nt* zeros of Bessel derivative  $Y_1'(z)$ , and value at each zero.

The values are given by  $Y_1(z_1)$  at each  $z_1$  where  $Y_1'(z_1)=0$ .

#### Parameters

**nt** [int] Number of zeros to return  
**complex** [bool, default False] Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

#### Returns

**z1pn** [ndarray] Location of *n*th zero of  $Y_1'(z)$   
**y1z1pn** [ndarray] Value of derivative  $Y_1(z_1)$  for *n*th zero

## References

| $k_0e(x)$ | Exponentially scaled modified Bessel function K of order 0         |
| $k_1(x)$  | Modified Bessel function of the second kind of order 1, $K_1(x)$ . |
| $k_1e(x)$ | Exponentially scaled modified Bessel function K of order 1         |

**scipy.special.j0**

`scipy.special.j0(x) = <ufunc 'j0'>`

Bessel function of the first kind of order 0.

**Parameters**

**x** [array\_like] Argument (float).

**Returns**

**J** [ndarray] Value of the Bessel function of the first kind of order 0 at  $x$ .

**See also:**

[jv](#)

Bessel function of real order and complex argument.

[spherical\\_jn](#)

spherical Bessel functions.

**Notes**

The domain is divided into the intervals  $[0, 5]$  and  $(5, \text{infinity})$ . In the first interval the following rational approximation is used:

$$J_0(x) \approx (w - r_1^2)(w - r_2^2) \frac{P_3(w)}{Q_8(w)},$$

where  $w = x^2$  and  $r_1, r_2$  are the zeros of  $J_0$ , and  $P_3$  and  $Q_8$  are polynomials of degrees 3 and 8, respectively.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine `j0`. It should not be confused with the spherical Bessel functions (see [spherical\\_jn](#)).

**References**

[1]

**scipy.special.j1**

`scipy.special.j1(x) = <ufunc 'j1'>`

Bessel function of the first kind of order 1.

**Parameters**

**x** [array\_like] Argument (float).

**Returns**

**J** [ndarray] Value of the Bessel function of the first kind of order 1 at  $x$ .

**See also:**

[jv](#)

### spherical\_jn

spherical Bessel functions.

#### Notes

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 24 term Chebyshev expansion is used. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine *j1*. It should not be confused with the spherical Bessel functions (see *spherical\_jn*).

#### References

[1]

### scipy.special.y0

`scipy.special.y0(x) = <ufunc 'y0'>`

Bessel function of the second kind of order 0.

#### Parameters

**x** [array\_like] Argument (float).

#### Returns

**Y** [ndarray] Value of the Bessel function of the second kind of order 0 at *x*.

See also:

[j0](#)

[yv](#)

#### Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval a rational approximation  $R(x)$  is employed to compute,

$$Y_0(x) = R(x) + \frac{2 \log(x) J_0(x)}{\pi},$$

where  $J_0$  is the Bessel function of the first kind of order 0.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [1] routine *y0*.

## References

[1]

### scipy.special.y1

`scipy.special.y1(x) = <ufunc 'y1'>`  
Bessel function of the second kind of order 1.

#### Parameters

**x** [array\_like] Argument (float).

#### Returns

**Y** [ndarray] Value of the Bessel function of the second kind of order 1 at  $x$ .

See also:

[j1](#)

[yn](#)

[yv](#)

## Notes

The domain is divided into the intervals  $[0, 8]$  and  $(8, \infty)$ . In the first interval a 25 term Chebyshev expansion is used, and computing  $J_1$  (the Bessel function of the first kind) is required. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [1] routine `y1`.

## References

[1]

### scipy.special.i0

`scipy.special.i0(x) = <ufunc 'i0'>`  
Modified Bessel function of order 0.

Defined as,

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(ix),$$

where  $J_0$  is the Bessel function of the first kind of order 0.

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**I** [ndarray] Value of the modified Bessel function of order 0 at  $x$ .

**See also:**

[iv](#)

[i0e](#)

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *i0*.

**References**

[1]

**scipy.special.i0e**

`scipy.special.i0e(x) = <ufunc 'i0e'>`  
 Exponentially scaled modified Bessel function of order 0.

Defined as:

$$i0e(x) = \exp(-\text{abs}(x)) * i0(x) .$$

**Parameters**

**x** [array\_like] Argument (float)

**Returns**

**I** [ndarray] Value of the exponentially scaled modified Bessel function of order 0 at *x*.

**See also:**

[iv](#)

[i0](#)

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in *i0*, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine *i0e*.

## References

[1]

### scipy.special.i1

`scipy.special.i1(x) = <ufunc 'i1'>`

Modified Bessel function of order 1.

Defined as,

$$I_1(x) = \frac{1}{2}x \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k+1)!} = -iJ_1(ix),$$

where  $J_1$  is the Bessel function of the first kind of order 1.

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**I** [ndarray] Value of the modified Bessel function of order 1 at  $x$ .

See also:

[iv](#)

[i1e](#)

## Notes

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine `i1`.

## References

[1]

### scipy.special.i1e

`scipy.special.i1e(x) = <ufunc 'i1e'>`

Exponentially scaled modified Bessel function of order 1.

Defined as:

```
i1e(x) = exp(-abs(x)) * i1(x)
```

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**I** [ndarray] Value of the exponentially scaled modified Bessel function of order 1 at  $x$ .

**See also:**

[iv](#)

[i1](#)

### Notes

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in [i1](#), but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine [i1e](#).

### References

[1]

## scipy.special.k0

`scipy.special.k0(x) = <ufunc 'k0'>`

Modified Bessel function of the second kind of order 0,  $K_0$ .

This function is also sometimes referred to as the modified Bessel function of the third kind of order 0.

#### *Parameters*

**x** [array\_like] Argument (float).

#### *Returns*

**K** [ndarray] Value of the modified Bessel function  $K_0$  at  $x$ .

**See also:**

[kv](#)

[k0e](#)

### Notes

The range is partitioned into the two intervals  $[0, 2]$  and  $(2, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine [k0](#).

## References

[1]

### scipy.special.k0e

`scipy.special.k0e(x) = <ufunc 'k0e'>`  
 Exponentially scaled modified Bessel function K of order 0

Defined as:

$$k0e(x) = \exp(x) * k0(x) .$$

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**K** [ndarray] Value of the exponentially scaled modified Bessel function K of order 0 at  $x$ .

See also:

[kv](#)

[k0](#)

#### Notes

The range is partitioned into the two intervals  $[0, 2]$  and  $(2, \infty)$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *k0e*.

## References

[1]

### scipy.special.k1

`scipy.special.k1(x) = <ufunc 'k1'>`  
 Modified Bessel function of the second kind of order 1,  $K_1(x)$ .

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**K** [ndarray] Value of the modified Bessel function K of order 1 at  $x$ .

See also:

[kv](#)

[k1e](#)

### Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *k1*.

### References

[1]

### scipy.special.k1e

`scipy.special.k1e(x) = <ufunc 'k1e'>`  
 Exponentially scaled modified Bessel function K of order 1

Defined as:

$$k1e(x) = \exp(x) * k1(x)$$

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**K** [ndarray] Value of the exponentially scaled modified Bessel function K of order 1 at *x*.

See also:

[kv](#)

[k1](#)

### Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *k1e*.

### scipy.special.itj0y0

`scipy.special.itj0y0(x, out=None) = <ufunc 'itj0y0'>`

Integrals of Bessel functions of the first kind of order 0.

Computes the integrals

$$\int_0^x J_0(t) dt$$

$$\int_0^x Y_0(t) dt.$$

For more on  $J_0$  and  $Y_0$  see `j0` and `y0`.

#### Parameters

**x** [array\_like] Values at which to evaluate the integrals.  
**out** [tuple of ndarrays, optional] Optional output arrays for the function results.

#### Returns

**ij0** [scalar or ndarray] The integral of `j0`  
**iy0** [scalar or ndarray] The integral of `y0`

### scipy.special.it2j0y0

`scipy.special.it2j0y0(x, out=None) = <ufunc 'it2j0y0'>`

Integrals related to Bessel functions of the first kind of order 0.

Computes the integrals

$$\int_0^x \frac{1 - J_0(t)}{t} dt$$

$$\int_x^\infty \frac{Y_0(t)}{t} dt.$$

For more on  $J_0$  and  $Y_0$  see `j0` and `y0`.

#### Parameters

**x** [array\_like] Values at which to evaluate the integrals.  
**out** [tuple of ndarrays, optional] Optional output arrays for the function results.

#### Returns

**ij0** [scalar or ndarray] The integral for `j0`  
**iy0** [scalar or ndarray] The integral for `y0`

### scipy.special.iti0k0

`scipy.special.iti0k0(x, out=None) = <ufunc 'iti0k0'>`

Integrals of modified Bessel functions of order 0.

Computes the integrals

$$\int_0^x I_0(t) dt$$

$$\int_0^x K_0(t) dt.$$

For more on  $I_0$  and  $K_0$  see [i0](#) and [k0](#).

#### Parameters

- x** [array\_like] Values at which to evaluate the integrals.
- out** [tuple of ndarrays, optional] Optional output arrays for the function results.

#### Returns

- ii0** [scalar or ndarray] The integral for [i0](#)
- ik0** [scalar or ndarray] The integral for [k0](#)

### scipy.special.it2i0k0

`scipy.special.it2i0k0(x, out=None) = <ufunc 'it2i0k0'>`

Integrals related to modified Bessel functions of order 0.

Computes the integrals

$$\int_0^x \frac{I_0(t) - 1}{t} dt$$

$$\int_x^\infty \frac{K_0(t)}{t} dt.$$

#### Parameters

- x** [array\_like] Values at which to evaluate the integrals.
- out** [tuple of ndarrays, optional] Optional output arrays for the function results.

#### Returns

- ii0** [scalar or ndarray] The integral for [i0](#)
- ik0** [scalar or ndarray] The integral for [k0](#)

### scipy.special.besselpoly

`scipy.special.besselpoly(a, lmb, nu, out=None) = <ufunc 'besselpoly'>`

Weighted integral of the Bessel function of the first kind.

Computes

$$\int_0^1 x^\lambda J_\nu(2ax) dx$$

where  $J_\nu$  is a Bessel function and  $\lambda = lmb, \nu = nu$ .

**Parameters**

|            |                                                                     |
|------------|---------------------------------------------------------------------|
| <b>a</b>   | [array_like] Scale factor inside the Bessel function.               |
| <b>lmb</b> | [array_like] Power of $x$                                           |
| <b>nu</b>  | [array_like] Order of the Bessel function.                          |
| <b>out</b> | [ndarray, optional] Optional output array for the function results. |

**Returns**

**scalar or ndarray**  
Value of the integral.

**Derivatives of Bessel functions**

|                              |                                                                             |
|------------------------------|-----------------------------------------------------------------------------|
| <code>jvp(v, z[, n])</code>  | Compute derivatives of Bessel functions of the first kind.                  |
| <code>yvp(v, z[, n])</code>  | Compute derivatives of Bessel functions of the second kind.                 |
| <code>kvp(v, z[, n])</code>  | Compute nth derivative of real-order modified Bessel function $K_v(z)$      |
| <code>ivp(v, z[, n])</code>  | Compute derivatives of modified Bessel functions of the first kind.         |
| <code>h1vp(v, z[, n])</code> | Compute nth derivative of Hankel function $H_{1v}(z)$ with respect to $z$ . |
| <code>h2vp(v, z[, n])</code> | Compute nth derivative of Hankel function $H_{2v}(z)$ with respect to $z$ . |

**scipy.special.jvp**

`scipy.special.jvp(v, z, n=1)`

Compute derivatives of Bessel functions of the first kind.

Compute the nth derivative of the Bessel function  $J_\nu$  with respect to  $z$ .

**Parameters**

|          |                                                                                 |
|----------|---------------------------------------------------------------------------------|
| <b>v</b> | [float] Order of Bessel function                                                |
| <b>z</b> | [complex] Argument at which to evaluate the derivative; can be real or complex. |
| <b>n</b> | [int, default 1] Order of derivative                                            |

**Returns**

**scalar or ndarray**  
Values of the derivative of the Bessel function.

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [2].

## References

[1], [2]

### scipy.special.yvp

`scipy.special.yvp` ( $v, z, n=1$ )

Compute derivatives of Bessel functions of the second kind.

Compute the  $n$ th derivative of the Bessel function  $Y_\nu$  with respect to  $z$ .

#### Parameters

|          |                                                        |
|----------|--------------------------------------------------------|
| <b>v</b> | [float] Order of Bessel function                       |
| <b>z</b> | [complex] Argument at which to evaluate the derivative |
| <b>n</b> | [int, default 1] Order of derivative                   |

#### Returns

**scalar or ndarray**  
nth derivative of the Bessel function.

## Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

## References

[1], [2]

### scipy.special.kvp

`scipy.special.kvp` ( $v, z, n=1$ )

Compute  $n$ th derivative of real-order modified Bessel function  $K_\nu(z)$

$K_\nu(z)$  is the modified Bessel function of the second kind. Derivative is calculated with respect to  $z$ .

#### Parameters

|          |                                                                      |
|----------|----------------------------------------------------------------------|
| <b>v</b> | [array_like of float] Order of Bessel function                       |
| <b>z</b> | [array_like of complex] Argument at which to evaluate the derivative |
| <b>n</b> | [int] Order of derivative. Default is first derivative.              |

#### Returns

**out** [ndarray] The results

## Notes

The derivative is computed using the relation DLFM 10.29.5 [2].

## References

[1], [2]

## Examples

Calculate multiple values at order 5:

```
>>> from scipy.special import kvp
>>> kvp(5, (1, 2, 3+5j))
array([-1.84903536e+03+0.j , -2.57735387e+01+0.j ,
 -3.06627741e-02+0.08750845j])
```

Calculate for a single value at multiple orders:

```
>>> kvp((4, 4.5, 5), 1)
array([-184.0309, -568.9585, -1849.0354])
```

## scipy.special.ivp

`scipy.special.ivp(v, z, n=1)`

Compute derivatives of modified Bessel functions of the first kind.

Compute the  $n$ th derivative of the modified Bessel function  $I_v$  with respect to  $z$ .

### Parameters

|          |                                                                                    |
|----------|------------------------------------------------------------------------------------|
| <b>v</b> | [array_like] Order of Bessel function                                              |
| <b>z</b> | [array_like] Argument at which to evaluate the derivative; can be real or complex. |
| <b>n</b> | [int, default 1] Order of derivative                                               |

### Returns

**scalar or ndarray**  
 $n$ th derivative of the modified Bessel function.

See also:

`iv`

## Notes

The derivative is computed using the relation DLFM 10.29.5 [2].

## References

[1], [2]

### scipy.special.h1vp

`scipy.special.h1vp` ( $v, z, n=1$ )

Compute nth derivative of Hankel function  $H_1v(z)$  with respect to  $z$ .

#### Parameters

**v** [array\_like] Order of Hankel function  
**z** [array\_like] Argument at which to evaluate the derivative. Can be real or complex.  
**n** [int, default 1] Order of derivative

#### Returns

**scalar or ndarray**  
Values of the derivative of the Hankel function.

## Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

## References

[1], [2]

### scipy.special.h2vp

`scipy.special.h2vp` ( $v, z, n=1$ )

Compute nth derivative of Hankel function  $H_2v(z)$  with respect to  $z$ .

#### Parameters

**v** [array\_like] Order of Hankel function  
**z** [array\_like] Argument at which to evaluate the derivative. Can be real or complex.  
**n** [int, default 1] Order of derivative

#### Returns

**scalar or ndarray**  
Values of the derivative of the Hankel function.

## Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

## References

[1], [2]

## Spherical Bessel functions

|                                               |                                                                          |
|-----------------------------------------------|--------------------------------------------------------------------------|
| <code>spherical_jn(n, z[, derivative])</code> | Spherical Bessel function of the first kind or its derivative.           |
| <code>spherical_yn(n, z[, derivative])</code> | Spherical Bessel function of the second kind or its derivative.          |
| <code>spherical_in(n, z[, derivative])</code> | Modified spherical Bessel function of the first kind or its derivative.  |
| <code>spherical_kn(n, z[, derivative])</code> | Modified spherical Bessel function of the second kind or its derivative. |

## scipy.special.spherical\_jn

`scipy.special.spherical_jn(n, z, derivative=False)`  
Spherical Bessel function of the first kind or its derivative.

Defined as [1],

$$j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z),$$

where  $J_n$  is the Bessel function of the first kind.

### Parameters

- n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).
- z** [complex or float, array\_like] Argument of the Bessel function.
- derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

### Returns

- jn** [ndarray]

## Notes

For real arguments greater than the order, the function is computed using the ascending recurrence [2]. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations [3],

$$j'_n(z) = j_{n-1}(z) - \frac{n+1}{z} j_n(z).$$

$$j'_0(z) = -j_1(z)$$

New in version 0.18.0.

## References

[1], [2], [3]

### scipy.special.spherical\_yn

`scipy.special.spherical_yn` ( $n, z, derivative=False$ )  
Spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z),$$

where  $Y_n$  is the Bessel function of the second kind.

#### Parameters

**n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).  
**z** [complex or float, array\_like] Argument of the Bessel function.  
**derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

#### Returns

**yn** [ndarray]

## Notes

For real arguments, the function is computed using the ascending recurrence [2]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [3],

$$y'_n = y_{n-1} - \frac{n+1}{z} y_n.$$
$$y'_0 = -y_1$$

New in version 0.18.0.

## References

[1], [2], [3]

### scipy.special.spherical\_in

`scipy.special.spherical_in` ( $n, z, derivative=False$ )  
Modified spherical Bessel function of the first kind or its derivative.

Defined as [1],

$$i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z),$$

where  $I_n$  is the modified Bessel function of the first kind.

#### Parameters

**n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).  
**z** [complex or float, array\_like] Argument of the Bessel function.  
**derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

**in** [ndarray]

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind.

The derivative is computed using the relations [2],

$$i'_n = i_{n-1} - \frac{n+1}{z} i_n.$$

$$i'_1 = i_0$$

New in version 0.18.0.

**References**

[1], [2]

**scipy.special.spherical\_kn**

`scipy.special.spherical_kn` ( $n, z, derivative=False$ )

Modified spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$k_n(z) = \sqrt{\frac{\pi}{2z}} K_{n+1/2}(z),$$

where  $K_n$  is the modified Bessel function of the second kind.

**Parameters**

**n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).  
**z** [complex or float, array\_like] Argument of the Bessel function.  
**derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

**kn** [ndarray]

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations [2],

$$k'_n = -k_{n-1} - \frac{n+1}{z} k_n.$$

$$k'_0 = -k_1$$

New in version 0.18.0.

## Riccati-Bessel functions

These are not universal functions:

|                               |                                                                        |
|-------------------------------|------------------------------------------------------------------------|
| <code>riccati_jn(n, x)</code> | Compute Riccati-Bessel function of the first kind and its derivative.  |
| <code>riccati_yn(n, x)</code> | Compute Riccati-Bessel function of the second kind and its derivative. |

## scipy.special.riccati\_jn

`scipy.special.riccati_jn(n, x)`

Compute Riccati-Bessel function of the first kind and its derivative.

The Riccati-Bessel function of the first kind is defined as  $xj_n(x)$ , where  $j_n$  is the spherical Bessel function of the first kind of order  $n$ .

This function computes the value and first derivative of the Riccati-Bessel function for all orders up to and including  $n$ .

### Parameters

**n** [int] Maximum order of function to compute  
**x** [float] Argument at which to evaluate

### Returns

**jn** [ndarray] Value of  $j_0(x), \dots, j_n(x)$   
**jnp** [ndarray] First derivative  $j_0'(x), \dots, j_n'(x)$

## Notes

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

## References

[1], [2]

## scipy.special.riccati\_yn

`scipy.special.riccati_yn(n, x)`

Compute Riccati-Bessel function of the second kind and its derivative.

The Riccati-Bessel function of the second kind is defined as  $xy_n(x)$ , where  $y_n$  is the spherical Bessel function of the second kind of order  $n$ .

This function computes the value and first derivative of the function for all orders up to and including  $n$ .

### Parameters

**n** [int] Maximum order of function to compute  
**x** [float] Argument at which to evaluate

### Returns

**yn** [ndarray] Value of  $y_0(x), \dots, y_n(x)$   
**ynp** [ndarray] First derivative  $y_0'(x), \dots, y_n'(x)$

### Notes

The computation is carried out via ascending recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

### References

[1], [2]

## Struve functions

|                              |                                                      |
|------------------------------|------------------------------------------------------|
| <code>struve(v, x)</code>    | Struve function.                                     |
| <code>modstruve(v, x)</code> | Modified Struve function.                            |
| <code>itstruve0(x)</code>    | Integral of the Struve function of order 0.          |
| <code>it2struve0(x)</code>   | Integral related to the Struve function of order 0.  |
| <code>itmodstruve0(x)</code> | Integral of the modified Struve function of order 0. |

## scipy.special.struve

`scipy.special.struve(v, x) = <ufunc 'struve'>`

Struve function.

Return the value of the Struve function of order  $\nu$  at  $x$ . The Struve function is defined as,

$$H_\nu(x) = (z/2)^{\nu+1} \sum_{n=0}^{\infty} \frac{(-1)^n (z/2)^{2n}}{\Gamma(n + \frac{3}{2})\Gamma(n + \nu + \frac{3}{2})},$$

where  $\Gamma$  is the gamma function.

### Parameters

**v** [array\_like] Order of the Struve function (float).  
**x** [array\_like] Argument of the Struve function (float; must be positive unless  $\nu$  is an integer).

### Returns

**H** [ndarray] Value of the Struve function of order  $\nu$  at  $x$ .

**See also:**

[modstruve](#)

### Notes

Three methods discussed in [1] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if  $|z| < |v| + 20$ )
- asymptotic large- $z$  expansion (if  $z \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

### References

[1]

## scipy.special.modstruve

`scipy.special.modstruve( $\nu, x$ ) = <ufunc 'modstruve'>`

Modified Struve function.

Return the value of the modified Struve function of order  $\nu$  at  $x$ . The modified Struve function is defined as,

$$L_\nu(x) = -i \exp(-\pi\nu/2) H_\nu(ix),$$

where  $H_\nu$  is the Struve function.

#### Parameters

- $\nu$**  [array\_like] Order of the modified Struve function (float).
- $x$**  [array\_like] Argument of the Struve function (float; must be positive unless  $\nu$  is an integer).

#### Returns

- L** [ndarray] Value of the modified Struve function of order  $\nu$  at  $x$ .

**See also:**

[struve](#)

### Notes

Three methods discussed in [1] are used to evaluate the function:

- power series
- expansion in Bessel functions (if  $|x| < |v| + 20$ )
- asymptotic large- $x$  expansion (if  $x \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

## References

### scipy.special.itstruve0

`scipy.special.itstruve0(x) = <ufunc 'itstruve0'>`  
Integral of the Struve function of order 0.

$$I = \int_0^x H_0(t) dt$$

#### Parameters

**x** [array\_like] Upper limit of integration (float).

#### Returns

**I** [ndarray] The integral of  $H_0$  from 0 to  $x$ .

See also:

`struve`

## Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

## References

[1]

### scipy.special.it2struve0

`scipy.special.it2struve0(x) = <ufunc 'it2struve0'>`  
Integral related to the Struve function of order 0.

Returns the integral,

$$\int_x^\infty \frac{H_0(t)}{t} dt$$

where  $H_0$  is the Struve function of order 0.

#### Parameters

**x** [array\_like] Lower limit of integration.

#### Returns

**I** [ndarray] The value of the integral.

See also:

`struve`

## Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

## References

| <i>gdtrix</i> (a, b, p[, out])    | Inverse of <i>gdttr</i> vs x.                                                      |
| <i>nbdtr</i> (k, n, p)            | Negative binomial cumulative distribution function.                                |
| <i>nbdtrc</i> (k, n, p)           | Negative binomial survival function.                                               |
| <i>nbdtri</i> (k, n, y)           | Inverse of <i>nbdtr</i> vs p.                                                      |
| <i>nbdtrik</i> (y, n, p)          | Inverse of <i>nbdtr</i> vs k.                                                      |
| <i>nbdtrin</i> (k, y, p)          | Inverse of <i>nbdtr</i> vs n.                                                      |
| <i>ncfdtr</i> (dfn, dfd, nc, f)   | Cumulative distribution function of the non-central F distribution.                |
| <i>ncfdtridfd</i> (dfn, p, nc, f) | Calculate degrees of freedom (denominator) for the non-central F-distribution.     |
| <i>ncfdtridfn</i> (p, dfd, nc, f) | Calculate degrees of freedom (numerator) for the non-central F-distribution.       |
| <i>ncfdtri</i> (dfn, dfd, nc, p)  | Inverse with respect to <i>f</i> of the CDF of the non-central F distribution.     |
| <i>ncfdtrinc</i> (dfn, dfd, p, f) | Calculate non-centrality parameter for non-central F distribution.                 |
| <i>nctdtr</i> (df, nc, t)         | Cumulative distribution function of the non-central <i>t</i> distribution.         |
| <i>nctdtridf</i> (p, nc, t)       | Calculate degrees of freedom for non-central <i>t</i> distribution.                |
| <i>nctdtrit</i> (df, nc, p)       | Inverse cumulative distribution function of the non-central <i>t</i> distribution. |
| <i>nctdtrinc</i> (df, p, t)       | Calculate non-centrality parameter for non-central <i>t</i> distribution.          |
| <i>nrtrimn</i> (p, x, std)        | Calculate mean of normal distribution given other params.                          |
| <i>nrtrisd</i> (p, x, mn)         | Calculate standard deviation of normal distribution given other params.            |
| <i>pdtr</i> (k, m[, out])         | Poisson cumulative distribution function.                                          |
| <i>pdtrc</i> (k, m)               | Poisson survival function                                                          |
| <i>pdtri</i> (k, y)               | Inverse to <i>pdtr</i> vs m                                                        |
| <i>pdtrik</i> (p, m)              | Inverse to <i>pdtr</i> vs k                                                        |
| <i>stdtr</i> (df, t)              | Student <i>t</i> distribution cumulative distribution function                     |
| <i>stdtridf</i> (p, t)            | Inverse of <i>stdtr</i> vs df                                                      |
| <i>stdtrit</i> (df, p)            | Inverse of <i>stdtr</i> vs <i>t</i>                                                |
| <i>chdtr</i> (v, x[, out])        | Chi square cumulative distribution function.                                       |
| <i>chdtrc</i> (v, x[, out])       | Chi square survival function.                                                      |
| <i>chdtri</i> (v, p[, out])       | Inverse to <i>chdtrc</i> with respect to <i>x</i> .                                |
| <i>chdtriv</i> (p, x[, out])      | Inverse to <i>chdtr</i> with respect to <i>v</i> .                                 |
| <i>ndtr</i> (x)                   | Gaussian cumulative distribution function.                                         |
| <i>log_ndtr</i> (x)               | Logarithm of Gaussian cumulative distribution function.                            |
| <i>ndtri</i> (y)                  | Inverse of <i>ndtr</i> vs <i>x</i>                                                 |
| <i>ndtri_exp</i> (y)              | Inverse of <i>log_ndtr</i> vs <i>x</i> .                                           |
| <i>chndtr</i> (x, df, nc)         | Non-central chi square cumulative distribution function                            |
| <i>chndtridf</i> (x, p, nc)       | Inverse to <i>chndtr</i> vs <i>df</i>                                              |
| <i>chndtrinc</i> (x, df, p)       | Inverse to <i>chndtr</i> vs <i>nc</i>                                              |
| <i>chndtrix</i> (p, df, nc)       | Inverse to <i>chndtr</i> vs <i>x</i>                                               |

| <code>boxcox(x, lmbda)</code>       | Compute the Box-Cox transformation.                                                            |
| <code>boxcox1p(x, lmbda)</code>     | Compute the Box-Cox transformation of $1 + x$ .                                                |
| <code>inv_boxcox(y, lmbda)</code>   | Compute the inverse of the Box-Cox transformation.                                             |
| <code>inv_boxcox1p(y, lmbda)</code> | Compute the inverse of the Box-Cox transformation.                                             |
| <code>owens_t(h, a)</code>          | Owen's T Function.                                                                             |

### scipy.special.bdtr

`scipy.special.bdtr(k, n, p) = <ufunc 'bdtr'>`

Binomial distribution cumulative distribution function.

Sum of the terms 0 through  $\text{floor}(k)$  of the Binomial probability density.

$$\text{bdtr}(k, n, p) = \sum_{j=0}^{\lfloor k \rfloor} \binom{n}{j} p^j (1-p)^{n-j}$$

#### Parameters

- k** [array\_like] Number of successes (double), rounded down to the nearest integer.
- n** [array\_like] Number of events (int).
- p** [array\_like] Probability of success in a single event (float).

#### Returns

- y** [ndarray] Probability of  $\text{floor}(k)$  or fewer successes in  $n$  independent events with success probabilities of  $p$ .

#### Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtr}(k, n, p) = I_{1-p}(n - \lfloor k \rfloor, \lfloor k \rfloor + 1).$$

Wrapper for the Cephes [1] routine `bdtr`.

## References

[1]

### scipy.special.bdtrc

`scipy.special.bdtrc(k, n, p) = <ufunc 'bdtrc'>`

Binomial distribution survival function.

Sum of the terms  $\text{floor}(k) + 1$  through  $n$  of the binomial probability density,

$$\text{bdtrc}(k, n, p) = \sum_{j=\lfloor k \rfloor + 1}^n \binom{n}{j} p^j (1-p)^{n-j}$$

#### Parameters

- k** [array\_like] Number of successes (double), rounded down to nearest integer.
- n** [array\_like] Number of events (int)
- p** [array\_like] Probability of success in a single event.

#### Returns

- y** [ndarray] Probability of  $\text{floor}(k) + 1$  or more successes in  $n$  independent events with success probabilities of  $p$ .

See also:

[bdtr](#)

[betainc](#)

## Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtrc}(k, n, p) = I_p(\lfloor k \rfloor + 1, n - \lfloor k \rfloor).$$

Wrapper for the Cephes [1] routine `bdtrc`.

## References

[1]

### scipy.special.bdtri

`scipy.special.bdtri(k, n, y) = <ufunc 'bdtri'>`

Inverse function to `bdtr` with respect to  $p$ .

Finds the event probability  $p$  such that the sum of the terms 0 through  $k$  of the binomial probability density is equal to the given cumulative probability  $y$ .

#### Parameters

- k** [array\_like] Number of successes (float), rounded down to the nearest integer.

**n** [array\_like] Number of events (float)  
**y** [array\_like] Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).

**Returns**

**p** [ndarray] The event probability such that  $bdtr(\lfloor k \rfloor, n, p) = y$ .

See also:

[bdtr](#)  
[betaincinv](#)

**Notes**

The computation is carried out using the inverse beta integral function and the relation,:

$$1 - p = \text{betaincinv}(n - k, k + 1, y).$$

Wrapper for the Cephes [1] routine *bdtri*.

**References**

[1]

**scipy.special.bdtrik**

`scipy.special.bdtrik(y, n, p) = <ufunc 'bdtrik'>`  
 Inverse function to *bdtr* with respect to  $k$ .

Finds the number of successes  $k$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for  $n$  events with probability  $p$  is equal to the given cumulative probability  $y$ .

**Parameters**

**y** [array\_like] Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).  
**n** [array\_like] Number of events (float).  
**p** [array\_like] Success probability (float).

**Returns**

**k** [ndarray] The number of successes  $k$  such that  $bdtr(k, n, p) = y$ .

See also:

[bdtr](#)

## Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

Wrapper for the CDFLIB [2] Fortran routine *cdfbin*.

## References

[1], [2]

## scipy.special.bdtrn

`scipy.special.bdtrn(k, y, p) = <ufunc 'bdtrn'>`

Inverse function to *bdtr* with respect to  $n$ .

Finds the number of events  $n$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for events with probability  $p$  is equal to the given cumulative probability  $y$ .

### Parameters

|          |                                                                                            |
|----------|--------------------------------------------------------------------------------------------|
| <b>k</b> | [array_like] Number of successes (float).                                                  |
| <b>y</b> | [array_like] Cumulative probability (probability of $k$ or fewer successes in $n$ events). |
| <b>p</b> | [array_like] Success probability (float).                                                  |

### Returns

|          |                                                                    |
|----------|--------------------------------------------------------------------|
| <b>n</b> | [ndarray] The number of events $n$ such that $bdtr(k, n, p) = y$ . |
|----------|--------------------------------------------------------------------|

See also:

[bdtr](#)

## Notes

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

Wrapper for the CDFLIB [2] Fortran routine *cdfbin*.

## References

[1], [2]

**scipy.special.btdtr**

`scipy.special.btdtr(a, b, x) = <ufunc 'btdtr'>`

Cumulative distribution function of the beta distribution.

Returns the integral from zero to  $x$  of the beta probability density function,

$$I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

where  $\Gamma$  is the gamma function.

**Parameters**

- a** [array\_like] Shape parameter ( $a > 0$ ).
- b** [array\_like] Shape parameter ( $b > 0$ ).
- x** [array\_like] Upper limit of integration, in  $[0, 1]$ .

**Returns**

- I** [ndarray] Cumulative distribution function of the beta distribution with parameters  $a$  and  $b$  at  $x$ .

See also:

[betainc](#)

**Notes**

This function is identical to the incomplete beta integral function [betainc](#).

Wrapper for the Cephes [1] routine [btdtr](#).

**References**

[1]

**scipy.special.btdtri**

`scipy.special.btdtri(a, b, p) = <ufunc 'btdtri'>`

The  $p$ -th quantile of the beta distribution.

This function is the inverse of the beta cumulative distribution function, [btdtr](#), returning the value of  $x$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**

- a** [array\_like] Shape parameter ( $a > 0$ ).
- b** [array\_like] Shape parameter ( $b > 0$ ).
- p** [array\_like] Cumulative probability, in  $[0, 1]$ .

**Returns**

- x** [ndarray] The quantile corresponding to  $p$ .

See also:

`betaincinv`

`btdtr`

## Notes

The value of  $x$  is found by interval halving or Newton iterations.

Wrapper for the Cephes [1] routine *incbi*, which solves the equivalent problem of finding the inverse of the incomplete beta integral.

## References

[1]

## `scipy.special.btdtria`

`scipy.special.btdtria(p, b, x) = <ufunc 'btdtria'>`

Inverse of `btdtr` with respect to  $a$ .

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of  $a$ , returning the value of  $a$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

### Parameters

**p** [array\_like] Cumulative probability, in [0, 1].  
**b** [array\_like] Shape parameter ( $b > 0$ ).  
**x** [array\_like] The quantile, in [0, 1].

### Returns

**a** [ndarray] The value of the shape parameter  $a$  such that  $btdtr(a, b, x) = p$ .

See also:

`btdtr`

Cumulative distribution function of the beta distribution.

`btdtri`

Inverse with respect to  $x$ .

`btdtrib`

Inverse with respect to  $b$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfbet*.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

## References

[1], [2]

## scipy.special.btdtrib

`scipy.special.btdtrib(a, p, x) = <ufunc 'btdtrib'>`  
Inverse of *btdtr* with respect to  $b$ .

This is the inverse of the beta cumulative distribution function, *btdtr*, considered as a function of  $b$ , returning the value of  $b$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

### Parameters

- a** [array\_like] Shape parameter ( $a > 0$ ).
- p** [array\_like] Cumulative probability, in  $[0, 1]$ .
- x** [array\_like] The quantile, in  $[0, 1]$ .

### Returns

- b** [ndarray] The value of the shape parameter  $b$  such that  $btdtr(a, b, x) = p$ .

See also:

### *btdtr*

Cumulative distribution function of the beta distribution.

### *btdtri*

Inverse with respect to  $x$ .

### *btdtria*

Inverse with respect to  $a$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfbet*.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $b$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $b$ .

## References

[1], [2]

### scipy.special.fdtf

`scipy.special.fdtf(dfn, dfd, x) = <ufunc 'fdtf'>`

F cumulative distribution function.

Returns the value of the cumulative distribution function of the F-distribution, also known as Snedecor's F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters  $d_n$  and  $d_d$  is the distribution of the random variable,

$$X = \frac{U_n/d_n}{U_d/d_d},$$

where  $U_n$  and  $U_d$  are random variables distributed  $\chi^2$ , with  $d_n$  and  $d_d$  degrees of freedom, respectively.

#### Parameters

**dfn** [array\_like] First parameter (positive float).  
**dfd** [array\_like] Second parameter (positive float).  
**x** [array\_like] Argument (nonnegative float).

#### Returns

**y** [ndarray] The CDF of the F-distribution with parameters  $dfn$  and  $dfd$  at  $x$ .

## Notes

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{x d_n / (d_d + x d_n)}(d_n/2, d_d/2).$$

Wrapper for the Cephes [1] routine `fdtr`.

## References

[1]

### scipy.special.fdtfc

`scipy.special.fdtfc(dfn, dfd, x) = <ufunc 'fdtfc'>`

F survival function.

Returns the complemented F-distribution function (the integral of the density from  $x$  to infinity).

#### Parameters

**dfn** [array\_like] First parameter (positive float).  
**dfd** [array\_like] Second parameter (positive float).  
**x** [array\_like] Argument (nonnegative float).

#### Returns

**y** [ndarray] The complemented F-distribution function with parameters *dfn* and *dfd* at *x*.

**See also:**

`fdtr`

### Notes

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{d_d/(d_d+x d_n)}(d_d/2, d_n/2).$$

Wrapper for the Cephes [1] routine `fdtrc`.

### References

[1]

### scipy.special.fdtri

`scipy.special.fdtri(dfn, dfd, p) = <ufunc 'fdtri'>`

The *p*-th quantile of the F-distribution.

This function is the inverse of the F-distribution CDF, `fdtr`, returning the *x* such that `fdtr(dfn, dfd, x) = p`.

#### Parameters

**dfn** [array\_like] First parameter (positive float).  
**dfd** [array\_like] Second parameter (positive float).  
**p** [array\_like] Cumulative probability, in [0, 1].

#### Returns

**x** [ndarray] The quantile corresponding to *p*.

### Notes

The computation is carried out using the relation to the inverse regularized beta function,  $I_x^{-1}(a, b)$ . Let  $z = I_p^{-1}(d_d/2, d_n/2)$ . Then,

$$x = \frac{d_d(1-z)}{d_n z}.$$

If *p* is such that  $x < 0.5$ , the following relation is used instead for improved stability: let  $z' = I_{1-p}^{-1}(d_n/2, d_d/2)$ . Then,

$$x = \frac{d_d z'}{d_n(1-z')}.$$

Wrapper for the Cephes [1] routine `fdtri`.

## References

[1]

### scipy.special.fdtridfd

`scipy.special.fdtridfd(dfn, p, x) = <ufunc 'fdtridfd'>`

Inverse to `fdtr` vs `dfd`

Finds the F density argument `dfd` such that `fdtr(dfn, dfd, x) == p`.

### scipy.special.gdtr

`scipy.special.gdtr(a, b, x) = <ufunc 'gdtr'>`

Gamma distribution cumulative distribution function.

Returns the integral from zero to  $x$  of the gamma probability density function,

$$F = \int_0^x \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

#### Parameters

- a** [array\_like] The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .
- b** [array\_like] The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).
- x** [array\_like] The quantile (upper limit of integration; float).

#### Returns

- F** [ndarray] The CDF of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

See also:

#### `gdtrc`

1 - CDF of the gamma distribution.

## Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [1] routine `gdtr`.

## References

[1]

## scipy.special.gdtrc

`scipy.special.gdtrc(a, b, x) = <ufunc 'gdtrc'>`

Gamma distribution survival function.

Integral from  $x$  to infinity of the gamma probability density function,

$$F = \int_x^{\infty} \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

### Parameters

- a** [array\_like] The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .
- b** [array\_like] The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).
- x** [array\_like] The quantile (lower limit of integration; float).

### Returns

- F** [ndarray] The survival function of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

See also:

[gdtr](#), [gdtrix](#)

## Notes

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [1] routine `gdtrc`.

## References

[1]

## scipy.special.gdtria

`scipy.special.gdtria(p, b, x, out=None) = <ufunc 'gdtria'>`

Inverse of `gdtr` vs  $a$ .

Returns the inverse with respect to the parameter  $a$  of  $p = \text{gdtr}(a, b, x)$ , the cumulative distribution function of the gamma distribution.

### Parameters

- p** [array\_like] Probability values.
- b** [array\_like]  $b$  parameter values of `gdtr(a, b, x)`.  $b$  is the “shape” parameter of the gamma distribution.
- x** [array\_like] Nonnegative real values, from the domain of the gamma distribution.
- out** [ndarray, optional] If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of  $a$ ,  $b$  and  $x$ . `out` is then the array returned by the function.

### Returns

**a** [ndarray] Values of the  $a$  parameter such that  $p = \text{gdr}(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.

**See also:**

**gdr**

CDF of the gamma distribution.

**gdtrib**

Inverse with respect to  $b$  of  $\text{gdr}(a, b, x)$ .

**gdtrix**

Inverse with respect to  $x$  of  $\text{gdr}(a, b, x)$ .

**Notes**

Wrapper for the CDFLIB [1] Fortran routine *cdfgam*.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

**References**

[1], [2]

**Examples**

First evaluate *gdr*.

```
>>> from scipy.special import gdr, gdtria
>>> p = gdr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtria(p, 3.4, 5.6)
1.2
```

**scipy.special.gdtrib**

`scipy.special.gdtrib(a, p, x, out=None) = <ufunc 'gdtrib'>`

Inverse of *gdr* vs  $b$ .

Returns the inverse with respect to the parameter  $b$  of  $p = \text{gdr}(a, b, x)$ , the cumulative distribution function of the gamma distribution.

**Parameters**

**a** [array\_like]  $a$  parameter values of  $\text{gdr}(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.

**p** [array\_like] Probability values.  
**x** [array\_like] Nonnegative real values, from the domain of the gamma distribution.  
**out** [ndarray, optional] If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of *a*, *b* and *x*. *out* is then the array returned by the function.

**Returns**

**b** [ndarray] Values of the *b* parameter such that  $p = gdr(a, b, x)$ . *b* is the “shape” parameter of the gamma distribution.

**See also:**

**gdr**

CDF of the gamma distribution.

**gdtria**

Inverse with respect to *a* of  $gdr(a, b, x)$ .

**gdtrix**

Inverse with respect to *x* of  $gdr(a, b, x)$ .

**Notes**

Wrapper for the CDFLIB [1] Fortran routine *cdfgam*.

The cumulative distribution function *p* is computed using a routine by DiDinato and Morris [2]. Computation of *b* involves a search for a value that produces the desired value of *p*. The search relies on the monotonicity of *p* with *b*.

**References**

[1], [2]

**Examples**

First evaluate *gdr*.

```
>>> from scipy.special import gdr, gdtrib
>>> p = gdr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtrib(1.2, p, 5.6)
3.3999999999723882
```

**scipy.special.gdtrix**

`scipy.special.gdtrix(a, b, p, out=None) = <ufunc 'gdtrix'>`

Inverse of `gdtr` vs  $x$ .

Returns the inverse with respect to the parameter  $x$  of  $p = \text{gdtr}(a, b, x)$ , the cumulative distribution function of the gamma distribution. This is also known as the  $p$ th quantile of the distribution.

**Parameters**

- a** [array\_like]  $a$  parameter values of  $\text{gdtr}(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.
- b** [array\_like]  $b$  parameter values of  $\text{gdtr}(a, b, x)$ .  $b$  is the “shape” parameter of the gamma distribution.
- p** [array\_like] Probability values.
- out** [ndarray, optional] If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of  $a$ ,  $b$  and  $x$ . `out` is then the array returned by the function.

**Returns**

- x** [ndarray] Values of the  $x$  parameter such that  $p = \text{gdtr}(a, b, x)$ .

See also:

**`gdtr`**

CDF of the gamma distribution.

**`gdtria`**

Inverse with respect to  $a$  of  $\text{gdtr}(a, b, x)$ .

**`gdtrib`**

Inverse with respect to  $b$  of  $\text{gdtr}(a, b, x)$ .

**Notes**

Wrapper for the CDFLIB [1] Fortran routine `cdfgam`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $x$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $x$ .

**References**

[1], [2]

## Examples

First evaluate `gdtr`.

```
>>> from scipy.special import gdtr, gdtrix
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtrix(1.2, 3.4, p)
5.5999999999999996
```

## scipy.special.nbdtr

`scipy.special.nbdtr(k, n, p) = <ufunc 'nbdtr'>`

Negative binomial cumulative distribution function.

Returns the sum of the terms 0 through  $k$  of the negative binomial distribution probability mass function,

$$F = \sum_{j=0}^k \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that  $k$  or fewer failures precede the  $n$ th success.

### Parameters

- k** [array\_like] The maximum number of allowed failures (nonnegative int).
- n** [array\_like] The target number of successes (positive int).
- p** [array\_like] Probability of success in a single event (float).

### Returns

- F** [ndarray] The probability of  $k$  or fewer failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

See also:

[nbdtrc](#)

## Notes

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdtr}(k, n, p) = I_p(n, k + 1).$$

Wrapper for the Cephes [1] routine `nbdtr`.

## References

[1]

### scipy.special.nbdtrc

`scipy.special.nbdtrc(k, n, p) = <ufunc 'nbdtrc'>`

Negative binomial survival function.

Returns the sum of the terms  $k + 1$  to infinity of the negative binomial distribution probability mass function,

$$F = \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that more than  $k$  failures precede the  $n$ th success.

#### Parameters

- k** [array\_like] The maximum number of allowed failures (nonnegative int).
- n** [array\_like] The target number of successes (positive int).
- p** [array\_like] Probability of success in a single event (float).

#### Returns

- F** [ndarray] The probability of  $k + 1$  or more failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

## Notes

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdtrc}(k, n, p) = I_{1-p}(k + 1, n).$$

Wrapper for the Cephes [1] routine `nbdtrc`.

## References

[1]

### scipy.special.nbdtri

`scipy.special.nbdtri(k, n, y) = <ufunc 'nbdtri'>`

Inverse of `nbdtr` vs  $p$ .

Returns the inverse with respect to the parameter  $p$  of  $y = \text{nbdtr}(k, n, p)$ , the negative binomial cumulative distribution function.

#### Parameters

- k** [array\_like] The maximum number of allowed failures (nonnegative int).
- n** [array\_like] The target number of successes (positive int).

**y** [array\_like] The probability of  $k$  or fewer failures before  $n$  successes (float).

**Returns**

**p** [ndarray] Probability of success in a single event (float) such that  $nbdf(k, n, p) = y$ .

**See also:**

**nbdf**

Cumulative distribution function of the negative binomial.

**nbdfik**

Inverse with respect to  $k$  of  $nbdf(k, n, p)$ .

**nbdfin**

Inverse with respect to  $n$  of  $nbdf(k, n, p)$ .

**Notes**

Wrapper for the Cephes [1] routine *nbdfi*.

**References**

[1]

**scipy.special.nbdfik**

`scipy.special.nbdfik(y, n, p) = <ufunc 'nbdfik'>`

Inverse of *nbdf* vs  $k$ .

Returns the inverse with respect to the parameter  $k$  of  $y = nbdf(k, n, p)$ , the negative binomial cumulative distribution function.

**Parameters**

**y** [array\_like] The probability of  $k$  or fewer failures before  $n$  successes (float).

**n** [array\_like] The target number of successes (positive int).

**p** [array\_like] Probability of success in a single event (float).

**Returns**

**k** [ndarray] The maximum number of allowed failures such that  $nbdf(k, n, p) = y$ .

**See also:**

**nbdf**

Cumulative distribution function of the negative binomial.

**nbdfi**

Inverse with respect to  $p$  of  $nbdf(k, n, p)$ .

**nbdfin**

Inverse with respect to  $n$  of  $nbdf(k, n, p)$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

## References

[1], [2]

### scipy.special.nbdtrin

```
scipy.special.nbdtrin(k, y, p) = <ufunc 'nbdtrin'>
```

Inverse of *nbdtr* vs  $n$ .

Returns the inverse with respect to the parameter  $n$  of  $y = \text{nbdtr}(k, n, p)$ , the negative binomial cumulative distribution function.

#### Parameters

|          |                                                                                     |
|----------|-------------------------------------------------------------------------------------|
| <b>k</b> | [array_like] The maximum number of allowed failures (nonnegative int).              |
| <b>y</b> | [array_like] The probability of $k$ or fewer failures before $n$ successes (float). |
| <b>p</b> | [array_like] Probability of success in a single event (float).                      |

#### Returns

|          |                                                                               |
|----------|-------------------------------------------------------------------------------|
| <b>n</b> | [ndarray] The number of successes $n$ such that $\text{nbdtr}(k, n, p) = y$ . |
|----------|-------------------------------------------------------------------------------|

#### See also:

##### [nbdtr](#)

Cumulative distribution function of the negative binomial.

Inverse with respect to  $p$  of  $\text{nbdtr}(k, n, p)$ .

##### [nbdtrik](#)

Inverse with respect to  $k$  of  $\text{nbdtr}(k, n, p)$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

## References

[1], [2]

## scipy.special.ncfdtr

`scipy.special.ncfdtr(dfn, dfd, nc, f) = <ufunc 'ncfdtr'>`

Cumulative distribution function of the non-central F distribution.

The non-central F describes the distribution of,

$$Z = \frac{X/d_n}{Y/d_d}$$

where  $X$  and  $Y$  are independently distributed, with  $X$  distributed non-central  $\chi^2$  with noncentrality parameter  $nc$  and  $d_n$  degrees of freedom, and  $Y$  distributed  $\chi^2$  with  $d_d$  degrees of freedom.

### Parameters

**dfn** [array\_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).  
**dfd** [array\_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (0, 1e4).  
**f** [array\_like] Quantiles, i.e. the upper limit of integration.

### Returns

**cdf** [float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

See also:

### `ncfdtri`

Quantile function; inverse of `ncfdtr` with respect to  $f$ .

### `ncfdtridfd`

Inverse of `ncfdtr` with respect to  $dfd$ .

### `ncfdtridfn`

Inverse of `ncfdtr` with respect to  $dfn$ .

### `ncfdtrinc`

Inverse of `ncfdtr` with respect to  $nc$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdffnc*.

The cumulative distribution function is computed using Formula 26.6.20 of [2]:

$$F(d_n, d_d, n_c, f) = \sum_{j=0}^{\infty} e^{-n_c/2} \frac{(n_c/2)^j}{j!} I_x\left(\frac{d_n}{2} + j, \frac{d_d}{2}\right),$$

where  $I$  is the regularized incomplete beta function, and  $x = fd_n/(fd_n + d_d)$ .

The computation time required for this routine is proportional to the noncentrality parameter  $nc$ . Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.

## References

[1], [2]

## Examples

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central F distribution, for  $nc=0$ . Compare with the F-distribution from `scipy.stats`:

```
>>> x = np.linspace(-1, 8, num=500)
>>> dfn = 3
>>> dfd = 2
>>> ncf_stats = stats.f.cdf(x, dfn, dfd)
>>> ncf_special = special.ncfdtr(dfn, dfd, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()
```

## scipy.special.ncfdtridfd

`scipy.special.ncfdtridfd(dfn, p, nc, f) = <ufunc 'ncfdtridfd'>`

Calculate degrees of freedom (denominator) for the noncentral F-distribution.

This is the inverse with respect to *dfd* of *ncfdtr*. See *ncfdtr* for more details.

### Parameters

- dfn** [array\_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
- p** [array\_like] Value of the cumulative distribution function. Must be in the range [0, 1].
- nc** [array\_like] Noncentrality parameter. Should be in range (0, 1e4).
- f** [array\_like] Quantiles, i.e., the upper limit of integration.

### Returns

**dfd** [float] Degrees of freedom of the denominator sum of squares.

See also:

**ncfdtr**

CDF of the non-central F distribution.

**ncfdtri**

Quantile function; inverse of *ncfdtr* with respect to *f*.

**ncfdtridfn**

Inverse of *ncfdtr* with respect to *dfn*.

**ncfdtrinc**

Inverse of *ncfdtr* with respect to *nc*.

## Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

## Examples

```
>>> from scipy.special import ncfdtr, ncfdtridfd
```

Compute the CDF for several values of *dfd*:

```
>>> dfd = [1, 2, 3]
>>> p = ncfdtr(2, dfd, 0.25, 15)
>>> p
array([0.8097138 , 0.93020416, 0.96787852])
```

Compute the inverse. We recover the values of *dfd*, as expected:

```
>>> ncfidtridfd(2, p, 0.25, 15)
array([1., 2., 3.]
```

### scipy.special.ncfdtridfn

`scipy.special.ncfdtridfn(p, dfd, nc, f) = <ufunc 'ncfdtridfn'>`  
 Calculate degrees of freedom (numerator) for the noncentral F-distribution.

This is the inverse with respect to *dfn* of *ncfdtr*. See *ncfdtr* for more details.

#### Parameters

**p** [array\_like] Value of the cumulative distribution function. Must be in the range [0, 1].  
**dfd** [array\_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (0, 1e4).  
**f** [float] Quantiles, i.e., the upper limit of integration.

#### Returns

**dfn** [float] Degrees of freedom of the numerator sum of squares.

See also:

#### [ncfdtr](#)

CDF of the non-central F distribution.

#### [ncfdtri](#)

Quantile function; inverse of *ncfdtr* with respect to *f*.

#### [ncfdtridfd](#)

Inverse of *ncfdtr* with respect to *dfd*.

#### [ncfdtrinc](#)

Inverse of *ncfdtr* with respect to *nc*.

### Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

### Examples

```
>>> from scipy.special import ncfidtr, ncfidtridfn
```

Compute the CDF for several values of *dfn*:

```
>>> dfn = [1, 2, 3]
>>> p = ncfidtr(dfn, 2, 0.25, 15)
>>> p
array([0.92562363, 0.93020416, 0.93188394])
```

Compute the inverse. We recover the values of *dfn*, as expected:

```
>>> ncfidtridf(p, 2, 0.25, 15)
array([1., 2., 3.]
```

## scipy.special.ncfdtri

`scipy.special.ncfdtri(dfn, dfd, nc, p) = <ufunc 'ncfdtri'>`

Inverse with respect to *f* of the CDF of the non-central F distribution.

See `ncfdtr` for more details.

### Parameters

|            |                                                                                          |
|------------|------------------------------------------------------------------------------------------|
| <b>dfn</b> | [array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).         |
| <b>dfd</b> | [array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).       |
| <b>nc</b>  | [array_like] Noncentrality parameter. Should be in range (0, 1e4).                       |
| <b>p</b>   | [array_like] Value of the cumulative distribution function. Must be in the range [0, 1]. |

### Returns

|          |                                                          |
|----------|----------------------------------------------------------|
| <b>f</b> | [float] Quantiles, i.e., the upper limit of integration. |
|----------|----------------------------------------------------------|

See also:

### `ncfdtr`

CDF of the non-central F distribution.

### `ncfdtridf`

Inverse of `ncfdtr` with respect to *dfd*.

### `ncfdtridf`

Inverse of `ncfdtr` with respect to *dfn*.

### `ncfdtrinc`

Inverse of `ncfdtr` with respect to *nc*.

## Examples

```
>>> from scipy.special import ncfidtr, ncfidtri
```

Compute the CDF for several values of *f*:

```
>>> f = [0.5, 1, 1.5]
>>> p = ncfidtr(2, 3, 1.5, f)
>>> p
array([0.20782291, 0.36107392, 0.47345752])
```

Compute the inverse. We recover the values of *f*, as expected:

```
>>> ncfidtri(2, 3, 1.5, p)
array([0.5, 1. , 1.5])
```

**scipy.special.ncfdtrinc**

```
scipy.special.ncfdtrinc(dfn, dfd, p, f) = <ufunc 'ncfdtrinc'>
```

Calculate non-centrality parameter for non-central F distribution.

This is the inverse with respect to *nc* of *ncfdtr*. See *ncfdtr* for more details.

**Parameters**

|            |                                                                                          |
|------------|------------------------------------------------------------------------------------------|
| <b>dfn</b> | [array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).         |
| <b>dfd</b> | [array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).       |
| <b>p</b>   | [array_like] Value of the cumulative distribution function. Must be in the range [0, 1]. |
| <b>f</b>   | [array_like] Quantiles, i.e., the upper limit of integration.                            |

**Returns**

|           |                                  |
|-----------|----------------------------------|
| <b>nc</b> | [float] Noncentrality parameter. |
|-----------|----------------------------------|

See also:

**ncfdtr**

CDF of the non-central F distribution.

**ncfdtri**

Quantile function; inverse of *ncfdtr* with respect to *f*.

**ncfdtridfd**

Inverse of *ncfdtr* with respect to *dfd*.

**ncfdtridfn**

Inverse of *ncfdtr* with respect to *dfn*.

**Examples**

```
>>> from scipy.special import ncfdtr, ncfdtrinc
```

Compute the CDF for several values of *nc*:

```
>>> nc = [0.5, 1.5, 2.0]
>>> p = ncfdtr(2, 3, nc, 15)
>>> p
array([0.96309246, 0.94327955, 0.93304098])
```

Compute the inverse. We recover the values of *nc*, as expected:

```
>>> ncfdtrinc(2, 3, p, 15)
array([0.5, 1.5, 2.])
```

## scipy.special.nctdtr

`scipy.special.nctdtr(df, nc, t) = <ufunc 'nctdtr'>`  
Cumulative distribution function of the non-central  $t$  distribution.

### Parameters

**df** [array\_like] Degrees of freedom of the distribution. Should be in range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (-1e6, 1e6).  
**t** [array\_like] Quantiles, i.e., the upper limit of integration.

### Returns

**cdf** [float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise, it will be an array.

### See also:

#### [nctdtrit](#)

Inverse CDF (iCDF) of the non-central  $t$  distribution.

#### [nctdtridf](#)

Calculate degrees of freedom, given CDF and iCDF values.

#### [nctdtrinc](#)

Calculate non-centrality parameter, given CDF iCDF values.

## Examples

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central  $t$  distribution, for  $nc=0$ . Compare with the  $t$ -distribution from `scipy.stats`:

```
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.nctdtr(df, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-')
>>> plt.show()
```

### scipy.special.ncdtridf

`scipy.special.ncdtridf(p, nc, t) = <ufunc 'ncdtridf'>`

Calculate degrees of freedom for non-central t distribution.

See `ncdtr` for more details.

#### Parameters

- p** [array\_like] CDF values, in range (0, 1].
- nc** [array\_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
- t** [array\_like] Quantiles, i.e., the upper limit of integration.

### scipy.special.ncdtrit

`scipy.special.ncdtrit(df, nc, p) = <ufunc 'ncdtrit'>`

Inverse cumulative distribution function of the non-central t distribution.

See `ncdtr` for more details.

#### Parameters

- df** [array\_like] Degrees of freedom of the distribution. Should be in range (0, inf).
- nc** [array\_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
- p** [array\_like] CDF values, in range (0, 1].

### scipy.special.nctdtrinc

`scipy.special.nctdtrinc(df, p, t) = <ufunc 'nctdtrinc'>`

Calculate non-centrality parameter for non-central t distribution.

See `nctdtr` for more details.

#### Parameters

|           |                                                                                   |
|-----------|-----------------------------------------------------------------------------------|
| <b>df</b> | [array_like] Degrees of freedom of the distribution. Should be in range (0, inf). |
| <b>p</b>  | [array_like] CDF values, in range (0, 1].                                         |
| <b>t</b>  | [array_like] Quantiles, i.e., the upper limit of integration.                     |

### scipy.special.nrdtrimn

`scipy.special.nrdtrimn(p, x, std) = <ufunc 'nrdtrimn'>`

Calculate mean of normal distribution given other params.

#### Parameters

|            |                                                              |
|------------|--------------------------------------------------------------|
| <b>p</b>   | [array_like] CDF values, in range (0, 1].                    |
| <b>x</b>   | [array_like] Quantiles, i.e. the upper limit of integration. |
| <b>std</b> | [array_like] Standard deviation.                             |

#### Returns

|           |                                                         |
|-----------|---------------------------------------------------------|
| <b>mn</b> | [float or ndarray] The mean of the normal distribution. |
|-----------|---------------------------------------------------------|

See also:

`nrdtrimn`, `ndtr`

### scipy.special.nrdtrisd

`scipy.special.nrdtrisd(p, x, mn) = <ufunc 'nrdtrisd'>`

Calculate standard deviation of normal distribution given other params.

#### Parameters

|           |                                                              |
|-----------|--------------------------------------------------------------|
| <b>p</b>  | [array_like] CDF values, in range (0, 1].                    |
| <b>x</b>  | [array_like] Quantiles, i.e. the upper limit of integration. |
| <b>mn</b> | [float or ndarray] The mean of the normal distribution.      |

#### Returns

|            |                                  |
|------------|----------------------------------|
| <b>std</b> | [array_like] Standard deviation. |
|------------|----------------------------------|

See also:

`ndtr`

**scipy.special.pdtr**

`scipy.special.pdtr(k, m, out=None) = <ufunc 'pdtr'>`

Poisson cumulative distribution function.

Defined as the probability that a Poisson-distributed random variable with event rate  $m$  is less than or equal to  $k$ . More concretely, this works out to be [1]

$$\exp(-m) \sum_{j=0}^{\lfloor k \rfloor} \frac{m^j}{j!}.$$

**Parameters**

**k** [array\_like] Nonnegative real argument  
**m** [array\_like] Nonnegative real shape parameter  
**out** [ndarray] Optional output array for the function results

**Returns**

**scalar or ndarray**

Values of the Poisson cumulative distribution function

See also:

`pdtrc`

Poisson survival function

`pdtrik`

inverse of `pdtr` with respect to  $k$

`pdtri`

inverse of `pdtr` with respect to  $m$

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

It is a cumulative distribution function, so it converges to 1 monotonically as  $k$  goes to infinity.

```
>>> sc.pdtr([1, 10, 100, np.inf], 1)
array([0.73575888, 0.99999999, 1. , 1.])
```

It is discontinuous at integers and constant between integers.

```
>>> sc.pdtr([1, 1.5, 1.9, 2], 1)
array([0.73575888, 0.73575888, 0.73575888, 0.9196986])
```

### scipy.special.pdtrc

`scipy.special.pdtrc(k, m) = <ufunc 'pdtrc'>`  
 Poisson survival function

Returns the sum of the terms from  $k+1$  to infinity of the Poisson distribution:  $\sum(\exp(-m) * m^{**j} / j!, j=k+1..inf)$   
 $= \text{gammainc}(k+1, m)$ . Arguments must both be non-negative doubles.

### scipy.special.pdtri

`scipy.special.pdtri(k, y) = <ufunc 'pdtri'>`  
 Inverse to `pdtr` vs  $m$

Returns the Poisson variable  $m$  such that the sum from 0 to  $k$  of the Poisson density is equal to the given probability  $y$ : calculated by `gammaincinv(k+1, y)`.  $k$  must be a nonnegative integer and  $y$  between 0 and 1.

### scipy.special.pdtrik

`scipy.special.pdtrik(p, m) = <ufunc 'pdtrik'>`  
 Inverse to `pdtr` vs  $k$

Returns the quantile  $k$  such that `pdtr(k, m) = p`

### scipy.special.stdtr

`scipy.special.stdtr(df, t) = <ufunc 'stdtr'>`  
 Student t distribution cumulative distribution function

Returns the integral from minus infinity to  $t$  of the Student t distribution with  $df > 0$  degrees of freedom:

$$\text{gamma}((df+1)/2) / (\text{sqrt}(df*\text{pi}) * \text{gamma}(df/2)) * \text{integral}((1+x**2/df)**(-df/2-1/2), x=-\text{inf}..t)$$

### scipy.special.stdtridf

`scipy.special.stdtridf(p, t) = <ufunc 'stdtridf'>`  
 Inverse of `stdtr` vs  $df$

Returns the argument  $df$  such that `stdtr(df, t)` is equal to  $p$ .

### scipy.special.stdtrit

`scipy.special.stdtrit(df, p) = <ufunc 'stdtrit'>`  
 Inverse of `stdtr` vs  $t$

Returns the argument  $t$  such that `stdtr(df, t)` is equal to  $p$ .

**scipy.special.chdtr**

`scipy.special.chdtr(v, x, out=None) = <ufunc 'chdtr'>`

Chi square cumulative distribution function.

Returns the area under the left tail (from 0 to  $x$ ) of the Chi square probability density function with  $\nu$  degrees of freedom:

$$\frac{1}{2^{\nu/2}\Gamma(\nu/2)} \int_0^x t^{\nu/2-1} e^{-t/2} dt$$

Here  $\Gamma$  is the Gamma function; see [gamma](#). This integral can be expressed in terms of the regularized lower incomplete gamma function [gammainc](#) as `gammainc(v / 2, x / 2)`. [1]

**Parameters**

- v** [array\_like] Degrees of freedom.
- x** [array\_like] Upper bound of the integral.
- out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**

Values of the cumulative distribution function.

See also:

[chdtrc](#), [chdtri](#), [chdtriv](#), [gammainc](#)

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

It can be expressed in terms of the regularized lower incomplete gamma function.

```
>>> v = 1
>>> x = np.arange(4)
>>> sc.chdtr(v, x)
array([0. , 0.68268949, 0.84270079, 0.91673548])
>>> sc.gammainc(v / 2, x / 2)
array([0. , 0.68268949, 0.84270079, 0.91673548])
```

**scipy.special.chdtrc**

```
scipy.special.chdtrc(v, x, out=None) = <ufunc 'chdtrc'>
```

Chi square survival function.

Returns the area under the right hand tail (from  $x$  to infinity) of the Chi square probability density function with  $v$  degrees of freedom:

$$\frac{1}{2^{v/2}\Gamma(v/2)} \int_x^\infty t^{v/2-1} e^{-t/2} dt$$

Here  $\Gamma$  is the Gamma function; see [gamma](#). This integral can be expressed in terms of the regularized upper incomplete gamma function [gammaincc](#) as `gammaincc(v / 2, x / 2)`. [1]

**Parameters**

**v** [array\_like] Degrees of freedom.  
**x** [array\_like] Lower bound of the integral.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
 Values of the survival function.

See also:

[chdtr](#), [chdtri](#), [chdtriv](#), [gammaincc](#)

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

It can be expressed in terms of the regularized upper incomplete gamma function.

```
>>> v = 1
>>> x = np.arange(4)
>>> sc.chdtrc(v, x)
array([1. , 0.31731051, 0.15729921, 0.08326452])
>>> sc.gammaincc(v / 2, x / 2)
array([1. , 0.31731051, 0.15729921, 0.08326452])
```

**scipy.special.chdtri**

`scipy.special.chdtri(v, p, out=None) = <ufunc 'chdtri'>`

Inverse to `chdtrc` with respect to  $x$ .

Returns  $x$  such that `chdtrc(v, x) == p`.

**Parameters**

**v** [array\_like] Degrees of freedom.  
**p** [array\_like] Probability.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**x** [scalar or ndarray] Value so that the probability a Chi square random variable with  $v$  degrees of freedom is greater than  $x$  equals  $p$ .

See also:

[chdtrc](#), [chdtr](#), [chdtriv](#)

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

It inverts `chdtrc`.

```
>>> v, p = 1, 0.3
>>> sc.chdtrc(v, sc.chdtri(v, p))
0.3
>>> x = 1
>>> sc.chdtri(v, sc.chdtrc(v, x))
1.0
```

**scipy.special.chdtriv**

`scipy.special.chdtriv(p, x, out=None) = <ufunc 'chdtriv'>`

Inverse to `chdtr` with respect to  $v$ .

Returns  $v$  such that `chdtr(v, x) == p`.

**Parameters**

**p** [array\_like] Probability that the Chi square random variable is less than or equal to  $x$ .  
**x** [array\_like] Nonnegative input.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
 Degrees of freedom.

See also:

`chdtr`, `chdtrc`, `chdtri`

## References

[1]

## Examples

```
>>> import scipy.special as sc
```

It inverts `chdtr`.

```
>>> p, x = 0.5, 1
>>> sc.chdtr(sc.chdtriv(p, x), x)
0.50000000000202172
>>> v = 1
>>> sc.chdtriv(sc.chdtr(v, x), v)
1.00000000000000013
```

## `scipy.special.ndtr`

`scipy.special.ndtr(x) = <ufunc 'ndtr'>`

Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to  $x$

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-t^2/2) dt$$

### *Parameters*

**x** [array\_like, real or complex] Argument

### *Returns*

**ndarray** The value of the normal CDF evaluated at  $x$

See also:

`erf`

`erfc`

`scipy.stats.norm`

`log_ndtr`

### scipy.special.log\_ndtr

`scipy.special.log_ndtr(x) = <ufunc 'log_ndtr'>`

Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to  $x$ :

```
log(1/sqrt(2*pi) * integral(exp(-t**2 / 2), t=-inf..x))
```

#### Parameters

**x** [array\_like, real or complex] Argument

#### Returns

**ndarray** The value of the log of the normal CDF evaluated at  $x$

See also:

`erf`

`erfc`

`scipy.stats.norm`

`ndtr`

### scipy.special.ndtri

`scipy.special.ndtri(y) = <ufunc 'ndtri'>`

Inverse of `ndtr` vs  $x$

Returns the argument  $x$  for which the area under the Gaussian probability density function (integrated from minus infinity to  $x$ ) is equal to  $y$ .

### scipy.special.ndtri\_exp

`scipy.special.ndtri_exp(y) = <ufunc 'ndtri_exp'>`

Inverse of `log_ndtr` vs  $x$ . Allows for greater precision than `ndtri` composed with `numpy.exp` for very small values of  $y$  and for  $y$  close to 0.

#### Parameters

**y** [array\_like of float]

#### Returns

**scalar or ndarray**

Inverse of the log CDF of the standard normal distribution, evaluated at  $y$ .

See also:

`log_ndtr`, `ndtri`, `ndtr`

## Examples

```
>>> import scipy.special as sc
```

`ndtri_exp` agrees with the naive implementation when the latter does not suffer from underflow.

```
>>> sc.ndtri_exp(-1)
-0.33747496376420244
>>> sc.ndtri(np.exp(-1))
-0.33747496376420244
```

For extreme values of  $y$ , the naive approach fails

```
>>> sc.ndtri(np.exp(-800))
-inf
>>> sc.ndtri(np.exp(-1e-20))
inf
```

whereas `ndtri_exp` is still able to compute the result to high precision.

```
>>> sc.ndtri_exp(-800)
-39.88469483825668
>>> sc.ndtri_exp(-1e-20)
9.262340089798409
```

## scipy.special.chndtr

`scipy.special.chndtr`( $x, df, nc$ ) = <ufunc 'chndtr'>  
Non-central chi square cumulative distribution function

## scipy.special.chndtridf

`scipy.special.chndtridf`( $x, p, nc$ ) = <ufunc 'chndtridf'>  
Inverse to `chndtr` vs  $df$

## scipy.special.chndtrinc

`scipy.special.chndtrinc`( $x, df, p$ ) = <ufunc 'chndtrinc'>  
Inverse to `chndtr` vs  $nc$

## scipy.special.chndtrix

`scipy.special.chndtrix`( $p, df, nc$ ) = <ufunc 'chndtrix'>  
Inverse to `chndtr` vs  $x$

**scipy.special.smirnov**

```
scipy.special.smirnov(n, d) = <ufunc 'smirnov'>
```

Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function,(aka the Survival Function) of  $D_n^+$  (or  $D_n^-$ ) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on  $n$  samples is greater than  $d$ .

**Parameters**

**n** [int] Number of samples  
**d** [float array\_like] Deviation between the Empirical CDF (ECDF) and the target CDF.

**Returns**

**float** The value(s) of `smirnov(n, d)`,  $\text{Prob}(D_n^+ \geq d)$  (Also  $\text{Prob}(D_n^- \geq d)$ )

**See also:****smirnovi**

The Inverse Survival Function for the distribution

**scipy.stats.kstest**

Provides the functionality as a continuous distribution

**kolmogorov, kolmogi**

Functions for the two-sided distribution

**Notes**

`smirnov` is used by `stats.kstest` in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in `scipy.special`, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the `stats.kstest` distribution.

**Examples**

```
>>> from scipy.special import smirnov
```

Show the probability of a gap at least as big as 0, 0.5 and 1.0 for a sample of size 5

```
>>> smirnov(5, [0, 0.5, 1.0])
array([1. , 0.056 , 0.])
```

Compare a sample of size 5 drawn from a source  $N(0.5, 1)$  distribution against a target  $N(0, 1)$  CDF.

```
>>> from scipy.stats import norm
>>> rng = np.random.default_rng()
>>> n = 5
>>> gendist = norm(0.5, 1) # Normal distribution, mean 0.5, stddev 1
>>> x = np.sort(gendist.rvs(size=n, random_state=rng))
>>> x
array([-1.3922078 , -0.13526532, 0.1371477 , 0.18981686, 1.81948167])
```

(continues on next page)

(continued from previous page)

```

>>> target = norm(0, 1)
>>> cdfs = target.cdf(x)
>>> cdfs
array([0.08192974, 0.44620105, 0.55454297, 0.57527368, 0.96558101])
Construct the Empirical CDF and the K-S statistics (Dn+, Dn-, Dn)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> cols = np.column_stack([x, ecdfs[1:], cdfs, cdfs - ecdfs[:n],
 ↪ecdfs[1:] - cdfs])
>>> np.set_printoptions(precision=3)
>>> cols
array([[-1.392, 0.2 , 0.082, 0.082, 0.118],
 [-0.135, 0.4 , 0.446, 0.246, -0.046],
 [0.137, 0.6 , 0.555, 0.155, 0.045],
 [0.19 , 0.8 , 0.575, -0.025, 0.225],
 [1.819, 1. , 0.966, 0.166, 0.034]])
>>> gaps = cols[:, -2:]
>>> Dnpm = np.max(gaps, axis=0)
>>> print('Dn-=%f, Dn+=%f' % (Dnpm[0], Dnpm[1]))
Dn-=0.246201, Dn+=0.224726
>>> probs = smirnov(n, Dnpm)
>>> print(chr(10).join(['For a sample of size %d drawn from a N(0, 1)
 ↪distribution:' % n,
... ' Smirnov n=%d: Prob(Dn- >= %f) = %.4f' % (n, Dnpm[0],
 ↪probs[0]),
... ' Smirnov n=%d: Prob(Dn+ >= %f) = %.4f' % (n, Dnpm[1],
 ↪probs[1])]))
For a sample of size 5 drawn from a N(0, 1) distribution:
Smirnov n=5: Prob(Dn- >= 0.246201) = 0.4713
Smirnov n=5: Prob(Dn+ >= 0.224726) = 0.5243

```

Plot the Empirical CDF against the target N(0, 1) CDF

```

>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[-3], x]), ecdfs, where='post', label=
 ↪'Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r',
 ↪linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='m',
 ↪linestyle='dashed', lw=4)
>>> plt.show()

```

### scipy.special.smirnovi

`scipy.special.smirnovi(n, p) = <ufunc 'smirnovi'>`

Inverse to `smirnov`

Returns  $d$  such that `smirnov(n, d) == p`, the critical value corresponding to  $p$ .

#### Parameters

**n** [int] Number of samples  
**p** [float array\_like] Probability

#### Returns

**float** The value(s) of `smirnovi(n, p)`, the critical values.

#### See also:

##### `smirnov`

The Survival Function (SF) for the distribution

##### `scipy.stats.kstest`

Provides the functionality as a continuous distribution

##### `kolmogorov`, `kolmogi`, `scipy.stats.kstwobign`

Functions for the two-sided distribution

## Notes

*smirnov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstest* distribution.

## scipy.special.kolmogorov

`scipy.special.kolmogorov(y) = <ufunc 'kolmogorov'>`

Complementary cumulative distribution (Survival Function) function of Kolmogorov distribution.

Returns the complementary cumulative distribution function of Kolmogorov's limiting distribution ( $D_n \sqrt{n}$ ) as  $n$  goes to infinity) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as  $n \rightarrow \infty$  of the) probability that  $\sqrt{n} \cdot \max \text{ absolute deviation} > Y$ .

### Parameters

**y** [float array\_like] Absolute deviation between the Empirical CDF (ECDF) and the target CDF, multiplied by  $\sqrt{n}$ .

### Returns

**float** The value(s) of `kolmogorov(y)`

### See also:

#### `kolmogi`

The Inverse Survival Function for the distribution

#### `scipy.stats.kstwobign`

Provides the functionality as a continuous distribution

#### `smirnov, smirnovi`

Functions for the one-sided distribution

## Notes

*kolmogorov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstwobign* distribution.

## Examples

Show the probability of a gap at least as big as 0, 0.5 and 1.0.

```
>>> from scipy.special import kolmogorov
>>> from scipy.stats import kstwobign
>>> kolmogorov([0, 0.5, 1.0])
array([1. , 0.96394524, 0.26999967])
```

Compare a sample of size 1000 drawn from a Laplace(0, 1) distribution against the target distribution, a Normal(0, 1) distribution.

```

>>> from scipy.stats import norm, laplace
>>> rng = np.random.default_rng()
>>> n = 1000
>>> lap01 = laplace(0, 1)
>>> x = np.sort(lap01.rvs(n, random_state=rng))
>>> np.mean(x), np.std(x)
(-0.05841730131499543, 1.3968109101997568)

```

Construct the Empirical CDF and the K-S statistic  $D_n$ .

```

>>> target = norm(0,1) # Normal mean 0, stddev 1
>>> cdfs = target.cdf(x)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> gaps = np.column_stack([cdfs - ecdfs[:n], ecdfs[1:] - cdfs])
>>> Dn = np.max(gaps)
>>> Kn = np.sqrt(n) * Dn
>>> print('Dn=%f, sqrt(n)*Dn=%f' % (Dn, Kn))
Dn=0.043363, sqrt(n)*Dn=1.371265
>>> print(chr(10).join(['For a sample of size n drawn from a N(0, 1) ↵
↵distribution:',
... ' the approximate Kolmogorov probability that sqrt(n)*Dn>=%f is %f
↵' % (Kn, kolmogorov(Kn)),
... ' the approximate Kolmogorov probability that sqrt(n)*Dn<=%f is %f
↵' % (Kn, kstwobign.cdf(Kn))]))
For a sample of size n drawn from a N(0, 1) distribution:
the approximate Kolmogorov probability that sqrt(n)*Dn>=1.371265 is 0.
↵046533
the approximate Kolmogorov probability that sqrt(n)*Dn<=1.371265 is 0.
↵953467

```

Plot the Empirical CDF against the target  $N(0, 1)$  CDF.

```

>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[-3], x]), ecdfs, where='post', label=
↵'Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
>>> # Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r', ↵
↵linestyle='dashed', lw=4)
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='r', ↵
↵linestyle='dashed', lw=4)
>>> plt.show()

```

### scipy.special.kolmogi

`scipy.special.kolmogi(p) = <ufunc 'kolmogi'>`

Inverse Survival Function of Kolmogorov distribution

It is the inverse function to `kolmogorov`. Returns  $y$  such that `kolmogorov(y) == p`.

#### Parameters

**p** [float array\_like] Probability

#### Returns

**float** The value(s) of `kolmogi(p)`

#### See also:

#### `kolmogorov`

The Survival Function for the distribution

#### `scipy.stats.kstwobign`

Provides the functionality as a continuous distribution

#### `smirnov`, `smirnovi`

Functions for the one-sided distribution

## Notes

`kolmogorov` is used by `stats.kstest` in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in `scipy.special`, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the `stats.kstwobign` distribution.

## Examples

```
>>> from scipy.special import kolmogi
>>> kolmogi([0, 0.1, 0.25, 0.5, 0.75, 0.9, 1.0])
array([inf, 1.22384787, 1.01918472, 0.82757356, 0.67644769,
 0.57117327, 0.])
```

## `scipy.special.tklmbda`

`scipy.special.tklmbda(x, lambda) = <ufunc 'tklmbda'>`  
 Tukey-Lambda cumulative distribution function

## `scipy.special.logit`

`scipy.special.logit(x) = <ufunc 'logit'>`  
 Logit ufunc for ndarrays.

The logit function is defined as  $\text{logit}(p) = \log(p/(1-p))$ . Note that  $\text{logit}(0) = -\text{inf}$ ,  $\text{logit}(1) = \text{inf}$ , and  $\text{logit}(p)$  for  $p < 0$  or  $p > 1$  yields nan.

### Parameters

**x** [ndarray] The ndarray to apply logit to element-wise.

### Returns

**out** [ndarray] An ndarray of the same shape as x. Its entries are logit of the corresponding entry of x.

### See also:

`expit`

## Notes

As a ufunc `logit` takes a number of optional keyword arguments. For more information see [ufuncs](#)

New in version 0.10.0.

## Examples

```
>>> from scipy.special import logit, expit
```

```
>>> logit([0, 0.25, 0.5, 0.75, 1])
array([-inf, -1.09861229, 0. , 1.09861229, inf])
```

*expit* is the inverse of *logit*:

```
>>> expit(logit([0.1, 0.75, 0.999]))
array([0.1 , 0.75 , 0.999])
```

Plot  $\text{logit}(x)$  for  $x$  in  $[0, 1]$ :

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 1, 501)
>>> y = logit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.ylim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('logit(x)')
>>> plt.show()
```

**scipy.special.expit**

`scipy.special.expit(x) = <ufunc 'expit'>`

Expit (a.k.a. logistic sigmoid) ufunc for ndarrays.

The expit function, also known as the logistic sigmoid function, is defined as  $\text{expit}(x) = 1 / (1 + \exp(-x))$ . It is the inverse of the logit function.

**Parameters**

**x** [ndarray] The ndarray to apply expit to element-wise.

**Returns**

**out** [ndarray] An ndarray of the same shape as x. Its entries are *expit* of the corresponding entry of x.

**See also:**

[logit](#)

**Notes**

As a ufunc expit takes a number of optional keyword arguments. For more information see [ufuncs](#)

New in version 0.10.0.

**Examples**

```
>>> from scipy.special import expit, logit
```

```
>>> expit([-np.inf, -1.5, 0, 1.5, np.inf])
array([0. , 0.18242552, 0.5 , 0.81757448, 1.])
```

*logit* is the inverse of *expit*:

```
>>> logit(expit([-2.5, 0, 3.1, 5.0]))
array([-2.5, 0. , 3.1, 5.])
```

Plot expit(x) for x in [-6, 6]:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-6, 6, 121)
>>> y = expit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.xlim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('expit(x)')
>>> plt.show()
```

### scipy.special.boxcox

`scipy.special.boxcox(x, lambda) = <ufunc 'boxcox'>`  
 Compute the Box-Cox transformation.

The Box-Cox transformation is:

$$y = \begin{cases} (x^{\lambda} - 1) / \lambda & \text{if } \lambda \neq 0 \\ \log(x) & \text{if } \lambda = 0 \end{cases}$$

Returns *nan* if  $x < 0$ . Returns *-inf* if  $x == 0$  and  $\lambda < 0$ .

#### Parameters

**x** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

#### Returns

**y** [array] Transformed data.

#### Notes

New in version 0.14.0.

#### Examples

```
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([0. , 12.4 , 126.09110641])
>>> boxcox(2, [0, 1, 2])
array([0.69314718, 1. , 1.5])
```

**scipy.special.boxcox1p**

`scipy.special.boxcox1p(x, lambda) = <ufunc 'boxcox1p'>`

Compute the Box-Cox transformation of  $1 + x$ .

The Box-Cox transformation computed by `boxcox1p` is:

```
y = ((1+x)**lambda - 1) / lambda if lambda != 0
 log(1+x) if lambda == 0
```

Returns *nan* if  $x < -1$ . Returns *-inf* if  $x == -1$  and  $lambda < 0$ .

**Parameters**

**x** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**y** [array] Transformed data.

**Notes**

New in version 0.14.0.

**Examples**

```
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([9.99950003e-05, 9.99975001e-05, 1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([0.00996272, 0.09645476])
```

**scipy.special.inv\_boxcox**

`scipy.special.inv_boxcox(y, lambda) = <ufunc 'inv_boxcox'>`

Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

```
y = (x**lambda - 1) / lambda if lambda != 0
 log(x) if lambda == 0
```

**Parameters**

**y** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**x** [array] Transformed data.

## Notes

New in version 0.16.0.

## Examples

```
>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.]
```

## scipy.special.inv\_boxcox1p

`scipy.special.inv_boxcox1p(y, lambda) = <ufunc 'inv_boxcox1p'>`

Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

```
y = ((1+x)**lambda - 1) / lambda if lambda != 0
 log(1+x) if lambda == 0
```

### Parameters

**y** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

### Returns

**x** [array] Transformed data.

## Notes

New in version 0.16.0.

## Examples

```
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.]
```

## scipy.special.owens\_t

`scipy.special.owens_t(h, a) = <ufunc 'owens_t'>`

Owen's T Function.

The function  $T(h, a)$  gives the probability of the event  $(X > h \text{ and } 0 < Y < a * X)$  where  $X$  and  $Y$  are independent standard normal random variables.

### Parameters

- h: array\_like**  
Input value.
- a: array\_like**  
Input value.

### Returns

- t: scalar or ndarray**  
Probability of the event  $(X > h \text{ and } 0 < Y < a * X)$ , where  $X$  and  $Y$  are independent standard normal random variables.

## References

[1]

## Examples

```
>>> from scipy import special
>>> a = 3.5
>>> h = 0.78
>>> special.owens_t(h, a)
0.10877216734852274
```

## Information Theory functions

|-------------------------------------|-----------------------------------------------------------------|
| <code>entr(x)</code>                | Elementwise function for computing entropy.                     |
| <code>rel_entr(x, y[, out])</code>  | Elementwise function for computing relative entropy.            |
| <code>kl_div(x, y[, out])</code>    | Elementwise function for computing Kullback-Leibler divergence. |
| <code>huber(delta, r)</code>        | Huber loss function.                                            |
| <code>pseudo_huber(delta, r)</code> | Pseudo-Huber loss function.                                     |

## scipy.special.entr

`scipy.special.entr(x) = <ufunc 'entr'>`

Elementwise function for computing entropy.

$$\text{entr}(x) = \begin{cases} -x \log(x) & x > 0 \\ 0 & x = 0 \\ -\infty & \text{otherwise} \end{cases}$$

### Parameters

**x** [ndarray] Input array.

**Returns**

**res** [ndarray] The value of the elementwise entropy function at the given points  $x$ .

See also:

[kl\\_div](#), [rel\\_entr](#)

**Notes**

This function is concave.

New in version 0.15.0.

**scipy.special.rel\_entr**

`scipy.special.rel_entr(x, y, out=None) = <ufunc 'rel_entr'>`  
 Elementwise function for computing relative entropy.

$$\text{rel\_entr}(x, y) = \begin{cases} x \log(x/y) & x > 0, y > 0 \\ 0 & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

**Parameters**

**x, y** [array\_like] Input arrays  
**out** [ndarray, optional] Optional output array for the function results

**Returns**

**scalar or ndarray**  
 Relative entropy of the inputs

See also:

[entr](#), [kl\\_div](#)

**Notes**

New in version 0.15.0.

This function is jointly convex in  $x$  and  $y$ .

The origin of this function is in convex programming; see [1]. Given two discrete probability distributions  $p_1, \dots, p_n$  and  $q_1, \dots, q_n$ , to get the relative entropy of statistics compute the sum

$$\sum_{i=1}^n \text{rel\_entr}(p_i, q_i).$$

See [2] for details.

## References

[1], [2]

### scipy.special.kl\_div

`scipy.special.kl_div(x, y, out=None)` = <ufunc 'kl\_div'>

Elementwise function for computing Kullback-Leibler divergence.

$$\text{kl\_div}(x, y) = \begin{cases} x \log(x/y) - x + y & x > 0, y > 0 \\ y & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

#### Parameters

**x, y** [array\_like] Real arguments  
**out** [ndarray, optional] Optional output array for the function results

#### Returns

**scalar or ndarray**  
 Values of the Kullback-Liebler divergence.

See also:

[entr](#), [rel\\_entr](#)

## Notes

New in version 0.15.0.

This function is non-negative and is jointly convex in  $x$  and  $y$ .

The origin of this function is in convex programming; see [1] for details. This is why the the function contains the extra  $-x + y$  terms over what might be expected from the Kullback-Leibler divergence. For a version of the function without the extra terms, see [rel\\_entr](#).

## References

[1]

### scipy.special.huber

`scipy.special.huber(delta, r)` = <ufunc 'huber'>

Huber loss function.

$$\text{huber}(\delta, r) = \begin{cases} \infty & \delta < 0 \\ \frac{1}{2}r^2 & 0 \leq \delta, |r| \leq \delta \\ \delta(|r| - \frac{1}{2}\delta) & \text{otherwise} \end{cases}$$

#### Parameters

**delta** [ndarray] Input array, indicating the quadratic vs. linear loss changepoint.  
**r** [ndarray] Input array, possibly representing residuals.

**Returns**

**res** [ndarray] The computed Huber loss function values.

**Notes**

This function is convex in  $r$ .

New in version 0.15.0.

**scipy.special.pseudo\_huber**

`scipy.special.pseudo_huber(delta, r) = <ufunc 'pseudo_huber'>`  
 Pseudo-Huber loss function.

$$\text{pseudo\_huber}(\delta, r) = \delta^2 \left( \sqrt{1 + \left(\frac{r}{\delta}\right)^2} - 1 \right)$$

**Parameters**

**delta** [ndarray] Input array, indicating the soft quadratic vs. linear loss changepoint.  
**r** [ndarray] Input array, possibly representing residuals.

**Returns**

**res** [ndarray] The computed Pseudo-Huber loss function values.

**Notes**

This function is convex in  $r$ .

New in version 0.15.0.

**Gamma and related functions**

## scipy.special.gamma

`scipy.special.gamma(z) = <ufunc 'gamma'>`  
gamma function.

The gamma function is defined as

$$\Gamma(z) = \int_0^{\infty} t^{z-1} e^{-t} dt$$

for  $\Re(z) > 0$  and is extended to the rest of the complex plane by analytic continuation. See [dlmf] for more details.

### Parameters

**z** [array\_like] Real or complex valued argument

### Returns

**scalar or ndarray**  
Values of the gamma function

## Notes

The gamma function is often referred to as the generalized factorial since  $\Gamma(n + 1) = n!$  for natural numbers  $n$ . More generally it satisfies the recurrence relation  $\Gamma(z + 1) = z \cdot \Gamma(z)$  for complex  $z$ , which, combined with the fact that  $\Gamma(1) = 1$ , implies the above identity for  $z = n$ .

## References

[dlmf]

## Examples

```
>>> from scipy.special import gamma, factorial
```

```
>>> gamma([0, 0.5, 1, 5])
array([inf, 1.77245385, 1. , 24.])
```

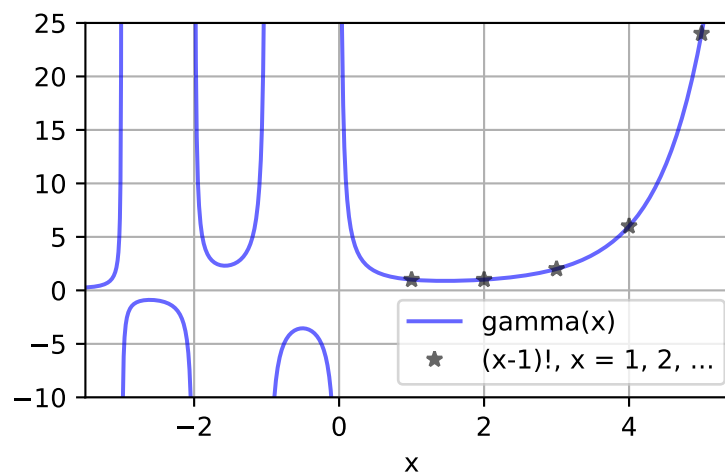

```
>>> z = 2.5 + 1j
>>> gamma(z)
(0.77476210455108352+0.70763120437959293j)
>>> gamma(z+1), z*gamma(z) # Recurrence property
((1.2292740569981171+2.5438401155000685j),
 (1.2292740569981158+2.5438401155000658j))
```

```
>>> gamma(0.5)**2 # gamma(0.5) = sqrt(pi)
3.1415926535897927
```

Plot  $\text{gamma}(x)$  for real  $x$

```
>>> x = np.linspace(-3.5, 5.5, 2251)
>>> y = gamma(x)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'b', alpha=0.6, label='gamma(x)')
>>> k = np.arange(1, 7)
>>> plt.plot(k, factorial(k-1), 'k*', alpha=0.6,
... label='(x-1)!, x = 1, 2, ...')
>>> plt.xlim(-3.5, 5.5)
>>> plt.ylim(-10, 25)
>>> plt.grid()
>>> plt.xlabel('x')
>>> plt.legend(loc='lower right')
>>> plt.show()
```

### scipy.special.gammaln

`scipy.special.gammaln(x, out=None)` = <ufunc 'gammaln'>  
 Logarithm of the absolute value of the gamma function.

Defined as

$$\ln(|\Gamma(x)|)$$

where  $\Gamma$  is the gamma function. For more details on the gamma function, see [dlmf].

#### Parameters

**x** [array\_like] Real argument

**out** [ndarray, optional] Optional output array for the function results

### Returns

**scalar or ndarray**

Values of the log of the absolute value of gamma

**See also:**

[gamma<sub>sgn</sub>](#)

sign of the gamma function

[loggamma](#)

principal branch of the logarithm of the gamma function

### Notes

It is the same function as the Python standard library function `math.lgamma`.

When used in conjunction with [gamma<sub>sgn</sub>](#), this function is useful for working in logspace on the real axis without having to deal with complex numbers via the relation  $\exp(\text{gammaln}(x)) = \text{gamma}_{\text{sgn}}(x) * \text{gamma}(x)$ .

For complex-valued log-gamma, use [loggamma](#) instead of [gammaln](#).

### References

[dlmf]

### Examples

```
>>> import scipy.special as sc
```

It has two positive zeros.

```
>>> sc.gammaln([1, 2])
array([0., 0.]
```

It has poles at nonpositive integers.

```
>>> sc.gammaln([0, -1, -2, -3, -4])
array([inf, inf, inf, inf, inf])
```

It asymptotically approaches  $x * \log(x)$  (Stirling's formula).

```
>>> x = np.array([1e10, 1e20, 1e40, 1e80])
>>> sc.gammaln(x)
array([2.20258509e+11, 4.50517019e+21, 9.11034037e+41, 1.83206807e+82])
>>> x * np.log(x)
array([2.30258509e+11, 4.60517019e+21, 9.21034037e+41, 1.84206807e+82])
```

## scipy.special.loggamma

`scipy.special.loggamma(z, out=None) = <ufunc 'loggamma'>`

Principal branch of the logarithm of the gamma function.

Defined to be  $\log(\Gamma(x))$  for  $x > 0$  and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

### Parameters

**z** [array-like] Values in the complex plain at which to compute `loggamma`  
**out** [ndarray, optional] Output array for computed values of `loggamma`

### Returns

**loggamma** [ndarray] Values of `loggamma` at `z`.

See also:

### `gamma1n`

logarithm of the absolute value of the gamma function

### `gamma1sgn`

sign of the gamma function

## Notes

It is not generally true that  $\log \Gamma(z) = \log(\Gamma(z))$ , though the real parts of the functions do agree. The benefit of not defining `loggamma` as  $\log(\Gamma(z))$  is that the latter function has a complicated branch cut structure whereas `loggamma` is analytic except for on the negative real axis.

The identities

$$\begin{aligned} \exp(\log \Gamma(z)) &= \Gamma(z) \\ \log \Gamma(z + 1) &= \log(z) + \log \Gamma(z) \end{aligned}$$

make `loggamma` useful for working in complex logspace.

On the real line `loggamma` is related to `gamma1n` via  $\exp(\loggamma(x + 0j)) = \text{gamma1sgn}(x) * \exp(\text{gamma1n}(x))$ , up to rounding error.

The implementation here is based on [hare1997].

## References

[hare1997]

## scipy.special.gammasgn

`scipy.special.gammasgn(x) = <ufunc 'gammasgn'>`

Sign of the gamma function.

It is defined as

$$\text{gammasgn}(x) = \begin{cases} +1 & \Gamma(x) > 0 \\ -1 & \Gamma(x) < 0 \end{cases}$$

where  $\Gamma$  is the gamma function; see [gamma](#). This definition is complete since the gamma function is never zero; see the discussion after [\[dlmf\]](#).

### Parameters

**x** [array\_like] Real argument

### Returns

**scalar or ndarray**

Sign of the gamma function

### See also:

#### [gamma](#)

the gamma function

#### [gammaln](#)

log of the absolute value of the gamma function

#### [loggamma](#)

analytic continuation of the log of the gamma function

### Notes

The gamma function can be computed as `gammasgn(x) * np.exp(gammaln(x))`.

### References

[\[dlmf\]](#)

### Examples

```
>>> import scipy.special as sc
```

It is 1 for  $x > 0$ .

```
>>> sc.gammasgn([1, 2, 3, 4])
array([1., 1., 1., 1.])
```

It alternates between -1 and 1 for negative integers.

```
>>> sc.gammasgn([-0.5, -1.5, -2.5, -3.5])
array([-1., 1., -1., 1.])
```

It can be used to compute the gamma function.

```
>>> x = [1.5, 0.5, -0.5, -1.5]
>>> sc.gammasgn(x) * np.exp(sc.gammaln(x))
array([0.88622693, 1.77245385, -3.5449077 , 2.3632718])
>>> sc.gamma(x)
array([0.88622693, 1.77245385, -3.5449077 , 2.3632718])
```

## scipy.special.gammainc

`scipy.special.gammainc(a, x) = <ufunc 'gammainc'>`  
 Regularized lower incomplete gamma function.

It is defined as

$$P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . See [dlmf] for details.

### Parameters

**a** [array\_like] Positive parameter  
**x** [array\_like] Nonnegative argument

### Returns

**scalar or ndarray**  
 Values of the lower incomplete gamma function

See also:

### `gammaincc`

regularized upper incomplete gamma function

### `gammaincinv`

inverse of the regularized lower incomplete gamma function with respect to  $x$

### `gammainccinv`

inverse of the regularized upper incomplete gamma function with respect to  $x$

## Notes

The function satisfies the relation `gammainc(a, x) + gammaincc(a, x) = 1` where `gammaincc` is the regularized upper incomplete gamma function.

The implementation largely follows that of [boost].

## References

[dlmf], [boost]

## Examples

```
>>> import scipy.special as sc
```

It is the CDF of the gamma distribution, so it starts at 0 and monotonically increases to 1.

```
>>> sc.gammainc(0.5, [0, 1, 10, 100])
array([0. , 0.84270079, 0.99999226, 1.])
```

It is equal to one minus the upper incomplete gamma function.

```
>>> a, x = 0.5, 0.4
>>> sc.gammainc(a, x)
0.6289066304773024
>>> 1 - sc.gammaincc(a, x)
0.6289066304773024
```

## scipy.special.gammaincinv

`scipy.special.gammaincinv(a, y) = <ufunc 'gammaincinv'>`

Inverse to the lower incomplete gamma function with respect to  $x$ .

Given an input  $y$  between 0 and 1, returns  $x$  such that  $y = P(a, x)$ . Here  $P$  is the regularized lower incomplete gamma function; see [gammainc](#). This is well-defined because the lower incomplete gamma function is monotonic as can be seen from its definition in [dlmf].

### Parameters

**a** [array\_like] Positive parameter  
**y** [array\_like] Parameter between 0 and 1, inclusive

### Returns

**scalar or ndarray**  
 Values of the inverse of the lower incomplete gamma function

See also:

### [gammainc](#)

regularized lower incomplete gamma function

### [gammaincc](#)

regularized upper incomplete gamma function

### [gammainccinv](#)

inverse of the regularized upper incomplete gamma function with respect to  $x$

## References

[dlmf]

## Examples

```
>>> import scipy.special as sc
```

It starts at 0 and monotonically increases to infinity.

```
>>> sc.gammaincinv(0.5, [0, 0.1, 0.5, 1])
array([0. , 0.00789539, 0.22746821, inf])
```

It inverts the lower incomplete gamma function.

```
>>> a, x = 0.5, [0, 0.1, 0.5, 1]
>>> sc.gammainc(a, sc.gammaincinv(a, x))
array([0. , 0.1, 0.5, 1.])
```

```
>>> a, x = 0.5, [0, 10, 25]
>>> sc.gammaincinv(a, sc.gammainc(a, x))
array([0. , 10. , 25.00001465])
```

## scipy.special.gammaincc

`scipy.special.gammaincc(a, x) = <ufunc 'gammaincc'>`  
Regularized upper incomplete gamma function.

It is defined as

$$Q(a, x) = \frac{1}{\Gamma(a)} \int_x^\infty t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . See [dlmf] for details.

### Parameters

**a** [array\_like] Positive parameter  
**x** [array\_like] Nonnegative argument

### Returns

**scalar or ndarray**  
Values of the upper incomplete gamma function

See also:

[gammainc](#)

regularized lower incomplete gamma function

[gammaincinv](#)

inverse of the regularized lower incomplete gamma function with respect to  $x$

[gammainccinv](#)

inverse to of the regularized upper incomplete gamma function with respect to  $x$

## Notes

The function satisfies the relation  $\text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1$  where *gammainc* is the regularized lower incomplete gamma function.

The implementation largely follows that of [boost].

## References

[dlmf], [boost]

## Examples

```
>>> import scipy.special as sc
```

It is the survival function of the gamma distribution, so it starts at 1 and monotonically decreases to 0.

```
>>> sc.gammaincc(0.5, [0, 1, 10, 100, 1000])
array([1.00000000e+00, 1.57299207e-01, 7.74421643e-06, 2.08848758e-45,
 0.00000000e+00])
```

It is equal to one minus the lower incomplete gamma function.

```
>>> a, x = 0.5, 0.4
>>> sc.gammaincc(a, x)
0.37109336952269756
>>> 1 - sc.gammainc(a, x)
0.37109336952269756
```

## scipy.special.gammainccinv

`scipy.special.gammainccinv(a, y) = <ufunc 'gammainccinv'>`

Inverse of the upper incomplete gamma function with respect to  $x$

Given an input  $y$  between 0 and 1, returns  $x$  such that  $y = Q(a, x)$ . Here  $Q$  is the upper incomplete gamma function; see *gammaincc*. This is well-defined because the upper incomplete gamma function is monotonic as can be seen from its definition in [dlmf].

### Parameters

**a** [array\_like] Positive parameter  
**y** [array\_like] Argument between 0 and 1, inclusive

### Returns

**scalar or ndarray**

Values of the inverse of the upper incomplete gamma function

See also:

### gammaincc

regularized upper incomplete gamma function

**gammainc**

regularized lower incomplete gamma function

**gammaincinv**

inverse of the regularized lower incomplete gamma function with respect to  $x$

**References**

[dlmf]

**Examples**

```
>>> import scipy.special as sc
```

It starts at infinity and monotonically decreases to 0.

```
>>> sc.gammaincinv(0.5, [0, 0.1, 0.5, 1])
array([inf, 1.35277173, 0.22746821, 0.])
```

It inverts the upper incomplete gamma function.

```
>>> a, x = 0.5, [0, 0.1, 0.5, 1]
>>> sc.gammainc(a, sc.gammaincinv(a, x))
array([0. , 0.1, 0.5, 1.])
```

```
>>> a, x = 0.5, [0, 10, 50]
>>> sc.gammaincinv(a, sc.gammainc(a, x))
array([0., 10., 50.])
```

**scipy.special.beta**

`scipy.special.beta(a, b, out=None)` = <ufunc 'beta'>  
Beta function.

This function is defined in [1] as

$$B(a, b) = \int_0^1 t^{a-1}(1-t)^{b-1} dt = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)},$$

where  $\Gamma$  is the gamma function.

**Parameters**

**a, b** [array-like] Real-valued arguments  
**out** [ndarray, optional] Optional output array for the function result

**Returns**

**scalar or ndarray**  
Value of the beta function

See also:

**gamma**

the gamma function

**betainc**

the incomplete beta function

**betaln**

the natural logarithm of the absolute value of the beta function

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

The beta function relates to the gamma function by the definition given above:

```
>>> sc.beta(2, 3)
0.08333333333333333
>>> sc.gamma(2)*sc.gamma(3)/sc.gamma(2 + 3)
0.08333333333333333
```

As this relationship demonstrates, the beta function is symmetric:

```
>>> sc.beta(1.7, 2.4)
0.16567527689031739
>>> sc.beta(2.4, 1.7)
0.16567527689031739
```

This function satisfies  $B(1, b) = 1/b$ :

```
>>> sc.beta(1, 4)
0.25
```

**scipy.special.betaln**

`scipy.special.betaln(a, b) = <ufunc 'betaln'>`

Natural logarithm of absolute value of beta function.

Computes  $\ln(\text{abs}(\text{beta}(a, b)))$ .

## scipy.special.betainc

`scipy.special.betainc(a, b, x, out=None)` = <ufunc 'betainc'>

Incomplete beta function.

Computes the incomplete beta function, defined as [1]:

$$I_x(a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1}(1-t)^{b-1} dt,$$

for  $0 \leq x \leq 1$ .

### Parameters

**a, b** [array-like] Positive, real-valued parameters  
**x** [array-like] Real-valued such that  $0 \leq x \leq 1$ , the upper limit of integration  
**out** [ndarray, optional] Optional output array for the function values

### Returns

**array-like** Value of the incomplete beta function

See also:

### beta

beta function

### betaincinv

inverse of the incomplete beta function

## Notes

The incomplete beta function is also sometimes defined without the *gamma* terms, in which case the above definition is the so-called regularized incomplete beta function. Under this definition, you can get the incomplete beta function by multiplying the result of the SciPy function by *beta*.

## References

[1]

## Examples

Let  $B(a, b)$  be the *beta* function.

```
>>> import scipy.special as sc
```

The coefficient in terms of *gamma* is equal to  $1/B(a, b)$ . Also, when  $x = 1$  the integral is equal to  $B(a, b)$ . Therefore,  $I_{x=1}(a, b) = 1$  for any  $a, b$ .

```
>>> sc.betainc(0.2, 3.5, 1.0)
1.0
```

It satisfies  $I_x(a, b) = x^a F(a, 1-b, a+1, x)/(aB(a, b))$ , where  $F$  is the hypergeometric function *hyp2f1*:

```
>>> a, b, x = 1.4, 3.1, 0.5
>>> x**a * sc.hyp2f1(a, 1 - b, a + 1, x) / (a * sc.beta(a, b))
0.8148904036225295
>>> sc.betainc(a, b, x)
0.8148904036225296
```

This function satisfies the relationship  $I_x(a, b) = 1 - I_{1-x}(b, a)$ :

```
>>> sc.betainc(2.2, 3.1, 0.4)
0.49339638807619446
>>> 1 - sc.betainc(3.1, 2.2, 1 - 0.4)
0.49339638807619446
```

### scipy.special.betaincinv

`scipy.special.betaincinv(a, b, y, out=None)` = <ufunc 'betaincinv'>  
Inverse of the incomplete beta function.

Computes  $x$  such that:

$$y = I_x(a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1}(1-t)^{b-1} dt,$$

where  $I_x$  is the normalized incomplete beta function `betainc` and  $\Gamma$  is the *gamma* function [1].

#### Parameters

**a, b** [array-like] Positive, real-valued parameters  
**y** [array-like] Real-valued input  
**out** [ndarray, optional] Optional output array for function values

#### Returns

**array-like** Value of the inverse of the incomplete beta function

See also:

#### `betainc`

incomplete beta function

#### `gamma`

gamma function

### References

[1]

## Examples

```
>>> import scipy.special as sc
```

This function is the inverse of *betainc* for fixed values of *a* and *b*.

```
>>> a, b = 1.2, 3.1
>>> y = sc.betainc(a, b, 0.2)
>>> sc.betaincinv(a, b, y)
0.2
>>>
>>> a, b = 7.5, 0.4
>>> x = sc.betaincinv(a, b, 0.5)
>>> sc.betainc(a, b, x)
0.5
```

## scipy.special.psi

`scipy.special.psi(z, out=None) = <ufunc 'psi'>`

The digamma function.

The logarithmic derivative of the gamma function evaluated at *z*.

### Parameters

**z** [array\_like] Real or complex argument.  
**out** [ndarray, optional] Array for the computed values of `psi`.

### Returns

**digamma** [ndarray] Computed values of `psi`.

## Notes

For large values not close to the negative real axis, `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis, the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis, the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

## References

[1], [2]

## Examples

```
>>> from scipy.special import psi
>>> z = 3 + 4j
>>> psi(z)
(1.55035981733341+1.0105022091860445j)
```

Verify  $\psi(z) = \psi(z + 1) - 1/z$ :

```
>>> psi(z + 1) - 1/z
(1.55035981733341+1.0105022091860445j)
```

## scipy.special.rgamma

`scipy.special.rgamma(z, out=None) = <ufunc 'rgamma'>`

Reciprocal of the gamma function.

Defined as  $1/\Gamma(z)$ , where  $\Gamma$  is the gamma function. For more on the gamma function see [gamma](#).

### Parameters

**z** [array\_like] Real or complex valued input  
**out** [ndarray, optional] Optional output array for the function results

### Returns

**scalar or ndarray**  
 Function results

See also:

[gamma](#), [gammaaln](#), [loggamma](#)

## Notes

The gamma function has no zeros and has simple poles at nonpositive integers, so *rgamma* is an entire function with zeros at the nonpositive integers. See the discussion in [\[dlmf\]](#) for more details.

## References

[\[dlmf\]](#)

## Examples

```
>>> import scipy.special as sc
```

It is the reciprocal of the gamma function.

```
>>> sc.rgamma([1, 2, 3, 4])
array([1. , 1. , 0.5 , 0.16666667])
>>> 1 / sc.gamma([1, 2, 3, 4])
array([1. , 1. , 0.5 , 0.16666667])
```

It is zero at nonpositive integers.

```
>>> sc.rgamma([0, -1, -2, -3])
array([0., 0., 0., 0.]
```

It rapidly underflows to zero along the positive real axis.

```
>>> sc.rgamma([10, 100, 179])
array([2.75573192e-006, 1.07151029e-156, 0.00000000e+000])
```

## scipy.special.polygamma

`scipy.special.polygamma` ( $n, x$ )

Polygamma functions.

Defined as  $\psi^{(n)}(x)$  where  $\psi$  is the *digamma* function. See [dlmf] for details.

### Parameters

**n** [array\_like] The order of the derivative of the digamma function; must be integral  
**x** [array\_like] Real valued input

### Returns

**ndarray** Function results

See also:

[digamma](#)

## References

[dlmf]

## Examples

```
>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([0.64493407, 0.39493407, 0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([True, True, True], dtype=bool)
```

## scipy.special.multigammaln

`scipy.special.multigammaln` ( $a, d$ )

Returns the log of multivariate gamma, also sometimes called the generalized gamma.

### Parameters

**a** [ndarray] The multivariate gamma is computed for each item of  $a$ .  
**d** [int] The dimension of the space of integration.

### Returns

**res** [ndarray] The values of the log multivariate gamma at the given points  $a$ .

## Notes

The formal definition of the multivariate gamma of dimension  $d$  for a real  $a$  is

$$\Gamma_d(a) = \int_{A>0} e^{-\text{tr}(A)} |A|^{a-(d+1)/2} dA$$

with the condition  $a > (d - 1)/2$ , and  $A > 0$  being the set of all the positive definite matrices of dimension  $d$ . Note that  $a$  is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

$$\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^d \Gamma(a - (i - 1)/2).$$

## References

R. J. Muirhead, Aspects of multivariate statistical theory (Wiley Series in probability and mathematical statistics).

## scipy.special.digamma

`scipy.special.digamma(z, out=None) = <ufunc 'psi'>`

The digamma function.

The logarithmic derivative of the gamma function evaluated at  $z$ .

### Parameters

**z** [array\_like] Real or complex argument.  
**out** [ndarray, optional] Array for the computed values of `psi`.

### Returns

**digamma** [ndarray] Computed values of `psi`.

## Notes

For large values not close to the negative real axis, `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis, the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis, the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

## References

[1], [2]

## Examples

```
>>> from scipy.special import psi
>>> z = 3 + 4j
>>> psi(z)
(1.55035981733341+1.0105022091860445j)
```

Verify  $\psi(z) = \psi(z + 1) - 1/z$ :

```
>>> psi(z + 1) - 1/z
(1.55035981733341+1.0105022091860445j)
```

## scipy.special.poch

`scipy.special.poch(z, m) = <ufunc 'poch'>`  
Pochhammer symbol.

The Pochhammer symbol (rising factorial) is defined as

$$(z)_m = \frac{\Gamma(z + m)}{\Gamma(z)}$$

For positive integer  $m$  it reads

$$(z)_m = z(z + 1)\dots(z + m - 1)$$

See [dlmf] for more details.

### *Parameters*

**z, m** [array\_like] Real-valued arguments.

### *Returns*

**scalar or ndarray**  
The value of the function.

## References

[dlmf]

## Examples

```
>>> import scipy.special as sc
```

It is 1 when  $m$  is 0.

```
>>> sc.poch([1, 2, 3, 4], 0)
array([1., 1., 1., 1.])
```

For  $z$  equal to 1 it reduces to the factorial function.

```
>>> sc.poch(1, 5)
120.0
>>> 1 * 2 * 3 * 4 * 5
120
```

It can be expressed in terms of the gamma function.

```
>>> z, m = 3.7, 2.1
>>> sc.poch(z, m)
20.529581933776953
>>> sc.gamma(z + m) / sc.gamma(z)
20.52958193377696
```

## Error function and Fresnel integrals

## scipy.special.erf

`scipy.special.erf(z) = <ufunc 'erf'>`

Returns the error function of complex argument.

It is defined as  $2/\sqrt{\pi} * \text{integral}(\exp(-t^2), t=0..z)$ .

### Parameters

**x** [ndarray] Input array.

### Returns

**res** [ndarray] The values of the error function at the given points  $x$ .

See also:

[erfc](#), [erfinv](#), [erfcinv](#), [wofz](#), [erfcx](#), [erfi](#)

## Notes

The cumulative of the unit normal distribution is given by  $\Phi(z) = 1/2[1 + \text{erf}(z/\sqrt{2})]$ .

## References

[1], [2], [3]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erf(x))
>>> plt.xlabel('x')
>>> plt.ylabel('$\text{erf}(x)$')
>>> plt.show()
```

## scipy.special.erfc

`scipy.special.erfc(x, out=None) = <ufunc 'erfc'>`

Complementary error function,  $1 - \text{erf}(x)$ .

### Parameters

**x** [array\_like] Real or complex valued argument  
**out** [ndarray, optional] Optional output array for the function results

### Returns

**scalar or ndarray**  
Values of the complementary error function

See also:

`erf`, `erfi`, `erfcx`, `dawsn`, `wofz`

## References

[1]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfc(x))
>>> plt.xlabel('x')
>>> plt.ylabel('$erfc(x)$')
>>> plt.show()
```

## scipy.special.erfcx

`scipy.special.erfcx(x, out=None) = <ufunc 'erfcx'>`  
 Scaled complementary error function,  $\exp(x^2) * \text{erfc}(x)$ .

### Parameters

**x** [array\_like] Real or complex valued argument  
**out** [ndarray, optional] Optional output array for the function results

### Returns

**scalar or ndarray**  
 Values of the scaled complementary error function

See also:

`erf`, `erfc`, `erfi`, `dawsn`, `wofz`

## Notes

New in version 0.12.0.

## References

[1]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfcx(x))
>>> plt.xlabel('x')
>>> plt.ylabel('$\text{erfcx}(x)$')
>>> plt.show()
```

## `scipy.special.erfi`

`scipy.special.erfi`(*z*, *out=None*) = <ufunc 'erfi'>

Imaginary error function,  $-i \operatorname{erf}(i z)$ .

### Parameters

**z** [array\_like] Real or complex valued argument  
**out** [ndarray, optional] Optional output array for the function results

### Returns

scalar or ndarray

Values of the imaginary error function

See also:

[erf](#), [erfc](#), [erfcx](#), [dawson](#), [wofz](#)

### Notes

New in version 0.12.0.

### References

[1]

### Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfi(x))
>>> plt.xlabel('x')
>>> plt.ylabel('$erfi(x)$')
>>> plt.show()
```

**scipy.special.erfinv**

```
scipy.special.erfinv(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None,
 subok=True[, signature, extobj]) = <ufunc 'erfinv'>
```

Inverse of the error function.

Computes the inverse of the error function.

In the complex domain, there is no unique complex number  $w$  satisfying  $\text{erf}(w)=z$ . This indicates a true inverse function would have multi-value. When the domain restricts to the real,  $-1 < x < 1$ , there is a unique real number satisfying  $\text{erf}(\text{erfinv}(x)) = x$ .

**Parameters**

**y** [ndarray] Argument at which to evaluate. Domain:  $[-1, 1]$

**Returns**

**erfinv** [ndarray] The inverse of erf of y, element-wise)

**See also:****erf**

Error function of a complex argument

**erfc**

Complementary error function,  $1 - \text{erf}(x)$

**erfcinv**

Inverse of the complementary error function

**Examples**

- 1) evaluating a float number

```
>>> from scipy import special
>>> special.erfinv(0.5)
0.4769362762044698
```

- 2) evaluating an ndarray

```
>>> from scipy import special
>>> y = np.linspace(-1.0, 1.0, num=10)
>>> special.erfinv(y)
array([-inf, -0.86312307, -0.5407314 , -0.30457019, -0.0987901 ,
 0.0987901 , 0.30457019, 0.5407314 , 0.86312307, inf])
```

**scipy.special.erfcinv**

`scipy.special.erfcinv(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature, extobj]) = <ufunc 'erfcinv'>`

Inverse of the complementary error function.

Computes the inverse of the complementary error function.

In the complex domain, there is no unique complex number  $w$  satisfying  $\operatorname{erfc}(w)=z$ . This indicates a true inverse function would have multi-value. When the domain restricts to the real,  $0 < x < 2$ , there is a unique real number satisfying  $\operatorname{erfc}(\operatorname{erfcinv}(x)) = \operatorname{erfcinv}(\operatorname{erfc}(x))$ .

It is related to inverse of the error function by  $\operatorname{erfcinv}(1-x) = \operatorname{erfinv}(x)$

**Parameters**

**y** [ndarray] Argument at which to evaluate. Domain: [0, 2]

**Returns**

**erfcinv** [ndarray] The inverse of  $\operatorname{erfc}$  of  $y$ , element-wise

**See also:****erf**

Error function of a complex argument

**erfc**

Complementary error function,  $1 - \operatorname{erf}(x)$

**erfinv**

Inverse of the error function

**Examples**

- 1) evaluating a float number

```
>>> from scipy import special
>>> special.erfcinv(0.5)
0.4769362762044698
```

- 2) evaluating an ndarray

```
>>> from scipy import special
>>> y = np.linspace(0.0, 2.0, num=11)
>>> special.erfcinv(y)
array([inf, 0.9061938 , 0.59511608, 0.37080716, 0.17914345,
 -0. , -0.17914345, -0.37080716, -0.59511608, -0.9061938 ,
 -inf])
```

## scipy.special.wofz

`scipy.special.wofz(z)` = <ufunc 'wofz'>

Faddeeva function

Returns the value of the Faddeeva function for complex argument:

```
exp(-z**2) * erfc(-i*z)
```

See also:

`dawsn`, `erf`, `erfc`, `erfcx`, `erfi`

## References

[1]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-3, 3)
>>> z = special.wofz(x)
```

```
>>> plt.plot(x, z.real, label='wofz(x).real')
>>> plt.plot(x, z.imag, label='wofz(x).imag')
>>> plt.xlabel('x')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```

## scipy.special.dawsn

`scipy.special.dawsn(x) = <ufunc 'dawsn'>`

Dawson's integral.

Computes:

```
exp(-x**2) * integral(exp(t**2), t=0..x).
```

See also:

`wofz`, `erf`, `erfc`, `erfcx`, `erfi`

## References

[1]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-15, 15, num=1000)
>>> plt.plot(x, special.dawsn(x))
>>> plt.xlabel('x')
>>> plt.ylabel('$dawsn(x)$')
>>> plt.show()
```

## scipy.special.fresnel

`scipy.special.fresnel` (*z*, *out=None*) = <ufunc 'fresnel'>  
Fresnel integrals.

The Fresnel integrals are defined as

$$S(z) = \int_0^z \sin(\pi t^2/2) dt$$

$$C(z) = \int_0^z \cos(\pi t^2/2) dt.$$

See [dlmf] for details.

### Parameters

**z** [array\_like] Real or complex valued argument  
**out** [2-tuple of ndarrays, optional] Optional output arrays for the function results

### Returns

**S, C** [2-tuple of scalar or ndarray] Values of the Fresnel integrals

See also:

### fresnel\_zeros

zeros of the Fresnel integrals

## References

[dlmf]

## Examples

```
>>> import scipy.special as sc
```

As *z* goes to infinity along the real axis, *S* and *C* converge to 0.5.

```
>>> S, C = sc.fresnel([0.1, 1, 10, 100, np.inf])
>>> S
array([0.00052359, 0.43825915, 0.46816998, 0.4968169 , 0.5])
>>> C
array([0.09999753, 0.7798934 , 0.49989869, 0.4999999 , 0.5])
```

They are related to the error function *erf*.

```
>>> z = np.array([1, 2, 3, 4])
>>> zeta = 0.5 * np.sqrt(np.pi) * (1 - 1j) * z
>>> S, C = sc.fresnel(z)
>>> C + 1j*S
array([0.7798934 +0.43825915j, 0.48825341+0.34341568j,
 0.60572079+0.496313j , 0.49842603+0.42051575j])
>>> 0.5 * (1 + 1j) * sc.erf(zeta)
array([0.7798934 +0.43825915j, 0.48825341+0.34341568j,
 0.60572079+0.496313j , 0.49842603+0.42051575j])
```

### scipy.special.fresnel\_zeros

`scipy.special.fresnel_zeros` (*nt*)

Compute *nt* complex zeros of sine and cosine Fresnel integrals  $S(z)$  and  $C(z)$ .

#### References

[1]

### scipy.special.modfresnelp

`scipy.special.modfresnelp` (*x*) = `<ufunc 'modfresnelp'>`

Modified Fresnel positive integrals

#### Returns

|           |                                                                                          |
|-----------|------------------------------------------------------------------------------------------|
| <b>fp</b> | Integral $F_+(x)$ : $\text{integral}(\exp(1j*t*t), t=x..\text{inf})$                     |
| <b>kp</b> | Integral $K_+(x)$ : $1/\text{sqrt}(\text{pi}) * \exp(-1j*(x*x+\text{pi}/4)) * \text{fp}$ |

### scipy.special.modfresnelm

`scipy.special.modfresnelm` (*x*) = `<ufunc 'modfresnelm'>`

Modified Fresnel negative integrals

#### Returns

|           |                                                                                         |
|-----------|-----------------------------------------------------------------------------------------|
| <b>fm</b> | Integral $F_-(x)$ : $\text{integral}(\exp(-1j*t*t), t=x..\text{inf})$                   |
| <b>km</b> | Integral $K_-(x)$ : $1/\text{sqrt}(\text{pi}) * \exp(1j*(x*x+\text{pi}/4)) * \text{fp}$ |

### scipy.special.voigt\_profile

`scipy.special.voigt_profile` (*x*, *sigma*, *gamma*, *out=None*) = `<ufunc 'voigt_profile'>`

Voigt profile.

The Voigt profile is a convolution of a 1-D Normal distribution with standard deviation *sigma* and a 1-D Cauchy distribution with half-width at half-maximum *gamma*.

If *sigma* = 0, PDF of Cauchy distribution is returned. Conversely, if *gamma* = 0, PDF of Normal distribution is returned. If *sigma* = *gamma* = 0, the return value is `Inf` for *x* = 0, and 0 for all other *x*.

#### Parameters

|              |                                                                             |
|--------------|-----------------------------------------------------------------------------|
| <b>x</b>     | [array_like] Real argument                                                  |
| <b>sigma</b> | [array_like] The standard deviation of the Normal distribution part         |
| <b>gamma</b> | [array_like] The half-width at half-maximum of the Cauchy distribution part |
| <b>out</b>   | [ndarray, optional] Optional output array for the function values           |

#### Returns

**scalar or ndarray**  
The Voigt profile at the given arguments

See also:

**wofz**

Faddeeva function

**Notes**

It can be expressed in terms of Faddeeva function

$$V(x; \sigma, \gamma) = \frac{\operatorname{Re}[w(z)]}{\sigma\sqrt{2\pi}},$$

$$z = \frac{x + i\gamma}{\sqrt{2}\sigma}$$

where  $w(z)$  is the Faddeeva function.

**scipy.special.erf\_zeros**

`scipy.special.erf_zeros` (*nt*)

Compute the first *nt* zero in the first quadrant, ordered by absolute value.

Zeros in the other quadrants can be obtained by using the symmetries  $\operatorname{erf}(-z) = -\operatorname{erf}(z)$  and  $\operatorname{erf}(\operatorname{conj}(z)) = \operatorname{conj}(\operatorname{erf}(z))$ .

**Parameters**

**nt** [int] The number of zeros to compute

**Returns**

**The locations of the zeros of erf**

[ndarray (complex)] Complex values at which zeros of erf(z)

**References**

[1]

## Examples

```
>>> from scipy import special
>>> special.erf_zeros(1)
array([1.45061616+1.880943j])
```

Check that erf is (close to) zero for the value returned by erf\_zeros

```
>>> special.erf(special.erf_zeros(1))
array([4.95159469e-14-1.16407394e-16j])
```

## scipy.special.fresnelc\_zeros

## Legendre functions

|                                                                           |                                                                |
|---------------------------------------------------------------------------|----------------------------------------------------------------|
| <code>lpmv</code> ( <i>m</i> , <i>v</i> , <i>x</i> )                      | Associated Legendre function of integer order and real degree. |
| <code>sph_harm</code> ( <i>m</i> , <i>n</i> , <i>theta</i> , <i>phi</i> ) | Compute spherical harmonics.                                   |

## scipy.special.lpmv

`scipy.special.lpmv` (*m*, *v*, *x*) = `<ufunc 'lpmv'>`  
Associated Legendre function of integer order and real degree.

Defined as

$$P_v^m = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_v(x)$$

where

$$P_v = \sum_{k=0}^{\infty} \frac{(-v)_k (v+1)_k}{(k!)^2} \left(\frac{1-x}{2}\right)^k$$

is the Legendre function of the first kind. Here  $(\cdot)_k$  is the Pochhammer symbol; see [poch](#).

**Parameters**

- m** [array\_like] Order (int or float). If passed a float not equal to an integer the function returns NaN.
- v** [array\_like] Degree (float).
- x** [array\_like] Argument (float). Must have  $|x| \leq 1$ .

**Returns**

- pmv** [ndarray] Value of the associated Legendre function.

See also:

[lpmn](#)

Compute the associated Legendre function for all orders  $0, \dots, m$  and degrees  $0, \dots, n$ .

[clpmn](#)

Compute the associated Legendre function at complex arguments.

**Notes**

Note that this implementation includes the Condon-Shortley phase.

**References**

- [1]

**scipy.special.sph\_harm**

`scipy.special.sph_harm(m, n, theta, phi) = <ufunc 'sph_harm'>`

Compute spherical harmonics.

The spherical harmonics are defined as

$$Y_n^m(\theta, \phi) = \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} e^{im\theta} P_n^m(\cos(\phi))$$

where  $P_n^m$  are the associated Legendre functions; see [lpmv](#).

**Parameters**

- m** [array\_like] Order of the harmonic (int); must have  $|m| \leq n$ .
- n** [array\_like] Degree of the harmonic (int); must have  $n \geq 0$ . This is often denoted by  $l$  (lower case L) in descriptions of spherical harmonics.
- theta** [array\_like] Azimuthal (longitudinal) coordinate; must be in  $[0, 2\pi]$ .
- phi** [array\_like] Polar (colatitudinal) coordinate; must be in  $[0, \pi]$ .

**Returns**

- y\_mn** [complex float] The harmonic  $Y_n^m$  sampled at `theta` and `phi`.

## Notes

There are different conventions for the meanings of the input arguments `theta` and `phi`. In SciPy `theta` is the azimuthal angle and `phi` is the polar angle. It is common to see the opposite convention, that is, `theta` as the polar angle and `phi` as the azimuthal angle.

Note that SciPy's spherical harmonics include the Condon-Shortley phase [2] because it is part of `lpmv`.

With SciPy's conventions, the first several spherical harmonics are

$$\begin{aligned}
 Y_0^0(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{1}{\pi}} \\
 Y_1^{-1}(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{-i\theta} \sin(\phi) \\
 Y_1^0(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos(\phi) \\
 Y_1^1(\theta, \phi) &= -\frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{i\theta} \sin(\phi).
 \end{aligned}$$

## scipy.special.clpmn

`scipy.special.clpmn(m, n, z, type=3)`

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order `m` and degree `n`,  $P_{mn}(z) = P_n^m(z)$ , and its derivative,  $P_{mn}'(z)$ . Returns two arrays of size `(m+1, n+1)` containing  $P_{mn}(z)$  and  $P_{mn}'(z)$  for all orders from `0..m` and degrees from `0..n`.

### Parameters

|             |                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>m</b>    | [int] <code> m  &lt;= n</code> ; the order of the Legendre function.                                                                                                     |
| <b>n</b>    | [int] where <code>n &gt;= 0</code> ; the degree of the Legendre function. Often called <code>l</code> (lower case L) in descriptions of the associated Legendre function |
| <b>z</b>    | [float or complex] Input value.                                                                                                                                          |
| <b>type</b> | [int, optional] takes values 2 or 3 2: cut on the real axis <code> x  &gt; 1</code> 3: cut on the real axis <code>-1 &lt; x &lt; 1</code> (default)                      |

### Returns

**Pmn\_z** [(m+1, n+1) array] Values for all orders 0 . . m and degrees 0 . . n  
**Pmn\_d\_z** [(m+1, n+1) array] Derivatives for all orders 0 . . m and degrees 0 . . n

**See also:**

[lpmn](#)

associated Legendre functions of the first kind for real z

### Notes

By default, i.e. for `type=3`, phase conventions are chosen according to [1] such that the function is analytic. The cut lies on the interval  $(-1, 1)$ . Approaching the cut from above or below in general yields a phase factor with respect to Ferrer's function of the first kind (cf. [lpmn](#)).

For `type=2` a cut at  $|x| > 1$  is chosen. Approaching the real values on the interval  $(-1, 1)$  in the complex plane yields Ferrer's function of the first kind.

### References

[1], [2]

### scipy.special.lpn

`scipy.special.lpn(n, z)`

Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials),  $P_n(z)$  and derivatives for all degrees from 0 to n (inclusive).

See also `special.legendre` for polynomial class.

### References

[1]

### scipy.special.lqn

`scipy.special.lqn(n, z)`

Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind,  $Q_n(z)$  and derivatives for all degrees from 0 to n (inclusive).

## References

[1]

### scipy.special.lpmn

`scipy.special.lpmn(m, n, z)`

Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order  $m$  and degree  $n$ ,  $P_m^n(z) = P_n^m(z)$ , and its derivative,  $P_m^n'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $P_m^n(z)$  and  $P_m^n'(z)$  for all orders from  $0..m$  and degrees from  $0..n$ .

This function takes a real argument  $z$ . For complex arguments  $z$  use `clpmn` instead.

#### Parameters

|          |                                                                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>m</b> | [int] $ m  \leq n$ ; the order of the Legendre function.                                                                                          |
| <b>n</b> | [int] where $n \geq 0$ ; the degree of the Legendre function. Often called $l$ (lower case L) in descriptions of the associated Legendre function |
| <b>z</b> | [float] Input value.                                                                                                                              |

#### Returns

|                |                                                                         |
|----------------|-------------------------------------------------------------------------|
| <b>Pmn_z</b>   | [(m+1, n+1) array] Values for all orders $0..m$ and degrees $0..n$      |
| <b>Pmn_d_z</b> | [(m+1, n+1) array] Derivatives for all orders $0..m$ and degrees $0..n$ |

See also:

#### `clpmn`

associated Legendre functions of the first kind for complex  $z$

## Notes

In the interval  $(-1, 1)$ , Ferrer's function of the first kind is returned. The phase convention used for the intervals  $(1, \text{inf})$  and  $(-\text{inf}, -1)$  is such that the result is always real.

## References

[1], [2]

### scipy.special.lqmn

`scipy.special.lqmn(m, n, z)`

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order  $m$  and degree  $n$ ,  $Q_m^n(z) = Q_n^m(z)$ , and its derivative,  $Q_m^n'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $Q_m^n(z)$  and  $Q_m^n'(z)$  for all orders from  $0..m$  and degrees from  $0..n$ .

#### Parameters

|          |                                                                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>m</b> | [int] $ m  \leq n$ ; the order of the Legendre function.                                                                                          |
| <b>n</b> | [int] where $n \geq 0$ ; the degree of the Legendre function. Often called $l$ (lower case L) in descriptions of the associated Legendre function |

**z** [complex] Input value.

**Returns**

**Qmn\_z** [(m+1, n+1) array] Values for all orders 0..m and degrees 0..n  
**Qmn\_d\_z** [(m+1, n+1) array] Derivatives for all orders 0..m and degrees 0..n

**Ellipsoidal harmonics**

|                                                          |                                                           |
|----------------------------------------------------------|-----------------------------------------------------------|
| <code>ellip_harm(h2, k2, n, p, s[, signm, signn])</code> | Ellipsoidal harmonic functions $E^p_n(l)$                 |
| <code>ellip_harm_2(h2, k2, n, p, s)</code>               | Ellipsoidal harmonic functions $F^p_n(l)$                 |
| <code>ellip_normal(h2, k2, n, p)</code>                  | Ellipsoidal harmonic normalization constants $\gamma^p_n$ |

**scipy.special.ellip\_harm**

`scipy.special.ellip_harm(h2, k2, n, p, s, signm=1, signn=1)`  
 Ellipsoidal harmonic functions  $E^p_n(l)$

These are also known as Lamé functions of the first kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

**Parameters**

**h2** [float]  $h^2$   
**k2** [float]  $k^2$ ; should be larger than  $h^2$   
**n** [int] Degree  
**s** [float] Coordinate  
**p** [int] Order, can range between  $[1, 2n+1]$   
**signm** [{1, -1}, optional] Sign of prefactor of functions. Can be +/-1. See Notes.  
**signn** [{1, -1}, optional] Sign of prefactor of functions. Can be +/-1. See Notes.

**Returns**

**E** [float] the harmonic  $E^p_n(s)$

See also:

`ellip_harm_2`, `ellip_normal`

## Notes

The geometric interpretation of the ellipsoidal functions is explained in [2], [3], [4]. The *signm* and *signn* arguments control the sign of prefactors for functions according to their type:

```
K : +1
L : signm
M : signn
N : signm*signn
```

New in version 0.15.0.

## References

[1], [2], [3], [4]

## Examples

```
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5, 8, 1, 1, 2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lamé equation:

```
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
... r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 -
... ↪k**2)*df - n*(n+1)*s**2*f)/f
... return -r.mean(), r.std()
>>> s = np.linspace(0.1, 10, 200)
>>> k, h, n, p = 8.0, 2.2, 3, 2
>>> E = ellip_harm(h**2, k**2, n, p, s)
>>> E_spl = UnivariateSpline(s, E)
>>> a, a_err = eigenvalue(E_spl(s), E_spl(s, 1), E_spl(s, 2))
>>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

## scipy.special.ellip\_harm\_2

`scipy.special.ellip_harm_2(h2, k2, n, p, s)`

Ellipsoidal harmonic functions  $F^p_n(l)$

These are also known as Lamé functions of the second kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

### Parameters

**h2** [float]  $h^2$   
**k2** [float]  $k^2$ ; should be larger than  $h^2$

**n** [int] Degree.  
**p** [int] Order, can range between [1,2n+1].  
**s** [float] Coordinate

**Returns**

**F** [float] The harmonic  $F_n^p(s)$

See also:

`ellip_harm`, `ellip_normal`

**Notes**

Lame functions of the second kind are related to the functions of the first kind:

$$F_n^p(s) = (2n + 1)E_n^p(s) \int_0^{1/s} \frac{du}{(E_n^p(1/u))^2 \sqrt{(1 - u^2k^2)(1 - u^2h^2)}}$$

New in version 0.15.0.

**Examples**

```
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5, 8, 2, 1, 10)
>>> w
0.00108056853382
```

**scipy.special.ellip\_normal**

`scipy.special.ellip_normal(h2, k2, n, p)`

Ellipsoidal harmonic normalization constants  $\gamma_n^p$

The normalization constant is defined as

$$\gamma_n^p = 8 \int_0^h dx \int_h^k dy \frac{(y^2 - x^2)(E_n^p(y)E_n^p(x))^2}{\sqrt{(k^2 - y^2)(y^2 - h^2)(h^2 - x^2)(k^2 - x^2)}}$$

**Parameters**

**h2** [float]  $h^{**2}$   
**k2** [float]  $k^{**2}$ ; should be larger than  $h^{**2}$   
**n** [int] Degree.  
**p** [int] Order, can range between [1,2n+1].

**Returns**

**gamma** [float] The normalization constant  $\gamma_n^p$

See also:

`ellip_harm`, `ellip_harm_2`

## Notes

New in version 0.15.0.

## Examples

```

>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5, 8, 3, 7)
>>> w
1723.38796997

```

## Orthogonal polynomials

The following functions evaluate values of orthogonal polynomials:

|                                                    |                                                                                   |
|----------------------------------------------------|-----------------------------------------------------------------------------------|
| <code>assoc_laguerre(x, n[, k])</code>             | Compute the generalized (associated) Laguerre polynomial of degree n and order k. |
| <code>eval_legendre(n, x[, out])</code>            | Evaluate Legendre polynomial at a point.                                          |
| <code>eval_chebyt(n, x[, out])</code>              | Evaluate Chebyshev polynomial of the first kind at a point.                       |
| <code>eval_chebyu(n, x[, out])</code>              | Evaluate Chebyshev polynomial of the second kind at a point.                      |
| <code>eval_chebyc(n, x[, out])</code>              | Evaluate Chebyshev polynomial of the first kind on [-2, 2] at a point.            |
| <code>eval_chebys(n, x[, out])</code>              | Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.           |
| <code>eval_jacobi(n, alpha, beta, x[, out])</code> | Evaluate Jacobi polynomial at a point.                                            |
| <code>eval_laguerre(n, x[, out])</code>            | Evaluate Laguerre polynomial at a point.                                          |
| <code>eval_genlaguerre(n, alpha, x[, out])</code>  | Evaluate generalized Laguerre polynomial at a point.                              |

| <code>eval_sh_jacobi(n, p, q, x[, out])</code>     | Evaluate shifted Jacobi polynomial at a point.                                    |

## scipy.special.assoc\_laguerre

`scipy.special.assoc_laguerre(x, n, k=0.0)`

Compute the generalized (associated) Laguerre polynomial of degree n and order k.

The polynomial  $L_n^{(k)}(x)$  is orthogonal over  $[0, \infty)$ , with weighting function  $\exp(-x) * x^{**k}$  with  $k > -1$ .

## Notes

`assoc_laguerre` is a simple wrapper around `eval_genlaguerre`, with reversed argument order (`x, n, k=0.0`)  $\rightarrow$  (`n, k, x`).

## scipy.special.eval\_legendre

`scipy.special.eval_legendre(n, x, out=None) = <ufunc 'eval_legendre'>`  
Evaluate Legendre polynomial at a point.

The Legendre polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$P_n(x) = {}_2F_1(-n, n + 1; 1; (1 - x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.49 in [AS] for details.

### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Legendre polynomial

### Returns

- P** [ndarray] Values of the Legendre polynomial

See also:

### roots\_legendre

roots and quadrature weights of Legendre polynomials

### legendre

Legendre polynomial object

### hyp2f1

Gauss hypergeometric function

### numpy.polynomial.legendre.Legendre

Legendre series

## References

[AS]

## Examples

```
>>> from scipy.special import eval_legendre
```

Evaluate the zero-order Legendre polynomial at  $x = 0$

```
>>> eval_legendre(0, 0)
1.0
```

Evaluate the first-order Legendre polynomial between -1 and 1

```
>>> X = np.linspace(-1, 1, 5) # Domain of Legendre polynomials
>>> eval_legendre(1, X)
array([-1. , -0.5, 0. , 0.5, 1.])
```

Evaluate Legendre polynomials of order 0 through 4 at  $x = 0$

```
>>> N = range(0, 5)
>>> eval_legendre(N, 0)
array([1. , 0. , -0.5 , 0. , 0.375])
```

Plot Legendre polynomials of order 0 through 4

```
>>> X = np.linspace(-1, 1)
```

```
>>> import matplotlib.pyplot as plt
>>> for n in range(0, 5):
... y = eval_legendre(n, X)
... plt.plot(X, y, label=r'$P_{%d}(x)$'.format(n))
```

```
>>> plt.title("Legendre Polynomials")
>>> plt.xlabel("x")
>>> plt.ylabel(r'$P_n(x)$')
>>> plt.legend(loc='lower right')
>>> plt.show()
```

**scipy.special.eval\_chebyt**

`scipy.special.eval_chebyt(n, x, out=None) = <ufunc 'eval_chebyt'>`

Evaluate Chebyshev polynomial of the first kind at a point.

The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$T_n(x) = {}_2F_1(n, -n; 1/2; (1-x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.47 in [AS] for details.

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

**Returns**

- T** [ndarray] Values of the Chebyshev polynomial

**See also:****roots\_chebyt**

roots and quadrature weights of Chebyshev polynomials of the first kind

**chebyu**

Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

**hyp2f1**

Gauss hypergeometric function

**numpy.polynomial.chebyshev.Chebyshev**

Chebyshev series

**Notes**

This routine is numerically stable for  $x$  in  $[-1, 1]$  at least up to order 10000.

**References**

[AS]

**scipy.special.eval\_chebyu**

`scipy.special.eval_chebyu(n, x, out=None) = <ufunc 'eval_chebyu'>`

Evaluate Chebyshev polynomial of the second kind at a point.

The Chebyshev polynomials of the second kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$U_n(x) = (n+1) {}_2F_1(-n, n+2; 3/2; (1-x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.48 in [AS] for details.

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

**Returns**

- U** [ndarray] Values of the Chebyshev polynomial

**See also:**

**roots\_chebyu**

roots and quadrature weights of Chebyshev polynomials of the second kind

**chebyu**

Chebyshev polynomial object

**eval\_chebyt**

evaluate Chebyshev polynomials of the first kind

Gauss hypergeometric function

**References**

[AS]

**scipy.special.eval\_chebyc**

`scipy.special.eval_chebyc(n, x, out=None) = <ufunc 'eval_chebyc'>`

Evaluate Chebyshev polynomial of the first kind on  $[-2, 2]$  at a point.

These polynomials are defined as

$$C_n(x) = 2T_n(x/2)$$

where  $T_n$  is a Chebyshev polynomial of the first kind. See 22.5.11 in [AS] for details.

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

**Returns**

**C** [ndarray] Values of the Chebyshev polynomial

## Examples

```
>>> import scipy.special as sc
```

They are a scaled version of the Chebyshev polynomials of the first kind.

```
>>> x = np.linspace(-2, 2, 6)
>>> sc.eval_chebyc(3, x)
array([-2. , 1.872, 1.136, -1.136, -1.872, 2.])
>>> 2 * sc.eval_chebyt(3, x / 2)
array([-2. , 1.872, 1.136, -1.136, -1.872, 2.])
```

## scipy.special.eval\_chebys

`scipy.special.eval_chebys(n, x, out=None) = <ufunc 'eval_chebys'>`

Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.

These polynomials are defined as

$$S_n(x) = U_n(x/2)$$

where  $U_n$  is a Chebyshev polynomial of the second kind. See 22.5.13 in [AS] for details.

### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to [eval\\_chebyu](#).
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

### Returns

- S** [ndarray] Values of the Chebyshev polynomial

**See also:**

**roots\_chebys**

roots and quadrature weights of Chebyshev polynomials of the second kind on [-2, 2]

**chebys**

Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

**References**

[AS]

**Examples**

```
>>> import scipy.special as sc
```

They are a scaled version of the Chebyshev polynomials of the second kind.

```
>>> x = np.linspace(-2, 2, 6)
>>> sc.eval_chebys(3, x)
array([-4. , 0.672, 0.736, -0.736, -0.672, 4.])
>>> sc.eval_chebyu(3, x / 2)
array([-4. , 0.672, 0.736, -0.736, -0.672, 4.])
```

**scipy.special.eval\_jacobi**

`scipy.special.eval_jacobi(n, alpha, beta, x, out=None) = <ufunc 'eval_jacobi'>`

Evaluate Jacobi polynomial at a point.

The Jacobi polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$P_n^{(\alpha, \beta)}(x) = \frac{(\alpha + 1)_n}{\Gamma(n + 1)} {}_2F_1(-n, 1 + \alpha + \beta + n; \alpha + 1; (1 - z)/2)$$

where  $(\cdot)_n$  is the Pochhammer symbol; see *poch*. When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.42 in [AS] for details.

**Parameters**

|              |                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>n</b>     | [array_like] Degree of the polynomial. If not an integer the result is determined via the relation to the Gauss hypergeometric function. |
| <b>alpha</b> | [array_like] Parameter                                                                                                                   |
| <b>beta</b>  | [array_like] Parameter                                                                                                                   |
| <b>x</b>     | [array_like] Points at which to evaluate the polynomial                                                                                  |

**Returns**

## `scipy.special.eval_laguerre`

`scipy.special.eval_laguerre` ( $n, x, out=None$ ) = <ufunc 'eval\_laguerre'>  
 Evaluate Laguerre polynomial at a point.

The Laguerre polynomials can be defined via the confluent hypergeometric function  ${}_1F_1$  as

$$L_n(x) = {}_1F_1(-n, 1, x).$$

See 22.5.16 and 22.5.54 in [AS] for details. When  $n$  is an integer the result is a polynomial of degree  $n$ .

### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.
- x** [array\_like] Points at which to evaluate the Laguerre polynomial

### Returns

- L** [ndarray] Values of the Laguerre polynomial

## References

[AS]

### scipy.special.eval\_genlaguerre

`scipy.special.eval_genlaguerre(n, alpha, x, out=None)` = <ufunc 'eval\_genlaguerre'>  
Evaluate generalized Laguerre polynomial at a point.

The generalized Laguerre polynomials can be defined via the confluent hypergeometric function  ${}_1F_1$  as

$$L_n^{(\alpha)}(x) = \binom{n+\alpha}{n} {}_1F_1(-n, \alpha+1, x).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.54 in [AS] for details. The Laguerre polynomials are the special case where  $\alpha = 0$ .

#### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the confluent hypergeometric function.
- alpha** [array\_like] Parameter; must have `alpha > -1`
- x** [array\_like] Points at which to evaluate the generalized Laguerre polynomial

#### Returns

- L** [ndarray] Values of the generalized Laguerre polynomial

## scipy.special.eval\_gegenbauer

`scipy.special.eval_gegenbauer(n, alpha, x, out=None)` = `<ufunc 'eval_gegenbauer'>`  
Evaluate Gegenbauer polynomial at a point.

The Gegenbauer polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$C_n^{(\alpha)} = \frac{(2\alpha)_n}{\Gamma(n+1)} {}_2F_1(-n, 2\alpha+n; \alpha+1/2; (1-z)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . See 22.5.46 in [AS] for details.

### Parameters

**n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

**alpha** [array\_like] Parameter

**x** [array\_like] Points at which to evaluate the Gegenbauer polynomial

### Returns

### scipy.special.eval\_sh\_jacobi

`scipy.special.eval_sh_jacobi(n, p, q, x, out=None)` = <ufunc 'eval\_sh\_jacobi'>  
 Evaluate shifted Jacobi polynomial at a point.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the n-th Jacobi polynomial. See 22.5.2 in [AS] for details.

#### Parameters

- n** [int] Degree of the polynomial. If not an integer, the result is determined via the relation to *binom* and *eval\_jacobi*.
- p** [float] Parameter
- q** [float] Parameter

#### Returns

- G** [ndarray] Values of the shifted Jacobi polynomial.

### scipy.special.roots\_legendre

`scipy.special.roots_legendre` (*n*, *mu=False*)

Gauss-Legendre quadrature.

Compute the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the *n*th degree Legendre polynomial  $P_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $w(x) = 1.0$ . See 2.2.10 in [AS] for more details.

#### Parameters

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

#### Returns

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

### `scipy.special.roots_hermite`

`scipy.special.roots_hermite` (*n*, *mu=False*)

Gauss-Hermite (physicist's) quadrature.

Compute the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the *n*th degree Hermite polynomial,  $H_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-\infty, \infty]$  with weight function  $w(x) = e^{-x^2}$ . See 22.2.14 in [AS] for details.

#### Parameters

|          |                        |
|----------|------------------------|
| <b>n</b> | [int] quadrature order |
|----------|------------------------|

**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

See also:

`scipy.integrate.quadrature`  
`scipy.integrate.fixed_quad`  
`numpy.polynomial.hermite.hermgauss`  
`roots_hermitenorm`

**Notes**

For small n up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For n larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large n (several thousand or more) feasible.

## `scipy.special.roots_gegenbauer`

`scipy.special.roots_gegenbauer` ( $n$ ,  $alpha$ ,  $mu=False$ )

Gauss-Gegenbauer quadrature.

Compute the sample points and weights for Gauss-Gegenbauer quadrature. The sample points are the roots of the  $n$ th degree Gegenbauer polynomial,  $C_n^\alpha(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $w(x) = (1 - x^2)^{\alpha-1/2}$ . See 22.2.3 in [AS] for more details.

### Parameters

|              |                                                                    |
|--------------|--------------------------------------------------------------------|
| <b>n</b>     | [int] quadrature order                                             |

### scipy.special.roots\_sh\_jacobi

`scipy.special.roots_sh_jacobi` ( $n$ ,  $p1$ ,  $q1$ ,  $mu=False$ )

Gauss-Jacobi (shifted) quadrature.

Compute the sample points and weights for Gauss-Jacobi (shifted) quadrature. The sample points are the roots of the  $n$ th degree shifted Jacobi polynomial,  $G_n^{p,q}(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $w(x) = (1 - x)^{p-q}x^{q-1}$ . See 22.2.2 in [AS] for details.

#### Parameters

**n** [int] quadrature order  
**p1** [float] ( $p1 - q1$ ) must be  $> -1$   
**q1** [float]  $q1$  must be  $> 0$   
**mu** [bool, optional] If True, return the sum of the weights, optional.

#### Returns

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

See also:

`scipy.integrate.quadrature`

## References

[AS]

The functions below, in turn, return the polynomial coefficients in `orthopoly1d` objects, which function similarly as `numpy.poly1d`. The `orthopoly1d` class also has an attribute `weights`, which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an  $n \times 3$  array with roots in the first column, weights in the second column, and total weights in the final column. Note that `orthopoly1d` objects are converted to `poly1d` when doing arithmetic, and lose information of the original orthogonal polynomial.

## `scipy.special.legendre`

`scipy.special.legendre` ( $n$ , `monic=False`)

Legendre polynomial.

Defined to be the solution of

$$\frac{d}{dx} \left[ (1 - x^2) \frac{d}{dx} P_n(x) \right] + n(n + 1)P_n(x) = 0;$$

$P_n(x)$  is a polynomial of degree  $n$ .

### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If `True`, scale the leading coefficient to be 1. Default is `False`.

### Returns

- P** [orthopoly1d] Legendre polynomial.

## Notes

The polynomials  $P_n$  are orthogonal over  $[-1, 1]$  with weight function 1.

## Examples

Generate the 3rd-order Legendre polynomial  $1/2*(5x^3 + 0x^2 - 3x + 0)$ :

```
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([2.5, 0. , -1.5, 0.])
```

## scipy.special.chebyt

`scipy.special.chebyt` ( $n$ , *monic=False*)

Chebyshev polynomial of the first kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} T_n - x \frac{d}{dx} T_n + n^2 T_n = 0;$$

$T_n$  is a polynomial of degree  $n$ .

### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

### Returns

- T** [orthopoly1d] Chebyshev polynomial of the first kind.

See also:

### [chebyu](#)

Chebyshev polynomial of the second kind.

## Notes

The polynomials  $T_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{-1/2}$ .

## scipy.special.chebyu

`scipy.special.chebyu` ( $n$ , *monic=False*)

Chebyshev polynomial of the second kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} U_n - 3x \frac{d}{dx} U_n + n(n + 2) U_n = 0;$$

$U_n$  is a polynomial of degree  $n$ .

### Parameters

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**U** [orthopoly1d] Chebyshev polynomial of the second kind.

**See also:**

[chebyt](#)

Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $U_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{1/2}$ .

**scipy.special.chebyc**

`scipy.special.chebyc` (*n*, *monic=False*)

Chebyshev polynomial of the first kind on  $[-2, 2]$ .

Defined as  $C_n(x) = 2T_n(x/2)$ , where  $T_n$  is the *n*th Chebyshev polynomial of the first kind.

**Parameters**

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**C** [orthopoly1d] Chebyshev polynomial of the first kind on  $[-2, 2]$ .

**See also:**

[chebyt](#)

Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $C_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $1/\sqrt{1 - (x/2)^2}$ .

**References**

[1]

**scipy.special.chebys**`scipy.special.chebys` (*n*, *monic=False*)Chebyshev polynomial of the second kind on  $[-2, 2]$ .Defined as  $S_n(x) = U_n(x/2)$  where  $U_n$  is the *n*th Chebychev polynomial of the second kind.**Parameters**

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**S** [orthopoly1d] Chebyshev polynomial of the second kind on  $[-2, 2]$ .

**See also:****chebyu**

Chebyshev polynomial of the second kind

**Notes**The polynomials  $S_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $\sqrt{1 - (x/2)^2}$ .**References**

[1]

**scipy.special.jacobi**`scipy.special.jacobi` (*n*, *alpha*, *beta*, *monic=False*)

Jacobi polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} P_n^{(\alpha, \beta)} + (\beta - \alpha - (\alpha + \beta + 2)x) \frac{d}{dx} P_n^{(\alpha, \beta)} + n(n + \alpha + \beta + 1) P_n^{(\alpha, \beta)} = 0$$

for  $\alpha, \beta > -1$ ;  $P_n^{(\alpha, \beta)}$  is a polynomial of degree *n*.**Parameters**

**n** [int] Degree of the polynomial.  
**alpha** [float] Parameter, must be greater than -1.  
**beta** [float] Parameter, must be greater than -1.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**P** [orthopoly1d] Jacobi polynomial.

## Notes

For fixed  $\alpha, \beta$ , the polynomials  $P_n^{(\alpha, \beta)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x)^\alpha(1 + x)^\beta$ .

## scipy.special.laguerre

`scipy.special.laguerre` ( $n$ , *monic=False*)  
Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n + (1 - x) \frac{d}{dx} L_n + n L_n = 0;$$

$L_n$  is a polynomial of degree  $n$ .

### Parameters

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

### Returns

**L** [orthopoly1d] Laguerre Polynomial.

## Notes

The polynomials  $L_n$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}$ .

## scipy.special.genlaguerre

`scipy.special.genlaguerre` ( $n$ , *alpha*, *monic=False*)  
Generalized (associated) Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n^{(\alpha)} + (\alpha + 1 - x) \frac{d}{dx} L_n^{(\alpha)} + n L_n^{(\alpha)} = 0,$$

where  $\alpha > -1$ ;  $L_n^{(\alpha)}$  is a polynomial of degree  $n$ .

### Parameters

**n** [int] Degree of the polynomial.  
**alpha** [float] Parameter, must be greater than -1.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

### Returns

**L** [orthopoly1d] Generalized Laguerre polynomial.

See also:

### laguerre

Laguerre polynomial.

## Notes

For fixed  $\alpha$ , the polynomials  $L_n^{(\alpha)}$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}x^\alpha$ .

The Laguerre polynomials are the special case where  $\alpha = 0$ .

## scipy.special.hermite

`scipy.special.hermite` ( $n$ , *monic=False*)

Physicist's Hermite polynomial.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$  is a polynomial of degree  $n$ .

### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

### Returns

- H** [orthopoly1d] Hermite polynomial.

## Notes

The polynomials  $H_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2}$ .

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> import numpy as np
```

```
>>> p_mononic = special.hermite(3, monic=True)
>>> p_mononic
poly1d([1. , 0. , -1.5, 0.])
>>> p_mononic(1)
-0.49999999999999983
>>> x = np.linspace(-3, 3, 400)
>>> y = p_mononic(x)
>>> plt.plot(x, y)
>>> plt.title("Monic Hermite polynomial of degree 3")
>>> plt.xlabel("x")
>>> plt.ylabel("H_3(x)")
>>> plt.show()
```

### scipy.special.hermitenorm

`scipy.special.hermitenorm` (*n*, *monic=False*)

Normalized (probabilist's) Hermite polynomial.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- He** [orthopoly1d] Hermite polynomial.

### Notes

The polynomials  $He_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2/2}$ .

### scipy.special.gegenbauer

`scipy.special.gegenbauer` (*n*, *alpha*, *monic=False*)

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} C_n^{(\alpha)} - (2\alpha + 1)x \frac{d}{dx} C_n^{(\alpha)} + n(n + 2\alpha) C_n^{(\alpha)} = 0$$

for  $\alpha > -1/2$ ;  $C_n^{(\alpha)}$  is a polynomial of degree  $n$ .

**Parameters**

|              |                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------|
| <b>n</b>     | [int] Degree of the polynomial.                                                                    |
| <b>alpha</b> | [float] Parameter, must be greater than -0.5.                                                      |
| <b>monic</b> | [bool, optional] If <i>True</i> , scale the leading coefficient to be 1. Default is <i>False</i> . |

**Returns**

|          |                                      |
|----------|--------------------------------------|
| <b>C</b> | [orthopoly1d] Gegenbauer polynomial. |
|----------|--------------------------------------|

**Notes**

The polynomials  $C_n^{(\alpha)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{(\alpha-1/2)}$ .

**Examples**

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

We can initialize a variable `p` as a Gegenbauer polynomial using the `gegenbauer` function and evaluate at a point `x = 1`.

```
>>> p = special.gegenbauer(3, 0.5, monic=False)
>>> p
poly1d([2.5, 0. , -1.5, 0.])
>>> p(1)
1.0
```

To evaluate `p` at various points `x` in the interval  $(-3, 3)$ , simply pass an array `x` to `p` as follows:

```
>>> x = np.linspace(-3, 3, 400)
>>> y = p(x)
```

We can then visualize `x`, `y` using `matplotlib.pyplot`.

```
>>> fig, ax = plt.subplots()
>>> ax.plot(x, y)
>>> ax.set_title("Gegenbauer (ultraspherical) polynomial of degree 3")
>>> ax.set_xlabel("x")
>>> ax.set_ylabel("G_3(x)")
>>> plt.show()
```

**scipy.special.sh\_legendre**

`scipy.special.sh_legendre` (*n*, *monic=False*)

Shifted Legendre polynomial.

Defined as  $P_n^*(x) = P_n(2x - 1)$  for  $P_n$  the *n*th Legendre polynomial.

**Parameters**

|              |                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------|
| <b>n</b>     | [int] Degree of the polynomial.                                                                    |
| <b>monic</b> | [bool, optional] If <i>True</i> , scale the leading coefficient to be 1. Default is <i>False</i> . |

**Returns**

**P** [orthopoly1d] Shifted Legendre polynomial.

**Notes**

The polynomials  $P_n^*$  are orthogonal over  $[0, 1]$  with weight function 1.

**scipy.special.sh\_chebyt**

`scipy.special.sh_chebyt` (*n*, *monic=False*)

Shifted Chebyshev polynomial of the first kind.

Defined as  $T_n^*(x) = T_n(2x - 1)$  for  $T_n$  the *n*th Chebyshev polynomial of the first kind.

**Parameters**

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**T** [orthopoly1d] Shifted Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $T_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{-1/2}$ .

**scipy.special.sh\_chebyu**`scipy.special.sh_chebyu` (*n*, *monic=False*)

Shifted Chebyshev polynomial of the second kind.

Defined as  $U_n^*(x) = U_n(2x - 1)$  for  $U_n$  the *n*th Chebyshev polynomial of the second kind.**Parameters**

- n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

- U** [orthopoly1d] Shifted Chebyshev polynomial of the second kind.

**Notes**The polynomials  $U_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{1/2}$ .**scipy.special.sh\_jacobi**`scipy.special.sh_jacobi` (*n*, *p*, *q*, *monic=False*)

Shifted Jacobi polynomial.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the *n*th Jacobi polynomial.**Parameters**

- n** [int] Degree of the polynomial.  
**p** [float] Parameter, must have  $p > q - 1$ .  
**q** [float] Parameter, must be greater than 0.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

- G** [orthopoly1d] Shifted Jacobi polynomial.

**Notes**For fixed  $p, q$ , the polynomials  $G_n^{(p,q)}$  are orthogonal over  $[0, 1]$  with weight function  $(1 - x)^{p-q} x^{q-1}$ .

**Warning:** Computing values of high-order polynomials (around `order > 20`) using polynomial coefficients is numerically unstable. To evaluate polynomial values, the `eval_*` functions should be used instead.

## Hypergeometric functions

|                                     |                                                     |
|-------------------------------------|-----------------------------------------------------|
| <code>hyp2f1(a, b, c, z)</code>     | Gauss hypergeometric function ${}_2F_1(a, b; c; z)$ |
| <code>hyp1f1(a, b, x[, out])</code> | Confluent hypergeometric function ${}_1F_1$ .       |
| <code>hyperu(a, b, x[, out])</code> | Confluent hypergeometric function $U$               |
| <code>hyp0f1(v, z[, out])</code>    | Confluent hypergeometric limit function ${}_0F_1$ . |

### scipy.special.hyp2f1

`scipy.special.hyp2f1(a, b, c, z) = <ufunc 'hyp2f1'>`  
 Gauss hypergeometric function  ${}_2F_1(a, b; c; z)$

#### Parameters

**a, b, c** [array\_like] Arguments, should be real-valued.  
**z** [array\_like] Argument, real or complex.

#### Returns

**hyp2f1** [scalar or ndarray] The values of the gaussian hypergeometric function.

See also:

#### hyp0f1

confluent hypergeometric limit function.

#### hyp1f1

Kummer's (confluent hypergeometric) function.

## Notes

This function is defined for  $|z| < 1$  as

$$\text{hyp2f1}(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n} \frac{z^n}{n!},$$

and defined on the rest of the complex  $z$ -plane by analytic continuation [1]. Here  $(\cdot)_n$  is the Pochhammer symbol; see *poch*. When  $n$  is an integer the result is a polynomial of degree  $n$ .

The implementation for complex values of  $z$  is described in [2].

## References

[1], [2], [3]

## Examples

```
>>> import scipy.special as sc
```

It has poles when  $c$  is a negative integer.

```
>>> sc.hyp2f1(1, 1, -2, 1)
inf
```

It is a polynomial when  $a$  or  $b$  is a negative integer.

```
>>> a, b, c = -1, 1, 1.5
>>> z = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, c, z)
array([1. , 0.83333333, 0.66666667, 0.5 , 0.33333333])
>>> 1 + a * b * z / c
array([1. , 0.83333333, 0.66666667, 0.5 , 0.33333333])
```

It is symmetric in  $a$  and  $b$ .

```
>>> a = np.linspace(0, 1, 5)
>>> b = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, 1, 0.5)
array([1. , 1.03997334, 1.1803406 , 1.47074441, 2.])
>>> sc.hyp2f1(b, a, 1, 0.5)
array([1. , 1.03997334, 1.1803406 , 1.47074441, 2.])
```

It contains many other functions as special cases.

```
>>> z = 0.5
>>> sc.hyp2f1(1, 1, 2, z)
1.3862943611198901
>>> -np.log(1 - z) / z
1.3862943611198906
```

```
>>> sc.hyp2f1(0.5, 1, 1.5, z**2)
1.098612288668109
>>> np.log((1 + z) / (1 - z)) / (2 * z)
1.0986122886681098
```

```
>>> sc.hyp2f1(0.5, 1, 1.5, -z**2)
0.9272952180016117
>>> np.arctan(z) / z
0.9272952180016123
```

**scipy.special.hyp1f1**

`scipy.special.hyp1f1(a, b, x, out=None)` = <ufunc 'hyp1f1'>  
 Confluent hypergeometric function 1F1.

The confluent hypergeometric function is defined by the series

$${}_1F_1(a; b; x) = \sum_{k=0}^{\infty} \frac{(a)_k}{(b)_k k!} x^k.$$

See [dlmf] for more details. Here  $(\cdot)_k$  is the Pochhammer symbol; see *poch*.

**Parameters**

**a, b** [array\_like] Real parameters  
**x** [array\_like] Real or complex argument  
**out** [ndarray, optional] Optional output array for the function results

**Returns****scalar or ndarray**

Values of the confluent hypergeometric function

**See also:**

**hyperu**

another confluent hypergeometric function

**hyp0f1**

confluent hypergeometric limit function

**hyp2f1**

Gaussian hypergeometric function

**References**

[dlmf]

**Examples**

```
>>> import scipy.special as sc
```

It is one when  $x$  is zero:

```
>>> sc.hyp1f1(0.5, 0.5, 0)
1.0
```

It is singular when  $b$  is a nonpositive integer.

```
>>> sc.hyp1f1(0.5, -1, 0)
inf
```

It is a polynomial when  $a$  is a nonpositive integer.

```
>>> a, b, x = -1, 0.5, np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.hyp1f1(a, b, x)
array([-1., -3., -5., -7.])
>>> 1 + (a / b) * x
array([-1., -3., -5., -7.])
```

It reduces to the exponential function when  $a = b$ .

```
>>> sc.hyp1f1(2, 2, [1, 2, 3, 4])
array([2.71828183, 7.3890561 , 20.08553692, 54.59815003])
>>> np.exp([1, 2, 3, 4])
array([2.71828183, 7.3890561 , 20.08553692, 54.59815003])
```

## scipy.special.hyperu

`scipy.special.hyperu(a, b, x, out=None)` = <ufunc 'hyperu'>  
Confluent hypergeometric function U

It is defined as the solution to the equation

$$x \frac{d^2 w}{dx^2} + (b - x) \frac{dw}{dx} - aw = 0$$

which satisfies the property

$$U(a, b, x) \sim x^{-a}$$

as  $x \rightarrow \infty$ . See [dlmf] for more details.

### Parameters

**a, b** [array\_like] Real-valued parameters  
**x** [array\_like] Real-valued argument  
**out** [ndarray] Optional output array for the function values

### Returns

**scalar or ndarray**  
Values of  $U$

## References

[dlmf]

## Examples

```
>>> import scipy.special as sc
```

It has a branch cut along the negative x axis.

```
>>> x = np.linspace(-0.1, -10, 5)
>>> sc.hyperu(1, 1, x)
array([nan, nan, nan, nan, nan])
```

It approaches zero as  $x$  goes to infinity.

```
>>> x = np.array([1, 10, 100])
>>> sc.hyperu(1, 1, x)
array([0.59634736, 0.09156333, 0.00990194])
```

It satisfies Kummer's transformation.

```
>>> a, b, x = 2, 1, 1
>>> sc.hyperu(a, b, x)
0.1926947246463881
>>> x**(1 - b) * sc.hyperu(a - b + 1, 2 - b, x)
0.1926947246463881
```

## scipy.special.hyp0f1

`scipy.special.hyp0f1(v, z, out=None)` = <ufunc 'hyp0f1'>  
 Confluent hypergeometric limit function 0F1.

### Parameters

**v** [array\_like] Real-valued parameter  
**z** [array\_like] Real- or complex-valued argument  
**out** [ndarray, optional] Optional output array for the function results

### Returns

**scalar or ndarray**  
 The confluent hypergeometric limit function

## Notes

This function is defined as:

$${}_0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.$$

It's also the limit as  $q \rightarrow \infty$  of  ${}_1F_1(q; v; z/q)$ , and satisfies the differential equation  $f''(z) + vf'(z) = f(z)$ . See [1] for more information.

## References

[1]

## Examples

```
>>> import scipy.special as sc
```

It is one when  $z$  is zero.

```
>>> sc.hyp0f1(1, 0)
1.0
```

It is the limit of the confluent hypergeometric function as  $q$  goes to infinity.

```
>>> q = np.array([1, 10, 100, 1000])
>>> v = 1
>>> z = 1
>>> sc.hyp1f1(q, v, z / q)
array([2.71828183, 2.31481985, 2.28303778, 2.27992985])
>>> sc.hyp0f1(v, z)
2.2795853023360673
```

It is related to Bessel functions.

```
>>> n = 1
>>> x = np.linspace(0, 1, 5)
>>> sc.jv(n, x)
array([0. , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
>>> (0.5 * x)**n / sc.factorial(n) * sc.hyp0f1(n + 1, -0.25 * x**2)
array([0. , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
```

## Parabolic cylinder functions

|                         |                                |
|-------------------------|--------------------------------|
| <code>pbdv(v, x)</code> | Parabolic cylinder function D  |
| <code>pbvv(v, x)</code> | Parabolic cylinder function V  |
| <code>pbwa(a, x)</code> | Parabolic cylinder function W. |

### scipy.special.pbdv

`scipy.special.pbdv(v, x) = <ufunc 'pbdv'>`  
Parabolic cylinder function D

Returns (d, dp) the parabolic cylinder function  $Dv(x)$  in d and the derivative,  $Dv'(x)$  in dp.

#### Returns

**d** Value of the function  
**dp** Value of the derivative vs x

### scipy.special.pbvv

`scipy.special.pbvv(v, x) = <ufunc 'pbvv'>`

Parabolic cylinder function V

Returns the parabolic cylinder function  $V_v(x)$  in `v` and the derivative,  $V_v'(x)$  in `vp`.

**Returns**

`v` Value of the function  
`vp` Value of the derivative vs `x`

### scipy.special.pbwa

`scipy.special.pbwa(a, x) = <ufunc 'pbwa'>`

Parabolic cylinder function W.

The function is a particular solution to the differential equation

$$y'' + \left(\frac{1}{4}x^2 - a\right)y = 0,$$

for a full definition see section 12.14 in [1].

**Parameters**

`a` [array\_like] Real parameter  
`x` [array\_like] Real argument

**Returns**

`w` [scalar or ndarray] Value of the function  
`wp` [scalar or ndarray] Value of the derivative in `x`

### Notes

The function is a wrapper for a Fortran routine by Zhang and Jin [2]. The implementation is accurate only for  $|a|, |x| < 5$  and returns NaN outside that range.

## Mathieu and related functions

|                              |                                                |
|------------------------------|------------------------------------------------|
| <code>mathieu_a(m, q)</code> | Characteristic value of even Mathieu functions |
| <code>mathieu_b(m, q)</code> | Characteristic value of odd Mathieu functions  |

### scipy.special.mathieu\_a

`scipy.special.mathieu_a(m, q) = <ufunc 'mathieu_a'>`  
 Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution,  $ce_m(z, q)$ , of Mathieu's equation.

### scipy.special.mathieu\_b

`scipy.special.mathieu_b(m, q) = <ufunc 'mathieu_b'>`  
 Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution,  $se_m(z, q)$ , of Mathieu's equation.

These are not universal functions:

|                                      |                                                                       |
|--------------------------------------|-----------------------------------------------------------------------|
| <code>mathieu_even_coef(m, q)</code> | Fourier coefficients for even Mathieu and modified Mathieu functions. |
| <code>mathieu_odd_coef(m, q)</code>  | Fourier coefficients for even Mathieu and modified Mathieu functions. |

### scipy.special.mathieu\_even\_coef

`scipy.special.mathieu_even_coef(m, q)`  
 Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

$$ce_{2n}(z, q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz$$

$$ce_{2n+1}(z, q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k+1)z$$

This function returns the coefficients  $A_{(2n)}^{(2k)}$  for even input  $m=2n$ , and the coefficients  $A_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

#### Parameters

- m** [int] Order of Mathieu functions. Must be non-negative.
- q** [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

#### Returns

- ak** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd  $m$ .

## References

[1], [2]

### scipy.special.mathieu\_odd\_coef

`scipy.special.mathieu_odd_coef(m, q)`

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

$$se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k+1)z$$

$$se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k+2)z$$

This function returns the coefficients  $B_{(2n+2)}^{(2k+2)}$  for even input  $m=2n+2$ , and the coefficients  $B_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

#### Parameters

**m** [int] Order of Mathieu functions. Must be non-negative.  
**q** [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

#### Returns

**Bk** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd  $m$ .

## References

| <code>mathieu_modsem2(m, q, x)</code> | Odd modified Mathieu function of the second kind and its derivative  |

### scipy.special.mathieu\_cem

`scipy.special.mathieu_cem(m, q, x) = <ufunc 'mathieu_cem'>`

Even Mathieu function and its derivative

Returns the even Mathieu function,  $ce_m(x, q)$ , of order  $m$  and parameter  $q$  evaluated at  $x$  (given in degrees). Also returns the derivative with respect to  $x$  of  $ce_m(x, q)$

**Parameters**

|          |                                                                |
|----------|----------------------------------------------------------------|
| <b>m</b> | Order of the function                                          |
| <b>q</b> | Parameter of the function                                      |
| <b>x</b> | Argument of the function, <i>given in degrees, not radians</i> |

**Returns**

|           |                              |
|-----------|------------------------------|
| <b>y</b>  | Value of the function        |
| <b>yp</b> | Value of the derivative vs x |

### scipy.special.mathieu\_sem

`scipy.special.mathieu_sem(m, q, x) = <ufunc 'mathieu_sem'>`

Odd Mathieu function and its derivative

Returns the odd Mathieu function,  $se_m(x, q)$ , of order  $m$  and parameter  $q$  evaluated at  $x$  (given in degrees). Also returns the derivative with respect to  $x$  of  $se_m(x, q)$ .

**Parameters**

|          |                                                                  |
|----------|------------------------------------------------------------------|
| <b>m</b> | Order of the function                                            |
| <b>q</b> | Parameter of the function                                        |
| <b>x</b> | Argument of the function, <i>given in degrees, not radians</i> . |

**Returns**

|           |                              |
|-----------|------------------------------|
| <b>y</b>  | Value of the function        |
| <b>yp</b> | Value of the derivative vs x |

### scipy.special.mathieu\_modcem1

`scipy.special.mathieu_modcem1(m, q, x) = <ufunc 'mathieu_modcem1'>`

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind,  $Mc1m(x, q)$ , and its derivative at  $x$  for order  $m$  and parameter  $q$ .

**Returns**

|           |                              |
|-----------|------------------------------|
| <b>y</b>  | Value of the function        |
| <b>yp</b> | Value of the derivative vs x |

**scipy.special.mathieu\_modcem2**

`scipy.special.mathieu_modcem2(m, q, x) = <ufunc 'mathieu_modcem2'>`

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind,  $Mc2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

**y**            Value of the function  
**yp**           Value of the derivative vs  $x$

**scipy.special.mathieu\_modsem1**

`scipy.special.mathieu_modsem1(m, q, x) = <ufunc 'mathieu_modsem1'>`

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind,  $Ms1m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

**y**            Value of the function  
**yp**           Value of the derivative vs  $x$

**scipy.special.mathieu\_modsem2**

`scipy.special.mathieu_modsem2(m, q, x) = <ufunc 'mathieu_modsem2'>`

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind,  $Ms2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

**y**            Value of the function  
**yp**           Value of the derivative vs  $x$

**Spheroidal wave functions**

|                                   |                                                                          |
|-----------------------------------|--------------------------------------------------------------------------|
| <code>pro_ang1(m, n, c, x)</code> | Prolate spheroidal angular function of the first kind and its derivative |
| <code>pro_rad1(m, n, c, x)</code> | Prolate spheroidal radial function of the first kind and its derivative  |
| <code>pro_rad2(m, n, c, x)</code> | Prolate spheroidal radial function of the second kind and its derivative |
| <code>obl_ang1(m, n, c, x)</code> | Oblate spheroidal angular function of the first kind and its derivative  |
| <code>obl_rad1(m, n, c, x)</code> | Oblate spheroidal radial function of the first kind and its derivative   |
| <code>obl_rad2(m, n, c, x)</code> | Oblate spheroidal radial function of the second kind and its derivative. |
| <code>pro_cv(m, n, c)</code>      | Characteristic value of prolate spheroidal function                      |
| <code>obl_cv(m, n, c)</code>      | Characteristic value of oblate spheroidal function                       |

### scipy.special.pro\_ang1

`scipy.special.pro_ang1(m, n, c, x) = <ufunc 'pro_ang1'>`

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

### scipy.special.pro\_rad1

`scipy.special.pro_rad1(m, n, c, x) = <ufunc 'pro_rad1'>`

Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

### scipy.special.pro\_rad2

`scipy.special.pro_rad2(m, n, c, x) = <ufunc 'pro_rad2'>`

Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

### scipy.special.obl\_ang1

`scipy.special.obl_ang1(m, n, c, x) = <ufunc 'obl_ang1'>`

Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

**scipy.special.obl\_rad1**

`scipy.special.obl_rad1(m, n, c, x) = <ufunc 'obl_rad1'>`

Oblate spheroidal radial function of the first kind and its derivative

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

|           |                                |
|-----------|--------------------------------|
| <b>s</b>  | Value of the function          |
| <b>sp</b> | Value of the derivative vs $x$ |

**scipy.special.obl\_rad2**

`scipy.special.obl_rad2(m, n, c, x) = <ufunc 'obl_rad2'>`

Oblate spheroidal radial function of the second kind and its derivative.

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

|           |                                |
|-----------|--------------------------------|
| <b>s</b>  | Value of the function          |
| <b>sp</b> | Value of the derivative vs $x$ |

**scipy.special.pro\_cv**

`scipy.special.pro_cv(m, n, c) = <ufunc 'pro_cv'>`

Characteristic value of prolate spheroidal function

Computes the characteristic value of prolate spheroidal wave functions of order  $m, n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

**scipy.special.obl\_cv**

`scipy.special.obl_cv(m, n, c) = <ufunc 'obl_cv'>`

Characteristic value of oblate spheroidal function

Computes the characteristic value of oblate spheroidal wave functions of order  $m, n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

**scipy.special.pro\_cv\_seq**

`scipy.special.pro_cv_seq(m, n, c)`

Characteristic values for prolate spheroidal wave functions.

Compute a sequence of characteristic values for the prolate spheroidal wave functions for mode  $m$  and  $n' = m..n$  and spheroidal parameter  $c$ .

## References

[1]

### scipy.special.obl\_cv\_seq

`scipy.special.obl_cv_seq(m, n, c)`

Characteristic values for oblate spheroidal wave functions.

Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode  $m$  and  $n'=m..n$  and spheroidal parameter  $c$ .

## References

[1]

The following functions require pre-computed characteristic value:

|                                          |                                                                                                |

### scipy.special.pro\_ang1\_cv

`scipy.special.pro_ang1_cv(m, n, c, cv, x) = <ufunc 'pro_ang1_cv'>`

Prolate spheroidal angular function `pro_ang1` for precomputed characteristic value

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

#### Returns

**s** Value of the function  
**sp** Value of the derivative vs  $x$

**scipy.special.pro\_rad1\_cv**

`scipy.special.pro_rad1_cv(m, n, c, cv, x) = <ufunc 'pro_rad1_cv'>`

Prolate spheroidal radial function `pro_rad1` for precomputed characteristic value

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

|           |                                |
|-----------|--------------------------------|
| <b>s</b>  | Value of the function          |
| <b>sp</b> | Value of the derivative vs $x$ |

**scipy.special.pro\_rad2\_cv**

`scipy.special.pro_rad2_cv(m, n, c, cv, x) = <ufunc 'pro_rad2_cv'>`

Prolate spheroidal radial function `pro_rad2` for precomputed characteristic value

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

|           |                                |
|-----------|--------------------------------|
| <b>s</b>  | Value of the function          |
| <b>sp</b> | Value of the derivative vs $x$ |

**scipy.special.obl\_ang1\_cv**

`scipy.special.obl_ang1_cv(m, n, c, cv, x) = <ufunc 'obl_ang1_cv'>`

Oblate spheroidal angular function `obl_ang1` for precomputed characteristic value

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

|           |                                |
|-----------|--------------------------------|
| <b>s</b>  | Value of the function          |
| <b>sp</b> | Value of the derivative vs $x$ |

**scipy.special.obl\_rad1\_cv**

`scipy.special.obl_rad1_cv(m, n, c, cv, x) = <ufunc 'obl_rad1_cv'>`

Oblate spheroidal radial function `obl_rad1` for precomputed characteristic value

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

|           |                                |
|-----------|--------------------------------|
| <b>s</b>  | Value of the function          |
| <b>sp</b> | Value of the derivative vs $x$ |

### scipy.special.obl\_rad2\_cv

`scipy.special.obl_rad2_cv(m, n, c, cv, x) = <ufunc 'obl_rad2_cv'>`

Oblate spheroidal radial function `obl_rad2` for precomputed characteristic value

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

- s** Value of the function
- sp** Value of the derivative vs  $x$

### Kelvin functions

|                               |                                                      |
|-------------------------------|------------------------------------------------------|
| <code>kelvin(x)</code>        | Kelvin functions as complex numbers                  |
| <code>kelvin_zeros(nt)</code> | Compute $nt$ zeros of all Kelvin functions.          |
| <code>ber(x[, out])</code>    | Kelvin function <code>ber</code> .                   |
| <code>bei(x[, out])</code>    | Kelvin function <code>bei</code> .                   |
| <code>berp(x[, out])</code>   | Derivative of the Kelvin function <code>ber</code> . |
| <code>beip(x[, out])</code>   | Derivative of the Kelvin function <code>bei</code> . |
| <code>ker(x[, out])</code>    | Kelvin function <code>ker</code> .                   |
| <code>kei(x[, out])</code>    | Kelvin function <code>kei</code> .                   |
| <code>kerp(x[, out])</code>   | Derivative of the Kelvin function <code>ker</code> . |
| <code>keip(x[, out])</code>   | Derivative of the Kelvin function <code>kei</code> . |

### scipy.special.kelvin

`scipy.special.kelvin(x) = <ufunc 'kelvin'>`

Kelvin functions as complex numbers

**Returns**

**Be, Ke, Bep, Kep**

The tuple (Be, Ke, Bep, Kep) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at  $x$ . For example, `kelvin(x)[0].real = ber x` and `kelvin(x)[0].imag = bei x` with similar relationships for `ker` and `kei`.

### scipy.special.kelvin\_zeros

`scipy.special.kelvin_zeros(nt)`

Compute  $nt$  zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length  $nt$ . The tuple contains the arrays of zeros of (ber, bei, ker, kei, ber', bei', ker', kei').

## References

[1]

## scipy.special.ber

`scipy.special.ber(x, out=None) = <ufunc 'ber'>`

Kelvin function ber.

Defined as

$$\text{ber}(x) = \Re[J_0(xe^{3\pi i/4})]$$

where  $J_0$  is the Bessel function of the first kind of order zero (see [jv](#)). See [dlmf](#) for more details.

### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
 Values of the Kelvin function.

### See also:

[bei](#)

the corresponding real part

[berp](#)

the derivative of bei

[jv](#)

Bessel function of the first kind

## References

[dlmf](#)

## Examples

It can be expressed using Bessel functions.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).real
array([0.98438178, 0.75173418, -0.22138025, -2.56341656])
>>> sc.ber(x)
array([0.98438178, 0.75173418, -0.22138025, -2.56341656])
```

**scipy.special.bei**

`scipy.special.bei(x, out=None)` = `<ufunc 'bei'>`  
Kelvin function bei.

Defined as

$$\text{bei}(x) = \Im[J_0(xe^{3\pi i/4})]$$

where  $J_0$  is the Bessel function of the first kind of order zero (see [jv](#)). See [dlmf](#) for more details.

**Parameters**

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
Values of the Kelvin function.

**See also:**

[ber](#)

the corresponding real part

[beip](#)

the derivative of bei

[jv](#)

Bessel function of the first kind

**References**

[dlmf](#)

**Examples**

It can be expressed using Bessel functions.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).imag
array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
>>> sc.bei(x)
array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
```

### scipy.special.berp

`scipy.special.berp(x, out=None) = <ufunc 'berp'>`

Derivative of the Kelvin function ber.

#### *Parameters*

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

#### *Returns*

**scalar or ndarray**  
The values of the derivative of ber.

**See also:**

[ber](#)

#### References

[dlmf]

### scipy.special.beip

`scipy.special.beip(x, out=None) = <ufunc 'beip'>`

Derivative of the Kelvin function bei.

#### *Parameters*

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

#### *Returns*

**scalar or ndarray**  
The values of the derivative of bei.

**See also:**

[bei](#)

#### References

[dlmf]

## scipy.special.ker

`scipy.special.ker(x, out=None) = <ufunc 'ker'>`  
Kelvin function `ker`.

Defined as

$$\text{ker}(x) = \Re[K_0(xe^{\pi i/4})]$$

Where  $K_0$  is the modified Bessel function of the second kind (see `kv`). See [dlmf] for more details.

### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
Values of the Kelvin function.

**See also:**

`kei`

the corresponding imaginary part

`kerp`

the derivative of `ker`

`kv`

modified Bessel function of the second kind

## References

[dlmf]

## Examples

It can be expressed using the modified Bessel function of the second kind.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.kv(0, x * np.exp(np.pi * 1j / 4)).real
array([0.28670621, -0.04166451, -0.06702923, -0.03617885])
>>> sc.ker(x)
array([0.28670621, -0.04166451, -0.06702923, -0.03617885])
```

**scipy.special.kei**

`scipy.special.kei(x, out=None)` = <ufunc 'kei'>  
Kelvin function kei.

Defined as

$$\text{kei}(x) = \Im[K_0(xe^{\pi i/4})]$$

where  $K_0$  is the modified Bessel function of the second kind (see `kv`). See [dlmf] for more details.

**Parameters**

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
Values of the Kelvin function.

**See also:**

`ker`

the corresponding real part

`keip`

the derivative of kei

`kv`

modified Bessel function of the second kind

**References**

[dlmf]

**Examples**

It can be expressed using the modified Bessel function of the second kind.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.kv(0, x * np.exp(np.pi * 1j / 4)).imag
array([-0.49499464, -0.20240007, -0.05112188, 0.0021984])
>>> sc.kei(x)
array([-0.49499464, -0.20240007, -0.05112188, 0.0021984])
```

## scipy.special.kerp

`scipy.special.kerp(x, out=None) = <ufunc 'kerp'>`

Derivative of the Kelvin function ker.

### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
 Values of the derivative of ker.

See also:

[ker](#)

### References

[dlmf]

## scipy.special.keip

`scipy.special.keip(x, out=None) = <ufunc 'keip'>`

Derivative of the Kelvin function kei.

### Parameters

**x** [array\_like] Real argument.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**  
 The values of the derivative of kei.

See also:

[kei](#)

## Combinatorics

|                                              |                                                                                                      |
|----------------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>comb(N, k[, exact, repetition])</code> | The number of combinations of <i>N</i> things taken <i>k</i> at a time.                              |
| <code>perm(N, k[, exact])</code>             | Permutations of <i>N</i> things taken <i>k</i> at a time, i.e., <i>k</i> -permutations of <i>N</i> . |

## scipy.special.comb

`scipy.special.comb` (*N, k, exact=False, repetition=False*)

The number of combinations of *N* things taken *k* at a time.

This is often expressed as “*N* choose *k*”.

### Parameters

**N** [int, ndarray] Number of things.

**k** [int, ndarray] Number of elements taken.

**exact** [bool, optional] If *exact* is `False`, then floating point precision is used, otherwise exact long integer is computed.

**repetition** [bool, optional] If *repetition* is `True`, then the number of combinations with repetition is computed.

### Returns

**val** [int, float, ndarray] The total number of combinations.

See also:

[binom](#)

Binomial coefficient `ufunc`

## Notes

- Array arguments accepted only for `exact=False` case.
- If  $N < 0$ , or  $k < 0$ , then 0 is returned.
- If  $k > N$  and `repetition=False`, then 0 is returned.

## Examples

```
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([120., 210.])
>>> comb(10, 3, exact=True)
120
>>> comb(10, 3, exact=True, repetition=True)
220
```

## scipy.special.perm

`scipy.special.perm(N, k, exact=False)`

Permutations of  $N$  things taken  $k$  at a time, i.e.,  $k$ -permutations of  $N$ .

It's also known as “partial permutations”.

### Parameters

|              |                                                                                                                             |
|--------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>N</b>     | [int, ndarray] Number of things.                                                                                            |
| <b>k</b>     | [int, ndarray] Number of elements taken.                                                                                    |
| <b>exact</b> | [bool, optional] If <i>exact</i> is False, then floating point precision is used, otherwise exact long integer is computed. |

### Returns

|            |                                                         |
|------------|---------------------------------------------------------|
| <b>val</b> | [int, ndarray] The number of $k$ -permutations of $N$ . |
|------------|---------------------------------------------------------|

## Notes

- Array arguments accepted only for `exact=False` case.
- If  $k > N$ ,  $N < 0$ , or  $k < 0$ , then a 0 is returned.

## Examples

```
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([720., 5040.])
>>> perm(10, 3, exact=True)
720
```

## Lambert W and related functions

|                                    |                        |
|------------------------------------|------------------------|
| <code>lambertw(z[, k, tol])</code> | Lambert W function.    |
| <code>wrightomega(z[, out])</code> | Wright Omega function. |

### scipy.special.lambertw

`scipy.special.lambertw(z, k=0, tol=1e-8)`

Lambert W function.

The Lambert W function  $W(z)$  is defined as the inverse function of  $w * \exp(w)$ . In other words, the value of  $W(z)$  is such that  $z = W(z) * \exp(W(z))$  for any complex number  $z$ .

The Lambert W function is a multivalued function with infinitely many branches. Each branch gives a separate solution of the equation  $z = w * \exp(w)$ . Here, the branches are indexed by the integer  $k$ .

#### Parameters

|            |                                         |
|------------|-----------------------------------------|
| <b>z</b>   | [array_like] Input argument.            |
| <b>k</b>   | [int, optional] Branch index.           |
| <b>tol</b> | [float, optional] Evaluation tolerance. |

#### Returns

|          |                                               |
|----------|-----------------------------------------------|
| <b>w</b> | [array] $w$ will have the same shape as $z$ . |
|----------|-----------------------------------------------|

See also:

`wrightomega`

the Wright Omega function

### Notes

All branches are supported by `lambertw`:

- `lambertw(z)` gives the principal solution (branch 0)
- `lambertw(z, k)` gives the solution on branch  $k$

The Lambert W function has two partially real branches: the principal branch ( $k = 0$ ) is real for real  $z > -1/e$ , and the  $k = -1$  branch is real for  $-1/e < z < 0$ . All branches except  $k = 0$  have a logarithmic singularity at  $z = 0$ .

### Possible issues

The evaluation can become inaccurate very close to the branch point at  $-1/e$ . In some corner cases, `lambertw` might currently fail to converge, or can end up on the wrong branch.

### Algorithm

Halley's iteration is used to invert  $w * \exp(w)$ , using a first-order asymptotic approximation ( $O(\log(w))$  or  $O(w)$ ) as the initial estimate.

The definition, implementation and choice of branches is based on [2].

## References

[1], [2]

## Examples

The Lambert W function is the inverse of  $w \exp(w)$ :

```
>>> from scipy.special import lambertw
>>> w = lambertw(1)
>>> w
(0.56714329040978384+0j)
>>> w * np.exp(w)
(1.0+0j)
```

Any branch gives a valid inverse:

```
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090377+17.113535539412148j)
>>> w*np.exp(w)
(1.0000000000000002+1.609823385706477e-15j)
```

## Applications to equation-solving

The Lambert W function may be used to solve various kinds of equations, such as finding the value of the infinite power tower  $z^{z^{z^{\dots}}}$ :

```
>>> def tower(z, n):
... if n == 0:
... return z
... return z ** tower(z, n-1)
...
>>> tower(0.5, 100)
0.641185744504986
>>> -lambertw(-np.log(0.5)) / np.log(0.5)
(0.64118574450498589+0j)
```

## scipy.special.wrightomega

`scipy.special.wrightomega(z, out=None)` = <ufunc 'wrightomega'>  
Wright Omega function.

Defined as the solution to

$$\omega + \log(\omega) = z$$

where `log` is the principal branch of the complex logarithm.

### Parameters

**z** [array\_like] Points at which to evaluate the Wright Omega function

### Returns

**omega** [ndarray] Values of the Wright Omega function

**See also:**

[lambertw](#)

The Lambert W function

### Notes

New in version 0.19.0.

The function can also be defined as

$$\omega(z) = W_{K(z)}(e^z)$$

where  $K(z) = \lceil (\Im(z) - \pi)/(2\pi) \rceil$  is the unwinding number and  $W$  is the Lambert W function.

The implementation here is taken from [1].

| <i>spence</i> (z[, out])          | Spence's function, also known as the dilogarithm.           |
| <i>zeta</i> (x[, q, out])         | Riemann or Hurwitz zeta function.                           |
| <i>zetac</i> (x)                  | Riemann zeta function minus 1.                              |

**scipy.special.agm**

`scipy.special.agm(a, b) = <ufunc 'agm'>`

Compute the arithmetic-geometric mean of  $a$  and  $b$ .

Start with  $a_0 = a$  and  $b_0 = b$  and iteratively compute:

$$\begin{aligned} a_{\{n+1\}} &= (a_n + b_n) / 2 \\ b_{\{n+1\}} &= \text{sqrt}(a_n * b_n) \end{aligned}$$

$a_n$  and  $b_n$  converge to the same limit as  $n$  increases; their common limit is  $\text{agm}(a, b)$ .

**Parameters**

**a, b** [array\_like] Real values only. If the values are both negative, the result is negative. If one value is negative and the other is positive, *nan* is returned.

**Returns**

**float** The arithmetic-geometric mean of  $a$  and  $b$ .

**Examples**

```
>>> from scipy.special import agm
>>> a, b = 24.0, 6.0
>>> agm(a, b)
13.458171481725614
```

Compare that result to the iteration:

```
>>> while a != b:
... a, b = (a + b)/2, np.sqrt(a*b)
... print("a = %19.16f b=%19.16f" % (a, b))
...
a = 15.000000000000000000 b=12.000000000000000000
a = 13.500000000000000000 b=13.4164078649987388
a = 13.4582039324993694 b=13.4581390309909850
a = 13.4581714817451772 b=13.4581714817060547
a = 13.4581714817256159 b=13.4581714817256159
```

When array-like arguments are given, broadcasting applies:

```
>>> a = np.array([[1.5], [3], [6]]) # a has shape (3, 1).
>>> b = np.array([6, 12, 24, 48]) # b has shape (4,).
>>> agm(a, b)
array([[3.36454287, 5.42363427, 9.05798751, 15.53650756],
 [4.37037309, 6.72908574, 10.84726853, 18.11597502],
 [6. , 8.74074619, 13.45817148, 21.69453707]])
```

## scipy.special.bernoulli

`scipy.special.bernoulli(n)`  
Bernoulli numbers  $B_0..B_n$  (inclusive).

### Parameters

**n** [int] Indicated the number of terms in the Bernoulli series to generate.

### Returns

**ndarray** The Bernoulli numbers  $[B(0), B(1), \dots, B(n)]$ .

## References

[1], [2]

## Examples

```
>>> from scipy.special import bernoulli, zeta
>>> bernoulli(4)
array([1. , -0.5 , 0.16666667, 0. , -0.03333333])
```

The Wikipedia article ([2]) points out the relationship between the Bernoulli numbers and the zeta function,  $B_n^{+} = -n * \text{zeta}(1 - n)$  for  $n > 0$ :

```
>>> n = np.arange(1, 5)
>>> -n * zeta(1 - n)
array([0.5 , 0.16666667, -0. , -0.03333333])
```

Note that, in the notation used in the wikipedia article, *bernoulli* computes  $B_n^{-}$  (i.e. it used the convention that  $B_1$  is  $-1/2$ ). The relation given above is for  $B_n^{+}$ , so the sign of 0.5 does not match the output of `bernoulli(4)`.

## scipy.special.binom

`scipy.special.binom(n, k) = <ufunc 'binom'>`  
Binomial coefficient

### See also:

#### `comb`

The number of combinations of  $N$  things taken  $k$  at a time.

## scipy.special.diric

`scipy.special.diric(x, n)`

Periodic sinc function, also called the Dirichlet function.

The Dirichlet function is defined as:

```
diric(x, n) = sin(x * n/2) / (n * sin(x / 2)),
```

where  $n$  is a positive integer.

### Parameters

|          |                                         |
|----------|-----------------------------------------|
| <b>x</b> | [array_like] Input data                 |
| <b>n</b> | [int] Integer defining the periodicity. |

### Returns

|              |           |
|--------------|-----------|
| <b>diric</b> | [ndarray] |
|--------------|-----------|

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-8*np.pi, 8*np.pi, num=201)
>>> plt.figure(figsize=(8, 8));
>>> for idx, n in enumerate([2, 3, 4, 9]):
... plt.subplot(2, 2, idx+1)
... plt.plot(x, special.diric(x, n))
... plt.title('diric, n={}'.format(n))
>>> plt.show()
```

The following example demonstrates that `diric` gives the magnitudes (modulo the sign and scaling) of the Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```
>>> np.set_printoptions(suppress=True)
```

Create a signal  $x$  of length  $m$  with  $k$  ones:

```
>>> m = 8
>>> k = 3
>>> x = np.zeros(m)
>>> x[:k] = 1
```

Use the FFT to compute the Fourier transform of  $x$ , and inspect the magnitudes of the coefficients:

```
>>> np.abs(np.fft.fft(x))
array([3. , 2.41421356, 1. , 0.41421356, 1. ,
 0.41421356, 1. , 2.41421356])
```

Now find the same values (up to sign) using `diric`. We multiply by  $k$  to account for the different scaling conventions of `numpy.fft.fft` and `diric`:

```
>>> theta = np.linspace(0, 2*np.pi, m, endpoint=False)
>>> k * special.diric(theta, k)
array([3. , 2.41421356, 1. , -0.41421356, -1. ,
 -0.41421356, 1. , 2.41421356])
```

### scipy.special.euler

scipy.special.euler(*n*)

Euler numbers  $E(0), E(1), \dots, E(n)$ .

The Euler numbers [1] are also known as the secant numbers.

Because `euler(n)` returns floating point values, it does not give exact values for large  $n$ . The first inexact value is  $E(22)$ .

#### Parameters

**n** [int] The highest index of the Euler number to be returned.

#### Returns

**ndarray** The Euler numbers  $[E(0), E(1), \dots, E(n)]$ . The odd Euler numbers, which are all zero, are included.

### References

[1], [2]

### Examples

```
>>> from scipy.special import euler
>>> euler(6)
array([1., 0., -1., 0., 5., 0., -61.])
```

```
>>> euler(13).astype(np.int64)
array([1, 0, -1, 0, 5, 0, -61,
 0, 1385, 0, -50521, 0, 2702765, 0])
```

```
>>> euler(22)[-1] # Exact value of E(22) is -69348874393137901.
-69348874393137976.0
```

### scipy.special.expn

scipy.special.expn(*n, x, out=None*) = <ufunc 'expn'>

Generalized exponential integral  $E_n$ .

For integer  $n \geq 0$  and real  $x \geq 0$  the generalized exponential integral is defined as [dlmf]

$$E_n(x) = x^{n-1} \int_x^\infty \frac{e^{-t}}{t^n} dt.$$

#### Parameters

**n:** `array_like`  
 Non-negative integers  
**x:** `array_like`  
 Real argument  
**out:** `ndarray, optional`  
 Optional output array for the function results

**Returns**

**scalar or ndarray**  
 Values of the generalized exponential integral

**See also:**

**`exp1`**

special case of  $E_n$  for  $n = 1$

**`expi`**

related to  $E_n$  when  $n = 1$

**References**

[dlmf]

**Examples**

```
>>> import scipy.special as sc
```

Its domain is nonnegative n and x.

```
>>> sc.expn(-1, 1.0), sc.expn(1, -1.0)
(nan, nan)
```

It has a pole at  $x = 0$  for  $n = 1, 2$ ; for larger n it is equal to  $1 / (n - 1)$ .

```
>>> sc.expn([0, 1, 2, 3, 4], 0)
array([inf, inf, 1. , 0.5 , 0.33333333])
```

For n equal to 0 it reduces to  $\exp(-x) / x$ .

```
>>> x = np.array([1, 2, 3, 4])
>>> sc.expn(0, x)
array([0.36787944, 0.06766764, 0.01659569, 0.00457891])
>>> np.exp(-x) / x
array([0.36787944, 0.06766764, 0.01659569, 0.00457891])
```

For n equal to 1 it reduces to `exp1`.

```
>>> sc.expn(1, x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

**scipy.special.exp1**

`scipy.special.exp1(z, out=None) = <ufunc 'exp1'>`  
 Exponential integral E1.

For complex  $z \neq 0$  the exponential integral can be defined as [1]

$$E_1(z) = \int_z^\infty \frac{e^{-t}}{t} dt,$$

where the path of the integral does not cross the negative real axis or pass through the origin.

**Parameters**

**z: array\_like**  
 Real or complex argument.  
**out: ndarray, optional**  
 Optional output array for the function results

**Returns**

**scalar or ndarray**  
 Values of the exponential integral E1

**See also:**

**exp1**

exponential integral  $Ei$

**expn**

generalization of  $E_1$

**Notes**

For  $x > 0$  it is related to the exponential integral  $Ei$  (see `exp1i`) via the relation

$$E_1(x) = -Ei(-x).$$

**References**

[1]

**Examples**

```
>>> import scipy.special as sc
```

It has a pole at 0.

```
>>> sc.exp1(0)
inf
```

It has a branch cut on the negative real axis.

```
>>> sc.exp1(-1)
nan
>>> sc.exp1(complex(-1, 0))
(-1.8951178163559368-3.141592653589793j)
>>> sc.exp1(complex(-1, -0.0))
(-1.8951178163559368+3.141592653589793j)
```

It approaches 0 along the positive real axis.

```
>>> sc.exp1([1, 10, 100, 1000])
array([2.19383934e-01, 4.15696893e-06, 3.68359776e-46, 0.00000000e+00])
```

It is related to *expi*.

```
>>> x = np.array([1, 2, 3, 4])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> -sc.expi(-x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

## scipy.special.expi

`scipy.special.expi(x, out=None) = <ufunc 'expi'>`  
Exponential integral  $Ei$ .

For real  $x$ , the exponential integral is defined as [1]

$$Ei(x) = \int_{-\infty}^x \frac{e^t}{t} dt.$$

For  $x > 0$  the integral is understood as a Cauchy principle value.

It is extended to the complex plane by analytic continuation of the function on the interval  $(0, \infty)$ . The complex variant has a branch cut on the negative real axis.

### Parameters

- x: array\_like**  
Real or complex valued argument
- out: ndarray, optional**  
Optional output array for the function results

### Returns

- scalar or ndarray**  
Values of the exponential integral

See also:

### exp1

Exponential integral  $E_1$

### expn

Generalized exponential integral  $E_n$

## Notes

The exponential integrals  $E_1$  and  $Ei$  satisfy the relation

$$E_1(x) = -Ei(-x)$$

for  $x > 0$ .

## References

[1]

## Examples

```
>>> import scipy.special as sc
```

It is related to `exp1`.

```
>>> x = np.array([1, 2, 3, 4])
>>> -sc.expi(-x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

The complex variant has a branch cut on the negative real axis.

```
>>> import scipy.special as sc
>>> sc.expi(-1 + 1e-12j)
(-0.21938393439552062+3.1415926535894254j)
>>> sc.expi(-1 - 1e-12j)
(-0.21938393439552062-3.1415926535894254j)
```

As the complex variant approaches the branch cut, the real parts approach the value of the real variant.

```
>>> sc.expi(-1)
-0.21938393439552062
```

The SciPy implementation returns the real variant for complex values on the branch cut.

```
>>> sc.expi(complex(-1, 0.0))
(-0.21938393439552062-0j)
>>> sc.expi(complex(-1, -0.0))
(-0.21938393439552062-0j)
```

## scipy.special.factorial

`scipy.special.factorial` (*n*, *exact=False*)

The factorial of a number or array of numbers.

The factorial of non-negative integer *n* is the product of all positive integers less than or equal to *n*:

$$n! = n * (n - 1) * (n - 2) * \dots * 1$$

### Parameters

- n** [int or array\_like of ints] Input values. If  $n < 0$ , the return value is 0.
- exact** [bool, optional] If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the *gamma* function. Default is False.

### Returns

- nf** [float or int or ndarray] Factorial of *n*, as integer or float depending on *exact*.

### Notes

For arrays with *exact=True*, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to `int64` or `object` if necessary.

With *exact=False* the factorial is approximated using the gamma function:

$$n! = \Gamma(n + 1)$$

### Examples

```
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([6., 24., 120.])
>>> factorial(arr, exact=True)
array([6, 24, 120])
>>> factorial(5, exact=True)
120
```

## scipy.special.factorial2

`scipy.special.factorial2` (*n*, *exact=False*)

Double factorial.

This is the factorial with every second value skipped. E.g.,  $7!! = 7 * 5 * 3 * 1$ . It can be approximated numerically as:

$$\begin{aligned} n!! &= \text{special.gamma}(n/2+1) * 2^{**}((m+1)/2) / \text{sqrt}(\text{pi}) & n \text{ odd} \\ &= 2^{**}(n/2) * (n/2)! & n \text{ even} \end{aligned}$$

### Parameters

**n** [int or array\_like] Calculate  $n!!$ . Arrays are only supported with *exact* set to False. If  $n < 0$ , the return value is 0.

**exact** [bool, optional] The result can be approximated rapidly using the gamma-formula above (default). If *exact* is set to True, calculate the answer exactly using integer arithmetic.

**Returns**

**nff** [float or int] Double factorial of  $n$ , as an int or a float depending on *exact*.

**Examples**

```
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105
```

**scipy.special.factorialk**

`scipy.special.factorialk` ( $n, k, exact=True$ )

Multifactorial of  $n$  of order  $k$ ,  $n(!\dots!)$ .

This is the multifactorial of  $n$  skipping  $k$  values. For example,

$$\text{factorialk}(17, 4) = 17!!!! = 17 * 13 * 9 * 5 * 1$$

In particular, for any integer  $n$ , we have

$$\begin{aligned}\text{factorialk}(n, 1) &= \text{factorial}(n) \\ \text{factorialk}(n, 2) &= \text{factorial2}(n)\end{aligned}$$

**Parameters**

**n** [int] Calculate multifactorial. If  $n < 0$ , the return value is 0.

**k** [int] Order of multifactorial.

**exact** [bool, optional] If *exact* is set to True, calculate the answer exactly using integer arithmetic.

**Returns**

**val** [int] Multifactorial of  $n$ .

**Raises**

**NotImplementedError**  
Raises when *exact* is False

**Examples**

```
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120
>>> factorialk(5, 3, exact=True)
10
```

## scipy.special.shichi

`scipy.special.shichi(x, out=None) = <ufunc 'shichi'>`

Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

$$\int_0^x \frac{\sinh t}{t} dt$$

and the hyperbolic cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and  $\log$  is the principle branch of the logarithm.

### Parameters

**x** [array\_like] Real or complex points at which to compute the hyperbolic sine and cosine integrals.

### Returns

**si** [ndarray] Hyperbolic sine integral at  $x$   
**ci** [ndarray] Hyperbolic cosine integral at  $x$

## Notes

For real arguments with  $x < 0$ , `chi` is the real part of the hyperbolic cosine integral. For such points `chi(x)` and `chi(x + 0j)` differ by a factor of  $1j \cdot \pi$ .

For real arguments the function is computed by calling Cephes' [1] *shichi* routine. For complex arguments the algorithm is based on Mpmath's [2] *shi* and *chi* routines.

## References

[1], [2]

## scipy.special.sici

`scipy.special.sici(x, out=None) = <ufunc 'sici'>`

Sine and cosine integrals.

The sine integral is

$$\int_0^x \frac{\sin t}{t} dt$$

and the cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and  $\log$  is the principle branch of the logarithm.

### Parameters

**x** [array\_like] Real or complex points at which to compute the sine and cosine integrals.

#### Returns

**si** [ndarray] Sine integral at  $x$   
**ci** [ndarray] Cosine integral at  $x$

#### Notes

For real arguments with  $x < 0$ , `ci` is the real part of the cosine integral. For such points `ci(x)` and `ci(x + 0j)` differ by a factor of  $1j\pi$ .

For real arguments the function is computed by calling Cephes' [1] `sici` routine. For complex arguments the algorithm is based on Mpmath's [2] `si` and `ci` routines.

#### References

[1], [2]

### scipy.special.softmax

`scipy.special.softmax(x, axis=None)`

Softmax function

The softmax function transforms each element of a collection by computing the exponential of each element divided by the sum of the exponentials of all the elements. That is, if  $x$  is a one-dimensional numpy array:

```
softmax(x) = np.exp(x) / sum(np.exp(x))
```

#### Parameters

**x** [array\_like] Input array.  
**axis** [int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array  $x$ .

#### Returns

**s** [ndarray] An array the same shape as  $x$ . The result will sum to 1 along the specified axis.

#### Notes

The formula for the softmax function  $\sigma(x)$  for a vector  $x = \{x_0, x_1, \dots, x_{n-1}\}$  is

$$\sigma(x)_j = \frac{e^{x_j}}{\sum_k e^{x_k}}$$

The `softmax` function is the gradient of `logsumexp`.

New in version 1.2.0.

**scipy.special.log\_softmax**

`scipy.special.log_softmax(x, axis=None)`

Logarithm of softmax function:

```
log_softmax(x) = log(softmax(x))
```

**Parameters**

**x** [array\_like] Input array.  
**axis** [int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array *x*.

**Returns**

**s** [ndarray or scalar] An array with the same shape as *x*. Exponential of the result will sum to 1 along the specified axis. If *x* is a scalar, a scalar is returned.

**Notes**

`log_softmax` is more accurate than `np.log(softmax(x))` with inputs that make `softmax` saturate (see examples below).

New in version 1.5.0.

**Examples**

```
>>> from scipy.special import log_softmax
>>> from scipy.special import softmax
>>> np.set_printoptions(precision=5)
```

```
>>> x = np.array([1000.0, 1.0])
```

```
>>> y = log_softmax(x)
>>> y
array([0., -999.])
```

```
>>> with np.errstate(divide='ignore'):
... y = np.log(softmax(x))
...
>>> y
array([0., -inf])
```

## scipy.special.spence

`scipy.special.spence(z, out=None) = <ufunc 'spence'>`

Spence's function, also known as the dilogarithm.

It is defined to be

$$\int_1^z \frac{\log(t)}{1-t} dt$$

for complex  $z$ , where the contour of integration is taken to avoid the branch cut of the logarithm. Spence's function is analytic everywhere except the negative real axis where it has a branch cut.

### Parameters

**z** [array\_like] Points at which to evaluate Spence's function

### Returns

**s** [ndarray] Computed values of Spence's function

## Notes

There is a different convention which defines Spence's function by the integral

$$-\int_0^z \frac{\log(1-t)}{t} dt;$$

this is our `spence(1 - z)`.

## scipy.special.zeta

`scipy.special.zeta(x, q=None, out=None)`

Riemann or Hurwitz zeta function.

### Parameters

**x** [array\_like of float] Input data, must be real  
**q** [array\_like of float, optional] Input data, must be real. Defaults to Riemann zeta.  
**out** [ndarray, optional] Output array for the computed values.

### Returns

**out** [array\_like] Values of  $\zeta(x)$ .

See also:

[zetac](#)

## Notes

The two-argument version is the Hurwitz zeta function

$$\zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x};$$

see [\[dlmf\]](#) for details. The Riemann zeta function corresponds to the case when  $q = 1$ .

## References

[dlmf]

## Examples

```
>>> from scipy.special import zeta, polygamma, factorial
```

Some specific values:

```
>>> zeta(2), np.pi**2/6
(1.6449340668482266, 1.6449340668482264)
```

```
>>> zeta(4), np.pi**4/90
(1.0823232337111381, 1.082323233711138)
```

Relation to the *polygamma* function:

```
>>> m = 3
>>> x = 1.25
>>> polygamma(m, x)
array(2.782144009188397)
>>> (-1)**(m+1) * factorial(m) * zeta(m+1, x)
2.7821440091883969
```

## scipy.special.zetac

`scipy.special.zetac(x) = <ufunc 'zetac'>`

Riemann zeta function minus 1.

This function is defined as

$$\zeta(x) = \sum_{k=2}^{\infty} 1/k^x,$$

where  $x > 1$ . For  $x < 1$  the analytic continuation is computed. For more information on the Riemann zeta function, see [dlmf].

### Parameters

**x** [array\_like of float] Values at which to compute  $\zeta(x) - 1$  (must be real).

### Returns

**out** [array\_like] Values of  $\zeta(x) - 1$ .

See also:

[zeta](#)

## References

[dlmf]

## Examples

```
>>> from scipy.special import zetac, zeta
```

Some special values:

```
>>> zetac(2), np.pi**2/6 - 1
(0.64493406684822641, 0.6449340668482264)
```

```
>>> zetac(-1), -1.0/12 - 1
(-1.0833333333333333, -1.0833333333333333)
```

Compare `zetac(x)` to `zeta(x) - 1` for large  $x$ :

```
>>> zetac(60), zeta(60) - 1
(8.673617380119933e-19, 0.0)
```

## Convenience functions

|                                                             |                                                                     |
|-------------------------------------------------------------|---------------------------------------------------------------------|
| <code>cbrt(x)</code>                                        | Element-wise cube root of $x$ .                                     |
| <code>exp10(x)</code>                                       | Compute $10^{**x}$ element-wise.                                    |
| <code>exp2(x)</code>                                        | Compute $2^{**x}$ element-wise.                                     |
| <code>radian(d, m, s[, out])</code>                         | Convert from degrees to radians.                                    |
| <code>cosdg(x[, out])</code>                                | Cosine of the angle $x$ given in degrees.                           |
| <code>sindg(x[, out])</code>                                | Sine of the angle $x$ given in degrees.                             |
| <code>tandg(x[, out])</code>                                | Tangent of angle $x$ given in degrees.                              |
| <code>cotdg(x[, out])</code>                                | Cotangent of the angle $x$ given in degrees.                        |
| <code>log1p(x[, out])</code>                                | Calculates $\log(1 + x)$ for use when $x$ is near zero.             |
| <code>expm1(x)</code>                                       | Compute $\exp(x) - 1$ .                                             |
| <code>cosm1(x[, out])</code>                                | $\cos(x) - 1$ for use when $x$ is near zero.                        |
| <code>round(x[, out])</code>                                | Round to the nearest integer.                                       |
| <code>xlogy(x, y)</code>                                    | Compute $x \cdot \log(y)$ so that the result is 0 if $x = 0$ .      |
| <code>xlog1py(x, y)</code>                                  | Compute $x \cdot \log_{1p}(y)$ so that the result is 0 if $x = 0$ . |
| <code>logsumexp(a[, axis, b, keepdims, return_sign])</code> | Compute the log of the sum of exponentials of input elements.       |
| <code>exprel(x)</code>                                      | Relative error exponential, $(\exp(x) - 1) / x$ .                   |
| <code>sinc(x)</code>                                        | Return the normalized sinc function.                                |

### scipy.special.cbrt

`scipy.special.cbrt(x) = <ufunc 'cbrt'>`  
 Element-wise cube root of  $x$ .

**Parameters**

**x** [array\_like]  $x$  must contain real numbers.

**Returns**

**float** The cube root of each value in  $x$ .

#### Examples

```
>>> from scipy.special import cbrt
```

```
>>> cbrt(8)
2.0
>>> cbrt([-8, -3, 0.125, 1.331])
array([-2. , -1.44224957, 0.5 , 1.1])
```

### scipy.special.exp10

`scipy.special.exp10(x) = <ufunc 'exp10'>`  
 Compute  $10^{**x}$  element-wise.

**Parameters**

**x** [array\_like]  $x$  must contain real numbers.

**Returns**

**float**  $10^{**x}$ , computed element-wise.

#### Examples

```
>>> from scipy.special import exp10
```

```
>>> exp10(3)
1000.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp10(x)
array([[0.1 , 0.31622777, 1.],
 [3.16227766, 10. , 31.6227766]])
```

**scipy.special.exp2**

`scipy.special.exp2(x) = <ufunc 'exp2'>`  
 Compute  $2^{**x}$  element-wise.

**Parameters**

**x** [array\_like]  $x$  must contain real numbers.

**Returns**

**float**  $2^{**x}$ , computed element-wise.

**Examples**

```
>>> from scipy.special import exp2
```

```
>>> exp2(3)
8.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp2(x)
array([[0.5 , 0.70710678, 1.],
 [1.41421356, 2. , 2.82842712]])
```

**scipy.special.radian**

`scipy.special.radian(d, m, s, out=None) = <ufunc 'radian'>`  
 Convert from degrees to radians.

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.

**Parameters**

**d** [array\_like] Degrees, can be real-valued.  
**m** [array\_like] Minutes, can be real-valued.  
**s** [array\_like] Seconds, can be real-valued.  
**out** [ndarray, optional] Optional output array for the function results.

**Returns**

**scalar or ndarray**  
 Values of the inputs in radians.

**Examples**

```
>>> import scipy.special as sc
```

There are many ways to specify an angle.

```
>>> sc.radian(90, 0, 0)
1.5707963267948966
>>> sc.radian(0, 60 * 90, 0)
1.5707963267948966
```

(continues on next page)

(continued from previous page)

```
>>> sc.radians(0, 0, 60**2 * 90)
1.5707963267948966
```

The inputs can be real-valued.

```
>>> sc.radians(1.5, 0, 0)
0.02617993877991494
>>> sc.radians(1, 30, 0)
0.02617993877991494
```

### scipy.special.cosdg

`scipy.special.cosdg(x, out=None) = <ufunc 'cosdg'>`  
Cosine of the angle  $x$  given in degrees.

#### Parameters

**x** [array\_like] Angle, given in degrees.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
Cosine of the input.

See also:

`sindg`, `tandg`, `cotdg`

### Examples

```
>>> import scipy.special as sc
```

It is more accurate than using cosine directly.

```
>>> x = 90 + 180 * np.arange(3)
>>> sc.cosdg(x)
array([-0., 0., -0.])
>>> np.cos(x * np.pi / 180)
array([6.1232340e-17, -1.8369702e-16, 3.0616170e-16])
```

### scipy.special.sindg

`scipy.special.sindg(x, out=None) = <ufunc 'sindg'>`  
Sine of the angle  $x$  given in degrees.

#### Parameters

**x** [array\_like] Angle, given in degrees.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**

Sine at the input.

See also:

[cosdg](#), [tandg](#), [cotdg](#)

### Examples

```
>>> import scipy.special as sc
```

It is more accurate than using sine directly.

```
>>> x = 180 * np.arange(3)
>>> sc.sindg(x)
array([0., -0., 0.])
>>> np.sin(x * np.pi / 180)
array([0.0000000e+00, 1.2246468e-16, -2.4492936e-16])
```

## scipy.special.tandg

`scipy.special.tandg(x, out=None) = <ufunc 'tandg'>`

Tangent of angle  $x$  given in degrees.

### Parameters

**x** [array\_like] Angle, given in degrees.  
**out** [ndarray, optional] Optional output array for the function results.

### Returns

**scalar or ndarray**

Tangent at the input.

See also:

[sindg](#), [cosdg](#), [cotdg](#)

### Examples

```
>>> import scipy.special as sc
```

It is more accurate than using tangent directly.

```
>>> x = 180 * np.arange(3)
>>> sc.tandg(x)
array([0., 0., 0.])
>>> np.tan(x * np.pi / 180)
array([0.0000000e+00, -1.2246468e-16, -2.4492936e-16])
```

### scipy.special.cotdg

`scipy.special.cotdg(x, out=None) = <ufunc 'cotdg'>`  
 Cotangent of the angle  $x$  given in degrees.

#### Parameters

**x** [array\_like] Angle, given in degrees.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
 Cotangent at the input.

See also:

[sindg](#), [cosdg](#), [tandg](#)

#### Examples

```
>>> import scipy.special as sc
```

It is more accurate than using cotangent directly.

```
>>> x = 90 + 180 * np.arange(3)
>>> sc.cotdg(x)
array([0., 0., 0.])
>>> 1 / np.tan(x * np.pi / 180)
array([6.1232340e-17, 1.8369702e-16, 3.0616170e-16])
```

### scipy.special.log1p

`scipy.special.log1p(x, out=None) = <ufunc 'log1p'>`  
 Calculates  $\log(1 + x)$  for use when  $x$  is near zero.

#### Parameters

**x** [array\_like] Real or complex valued input.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
 Values of  $\log(1 + x)$ .

See also:

[expm1](#), [cosm1](#)

## Examples

```
>>> import scipy.special as sc
```

It is more accurate than using  $\log(1 + x)$  directly for  $x$  near 0. Note that in the below example  $1 + 1e-17 == 1$  to double precision.

```
>>> sc.log1p(1e-17)
1e-17
>>> np.log(1 + 1e-17)
0.0
```

## scipy.special.expm1

`scipy.special.expm1(x) = <ufunc 'expm1'>`

Compute  $\exp(x) - 1$ .

When  $x$  is near zero,  $\exp(x)$  is near 1, so the numerical calculation of  $\exp(x) - 1$  can suffer from catastrophic loss of precision. `expm1(x)` is implemented to avoid the loss of precision that occurs when  $x$  is near zero.

### Parameters

**x** [array\_like]  $x$  must contain real numbers.

### Returns

**float**  $\exp(x) - 1$  computed element-wise.

## Examples

```
>>> from scipy.special import expm1
```

```
>>> expm1(1.0)
1.7182818284590451
>>> expm1([-0.2, -0.1, 0, 0.1, 0.2])
array([-0.18126925, -0.09516258, 0. , 0.10517092, 0.22140276])
```

The exact value of  $\exp(7.5e-13) - 1$  is:

```
7.5000000000028125000000007031250000001318...*10**-13.
```

Here is what `expm1(7.5e-13)` gives:

```
>>> expm1(7.5e-13)
7.5000000000028135e-13
```

Compare that to  $\exp(7.5e-13) - 1$ , where the subtraction results in a “catastrophic” loss of precision:

```
>>> np.exp(7.5e-13) - 1
7.5006667543675576e-13
```

### scipy.special.cosm1

`scipy.special.cosm1(x, out=None) = <ufunc 'cosm1'>`  
`cos(x) - 1` for use when  $x$  is near zero.

#### Parameters

**x** [array\_like] Real valued argument.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
 Values of `cos(x) - 1`.

See also:

[expm1](#), [log1p](#)

#### Examples

```
>>> import scipy.special as sc
```

It is more accurate than computing `cos(x) - 1` directly for  $x$  around 0.

```
>>> x = 1e-30
>>> np.cos(x) - 1
0.0
>>> sc.cosm1(x)
-5.0000000000000005e-61
```

### scipy.special.round

`scipy.special.round(x, out=None) = <ufunc 'round'>`  
 Round to the nearest integer.

Returns the nearest integer to  $x$ . If  $x$  ends in 0.5 exactly, the nearest even integer is chosen.

#### Parameters

**x** [array\_like] Real valued input.  
**out** [ndarray, optional] Optional output array for the function results.

#### Returns

**scalar or ndarray**  
 The nearest integers to the elements of  $x$ . The result is of floating type, not integer type.

## Examples

```
>>> import scipy.special as sc
```

It rounds to even.

```
>>> sc.round([0.5, 1.5])
array([0., 2.]
```

## scipy.special.xlogy

`scipy.special.xlogy(x, y) = <ufunc 'xlogy'>`  
Compute  $x \cdot \log(y)$  so that the result is 0 if  $x = 0$ .

### Parameters

**x** [array\_like] Multiplier  
**y** [array\_like] Argument

### Returns

**z** [array\_like] Computed  $x \cdot \log(y)$

## Notes

New in version 0.13.0.

## scipy.special.xlog1py

`scipy.special.xlog1py(x, y) = <ufunc 'xlog1py'>`  
Compute  $x \cdot \log_1 p(y)$  so that the result is 0 if  $x = 0$ .

### Parameters

**x** [array\_like] Multiplier  
**y** [array\_like] Argument

### Returns

**z** [array\_like] Computed  $x \cdot \log_1 p(y)$

## Notes

New in version 0.13.0.

**scipy.special.logsumexp**

`scipy.special.logsumexp(a, axis=None, b=None, keepdims=False, return_sign=False)`

Compute the log of the sum of exponentials of input elements.

**Parameters**

- a** [array\_like] Input array.
- axis** [None or int or tuple of ints, optional] Axis or axes over which the sum is taken. By default *axis* is None, and all elements are summed.  
New in version 0.11.0.
- keepdims** [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.  
New in version 0.15.0.
- b** [array-like, optional] Scaling factor for  $\exp(a)$  must be of the same shape as *a* or broadcastable to *a*. These values may be negative in order to implement subtraction.  
New in version 0.12.0.
- return\_sign** [bool, optional] If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).  
New in version 0.16.0.

**Returns**

- res** [ndarray] The result,  $\text{np.log}(\text{np.sum}(\text{np.exp}(a)))$  calculated in a numerically more stable way. If *b* is given then  $\text{np.log}(\text{np.sum}(b*\text{np.exp}(a)))$  is returned.
- sgn** [ndarray] If *return\_sign* is True, this will be an array of floating-point numbers matching *res* and +1, 0, or -1 depending on the sign of the result. If False, only one result is returned.

See also:

[\*numpy.logaddexp\*](#), [\*numpy.logaddexp2\*](#)

**Notes**

NumPy has a `logaddexp` function which is very similar to `logsumexp`, but only handles two arguments. `logaddexp.reduce` is similar to this function, but may be less stable.

**Examples**

```
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.4586297444267107
>>> logsumexp(a)
9.4586297444267107
```

With weights

```
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
9.9170178533034665
```

(continues on next page)

(continued from previous page)

```
>>> np.log(np.sum(b*np.exp(a)))
9.9170178533034647
```

Returning a sign flag

```
>>> logsumexp([1,2],b=[1,-1],return_sign=True)
(1.5413248546129181, -1.0)
```

Notice that `logsumexp` does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
... mask=[False, True, False])
>>> b = (~a.mask).astype(int)
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005
```

## scipy.special.exprel

`scipy.special.exprel(x) = <ufunc 'exprel'>`

Relative error exponential,  $(\exp(x) - 1)/x$ .

When  $x$  is near zero,  $\exp(x)$  is near 1, so the numerical calculation of  $\exp(x) - 1$  can suffer from catastrophic loss of precision. `exprel(x)` is implemented to avoid the loss of precision that occurs when  $x$  is near zero.

### Parameters

**x** [ndarray] Input array.  $x$  must contain real numbers.

### Returns

**float**  $(\exp(x) - 1)/x$ , computed element-wise.

See also:

[expm1](#)

### Notes

New in version 0.17.0.

### Examples

```
>>> from scipy.special import exprel
```

```
>>> exprel(0.01)
1.0050167084168056
>>> exprel([-0.25, -0.1, 0, 0.1, 0.25])
array([0.88479687, 0.95162582, 1. , 1.05170918, 1.13610167])
```

Compare `exprel(5e-9)` to the naive calculation. The exact value is `1.00000000250000000416...`

```
>>> exprel(5e-9)
1.0000000025
```

```
>>> (np.exp(5e-9) - 1)/5e-9
0.99999999392252903
```

## scipy.special.sinc

`scipy.special.sinc(x)`

Return the normalized sinc function.

The sinc function is  $\sin(\pi x)/(\pi x)$ .

---

**Note:** Note the normalization factor of `pi` used in the definition. This is the most commonly used definition in signal processing. Use `sinc(x / np.pi)` to obtain the unnormalized sinc function  $\sin(x)/x$  that is more common in mathematics.

---

### Parameters

**x** [ndarray] Array (possibly multi-dimensional) of values for which to calculate `sinc(x)`.

### Returns

**out** [ndarray] `sinc(x)`, which has the same shape as the input.

## Notes

`sinc(0)` is the limit value 1.

The name `sinc` is short for “sine cardinal” or “sinus cardinalis”.

The sinc function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the sinc function.

### 3.3.29 Statistical functions (`scipy.stats`)

This module contains a large number of probability distributions, summary and frequency statistics, correlation functions and statistical tests, masked statistics, kernel density estimation, quasi-Monte Carlo functionality, and more.

Statistics is a very large area, and there are topics that are out of scope for SciPy and are covered by other packages. Some of the most important ones are:

- **statsmodels**: regression, linear models, time series analysis, extensions to topics also covered by `scipy.stats`.
- **Pandas**: tabular data, time series functionality, interfaces to other statistical languages.
- **PyMC3**: Bayesian statistical modeling, probabilistic machine learning.

- `scikit-learn`: classification, regression, model selection.
- `Seaborn`: statistical data visualization.
- `rpy2`: Python to R bridge.

## Probability distributions

Each univariate distribution is an instance of a subclass of `rv_continuous` (`rv_discrete` for discrete distributions):

|                                                         |                                                                   |
|---------------------------------------------------------|-------------------------------------------------------------------|
| <code>rv_continuous</code> ([momtype, a, b, xtol, ...]) | A generic continuous random variable class meant for subclassing. |
| <code>rv_discrete</code> ([a, b, name, badvalue, ...])  | A generic discrete random variable class meant for subclassing.   |
| <code>rv_histogram</code> (histogram, *args, **kwargs)  | Generates a distribution given by a histogram.                    |

### `scipy.stats.rv_continuous`

**class** `scipy.stats.rv_continuous` (*momtype=1, a=None, b=None, xtol=1e-14, badvalue=None, name=None, longname=None, shapes=None, extradoc=None, seed=None*)

A generic continuous random variable class meant for subclassing.

`rv_continuous` is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

#### *Parameters*

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>momtype</b>  | [int, optional] The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.                                                                                                                                                                                                                                                                                                                                                         |
| <b>a</b>        | [float, optional] Lower bound of the support of the distribution, default is minus infinity.                                                                                                                                                                                                                                                                                                                                                           |
| <b>b</b>        | [float, optional] Upper bound of the support of the distribution, default is plus infinity.                                                                                                                                                                                                                                                                                                                                                            |
| <b>xtol</b>     | [float, optional] The tolerance for fixed point calculation for generic ppf.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>badvalue</b> | [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is <code>np.nan</code> .                                                                                                                                                                                                                                                                                           |
| <b>name</b>     | [str, optional] The name of the instance. This string is used to construct the default example for distributions.                                                                                                                                                                                                                                                                                                                                      |
| <b>longname</b> | [str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: <i>longname</i> exists for backwards compatibility, do not use for new subclasses.                                                                                                                                                                                                                          |
| <b>shapes</b>   | [str, optional] The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, <code>_pdf</code> and <code>_cdf</code> of the instance.                                                                                                                                    |
| <b>extradoc</b> | [str, optional, deprecated] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: <i>extradoc</i> exists for backwards compatibility, do not use for new subclasses.                                                                                                                                                                                                                       |
| <b>seed</b>     | [{None, int, <code>numpy.random.Generator</code> ,<br><code>numpy.random.RandomState</code> }, optional]<br>If <i>seed</i> is None (or <code>np.random</code> ), the <code>numpy.random.RandomState</code> singleton is used. If <i>seed</i> is an int, a new <code>RandomState</code> instance is used, seeded with <i>seed</i> . If <i>seed</i> is already a <code>Generator</code> or <code>RandomState</code> instance then that instance is used. |

## Notes

Public methods of an instance of a distribution class (e.g., `pdf`, `cdf`) check their arguments and pass valid arguments to private, computational methods (`_pdf`, `_cdf`). For `pdf(x)`, `x` is valid if it is within the support of the distribution. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.)

## Subclassing

New random variables can be defined by subclassing the `rv_continuous` class and re-defining at least the `_pdf` or the `_cdf` method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the `_argcheck` method.

For most of the `scipy.stats` distributions, the support interval doesn't depend on the shape parameters. `x` being in the support interval is equivalent to `self.a <= x <= self.b`. If either of the endpoints of the support do depend on the shape parameters, then i) the distribution must implement the `_get_support` method; and ii) those dependent endpoints must be omitted from the distribution's call to the `rv_continuous` initializer.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can override:

```
_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf
```

The default method `_rvs` relies on the inverse of the cdf, `_ppf`, applied to a uniform random variate. In order to generate random variates efficiently, either the default `_ppf` needs to be overwritten (e.g. if the inverse cdf can be expressed in an explicit form) or a sampling method needs to be implemented in a custom `_rvs` method.

If possible, you should override `_isf`, `_sf` or `_logsf`. The main reason would be to improve numerical accuracy: for example, the survival function `_sf` is computed as `1 - _cdf` which can result in loss of precision if `_cdf(x)` is close to one.

## Methods that can be overwritten by subclasses

```
_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
_get_support
```

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.

A note on `shapes`: subclasses need not specify them explicitly. In this case, `shapes` will be automatically deduced from the signatures of the overridden methods (`pdf`, `cdf` etc). If, for some reason, you prefer to avoid relying on introspection, you can specify `shapes` explicitly as an argument to the instance constructor.

## Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters to each call of a method of a distribution.

Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a “frozen” continuous RV object:

```
rv = generic(<shape(s)>, loc=0, scale=1)
```

*rv\_frozen* object with the same methods but holding the given shape, location, and scale fixed

### Statistics

Statistics are computed using numerical integration by default. For speed you can redefine this using `_stats`:

- take shape parameters and return `mu, mu2, g1, g2`
- If you can’t compute one of these, return it as `None`
- Can also be defined with a keyword argument `moments`, which is a string composed of “m”, “v”, “s”, and/or “k”. Only the components appearing in string should be computed and returned in the order “m”, “v”, “s”, or “k” with missing values returned as `None`.

Alternatively, you can override `_munp`, which takes `n` and shape parameters and returns the `n`-th non-central moment of the distribution.

### Examples

To create a new Gaussian distribution, we would do the following:

```
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
... "Gaussian distribution"
... def _pdf(self, x):
... return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

`scipy.stats` distributions are *instances*, so here we subclass `rv_continuous` and create an instance. With this, we now have a fully functional distribution with all relevant methods automatically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using `loc` and `scale` parameters: `gaussian.pdf(x, loc, scale)` essentially computes  $y = (x - \text{loc}) / \text{scale}$  and `gaussian._pdf(y) / scale`.

#### Attributes

##### `random_state`

Get or set the generator object for generating random variates.

### Methods

|                                         |                                                                                |
|-----------------------------------------|--------------------------------------------------------------------------------|
| <code>rvs(*args, **kwargs)</code>       | Random variates of given type.                                                 |
| <code>pdf(x, *args, **kwargs)</code>    | Probability density function at <code>x</code> of the given RV.                |
| <code>logpdf(x, *args, **kwargs)</code> | Log of the probability density function at <code>x</code> of the given RV.     |
| <code>cdf(x, *args, **kwargs)</code>    | Cumulative distribution function of the given RV.                              |
| <code>logcdf(x, *args, **kwargs)</code> | Log of the cumulative distribution function at <code>x</code> of the given RV. |
| <code>sf(x, *args, **kwargs)</code>     | Survival function ( $1 - \text{cdf}$ ) at <code>x</code> of the given RV.      |
| <code>logsf(x, *args, **kwargs)</code>  | Log of the survival function of the given RV.                                  |

|------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| <code>ppf(q, *args, **kwargs)</code>                       | Percent point function (inverse of <i>cdf</i> ) at <i>q</i> of the given RV.                      |
| <code>isf(q, *args, **kwargs)</code>                       | Inverse survival function (inverse of <i>sf</i> ) at <i>q</i> of the given RV.                    |
| <code>moment(n, *args, **kwargs)</code>                    | <i>n</i> -th order non-central moment of distribution.                                            |
| <code>stats(*args, **kwargs)</code>                        | Some statistics of the given RV.                                                                  |
| <code>entropy(*args, **kwargs)</code>                      | Differential entropy of the RV.                                                                   |
| <code>expect([func, args, loc, scale, lb, ub, ...])</code> | Calculate expected value of a function with respect to the distribution by numerical integration. |
| <code>median(*args, **kwargs)</code>                       | Median of the distribution.                                                                       |
| <code>mean(*args, **kwargs)</code>                         | Mean of the distribution.                                                                         |
| <code>std(*args, **kwargs)</code>                          | Standard deviation of the distribution.                                                           |
| <code>var(*args, **kwargs)</code>                          | Variance of the distribution.                                                                     |
| <code>interval(alpha, *args, **kwargs)</code>              | Confidence interval with equal areas around the median.                                           |
| <code>__call__(*args, **kwargs)</code>                     | Freeze the distribution for the given arguments.                                                  |
| <code>fit(data, *args, **kwargs)</code>                    | Return estimates of shape (if applicable), location, and scale parameters from data.              |
| <code>fit_loc_scale(data, *args)</code>                    | Estimate loc and scale parameters from data using 1st and 2nd moments.                            |
| <code>nllf(theta, x)</code>                                | Negative loglikelihood function.                                                                  |
| <code>support(*args, **kwargs)</code>                      | Support of the distribution.                                                                      |

### scipy.stats.rv\_continuous.rvs

`rv_continuous.rvs (*args, **kwargs)`  
 Random variates of given type.

#### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional] Scale parameter (default=1).

**size** [int or tuple of ints, optional] Defining number of random variates (default is 1).

**random\_state**

[{None, int, `numpy.random.Generator`,  
`numpy.random.RandomState`}, optional

If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

#### Returns

**rvs** [ndarray or scalar] Random variates of given *size*.

**scipy.stats.rv\_continuous.pdf**

`rv_continuous.pdf(x, *args, **kwargs)`

Probability density function at  $x$  of the given RV.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**pdf** [ndarray] Probability density function evaluated at  $x$

**scipy.stats.rv\_continuous.logpdf**

`rv_continuous.logpdf(x, *args, **kwargs)`

Log of the probability density function at  $x$  of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logpdf** [array\_like] Log of the probability density function evaluated at  $x$

**scipy.stats.rv\_continuous.cdf**

`rv_continuous.cdf(x, *args, **kwargs)`

Cumulative distribution function of the given RV.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**cdf** [ndarray] Cumulative distribution function evaluated at  $x$

### scipy.stats.rv\_continuous.logcdf

`rv_continuous.logcdf(x, *args, **kws)`

Log of the cumulative distribution function at  $x$  of the given RV.

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**logcdf** [array\_like] Log of the cumulative distribution function evaluated at  $x$

### scipy.stats.rv\_continuous.sf

`rv_continuous.sf(x, *args, **kws)`

Survival function ( $1 - cdf$ ) at  $x$  of the given RV.

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**sf** [array\_like] Survival function evaluated at  $x$

### scipy.stats.rv\_continuous.logsf

`rv_continuous.logsf(x, *args, **kws)`

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as  $(1 - cdf)$ , evaluated at  $x$ .

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**logsf** [ndarray] Log of the survival function evaluated at  $x$ .

**scipy.stats.rv\_continuous.ppf**`rv_continuous.ppf` (*q*, \*args, \*\*kwargs)Percent point function (inverse of *cdf*) at *q* of the given RV.**Parameters**

**q** [array\_like] lower tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [array\_like] quantile corresponding to the lower tail probability *q*.

**scipy.stats.rv\_continuous.isf**`rv_continuous.isf` (*q*, \*args, \*\*kwargs)Inverse survival function (inverse of *sf*) at *q* of the given RV.**Parameters**

**q** [array\_like] upper tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [ndarray or scalar] Quantile corresponding to the upper tail probability *q*.

**scipy.stats.rv\_continuous.moment**`rv_continuous.moment` (*n*, \*args, \*\*kwargs)*n*-th order non-central moment of distribution.**Parameters**

**n** [int, *n* >= 1] Order of moment.  
**arg1, arg2, arg3,...** [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

### scipy.stats.rv\_continuous.stats

`rv_continuous.stats` (\*args, \*\*kws)

Some statistics of the given RV.

#### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)

**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

#### Returns

**stats** [sequence] of requested moments.

### scipy.stats.rv\_continuous.entropy

`rv_continuous.entropy` (\*args, \*\*kws)

Differential entropy of the RV.

#### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional (continuous distributions only).] Scale parameter (default=1).

#### Notes

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

### scipy.stats.rv\_continuous.expect

`rv_continuous.expect` (func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, \*\*kws)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[f(x)] = \int_{lb}^{ub} f(x) * dist.pdf(x),$$

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of `f(x)`. Also, the function `f(x)` may be defined such that `f(x)` is 0 outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

#### Parameters

|                    |                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>func</b>        | [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping <code>f(x) = x</code> .                                                                               |
| <b>args</b>        | [tuple, optional] Shape parameters of the distribution.                                                                                                                                                                            |
| <b>loc</b>         | [float, optional] Location parameter (default=0).                                                                                                                                                                                  |
| <b>scale</b>       | [float, optional] Scale parameter (default=1).                                                                                                                                                                                     |
| <b>lb, ub</b>      | [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.                                                                                                                       |
| <b>conditional</b> | [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False. |

**Additional keyword arguments are passed to the integration routine.**

#### Returns

|               |                                        |
|---------------|----------------------------------------|
| <b>expect</b> | [float] The calculated expected value. |
|---------------|----------------------------------------|

#### Notes

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

The function is not vectorized.

#### Examples

To understand the effect of the bounds of integration consider

```
>>> from scipy.stats import expon
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

### scipy.stats.rv\_continuous.median

`rv_continuous.median(*args, **kwargs)`  
 Median of the distribution.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] Location parameter, Default is 0.

**scale** [array\_like, optional] Scale parameter, Default is 1.

#### Returns

**median** [float] The median of the distribution.

See also:

[`rv\_discrete.ppf`](#)

Inverse of the CDF

### scipy.stats.rv\_continuous.mean

`rv_continuous.mean(*args, **kwargs)`  
 Mean of the distribution.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**mean** [float] the mean of the distribution

### scipy.stats.rv\_continuous.std

`rv_continuous.std(*args, **kwargs)`  
 Standard deviation of the distribution.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**std** [float] standard deviation of the distribution

**scipy.stats.rv\_continuous.var**`rv_continuous.var (*args, **kwargs)`

Variance of the distribution.

**Parameters****arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)**scale** [array\_like, optional] scale parameter (default=1)**Returns****var** [float] the variance of the distribution**scipy.stats.rv\_continuous.interval**`rv_continuous.interval (alpha, *args, **kwargs)`

Confidence interval with equal areas around the median.

**Parameters****alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].**arg1, arg2, ...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.**scale** [array\_like, optional] scale parameter, Default is 1.**Returns****a, b** [ndarray of float] end-points of range that contain  $100 * \alpha$  % of the rv's possible values.**scipy.stats.rv\_continuous.\_\_call\_\_**`rv_continuous.__call__ (*args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters****arg1, arg2, arg3,...**[array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.**Returns****rv\_frozen** [rv\_frozen instance] The frozen distribution.

**scipy.stats.rv\_continuous.fit**

`rv_continuous.fit` (*data*, \**args*, \*\**kwds*)

Return estimates of shape (if applicable), location, and scale parameters from data. The default estimation method is Maximum Likelihood Estimation (MLE), but Method of Moments (MM) is also available.

Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

**Parameters**

**data** [array\_like] Data to use in estimating the distribution parameters.

**arg1, arg2, arg3,...**

[floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

**kwds** [floats, optional]

- *loc*: initial guess of the distribution's location parameter.
- *scale*: initial guess of the distribution's scale parameter.

Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.
- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.
- `method` : The method to use. The default is "MLE" (Maximum Likelihood Estimate); "MM" (Method of Moments) is also available.

**Returns**

**parameter\_tuple**

[tuple of floats] Estimates for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

**Notes**

With `method="MLE"` (default), the fit is computed by minimizing the negative log-likelihood function. A large, finite penalty (rather than infinite negative log-likelihood) is applied for observations beyond the support of the distribution.

With `method="MM"`, the fit is computed by minimizing the L2 norm of the relative errors between the first *k* raw (about zero) data moments and the corresponding distribution moments, where *k* is the number of non-fixed parameters. More precisely, the objective function is:

```
((data_moments - dist_moments)
 / np.maximum(np.abs(data_moments), 1e-8))**2).sum()
```

where the constant `1e-8` avoids division by zero in case of vanishing data moments. Typically, this error norm can be reduced to zero. Note that the standard method of moments can produce parameters for which some data are outside the support of the fitted distribution; this implementation does nothing to prevent this.

For either method, the returned answer is not guaranteed to be globally optimal; it may only be locally optimal, or the optimization may fail altogether. If the data contain any of `np.nan`, `np.inf`, or `-np.inf`, the `fit` method will raise a `RuntimeError`.

## Examples

Generate some data to fit: draw random variates from the `beta` distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

## `scipy.stats.rv_continuous.fit_loc_scale`

`rv_continuous.fit_loc_scale` (*data*, \*args)

Estimate `loc` and `scale` parameters from data using 1st and 2nd moments.

### Parameters

**data** [array\_like] Data to fit.

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

### Returns

**Lhat** [float] Estimated location parameter for the data.

**Shat** [float] Estimated scale parameter for the data.

### scipy.stats.rv\_continuous.nnlf

`rv_continuous.nnlf(theta, x)`  
 Negative loglikelihood function.

#### Notes

This is `-sum(log pdf(x, theta), axis=0)` where *theta* are the parameters (including loc and scale).

### scipy.stats.rv\_continuous.support

`rv_continuous.support(*args, **kwargs)`  
 Support of the distribution.

#### Parameters

**arg1, arg2, ...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

#### Returns

**a, b** [array\_like] end-points of the distribution's support.

### scipy.stats.rv\_discrete

**class** `scipy.stats.rv_discrete(a=0, b=inf, name=None, badvalue=None, moment_tol=1e-08, values=None, inc=1, longname=None, shapes=None, extradoc=None, seed=None)`

A generic discrete random variable class meant for subclassing.

`rv_discrete` is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

#### Parameters

**a** [float, optional] Lower bound of the support of the distribution, default: 0

**b** [float, optional] Upper bound of the support of the distribution, default: plus infinity

**moment\_tol**

[float, optional] The tolerance for the generic calculation of moments.

**values** [tuple of two array\_like, optional] ( $x_k, p_k$ ) where  $x_k$  are integers and  $p_k$  are the non-zero probabilities between 0 and 1 with  $\sum(p_k) = 1$ .  $x_k$  and  $p_k$  must have the same shape.

**inc** [integer, optional] Increment for the support of the distribution. Default is 1. (other values have not been tested)

**badvalue** [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is `np.nan`.

**name** [str, optional] The name of the instance. This string is used to construct the default example for distributions.

**longname** [str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: *longname* exists for backwards compatibility, do not use for new subclasses.

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>shapes</b>   | [str, optional] The shape of the distribution. For example “m, n” for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signatures of the private methods, <code>_pmf</code> and <code>_cdf</code> of the instance.                                                                                                                                   |
| <b>extradoc</b> | [str, optional] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: <i>extradoc</i> exists for backwards compatibility, do not use for new subclasses.                                                                                                                                                                                                                                   |
| <b>seed</b>     | [{None, int, <code>numpy.random.Generator</code> ,<br><code>numpy.random.RandomState</code> }, optional]<br>If <i>seed</i> is None (or <code>np.random</code> ), the <code>numpy.random.RandomState</code> singleton is used. If <i>seed</i> is an int, a new <code>RandomState</code> instance is used, seeded with <i>seed</i> . If <i>seed</i> is already a <code>Generator</code> or <code>RandomState</code> instance then that instance is used. |

## Notes

This class is similar to `rv_continuous`. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.) The main differences are:

- the support of the distribution is a set of integers
- instead of the probability density function, `pdf` (and the corresponding private `_pdf`), this class defines the *probability mass function*, `pmf` (and the corresponding private `_pmf`.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
... "Poisson distribution"
... def _pmf(self, k, mu):
... return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the `loc` parameter to the methods of the instance. For example, `poisson.pmf(x, mu, loc)` delegates the work to `poisson._pmf(x-loc, mu)`.

## Discrete distributions from a list of probabilities

Alternatively, you can construct an arbitrary discrete rv defined on a finite set of values  $x_k$  with  $\text{Prob}\{X=x_k\} = p_k$  by using the `values` keyword argument to the `rv_discrete` constructor.

## Examples

Custom made discrete distribution:

```
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.1, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
>>>
>>> import matplotlib.pyplot as plt
```

(continues on next page)

(continued from previous page)

```
>>> fig, ax = plt.subplots(1, 1)
>>> ax.plot(xk, custm.pmf(xk), 'ro', ms=12, mec='r')
>>> ax.vlines(xk, 0, custm.pmf(xk), colors='r', lw=4)
>>> plt.show()
```

Random number generation:

```
>>> R = custm.rvs(size=100)
```

### Attributes

#### **random\_state**

Get or set the generator object for generating random variates.

### Methods

|                                    |                                                                         |
|------------------------------------|-------------------------------------------------------------------------|
| <i>rvs</i> (*args, **kwargs)       | Random variates of given type.                                          |
| <i>pmf</i> (k, *args, **kwargs)    | Probability mass function at k of the given RV.                         |
| <i>logpmf</i> (k, *args, **kwargs) | Log of the probability mass function at k of the given RV.              |
| <i>cdf</i> (k, *args, **kwargs)    | Cumulative distribution function of the given RV.                       |
| <i>logcdf</i> (k, *args, **kwargs) | Log of the cumulative distribution function at k of the given RV.       |
| <i>sf</i> (k, *args, **kwargs)     | Survival function (1 - <i>cdf</i> ) at k of the given RV.               |
| <i>logsf</i> (k, *args, **kwargs)  | Log of the survival function of the given RV.                           |
| <i>ppf</i> (q, *args, **kwargs)    | Percent point function (inverse of <i>cdf</i> ) at q of the given RV.   |
| <i>isf</i> (q, *args, **kwargs)    | Inverse survival function (inverse of <i>sf</i> ) at q of the given RV. |
| <i>moment</i> (n, *args, **kwargs) | n-th order non-central moment of distribution.                          |
| <i>stats</i> (*args, **kwargs)     | Some statistics of the given RV.                                        |

|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>entropy(*args, **kwargs)</code>               | Differential entropy of the RV.                                                                                           |
| <code>expect([func, args, loc, lb, ub, ...])</code> | Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation. |
| <code>median(*args, **kwargs)</code>                | Median of the distribution.                                                                                               |
| <code>mean(*args, **kwargs)</code>                  | Mean of the distribution.                                                                                                 |
| <code>std(*args, **kwargs)</code>                   | Standard deviation of the distribution.                                                                                   |
| <code>var(*args, **kwargs)</code>                   | Variance of the distribution.                                                                                             |
| <code>interval(alpha, *args, **kwargs)</code>       | Confidence interval with equal areas around the median.                                                                   |
| <code>__call__(*args, **kwargs)</code>              | Freeze the distribution for the given arguments.                                                                          |
| <code>support(*args, **kwargs)</code>               | Support of the distribution.                                                                                              |

**scipy.stats.rv\_discrete.rvs**

`rv_discrete.rvs(*args, **kwargs)`

Random variates of given type.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**size** [int or tuple of ints, optional] Defining number of random variates (Default is 1). Note that *size* has to be given as keyword, not as positional argument.

**random\_state**

[{None, int, `numpy.random.Generator`,  
`numpy.random.RandomState`}, optional

If *seed* is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

**Returns**

**rvs** [ndarray or scalar] Random variates of given *size*.

**scipy.stats.rv\_discrete.pmf**

`rv_discrete.pmf(k, *args, **kwargs)`

Probability mass function at k of the given RV.

**Parameters**

**k** [array\_like] Quantiles.

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**pmf** [array\_like] Probability mass function evaluated at k

**scipy.stats.rv\_discrete.logpmf**`rv_discrete.logpmf(k, *args, **kwargs)`Log of the probability mass function at  $k$  of the given RV.**Parameters**

- k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter. Default is 0.

**Returns**

- logpmf** [array\_like] Log of the probability mass function evaluated at  $k$ .

**scipy.stats.rv\_discrete.cdf**`rv_discrete.cdf(k, *args, **kwargs)`

Cumulative distribution function of the given RV.

**Parameters**

- k** [array\_like, int] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

- cdf** [ndarray] Cumulative distribution function evaluated at  $k$ .

**scipy.stats.rv\_discrete.logcdf**`rv_discrete.logcdf(k, *args, **kwargs)`Log of the cumulative distribution function at  $k$  of the given RV.**Parameters**

- k** [array\_like, int] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

- logcdf** [array\_like] Log of the cumulative distribution function evaluated at  $k$ .

**scipy.stats.rv\_discrete.sf**

`rv_discrete.sf(k, *args, **kwargs)`  
Survival function ( $1 - cdf$ ) at  $k$  of the given RV.

**Parameters**

**k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**sf** [array\_like] Survival function evaluated at  $k$ .

**scipy.stats.rv\_discrete.logsf**

`rv_discrete.logsf(k, *args, **kwargs)`  
Log of the survival function of the given RV.  
Returns the log of the “survival function,” defined as  $1 - cdf$ , evaluated at  $k$ .

**Parameters**

**k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**logsf** [ndarray] Log of the survival function evaluated at  $k$ .

**scipy.stats.rv\_discrete.ppf**

`rv_discrete.ppf(q, *args, **kwargs)`  
Percent point function (inverse of  $cdf$ ) at  $q$  of the given RV.

**Parameters**

**q** [array\_like] Lower tail probability.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**k** [array\_like] Quantile corresponding to the lower tail probability,  $q$ .

### scipy.stats.rv\_discrete.isf

`rv_discrete.isf(q, *args, **kwargs)`

Inverse survival function (inverse of *sf*) at *q* of the given RV.

#### Parameters

- q** [array\_like] Upper tail probability.
- arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** [array\_like, optional] Location parameter (default=0).

#### Returns

- k** [ndarray or scalar] Quantile corresponding to the upper tail probability, *q*.

### scipy.stats.rv\_discrete.moment

`rv_discrete.moment(n, *args, **kwargs)`

*n*-th order non-central moment of distribution.

#### Parameters

- n** [int, *n* >= 1] Order of moment.
- arg1, arg2, arg3,...** [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** [array\_like, optional] location parameter (default=0)
- scale** [array\_like, optional] scale parameter (default=1)

### scipy.stats.rv\_discrete.stats

`rv_discrete.stats(*args, **kwargs)`

Some statistics of the given RV.

#### Parameters

- arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc** [array\_like, optional] location parameter (default=0)
- scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)
- moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

#### Returns

- stats** [sequence] of requested moments.

**scipy.stats.rv\_discrete.entropy**`rv_discrete.entropy(*args, **kwargs)`

Differential entropy of the RV.

**Parameters****arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).**scale** [array\_like, optional (continuous distributions only).] Scale parameter (default=1).**Notes**Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

**scipy.stats.rv\_discrete.expect**`rv_discrete.expect(func=None, args=(), loc=0, lb=None, ub=None, conditional=False, maxcount=1000, tolerance=1e-10, chunksize=32)`

Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.

**Parameters****func** [callable, optional] Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping  $f(k) = k$ .**args** [tuple, optional] Shape parameters of the distribution.**loc** [float, optional] Location parameter. Default is 0.**lb, ub** [int, optional] Lower and upper bound for the summation, default is set to the support of the distribution, inclusive ( $lb \leq k \leq ub$ ).**conditional**[bool, optional] If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, *func*, conditional on being in the given interval ( $k$  such that  $lb \leq k \leq ub$ ). Default is False.**maxcount** [int, optional] Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.**tolerance** [float, optional] Absolute tolerance for the summation. Default is 1e-10.**chunksize** [int, optional] Iterate over the support of a distributions in chunks of this size. Default is 32.**Returns****expect** [float] Expected value.

## Notes

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, *func*. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only 1e-5. increasing *maxcount* and/or *chunksize* may improve the result, but may also make `zipf` very slow.

The function is not vectorized.

## `scipy.stats.rv_discrete.median`

`rv_discrete.median(*args, **kws)`

Median of the distribution.

### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] Location parameter, Default is 0.

**scale** [array\_like, optional] Scale parameter, Default is 1.

### Returns

**median** [float] The median of the distribution.

See also:

`rv_discrete.ppf`

Inverse of the CDF

## `scipy.stats.rv_discrete.mean`

`rv_discrete.mean(*args, **kws)`

Mean of the distribution.

### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

### Returns

**mean** [float] the mean of the distribution

**scipy.stats.rv\_discrete.std**

`rv_discrete.std` (*\*args, \*\*kwargs*)  
Standard deviation of the distribution.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc**  
[array\_like, optional] location parameter (default=0)

**scale**  
[array\_like, optional] scale parameter (default=1)

**Returns**

**std** [float] standard deviation of the distribution

**scipy.stats.rv\_discrete.var**

`rv_discrete.var` (*\*args, \*\*kwargs*)  
Variance of the distribution.

**Parameters**

**arg1, arg2, arg3,...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc**  
[array\_like, optional] location parameter (default=0)

**scale**  
[array\_like, optional] scale parameter (default=1)

**Returns**

**var** [float] the variance of the distribution

**scipy.stats.rv\_discrete.interval**

`rv_discrete.interval` (*alpha, \*args, \*\*kwargs*)  
Confidence interval with equal areas around the median.

**Parameters**

**alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

**arg1, arg2, ...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc**  
[array\_like, optional] location parameter, Default is 0.

**scale**  
[array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [ndarray of float] end-points of range that contain  $100 * \text{alpha} \%$  of the rv's possible values.

**scipy.stats.rv\_discrete.\_\_call\_\_**

`rv_discrete.__call__(*args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns**

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

**scipy.stats.rv\_discrete.support**

`rv_discrete.support(*args, **kwargs)`

Support of the distribution.

**Parameters**

**arg1, arg2, ...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [array\_like] end-points of the distribution's support.

**scipy.stats.rv\_histogram**

**class** `scipy.stats.rv_histogram` (*histogram*, \*args, \*\*kwargs)

Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned datasample.

As a subclass of the *rv\_continuous* class, *rv\_histogram* inherits from it a collection of generic methods (see *rv\_continuous* for the full list), and implements them based on the properties of the provided binned datasample.

**Parameters**

**histogram** [tuple of array\_like] Tuple containing two array\_like objects The first containing the content of n bins The second containing the (n+1) bin boundaries In particular the return value `np.histogram` is accepted

**Notes**

There are no additional shape parameters except for the `loc` and `scale`. The pdf is defined as a stepwise function from the provided histogram The cdf is a linear interpolation of the pdf.

New in version 0.19.0.

## Examples

Create a `scipy.stats` distribution from a numpy histogram

```
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_
↳state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary `scipy rv_continuous` distribution

```
>>> hist_dist.pdf(1.0)
0.20538577847618705
>>> hist_dist.cdf(2.0)
0.90818568543056499
```

PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the max (min) of the original dataset

```
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.7591907244498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram

```
>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, density=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()
```

### Attributes

#### `random_state`

Get or set the generator object for generating random variates.

### Methods

|                                                            |                                                                                                   |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| <code>__call__(*args, **kwargs)</code>                     | Freeze the distribution for the given arguments.                                                  |
| <code>cdf(x, *args, **kwargs)</code>                       | Cumulative distribution function of the given RV.                                                 |
| <code>entropy(*args, **kwargs)</code>                      | Differential entropy of the RV.                                                                   |
| <code>expect([func, args, loc, scale, lb, ub, ...])</code> | Calculate expected value of a function with respect to the distribution by numerical integration. |

| <i>sf</i> (x, *args, **kws)           | Survival function (1 - <i>cdf</i> ) at x of the given RV.                            |
| <i>stats</i> (*args, **kws)           | Some statistics of the given RV.                                                     |
| <i>std</i> (*args, **kws)             | Standard deviation of the distribution.                                              |
| <i>support</i> (*args, **kws)         | Support of the distribution.                                                         |
| <i>var</i> (*args, **kws)             | Variance of the distribution.                                                        |

### scipy.stats.rv\_histogram.\_\_call\_\_

`rv_histogram.__call__(*args, **kws)`  
 Freeze the distribution for the given arguments.

#### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

#### Returns

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

### scipy.stats.rv\_histogram.cdf

`rv_histogram.cdf(x, *args, **kws)`

Cumulative distribution function of the given RV.

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**cdf** [ndarray] Cumulative distribution function evaluated at  $x$

### scipy.stats.rv\_histogram.entropy

`rv_histogram.entropy(*args, **kws)`

Differential entropy of the RV.

#### Parameters

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).  
**scale** [array\_like, optional (continuous distributions only).] Scale parameter (default=1).

## Notes

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

## scipy.stats.rv\_histogram.expect

`rv_histogram.expect` (*func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, \*\*kws*)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[f(x)] = \int_{lb}^{ub} f(x) * dist.pdf(x),$$

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of  $f(x)$ . Also, the function  $f(x)$  may be defined such that  $f(x)$  is 0 outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

### Parameters

- func** [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping  $f(x) = x$ .
- args** [tuple, optional] Shape parameters of the distribution.
- loc** [float, optional] Location parameter (default=0).
- scale** [float, optional] Scale parameter (default=1).
- lb, ub** [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.
- conditional** [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

**Additional keyword arguments are passed to the integration routine.**

### Returns

- expect** [float] The calculated expected value.

## Notes

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

The function is not vectorized.

## Examples

To understand the effect of the bounds of integration consider

```
>>> from scipy.stats import expon
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

## scipy.stats.rv\_histogram.fit

`rv_histogram.fit` (*data*, \**args*, \*\**kwds*)

Return estimates of shape (if applicable), location, and scale parameters from data. The default estimation method is Maximum Likelihood Estimation (MLE), but Method of Moments (MM) is also available.

Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

### Parameters

**data** [array\_like] Data to use in estimating the distribution parameters.

**arg1, arg2, arg3,...**

[floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

**kwds** [floats, optional]

- *loc*: initial guess of the distribution's location parameter.
- *scale*: initial guess of the distribution's scale parameter.

Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.
- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.
- `method` : The method to use. The default is "MLE" (Maximum Likelihood Estimate); "MM" (Method of Moments) is also available.

### Returns

**parameter\_tuple**

[tuple of floats] Estimates for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

**Notes**

With `method="MLE"` (default), the fit is computed by minimizing the negative log-likelihood function. A large, finite penalty (rather than infinite negative log-likelihood) is applied for observations beyond the support of the distribution.

With `method="MM"`, the fit is computed by minimizing the L2 norm of the relative errors between the first  $k$  raw (about zero) data moments and the corresponding distribution moments, where  $k$  is the number of non-fixed parameters. More precisely, the objective function is:

```
((data_moments - dist_moments)
 / np.maximum(np.abs(data_moments), 1e-8))**2).sum()
```

where the constant `1e-8` avoids division by zero in case of vanishing data moments. Typically, this error norm can be reduced to zero. Note that the standard method of moments can produce parameters for which some data are outside the support of the fitted distribution; this implementation does nothing to prevent this.

For either method, the returned answer is not guaranteed to be globally optimal; it may only be locally optimal, or the optimization may fail altogether. If the data contain any of `np.nan`, `np.inf`, or `-np.inf`, the `fit` method will raise a `RuntimeError`.

**Examples**

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```

>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)

```

### scipy.stats.rv\_histogram.fit\_loc\_scale

`rv_histogram.fit_loc_scale` (*data*, \**args*)

Estimate loc and scale parameters from data using 1st and 2nd moments.

#### Parameters

**data** [array\_like] Data to fit.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

#### Returns

**Lhat** [float] Estimated location parameter for the data.  
**Shat** [float] Estimated scale parameter for the data.

### scipy.stats.rv\_histogram.freeze

`rv_histogram.freeze` (\**args*, \*\**kws*)

Freeze the distribution for the given arguments.

#### Parameters

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

#### Returns

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

### scipy.stats.rv\_histogram.interval

`rv_histogram.interval` (*alpha*, \**args*, \*\**kws*)

Confidence interval with equal areas around the median.

#### Parameters

**alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].  
**arg1, arg2, ...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter, Default is 0.  
**scale** [array\_like, optional] scale parameter, Default is 1.

#### Returns

**a, b** [ndarray of float] end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

### scipy.stats.rv\_histogram.isf

`rv_histogram.isf(q, *args, **kwargs)`

Inverse survival function (inverse of `sf`) at `q` of the given RV.

#### Parameters

**q** [array\_like] upper tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**x** [ndarray or scalar] Quantile corresponding to the upper tail probability `q`.

### scipy.stats.rv\_histogram.logcdf

`rv_histogram.logcdf(x, *args, **kwargs)`

Log of the cumulative distribution function at `x` of the given RV.

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**logcdf** [array\_like] Log of the cumulative distribution function evaluated at `x`

### scipy.stats.rv\_histogram.logpdf

`rv_histogram.logpdf(x, *args, **kwargs)`

Log of the probability density function at `x` of the given RV.

This uses a more numerically accurate calculation if available.

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**logpdf** [array\_like] Log of the probability density function evaluated at x

### scipy.stats.rv\_histogram.logsf

`rv_histogram.logsf(x, *args, **kws)`

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as  $(1 - cdf)$ , evaluated at x.

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**logsf** [ndarray] Log of the survival function evaluated at x.

### scipy.stats.rv\_histogram.mean

`rv_histogram.mean(*args, **kws)`

Mean of the distribution.

#### Parameters

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**mean** [float] the mean of the distribution

### scipy.stats.rv\_histogram.median

`rv_histogram.median(*args, **kws)`

Median of the distribution.

#### Parameters

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] Location parameter, Default is 0.  
**scale** [array\_like, optional] Scale parameter, Default is 1.

#### Returns

**median** [float] The median of the distribution.

See also:

`rv_discrete.ppf`

Inverse of the CDF

### `scipy.stats.rv_histogram.moment`

`rv_histogram.moment` (*n*, \**args*, \*\**kws*)  
 n-th order non-central moment of distribution.

#### *Parameters*

**n** [int, n >= 1] Order of moment.  
**arg1, arg2, arg3,...** [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

### `scipy.stats.rv_histogram.nnlf`

`rv_histogram.nnlf` (*theta*, *x*)  
 Negative loglikelihood function.

#### **Notes**

This is  $-\text{sum}(\log \text{pdf}(x, \text{theta}), \text{axis}=0)$  where *theta* are the parameters (including loc and scale).

### `scipy.stats.rv_histogram.pdf`

`rv_histogram.pdf` (*x*, \**args*, \*\**kws*)  
 Probability density function at *x* of the given RV.

#### *Parameters*

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### *Returns*

**pdf** [ndarray] Probability density function evaluated at *x*

**scipy.stats.rv\_histogram.ppf**

`rv_histogram.ppf` (*q*, \**args*, \*\**kwds*)

Percent point function (inverse of *cdf*) at *q* of the given RV.

**Parameters**

**q** [array\_like] lower tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [array\_like] quantile corresponding to the lower tail probability *q*.

**scipy.stats.rv\_histogram.rvs**

`rv_histogram.rvs` (\**args*, \*\**kwds*)

Random variates of given type.

**Parameters**

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).  
**scale** [array\_like, optional] Scale parameter (default=1).  
**size** [int or tuple of ints, optional] Defining number of random variates (default is 1).

**random\_state**

[{None, int, `numpy.random.Generator`,  
`numpy.random.RandomState`}, optional

If *seed* is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

**Returns**

**rvs** [ndarray or scalar] Random variates of given *size*.

**scipy.stats.rv\_histogram.sf**

`rv_histogram.sf` (*x*, \**args*, \*\**kwds*)

Survival function (1 - *cdf*) at *x* of the given RV.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**sf** [array\_like] Survival function evaluated at x

### scipy.stats.rv\_histogram.stats

`rv_histogram.stats` (\*args, \*\*kws)

Some statistics of the given RV.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)

**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

#### Returns

**stats** [sequence] of requested moments.

### scipy.stats.rv\_histogram.std

`rv_histogram.std` (\*args, \*\*kws)

Standard deviation of the distribution.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**std** [float] standard deviation of the distribution

### scipy.stats.rv\_histogram.support

`rv_histogram.support` (\*args, \*\*kwargs)

Support of the distribution.

#### Parameters

**arg1, arg2, ...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

#### Returns

**a, b** [array\_like] end-points of the distribution's support.

**scipy.stats.rv\_histogram.var**

`rv_histogram.var` (\*args, \*\*kwargs)

Variance of the distribution.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**var** [float] the variance of the distribution

**Continuous distributions**

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>alpha</i>       | An alpha continuous random variable.                           |
| <i>anglit</i>      | An anglit continuous random variable.                          |
| <i>arcsine</i>     | An arcsine continuous random variable.                         |
| <i>argus</i>       | Argus distribution                                             |
| <i>beta</i>        | A beta continuous random variable.                             |
| <i>betaprime</i>   | A beta prime continuous random variable.                       |
| <i>bradford</i>    | A Bradford continuous random variable.                         |
| <i>burr</i>        | A Burr (Type III) continuous random variable.                  |
| <i>burr12</i>      | A Burr (Type XII) continuous random variable.                  |
| <i>cauchy</i>      | A Cauchy continuous random variable.                           |
| <i>chi</i>         | A chi continuous random variable.                              |
| <i>chi2</i>        | A chi-squared continuous random variable.                      |
| <i>cosine</i>      | A cosine continuous random variable.                           |
| <i>crystalball</i> | Crystalball distribution                                       |
| <i>dgamma</i>      | A double gamma continuous random variable.                     |
| <i>dweibull</i>    | A double Weibull continuous random variable.                   |
| <i>erlang</i>      | An Erlang continuous random variable.                          |
| <i>expon</i>       | An exponential continuous random variable.                     |
| <i>exponnorm</i>   | An exponentially modified Normal continuous random variable.   |
| <i>exponweib</i>   | An exponentiated Weibull continuous random variable.           |
| <i>exponpow</i>    | An exponential power continuous random variable.               |
| <i>f</i>           | An F continuous random variable.                               |
| <i>fatiguelife</i> | A fatigue-life (Birnbaum-Saunders) continuous random variable. |
| <i>fisk</i>        | A Fisk continuous random variable.                             |
| <i>foldcauchy</i>  | A folded Cauchy continuous random variable.                    |
| <i>foldnorm</i>    | A folded normal continuous random variable.                    |
| <i>genlogistic</i> | A generalized logistic continuous random variable.             |
| <i>gennorm</i>     | A generalized normal continuous random variable.               |
| <i>genpareto</i>   | A generalized Pareto continuous random variable.               |
| <i>genexpon</i>    | A generalized exponential continuous random variable.          |
| <i>genextreme</i>  | A generalized extreme value continuous random variable.        |
| <i>gausshyper</i>  | A Gauss hypergeometric continuous random variable.             |

|---------------------------|------------------------------------------------------------------------------|
| <i>gamma</i>              | A gamma continuous random variable.                                          |
| <i>gengamma</i>           | A generalized gamma continuous random variable.                              |
| <i>genhalflogistic</i>    | A generalized half-logistic continuous random variable.                      |
| <i>genhyperbolic</i>      | A generalized hyperbolic continuous random variable.                         |
| <i>geninvgauss</i>        | A Generalized Inverse Gaussian continuous random variable.                   |
| <i>gilbrat</i>            | A Gilbrat continuous random variable.                                        |
| <i>gompertz</i>           | A Gompertz (or truncated Gumbel) continuous random variable.                 |
| <i>gumbel_r</i>           | A right-skewed Gumbel continuous random variable.                            |
| <i>gumbel_l</i>           | A left-skewed Gumbel continuous random variable.                             |
| <i>halfcauchy</i>         | A Half-Cauchy continuous random variable.                                    |
| <i>halflogistic</i>       | A half-logistic continuous random variable.                                  |
| <i>halfnorm</i>           | A half-normal continuous random variable.                                    |
| <i>halfgennorm</i>        | The upper half of a generalized normal continuous random variable.           |
| <i>hypsecant</i>          | A hyperbolic secant continuous random variable.                              |
| <i>invgamma</i>           | An inverted gamma continuous random variable.                                |
| <i>invgauss</i>           | An inverse Gaussian continuous random variable.                              |
| <i>invweibull</i>         | An inverted Weibull continuous random variable.                              |
| <i>johnsonsb</i>          | A Johnson SB continuous random variable.                                     |
| <i>johnsonsu</i>          | A Johnson SU continuous random variable.                                     |
| <i>kappa4</i>             | Kappa 4 parameter distribution.                                              |
| <i>kappa3</i>             | Kappa 3 parameter distribution.                                              |
| <i>ksone</i>              | Kolmogorov-Smirnov one-sided test statistic distribution.                    |
| <i>kstwo</i>              | Kolmogorov-Smirnov two-sided test statistic distribution.                    |
| <i>kstwobign</i>          | Limiting distribution of scaled Kolmogorov-Smirnov two-sided test statistic. |
| <i>laplace</i>            | A Laplace continuous random variable.                                        |
| <i>laplace_asymmetric</i> | An asymmetric Laplace continuous random variable.                            |
| <i>levy</i>               | A Levy continuous random variable.                                           |
| <i>levy_l</i>             | A left-skewed Levy continuous random variable.                               |
| <i>levy_stable</i>        | A Levy-stable continuous random variable.                                    |
| <i>logistic</i>           | A logistic (or Sech-squared) continuous random variable.                     |
| <i>loggamma</i>           | A log gamma continuous random variable.                                      |
| <i>loglaplace</i>         | A log-Laplace continuous random variable.                                    |
| <i>lognorm</i>            | A lognormal continuous random variable.                                      |
| <i>loguniform</i>         | A loguniform or reciprocal continuous random variable.                       |
| <i>lomax</i>              | A Lomax (Pareto of the second kind) continuous random variable.              |
| <i>maxwell</i>            | A Maxwell continuous random variable.                                        |
| <i>mielke</i>             | A Mielke Beta-Kappa / Dagum continuous random variable.                      |
| <i>moyal</i>              | A Moyal continuous random variable.                                          |
| <i>nakagami</i>           | A Nakagami continuous random variable.                                       |
| <i>ncx2</i>               | A non-central chi-squared continuous random variable.                        |
| <i>ncf</i>                | A non-central F distribution continuous random variable.                     |
| <i>nct</i>                | A non-central Student's t continuous random variable.                        |
| <i>norm</i>               | A normal continuous random variable.                                         |
| <i>norminvgauss</i>       | A Normal Inverse Gaussian continuous random variable.                        |

| <i>semicircular</i>      | A semicircular continuous random variable.                    |
| <i>skewcauchy</i>        | A skewed Cauchy random variable.                              |
| <i>skewnorm</i>          | A skew-normal random variable.                                |
| <i>studentized_range</i> | A studentized range continuous random variable.               |
| <i>t</i>                 | A Student's t continuous random variable.                     |
| <i>trapezoid</i>         | A trapezoidal continuous random variable.                     |
| <i>triang</i>            | A triangular continuous random variable.                      |
| <i>truncexpon</i>        | A truncated exponential continuous random variable.           |
| <i>truncnorm</i>         | A truncated normal continuous random variable.                |
| <i>tukeylambda</i>       | A Tukey-Lambda continuous random variable.                    |
| <i>uniform</i>           | A uniform continuous random variable.                         |
| <i>vonmises</i>          | A Von Mises continuous random variable.                       |
| <i>vonmises_line</i>     | A Von Mises continuous random variable.                       |
| <i>wald</i>              | A Wald continuous random variable.                            |
| <i>weibull_min</i>       | Weibull minimum continuous random variable.                   |
| <i>weibull_max</i>       | Weibull maximum continuous random variable.                   |
| <i>wrapcauchy</i>        | A wrapped Cauchy continuous random variable.                  |

### scipy.stats.alpha

`scipy.stats.alpha = <scipy.stats._continuous_distns.alpha_gen object>`

An alpha continuous random variable.

As an instance of the *rv\_continuous* class, *alpha* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

#### Notes

The probability density function for *alpha* ([1], [2]) is:

$$f(x, a) = \frac{1}{x^2 \Phi(a) \sqrt{2\pi}} * \exp\left(-\frac{1}{2}(a - 1/x)^2\right)$$

where  $\Phi$  is the normal CDF,  $x > 0$ , and  $a > 0$ .

*alpha* takes *a* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `alpha.pdf(x, a, loc, scale)` is identically equivalent to `alpha.pdf(y, a) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1], [2]

## Examples

```
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(alpha.ppf(0.01, a),
... alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = alpha.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats anglit

`scipy.stats.anglit` = <`scipy.stats._continuous_distns.anglit_gen` object>

An `anglit` continuous random variable.

As an instance of the `rv_continuous` class, `anglit` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `anglit` is:

$$f(x) = \sin(2x + \pi/2) = \cos(2x)$$

for  $-\pi/4 \leq x \leq \pi/4$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `anglit.pdf(x, loc, scale)` is identically equivalent to `anglit.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import anglit
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(anglit.ppf(0.01),
... anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
... 'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.arcsine

`scipy.stats.arcsine = <scipy.stats._continuous_distns.arcsine_gen object>`

An arcsine continuous random variable.

As an instance of the *rv\_continuous* class, *arcsine* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *arcsine* is:

$$f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$$

for  $0 < x < 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `arcsine.pdf(x, loc, scale)` is identically equivalent to `arcsine.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(arcsine.ppf(0.01),
... arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
... 'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.argus

`scipy.stats.argus` = <`scipy.stats._continuous_distns.argus_gen` object>

Argus distribution

As an instance of the `rv_continuous` class, `argus` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `argus` is:

$$f(x, \chi) = \frac{\chi^3}{\sqrt{2\pi}\Psi(\chi)} x \sqrt{1-x^2} \exp(-\chi^2(1-x^2)/2)$$

for  $0 < x < 1$  and  $\chi > 0$ , where

$$\Psi(\chi) = \Phi(\chi) - \chi\phi(\chi) - 1/2$$

with  $\Phi$  and  $\phi$  being the CDF and PDF of a standard normal distribution, respectively.

`argus` takes  $\chi$  as shape a parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `argus.pdf(x, chi, loc, scale)` is identically equivalent to `argus.pdf(y, chi) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

New in version 0.19.0.

### References

[1]

### Examples

```
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(argus.ppf(0.01, chi),
... argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi),
... 'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
True
```

Generate random numbers:

```
>>> r = argus.rvs(chi, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.beta

`scipy.stats.beta = <scipy.stats._continuous_distns.beta_gen object>`

A beta continuous random variable.

As an instance of the `rv_continuous` class, `beta` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `beta` is:

$$f(x, a, b) = \frac{\Gamma(a + b)x^{a-1}(1 - x)^{b-1}}{\Gamma(a)\Gamma(b)}$$

for  $0 \leq x \leq 1$ ,  $a > 0$ ,  $b > 0$ , where  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`beta` takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `beta.pdf(x, a, b, loc, scale)` is identically equivalent to `beta.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(beta.ppf(0.01, a, b),
... beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.betaprime

`scipy.stats.betaprime` = <`scipy.stats._continuous_distns.betaprime_gen` object>  
 A beta prime continuous random variable.

As an instance of the `rv_continuous` class, `betaprime` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `betaprime` is:

$$f(x, a, b) = \frac{x^{a-1}(1+x)^{-a-b}}{\beta(a, b)}$$

for  $x \geq 0$ ,  $a > 0$ ,  $b > 0$ , where  $\beta(a, b)$  is the beta function (see `scipy.special.beta`).

`betaprime` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `betaprime.pdf(x, a, b, loc, scale)` is identically equivalent to `betaprime.pdf(y, a, b) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(betaprime.ppf(0.01, a, b),
... betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='betaprime pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = betaprime(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.bradford

`scipy.stats.bradford` = <`scipy.stats._continuous_distns.bradford_gen` object>

A Bradford continuous random variable.

As an instance of the `rv_continuous` class, `bradford` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `bradford` is:

$$f(x, c) = \frac{c}{\log(1+c)(1+cx)}$$

for  $0 \leq x \leq 1$  and  $c > 0$ .

`bradford` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `bradford.pdf(x, c, loc, scale)` is identically equivalent to `bradford.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(bradford.ppf(0.01, c),
... bradford.ppf(0.99, c), 100)
>>> ax.plot(x, bradford.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], bradford.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.burr

`scipy.stats.burr` = <`scipy.stats._continuous_distns.burr_gen` object>

A Burr (Type III) continuous random variable.

As an instance of the `rv_continuous` class, `burr` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

### `fisk`

a special case of either `burr` or `burr12` with `d=1`

### `burr12`

Burr Type XII distribution

### `mielke`

Mielke Beta-Kappa / Dagum distribution

## Notes

The probability density function for `burr` is:

$$f(x, c, d) = cdx^{-c-1}/(1+x^{-c})^{d+1}$$

for  $x \geq 0$  and  $c, d > 0$ .

`burr` takes  $c$  and  $d$  as shape parameters.

This is the PDF corresponding to the third CDF given in Burr's list; specifically, it is equation (11) in Burr's paper [1]. The distribution is also commonly referred to as the Dagum distribution [2]. If the parameter  $c < 1$  then the mean of the distribution does not exist and if  $c < 2$  the variance does not exist [2]. The PDF is finite at the left endpoint  $x = 0$  if  $c * d \geq 1$ .

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr.pdf(x, c, d, loc, scale)` is identically equivalent to `burr.pdf(y, c, d) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1], [2], [3]

## Examples

```
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, d = 10.5, 4.3
>>> mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr.ppf(0.01, c, d),
... burr.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr.pdf(x, c, d),
... 'r-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.burr12

`scipy.stats.burr12 = <scipy.stats._continuous_distns.burr12_gen object>`

A Burr (Type XII) continuous random variable.

As an instance of the *rv\_continuous* class, *burr12* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**fisk**

a special case of either *burr* or *burr12* with *d*=1

**burr**

Burr Type III distribution

## Notes

The probability density function for *burr* is:

$$f(x, c, d) = cdx^{c-1}/(1+x^c)^{d+1}$$

for  $x \geq 0$  and  $c, d > 0$ .

*burr12* takes *c* and *d* as shape parameters for *c* and *d*.

This is the PDF corresponding to the twelfth CDF given in Burr's list; specifically, it is equation (20) in Burr's paper [1].

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `burr12.pdf(x, c, d, loc, scale)` is identically equivalent to `burr12.pdf(y, c, d) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [2].

## References

[1], [2], [3]

## Examples

```
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr12.ppf(0.01, c, d),
... burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
... 'r-', lw=5, alpha=0.6, label='burr12 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr12.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.cauchy

`scipy.stats.cauchy = <scipy.stats._continuous_distns.cauchy_gen object>`

A Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `cauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `cauchy` is

$$f(x) = \frac{1}{\pi(1+x^2)}$$

for a real number *x*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cauchy.ppf(0.01),
... cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
... 'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

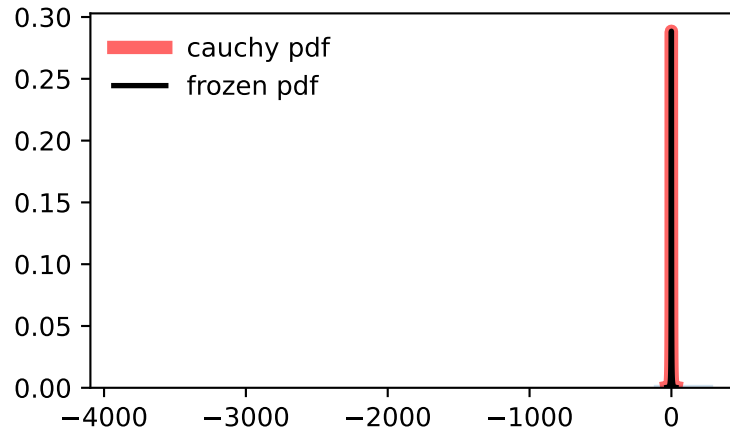

```
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.chi

`scipy.stats.chi` = <`scipy.stats._continuous_distns.chi_gen` object>

A chi continuous random variable.

As an instance of the `rv_continuous` class, `chi` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `chi` is:

$$f(x, k) = \frac{1}{2^{k/2-1}\Gamma(k/2)} x^{k-1} \exp(-x^2/2)$$

for  $x \geq 0$  and  $k > 0$  (degrees of freedom, denoted `df` in the implementation).  $\Gamma$  is the gamma function (`scipy.special.gamma`).

Special cases of `chi` are:

- `chi(1, loc, scale)` is equivalent to `halfnorm`
- `chi(2, 0, scale)` is equivalent to `rayleigh`
- `chi(3, 0, scale)` is equivalent to `maxwell`

`chi` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi.pdf(x, df, loc, scale)` is identically equivalent to `chi.pdf(y, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi.ppf(0.01, df),
... chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),
... 'r-', lw=5, alpha=0.6, label='chi pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.chi2

`scipy.stats.chi2 = <scipy.stats._continuous_distns.chi2_gen object>`

A chi-squared continuous random variable.

For the noncentral chi-square distribution, see [ncx2](#).

As an instance of the *rv\_continuous* class, *chi2* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[ncx2](#)

## Notes

The probability density function for `chi2` is:

$$f(x, k) = \frac{1}{2^{k/2} \Gamma(k/2)} x^{k/2-1} \exp(-x/2)$$

for  $x > 0$  and  $k > 0$  (degrees of freedom, denoted `df` in the implementation).

`chi2` takes `df` as a shape parameter.

The chi-squared distribution is a special case of the gamma distribution, with gamma parameters  $a = df/2$ ,  $loc = 0$  and  $scale = 2$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi2.ppf(0.01, df),
... chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
... 'r-', lw=5, alpha=0.6, label='chi2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi2.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.cosine**

`scipy.stats.cosine` = <`scipy.stats._continuous_distns.cosine_gen` object>

A cosine continuous random variable.

As an instance of the `rv_continuous` class, `cosine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The cosine distribution is an approximation to the normal distribution. The probability density function for `cosine` is:

$$f(x) = \frac{1}{2\pi}(1 + \cos(x))$$

for  $-\pi \leq x \leq \pi$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cosine.pdf(x, loc, scale)` is identically equivalent to `cosine.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cosine.ppf(0.01),
... cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x),
... 'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cosine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cosine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cosine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.crystalball

`scipy.stats.crystalball = <scipy.stats._continuous_distns.crystalball_gen object>`  
 Crystalball distribution

As an instance of the *rv\_continuous* class, *crystalball* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *crystalball* is:

$$f(x, \beta, m) = \begin{cases} N \exp(-x^2/2), & \text{for } x > -\beta \\ NA(B - x)^{-m} & \text{for } x \leq -\beta \end{cases}$$

where  $A = (m/|\beta|)^m \exp(-\beta^2/2)$ ,  $B = m/|\beta| - |\beta|$  and  $N$  is a normalisation constant.

*crystalball* takes  $\beta > 0$  and  $m > 1$  as shape parameters.  $\beta$  defines the point where the pdf changes from a power-law to a Gaussian distribution.  $m$  is the power of the power-law tail.

## References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `crystalball.pdf(x, beta, m, loc, scale)` is identically equivalent to `crystalball.pdf(y, beta, m) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

New in version 0.19.0.

[1]

## Examples

```
>>> from scipy.stats import crystalball
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta, m = 2, 3
>>> mean, var, skew, kurt = crystalball.stats(beta, m, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(crystalball.ppf(0.01, beta, m),
... crystalball.ppf(0.99, beta, m), 100)
>>> ax.plot(x, crystalball.pdf(x, beta, m),
... 'r-', lw=5, alpha=0.6, label='crystalball pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = crystalball(beta, m)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

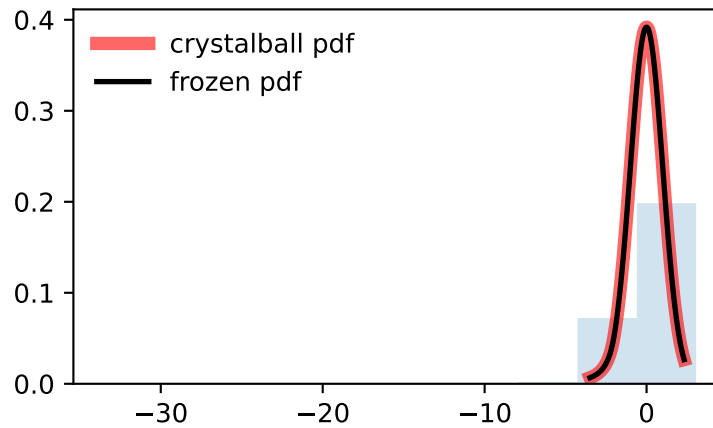

```
>>> vals = crystalball.ppf([0.001, 0.5, 0.999], beta, m)
>>> np.allclose([0.001, 0.5, 0.999], crystalball.cdf(vals, beta, m))
True
```

Generate random numbers:

```
>>> r = crystalball.rvs(beta, m, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

| <code>std(beta, m, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                                                                      |
| <code>interval(alpha, beta, m, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.dgamma

`scipy.stats.dgamma` = <`scipy.stats._continuous_distns.dgamma_gen` object>

A double gamma continuous random variable.

As an instance of the `rv_continuous` class, `dgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `dgamma` is:

$$f(x, a) = \frac{1}{2\Gamma(a)} |x|^{a-1} \exp(-|x|)$$

for a real number  $x$  and  $a > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`dgamma` takes  $a$  as a shape parameter for  $a$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dgamma.ppf(0.01, a),
... dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>var(a, loc=0, scale=1)</code>                                                              | Variance of the distribution.                                                                                                                |
| <code>std(a, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                                                                      |
| <code>interval(alpha, a, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.dweibull

`scipy.stats.dweibull = <scipy.stats._continuous_distns.dweibull_gen object>`

A double Weibull continuous random variable.

As an instance of the `rv_continuous` class, `dweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `dweibull` is given by

$$f(x, c) = c/2|x|^{c-1} \exp(-|x|^c)$$

for a real number *x* and *c* > 0.

`dweibull` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dweibull.pdf(x, c, loc, scale)` is identically equivalent to `dweibull.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 2.07
>>> mean, var, skew, kurt = dweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dweibull.ppf(0.01, c),
... dweibull.ppf(0.99, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.erlang

`scipy.stats.erlang` = <`scipy.stats._continuous_distns.erlang_gen` object>

An Erlang continuous random variable.

As an instance of the `rv_continuous` class, `erlang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[gamma](#)

### Notes

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter  $a$  an integer. Note that this restriction is not enforced by `erlang`. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to [gamma](#) for examples.

## scipy.stats.expon

`scipy.stats.expon` = <`scipy.stats._continuous_distns.expon_gen` object>

An exponential continuous random variable.

As an instance of the `rv_continuous` class, `expon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `expon` is:

$$f(x) = \exp(-x)$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `expon.pdf(x, loc, scale)` is identically equivalent to `expon.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A common parameterization for `expon` is in terms of the rate parameter `lambda`, such that `pdf = lambda * exp(-lambda * x)`. This parameterization corresponds to using `scale = 1 / lambda`.

The exponential distribution is a special case of the gamma distributions, with gamma shape parameter  $a = 1$ .

### Examples

```
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(expon.ppf(0.01),
... expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
... 'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
True
```

Generate random numbers:

```
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.exponnorm

`scipy.stats.exponnorm` = <`scipy.stats._continuous_distns.exponnorm_gen` object>

An exponentially modified Normal continuous random variable.

Also known as the exponentially modified Gaussian distribution [1].

As an instance of the `rv_continuous` class, `exponnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `exponnorm` is:

$$f(x, K) = \frac{1}{2K} \exp\left(\frac{1}{2K^2} - x/K\right) \operatorname{erfc}\left(-\frac{x - 1/K}{\sqrt{2}}\right)$$

where  $x$  is a real number and  $K > 0$ .

It can be thought of as the sum of a standard normal random variable and an independent exponentially distributed random variable with rate  $1/K$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent

to `exponnorm.pdf(y, K) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

An alternative parameterization of this distribution (for example, in the Wikipedia article [1]) involves three parameters,  $\mu$ ,  $\lambda$  and  $\sigma$ .

In the present parameterization this corresponds to having `loc` and `scale` equal to  $\mu$  and  $\sigma$ , respectively, and shape parameter  $K = 1/(\sigma\lambda)$ .

New in version 0.16.0.

## References

[1]

## Examples

```
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponnorm.ppf(0.01, K),
... exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
... 'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
True
```

Generate random numbers:

```
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## scipy.stats.exponweib

`scipy.stats.exponweib` = <`scipy.stats._continuous_distns.exponweib_gen` object>  
An exponentiated Weibull continuous random variable.

As an instance of the `rv_continuous` class, `exponweib` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`weibull_min`, `numpy.random.Generator.weibull`

### Notes

The probability density function for `exponweib` is:

$$f(x, a, c) = ac[1 - \exp(-x^c)]^{a-1} \exp(-x^c)x^{c-1}$$

and its cumulative distribution function is:

$$F(x, a, c) = [1 - \exp(-x^c)]^a$$

for  $x > 0, a > 0, c > 0$ .

`exponweib` takes  $a$  and  $c$  as shape parameters:

- $a$  is the exponentiation parameter, with the special case  $a = 1$  corresponding to the (non-exponentiated) Weibull distribution `weibull_min`.
- $c$  is the shape parameter of the non-exponentiated Weibull law.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponweib.pdf(x, a, c, loc, scale)` is identically equivalent to `exponweib.pdf(y, a, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

### Examples

```
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
... exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
... 'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

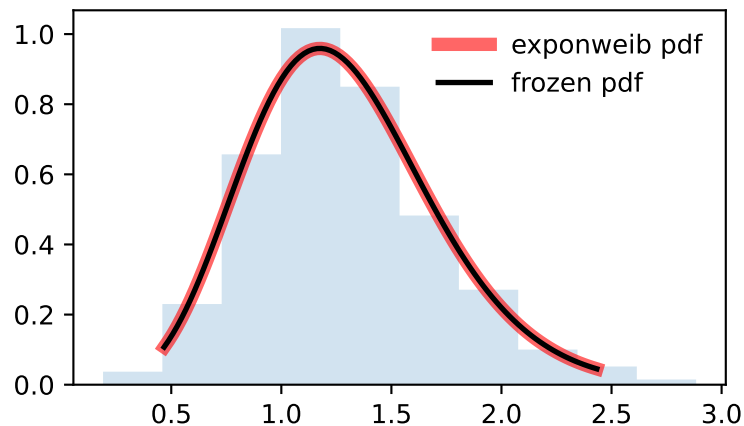

```
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, a, c, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.exponpow

`scipy.stats.exponpow = <scipy.stats._continuous_distns.exponpow_gen object>`

An exponential power continuous random variable.

As an instance of the *rv\_continuous* class, *exponpow* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *exponpow* is:

$$f(x, b) = bx^{b-1} \exp(1 + x^b - \exp(x^b))$$

for  $x \geq 0$ ,  $b > 0$ . Note that this is a different distribution from the exponential power distribution that is also known under the names “generalized normal” or “generalized Gaussian”.

*exponpow* takes *b* as a shape parameter for *b*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `exponpow.pdf(x, b, loc, scale)` is identically equivalent to `exponpow.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

<http://www.math.wm.edu/~leemis/chart/UDR/PDFs/Exponentialpower.pdf>

## Examples

```
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponpow.ppf(0.01, b),
... exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.f

`scipy.stats.f` = <`scipy.stats._continuous_distns.f_gen` object>

An F continuous random variable.

For the noncentral F distribution, see `ncf`.

As an instance of the `rv_continuous` class, `f` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`ncf`

### Notes

The probability density function for `f` is:

$$f(x, df_1, df_2) = \frac{df_2^{df_2/2} df_1^{df_1/2} x^{df_1/2-1}}{(df_2 + df_1 x)^{(df_1+df_2)/2} B(df_1/2, df_2/2)}$$

for  $x > 0$ .

`f` takes `dfn` and `dfd` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `f.pdf(x, dfn, dfd, loc, scale)` is identically equivalent to `f.pdf(y, dfn, dfd) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(f.ppf(0.01, dfn, dfd),
... f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd),
... 'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.fatiguelife

`scipy.stats.fatiguelife = <scipy.stats._continuous_distns.fatiguelife_gen object>`  
 A fatigue-life (Birnbbaum-Saunders) continuous random variable.

As an instance of the *rv\_continuous* class, *fatiguelife* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *fatiguelife* is:

$$f(x, c) = \frac{x + 1}{2c\sqrt{2\pi x^3}} \exp\left(-\frac{(x - 1)^2}{2xc^2}\right)$$

for  $x \geq 0$  and  $c > 0$ .

*fatiguelife* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `fatiguelife.pdf(x, c, loc, scale)` is identically equivalent to `fatiguelife.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that

shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 29
>>> mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fatiguelife.ppf(0.01, c),
... fatiguelife.ppf(0.99, c), 100)
>>> ax.plot(x, fatiguelife.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='fatiguelife pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fatiguelife(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fatiguelife.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.fisk

`scipy.stats.fisk = <scipy.stats._continuous_distns.fisk_gen object>`

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution.

As an instance of the `rv_continuous` class, `fisk` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[burr](#)

### Notes

The probability density function for `fisk` is:

$$f(x, c) = cx^{-c-1}(1 + x^{-c})^{-2}$$

for  $x \geq 0$  and  $c > 0$ .

`fisk` takes  $c$  as a shape parameter for  $c$ .

`fisk` is a special case of `burr` or `burr12` with  $d=1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fisk.pdf(x, c, loc, scale)` is identically equivalent to `fisk.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fisk.ppf(0.01, c),
... fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='fisk pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fisk(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fisk.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fisk.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fisk.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, c, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.foldcauchy

`scipy.stats.foldcauchy = <scipy.stats._continuous_distns.foldcauchy_gen object>`

A folded Cauchy continuous random variable.

As an instance of the *rv\_continuous* class, *foldcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *foldcauchy* is:

$$f(x, c) = \frac{1}{\pi(1 + (x - c)^2)} + \frac{1}{\pi(1 + (x + c)^2)}$$

for  $x \geq 0$ .

*foldcauchy* takes *c* as a shape parameter for *c*.

## Examples

```
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 4.72
>>> mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldcauchy.ppf(0.01, c),
... foldcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, foldcauchy.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

| <code>std(c, loc=0, scale=1)</code>                                                               | Standard deviation of the distribution.                                                                                                      |
| <code>interval(alpha, c, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.foldnorm

`scipy.stats.foldnorm` = <`scipy.stats._continuous_distns.foldnorm_gen` object>

A folded normal continuous random variable.

As an instance of the `rv_continuous` class, `foldnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `foldnorm` is:

$$f(x, c) = \sqrt{2/\pi} \cosh(cx) \exp\left(-\frac{x^2 + c^2}{2}\right)$$

for  $c \geq 0$ .

`foldnorm` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `foldnorm.pdf(x, c, loc, scale)` is identically equivalent to `foldnorm.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.95
>>> mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldnorm.ppf(0.01, c),
... foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>std(c, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                                                                      |
| <code>interval(alpha, c, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.genlogistic

`scipy.stats.genlogistic` = <`scipy.stats._continuous_distns.genlogistic_gen` object>

A generalized logistic continuous random variable.

As an instance of the `rv_continuous` class, `genlogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `genlogistic` is:

$$f(x, c) = c \frac{\exp(-x)}{(1 + \exp(-x))^{c+1}}$$

for  $x \geq 0, c > 0$ .

`genlogistic` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `genlogistic.pdf(x, c, loc, scale)` is identically equivalent to `genlogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genlogistic.ppf(0.01, c),
... genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='genlogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.gennorm**

`scipy.stats.gennorm` = <`scipy.stats._continuous_distns.gennorm_gen` object>

A generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `gennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**laplace**

Laplace distribution

**norm**

normal distribution

**Notes**

The probability density function for `gennorm` is [1]:

$$f(x, \beta) = \frac{\beta}{2\Gamma(1/\beta)} \exp(-|x|^\beta)$$

$\Gamma$  is the gamma function (`scipy.special.gamma`).

`gennorm` takes `beta` as a shape parameter for  $\beta$ . For  $\beta = 1$ , it is identical to a Laplace distribution. For  $\beta = 2$ , it is identical to a normal distribution (with `scale=1/sqrt(2)`).

**References**

[1]

**Examples**

```
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gennorm.ppf(0.01, beta),
... gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
... 'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = gennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.genpareto

`scipy.stats.genpareto = <scipy.stats._continuous_distns.genpareto_gen object>`

A generalized Pareto continuous random variable.

As an instance of the *rv\_continuous* class, *genpareto* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *genpareto* is:

$$f(x, c) = (1 + cx)^{-1-1/c}$$

defined for  $x \geq 0$  if  $c \geq 0$ , and for  $0 \leq x \leq -1/c$  if  $c < 0$ .

*genpareto* takes *c* as a shape parameter for *c*.

For  $c = 0$ , *genpareto* reduces to the exponential distribution, *expon*:

$$f(x, 0) = \exp(-x)$$

For  $c = -1$ , *genpareto* is uniform on  $[0, 1]$ :

$$f(x, -1) = 1$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genpareto.pdf(x, c, loc, scale)` is identically equivalent to `genpareto.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.1
>>> mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genpareto.ppf(0.01, c),
... genpareto.ppf(0.99, c), 100)
>>> ax.plot(x, genpareto.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='genpareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genpareto(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genpareto.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.genexpon

`scipy.stats.genexpon` = <`scipy.stats._continuous_distns.genexpon_gen` object>

A generalized exponential continuous random variable.

As an instance of the `rv_continuous` class, `genexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `genexpon` is:

$$f(x, a, b, c) = (a + b(1 - \exp(-cx))) \exp(-ax - bx + \frac{b}{c}(1 - \exp(-cx)))$$

for  $x \geq 0$ ,  $a, b, c > 0$ .

`genexpon` takes  $a$ ,  $b$  and  $c$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genexpon.pdf(x, a, b, c, loc, scale)` is identically equivalent to `genexpon.pdf(y, a, b, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b, c = 9.13, 16.2, 3.28
>>> mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genexpon.ppf(0.01, a, b, c),
... genexpon.ppf(0.99, a, b, c), 100)
>>> ax.plot(x, genexpon.pdf(x, a, b, c),
... 'r-', lw=5, alpha=0.6, label='genexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genexpon(a, b, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
>>> np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
True
```

Generate random numbers:

```
>>> r = genexpon.rvs(a, b, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.genextreme

`scipy.stats.genextreme = <scipy.stats._continuous_distns.genextreme_gen object>`

A generalized extreme value continuous random variable.

As an instance of the *rv\_continuous* class, *genextreme* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[gumbel\\_r](#)

## Notes

For  $c = 0$ , *genextreme* is equal to *gumbel\_r*. The probability density function for *genextreme* is:

$$f(x, c) = \begin{cases} \exp(-\exp(-x)) \exp(-x) & \text{for } c = 0 \\ \exp(-(1 - cx)^{1/c})(1 - cx)^{1/c-1} & \text{for } x \leq 1/c, c > 0 \end{cases}$$

Note that several sources and software packages use the opposite convention for the sign of the shape parameter *c*. *genextreme* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genextreme.ppf(0.01, c),
... genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='genextreme pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genextreme.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.gausshyper

`scipy.stats.gausshyper` = <`scipy.stats._continuous_distns.gausshyper_gen` object>  
 A Gauss hypergeometric continuous random variable.

As an instance of the `rv_continuous` class, `gausshyper` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `gausshyper` is:

$$f(x, a, b, c, z) = Cx^{a-1}(1-x)^{b-1}(1+zx)^{-c}$$

for  $0 \leq x \leq 1$ ,  $a > 0$ ,  $b > 0$ ,  $z > -1$ , and  $C = \frac{1}{B(a,b)F[2,1](c,a;a+b;-z)}$ .  $F[2,1]$  is the Gauss hypergeometric function `scipy.special.hyp2f1`.

`gausshyper` takes  $a$ ,  $b$ ,  $c$  and  $z$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gausshyper.pdf(x, a, b, c, z, loc, scale)` is identically equivalent to `gausshyper.pdf(y, a, b, c, z) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1]

### Examples

```
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
... gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
... 'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
True
```

Generate random numbers:

```
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.gamma

`scipy.stats.gamma = <scipy.stats._continuous_distns.gamma_gen object>`

A gamma continuous random variable.

As an instance of the *rv\_continuous* class, *gamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[erlang](#), [expon](#)

## Notes

The probability density function for *gamma* is:

$$f(x, a) = \frac{x^{a-1}e^{-x}}{\Gamma(a)}$$

for  $x \geq 0$ ,  $a > 0$ . Here  $\Gamma(a)$  refers to the gamma function.

*gamma* takes *a* as a shape parameter for *a*.

When *a* is an integer, *gamma* reduces to the Erlang distribution, and when  $a = 1$  to the exponential distribution.

Gamma distributions are sometimes parameterized with two variables, with a probability density function of:

$$f(x, \alpha, \beta) = \frac{\beta^\alpha x^{\alpha-1} e^{-\beta x}}{\Gamma(\alpha)}$$

Note that this parameterization is equivalent to the above, with  $\text{scale} = 1 / \text{beta}$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gamma.pdf(x, a, loc, scale)` is identically equivalent to `gamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gamma.ppf(0.01, a),
... gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = gamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.gengamma

`scipy.stats.gengamma = <scipy.stats._continuous_distns.gengamma_gen object>`

A generalized gamma continuous random variable.

As an instance of the `rv_continuous` class, `gengamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gamma`, `invgamma`, `weibull_min`

## Notes

The probability density function for `gengamma` is ([1]):

$$f(x, a, c) = \frac{|c|x^{ca-1} \exp(-x^c)}{\Gamma(a)}$$

for  $x \geq 0$ ,  $a > 0$ , and  $c \neq 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`gengamma` takes *a* and *c* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gengamma.pdf(x, a, c, loc, scale)` is identically equivalent to `gengamma.pdf(y, a, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gengamma.ppf(0.01, a, c),
... gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
... 'r-', lw=5, alpha=0.6, label='gengamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gengamma(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gengamma.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], gengamma.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = gengamma.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.genhalflogistic

`scipy.stats.genhalflogistic` = <`scipy.stats._continuous_distns.genhalflogistic_gen` object>

A generalized half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `genhalflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `genhalflogistic` is:

$$f(x, c) = \frac{2(1 - cx)^{1/(c-1)}}{[1 + (1 - cx)^{1/c}]^2}$$

for  $0 \leq x \leq 1/c$ , and  $c > 0$ .

`genhalflogistic` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
... genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genhalflogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.genhyperbolic

`scipy.stats.genhyperbolic` = <`scipy.stats._continuous_distns.genhyperbolic_gen` object>

A generalized hyperbolic continuous random variable.

As an instance of the `rv_continuous` class, `genhyperbolic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`t`, `norminvgauss`, `geninvgauss`, `laplace`, `cauchy`

## Notes

The probability density function for `genhyperbolic` is:

$$f(x, p, a, b) = \frac{(a^2 - b^2)^{p/2}}{\sqrt{2\pi} a^{p-0.5} K_p(\sqrt{a^2 - b^2})} e^{bx} \times \frac{K_{p-1/2}(a\sqrt{1+x^2})}{(\sqrt{1+x^2})^{1/2-p}}$$

for  $x, p \in (-\infty; \infty)$ ,  $|b| < a$  if  $p \geq 0$ ,  $|b| \leq a$  if  $p < 0$ .  $K_p(\cdot)$  denotes the modified Bessel function of the second kind and order  $p$  (`scipy.special.kn`)

`genhyperbolic` takes *p* as a tail parameter, *a* as a shape parameter, *b* as a skewness parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhyperbolic.pdf(x, p, a, b, loc, scale)` is identically equivalent to `genhyperbolic.pdf(y, p, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The original parameterization of the Generalized Hyperbolic Distribution is found in [1] as follows

$$f(x, \lambda, \alpha, \beta, \delta, \mu) = \frac{(\gamma/\delta)^\lambda}{\sqrt{2\pi}K_\lambda(\delta\gamma)} e^{\beta(x-\mu)} \times \frac{K_{\lambda-1/2}(\alpha\sqrt{\delta^2 + (x-\mu)^2})}{(\sqrt{\delta^2 + (x-\mu)^2}/\alpha)^{1/2-\lambda}}$$

for  $x \in (-\infty; \infty)$ ,  $\gamma := \sqrt{\alpha^2 - \beta^2}$ ,  $\lambda, \mu \in (-\infty; \infty)$ ,  $\delta \geq 0$ ,  $|\beta| < \alpha$  if  $\lambda \geq 0$ ,  $\delta > 0$ ,  $|\beta| \leq \alpha$  if  $\lambda < 0$ .

The location-scale-based parameterization implemented in SciPy is based on [2], where  $a = \alpha\delta$ ,  $b = \beta\delta$ ,  $p = \lambda$ ,  $scale = \delta$  and  $loc = \mu$

Moments are implemented based on [3] and [4].

For the distributions that are a special case such as Student’s t, it is not recommended to rely on the implementation of `genhyperbolic`. To avoid potential numerical problems and for performance reasons, the methods of the specific distributions should be used.

## References

## Examples

```
>>> from scipy.stats import genhyperbolic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p, a, b = 0.5, 1.5, -0.5
>>> mean, var, skew, kurt = genhyperbolic.stats(p, a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genhyperbolic.ppf(0.01, p, a, b),
... genhyperbolic.ppf(0.99, p, a, b), 100)
>>> ax.plot(x, genhyperbolic.pdf(x, p, a, b),
... 'r-', lw=5, alpha=0.6, label='genhyperbolic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genhyperbolic(p, a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genhyperbolic.ppf([0.001, 0.5, 0.999], p, a, b)
>>> np.allclose([0.001, 0.5, 0.999], genhyperbolic.cdf(vals, p, a, b))
True
```

Generate random numbers:

```
>>> r = genhyperbolic.rvs(p, a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.geninvgauss

`scipy.stats.geninvgauss = <scipy.stats._continuous_distns.geninvgauss_gen object>`

A Generalized Inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `geninvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `geninvgauss` is:

$$f(x, p, b) = x^{p-1} \exp(-b(x + 1/x)/2) / (2K_p(b))$$

where  $x > 0$ , and the parameters  $p, b$  satisfy  $b > 0$  ([1]).  $K_p$  is the modified Bessel function of second kind of order  $p$  (`scipy.special.kv`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `geninvgauss.pdf(x, p, b, loc, scale)` is identically equivalent to `geninvgauss.pdf(y, p, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The inverse Gaussian distribution `stats.invgauss(mu)` is a special case of `geninvgauss` with  $p = -1/2$ ,  $b = 1 / \mu$  and `scale = mu`.

Generating random variates is challenging for this distribution. The implementation is based on [2].

## References

[1], [2]

## Examples

```
>>> from scipy.stats import geninvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p, b = 2.3, 1.5
>>> mean, var, skew, kurt = geninvgauss.stats(p, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(geninvgauss.ppf(0.01, p, b),
... geninvgauss.ppf(0.99, p, b), 100)
>>> ax.plot(x, geninvgauss.pdf(x, p, b),
... 'r-', lw=5, alpha=0.6, label='geninvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = geninvgauss(p, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = geninvgauss.ppf([0.001, 0.5, 0.999], p, b)
>>> np.allclose([0.001, 0.5, 0.999], geninvgauss.cdf(vals, p, b))
True
```

Generate random numbers:

```
>>> r = geninvgauss.rvs(p, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, p, b, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

**scipy.stats.gilbrat**

`scipy.stats.gilbrat` = <`scipy.stats._continuous_distns.gilbrat_gen` object>

A Gilbrat continuous random variable.

As an instance of the `rv_continuous` class, `gilbrat` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `gilbrat` is:

$$f(x) = \frac{1}{x\sqrt{2\pi}} \exp\left(-\frac{1}{2}(\log(x))^2\right)$$

`gilbrat` is a special case of `lognorm` with `s=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gilbrat.ppf(0.01),
... gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
... 'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.gompertz

`scipy.stats.gompertz = <scipy.stats._continuous_distns.gompertz_gen object>`

A Gompertz (or truncated Gumbel) continuous random variable.

As an instance of the *rv\_continuous* class, *gompertz* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *gompertz* is:

$$f(x, c) = c \exp(x) \exp(-c(e^x - 1))$$

for  $x \geq 0, c > 0$ .

*gompertz* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `gompertz.pdf(x, c, loc, scale)` is identically equivalent to `gompertz.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gompertz.ppf(0.01, c),
... gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.gumbel\_r

`scipy.stats.gumbel_r` = <`scipy.stats._continuous_distns.gumbel_r_gen` object>

A right-skewed Gumbel continuous random variable.

As an instance of the `rv_continuous` class, `gumbel_r` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[gumbel\\_l](#), [gompertz](#), [genextreme](#)

### Notes

The probability density function for `gumbel_r` is:

$$f(x) = \exp(-(x + e^{-x}))$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_r.pdf(x, loc, scale)` is identically equivalent to `gumbel_r.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_r.ppf(0.01),
... gumbel_r.ppf(0.99), 100)
>>> ax.plot(x, gumbel_r.pdf(x),
... 'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.gumbel\_l

`scipy.stats.gumbel_l = <scipy.stats._continuous_distns.gumbel_l_gen object>`

A left-skewed Gumbel continuous random variable.

As an instance of the *rv\_continuous* class, *gumbel\_l* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[gumbel\\_r](#), [gompertz](#), [genextreme](#)

## Notes

The probability density function for *gumbel\_l* is:

$$f(x) = \exp(x - e^x)$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `gumbel_l.pdf(x, loc, scale)` is identically equivalent to

$\text{gumbel\_1.pdf}(y) / \text{scale}$  with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import gumbel_1
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gumbel_1.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_1.ppf(0.01),
... gumbel_1.ppf(0.99), 100)
>>> ax.plot(x, gumbel_1.pdf(x),
... 'r-', lw=5, alpha=0.6, label='gumbel_1 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_1()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gumbel_1.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_1.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_1.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.halfcauchy**

`scipy.stats.halfcauchy` = <`scipy.stats._continuous_distns.halfcauchy_gen` object>  
 A Half-Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `halfcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `halfcauchy` is:

$$f(x) = \frac{2}{\pi(1+x^2)}$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import halfcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halfcauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfcauchy.ppf(0.01),
... halfcauchy.ppf(0.99), 100)
>>> ax.plot(x, halfcauchy.pdf(x),
... 'r-', lw=5, alpha=0.6, label='halfcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfcauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfcauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfcauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfcauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.halflogistic

`scipy.stats.halflogistic = <scipy.stats._continuous_distns.halflogistic_gen object>`

A half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `halflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `halflogistic` is:

$$f(x) = \frac{2e^{-x}}{(1+e^{-x})^2} = \frac{1}{2} \operatorname{sech}(x/2)^2$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halflogistic.pdf(x, loc, scale)` is identically equivalent to `halflogistic.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import halflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halflogistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halflogistic.ppf(0.01),
... halflogistic.ppf(0.99), 100)
>>> ax.plot(x, halflogistic.pdf(x),
... 'r-', lw=5, alpha=0.6, label='halflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halflogistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halflogistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halflogistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halflogistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.halfnorm

`scipy.stats.halfnorm` = <`scipy.stats._continuous_distns.halfnorm_gen` object>  
 A half-normal continuous random variable.

As an instance of the `rv_continuous` class, `halfnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `halfnorm` is:

$$f(x) = \sqrt{2/\pi} \exp(-x^2/2)$$

for  $x \geq 0$ .

`halfnorm` is a special case of `chi` with `df=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfnorm.pdf(x, loc, scale)` is identically equivalent to `halfnorm.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfnorm.ppf(0.01),
... halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x),
... 'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfnorm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

| <code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code> | Expected value of a function (of one argument) with respect to the distribution.                                                             |
| <code>median(loc=0, scale=1)</code>                                                            | Median of the distribution.                                                                                                                  |
| <code>mean(loc=0, scale=1)</code>                                                              | Mean of the distribution.                                                                                                                    |
| <code>var(loc=0, scale=1)</code>                                                               | Variance of the distribution.                                                                                                                |
| <code>std(loc=0, scale=1)</code>                                                               | Standard deviation of the distribution.                                                                                                      |
| <code>interval(alpha, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

### scipy.stats.halfgennorm

`scipy.stats.halfgennorm = <scipy.stats._continuous_distns.halfgennorm_gen object>`

The upper half of a generalized normal continuous random variable.

As an instance of the *rv\_continuous* class, *halfgennorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

#### *gennorm*

generalized normal distribution

#### *expon*

exponential distribution

#### *halfnorm*

half normal distribution

## Notes

The probability density function for *halfgennorm* is:

$$f(x, \beta) = \frac{\beta}{\Gamma(1/\beta)} \exp(-|x|^\beta)$$

for  $x > 0$ .  $\Gamma$  is the gamma function (*scipy.special.gamma*).

*gennorm* takes *beta* as a shape parameter for  $\beta$ . For  $\beta = 1$ , it is identical to an exponential distribution. For  $\beta = 2$ , it is identical to a half normal distribution (with *scale*=1/sqrt(2)).

## References

[1]

## Examples

```
>>> from scipy.stats import halfgennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta = 0.675
>>> mean, var, skew, kurt = halfgennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
... halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
... 'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfgennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = halfgennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.hypsecant**

`scipy.stats.hypsecant` = <`scipy.stats._continuous_distns.hypsecant_gen` object>

A hyperbolic secant continuous random variable.

As an instance of the `rv_continuous` class, `hypsecant` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `hypsecant` is:

$$f(x) = \frac{1}{\pi} \operatorname{sech}(x)$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = hypsecant.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(hypsecant.ppf(0.01),
... hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
... 'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
True
```

Generate random numbers:

```
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.invgamma

`scipy.stats.invgamma = <scipy.stats._continuous_distns.invgamma_gen object>`

An inverted gamma continuous random variable.

As an instance of the *rv\_continuous* class, *invgamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *invgamma* is:

$$f(x, a) = \frac{x^{-a-1}}{\Gamma(a)} \exp\left(-\frac{1}{x}\right)$$

for  $x \geq 0$ ,  $a > 0$ .  $\Gamma$  is the gamma function ([scipy.special.gamma](#)).

*invgamma* takes *a* as a shape parameter for *a*.

*invgamma* is a special case of *gengamma* with  $c=-1$ , and it is a different parameterization of the scaled inverse chi-squared distribution. Specifically, if the scaled inverse chi-squared distribution is parameterized with degrees of freedom  $\nu$  and scaling parameter  $\tau^2$ , then it can be modeled using *invgamma* with  $a = \nu/2$  and  $\text{scale} = \nu\tau^2/2$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgamma.pdf(x, a, loc, scale)` is identically equivalent to `invgamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgamma.ppf(0.01, a),
... invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.invgauss

`scipy.stats.invgauss` = <`scipy.stats._continuous_distns.invgauss_gen` object>

An inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `invgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `invgauss` is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x - \mu)^2}{2x\mu^2}\right)$$

for  $x \geq 0$  and  $\mu > 0$ .

`invgauss` takes `mu` as a shape parameter for  $\mu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgauss.pdf(x, mu, loc, scale)` is identically equivalent to `invgauss.pdf(y, mu) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgauss.ppf(0.01, mu),
... invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
... 'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.invweibull

`scipy.stats.invweibull = <scipy.stats._continuous_distns.invweibull_gen object>`  
 An inverted Weibull continuous random variable.

This distribution is also known as the Fréchet distribution or the type II extreme value distribution.

As an instance of the `rv_continuous` class, `invweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `invweibull` is:

$$f(x, c) = cx^{-c-1} \exp(-x^{-c})$$

for  $x > 0, c > 0$ .

`invweibull` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c, loc, scale)` is identically equivalent to `invweibull.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

F.R.S. de Gusmao, E.M.M Ortega and G.M. Cordeiro, “The generalized inverse Weibull distribution”, Stat. Papers, vol. 52, pp. 591-619, 2011.

## Examples

```
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invweibull.ppf(0.01, c),
... invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.johnsonsb

`scipy.stats.johnsonsb` = <`scipy.stats._continuous_distns.johnsonsb_gen` object>  
 A Johnson SB continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsb` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[johnsonsu](#)

### Notes

The probability density function for `johnsonsb` is:

$$f(x, a, b) = \frac{b}{x(1-x)} \phi\left(a + b \log \frac{x}{1-x}\right)$$

where  $x$ ,  $a$ , and  $b$  are real scalars;  $b > 0$  and  $x \in [0, 1]$ .  $\phi$  is the pdf of the normal distribution.

`johnsonsb` takes  $a$  and  $b$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsb.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsb.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 4.32, 3.18
>>> mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b),
... johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

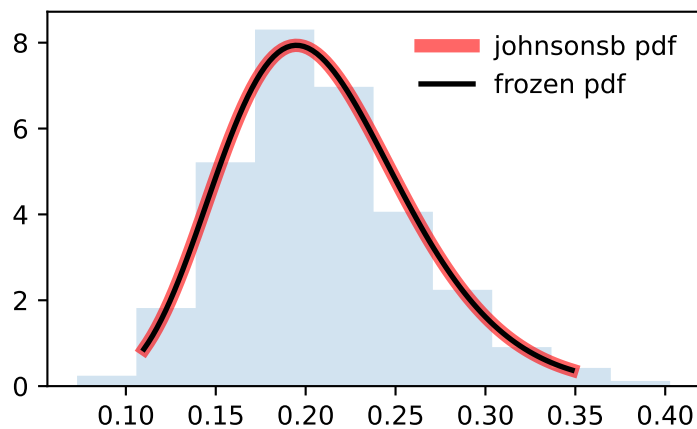

```
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsb.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.johnsonsu

`scipy.stats.johnsonsu = <scipy.stats._continuous_distns.johnsonsu_gen object>`

A Johnson SU continuous random variable.

As an instance of the *rv\_continuous* class, *johnsonsu* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[johnsonsb](#)

## Notes

The probability density function for *johnsonsu* is:

$$f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))$$

where *x*, *a*, and *b* are real scalars; *b* > 0.  $\phi$  is the pdf of the normal distribution.

*johnsonsu* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsu.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsu.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b),
... johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

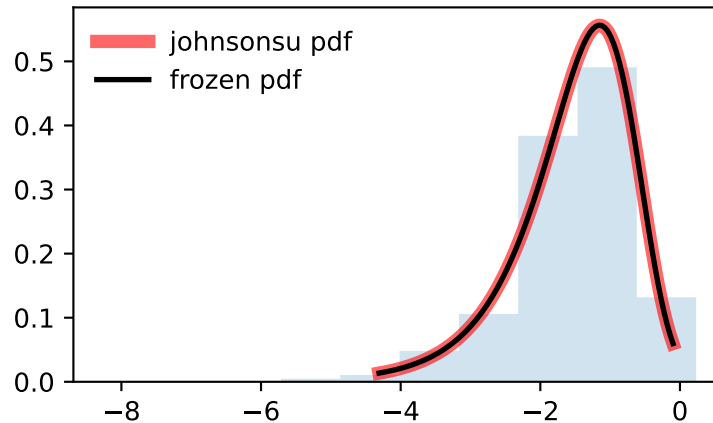

```
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.kappa4

`scipy.stats.kappa4` = <`scipy.stats._continuous_distns.kappa4_gen` object>

Kappa 4 parameter distribution.

As an instance of the `rv_continuous` class, `kappa4` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for kappa4 is:

$$f(x, h, k) = (1 - kx)^{1/k-1} (1 - h(1 - kx)^{1/k})^{1/h-1}$$

if  $h$  and  $k$  are not equal to 0.

If  $h$  or  $k$  are zero then the pdf can be simplified:

$h = 0$  and  $k \neq 0$ :

$$\text{kappa4.pdf}(x, h, k) = (1.0 - k*x)^{(1.0/k - 1.0)} * \exp(-(1.0 - k*x)^{(1.0/k)})$$

$h \neq 0$  and  $k = 0$ :

$$\text{kappa4.pdf}(x, h, k) = \exp(-x) * (1.0 - h*\exp(-x))^{(1.0/h - 1.0)}$$

$h = 0$  and  $k = 0$ :

$$\text{kappa4.pdf}(x, h, k) = \exp(-x) * \exp(-\exp(-x))$$

`kappa4` takes  $h$  and  $k$  as shape parameters.

The `kappa4` distribution returns other distributions when certain  $h$  and  $k$  values are used.

| h    | k=0.0                   | k=1.0                  | -inf<=k<=inf                                  |
|------|-------------------------|------------------------|-----------------------------------------------|
| -1.0 | Logistic<br>logistic(x) |                        | Generalized Logistic(1)                       |
| 0.0  | Gumbel<br>gumbel_r(x)   | Reverse Exponential(2) | Generalized Extreme Value<br>genextreme(x, k) |
| 1.0  | Exponential<br>expon(x) | Uniform<br>uniform(x)  | Generalized Pareto<br>genpareto(x, -k)        |

- (1) There are at least five generalized logistic distributions. Four are described here: [https://en.wikipedia.org/wiki/Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Generalized_logistic_distribution) The “fifth” one is the one `kappa4` should match which currently isn’t implemented in `scipy`: [https://en.wikipedia.org/wiki/Talk:Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Talk:Generalized_logistic_distribution) [https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen\\_logistic.html](https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen_logistic.html)
- (2) This distribution is currently not in `scipy`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa4.pdf(x, h, k, loc, scale)` is identically equivalent to `kappa4.pdf(y, h, k) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
... kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
... 'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
True
```

Generate random numbers:

```
>>> r = kappa4.rvs(h, k, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, h, k, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                                                               |

## scipy.stats.kappa3

`scipy.stats.kappa3 = <scipy.stats._continuous_distns.kappa3_gen object>`

Kappa 3 parameter distribution.

As an instance of the *rv\_continuous* class, *kappa3* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *kappa3* is:

$$f(x, a) = a(a + x^a)^{-(a+1)/a}$$

for  $x > 0$  and  $a > 0$ .

*kappa3* takes *a* as a shape parameter for *a*.

P.W. Mielke and E.S. Johnson, “Three-Parameter Kappa Distribution Maximum Likelihood and Likelihood Ratio Tests”, *Methods in Weather Research*, 701-707, (September, 1973), DOI:10.1175/1520-0493(1973)101<0701:TKDMLE>2.3.CO;2

B. Kumphon, “Maximum Entropy and Maximum Likelihood Estimation for the Three-Parameter Kappa Distribution”, *Open Journal of Statistics*, vol 2, 415-419 (2012), DOI:10.4236/ojs.2012.24050

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa3.pdf(x, a, loc, scale)` is identically equivalent to `kappa3.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import kappa3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1
>>> mean, var, skew, kurt = kappa3.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa3.ppf(0.01, a),
... kappa3.ppf(0.99, a), 100)
>>> ax.plot(x, kappa3.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='kappa3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa3(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kappa3.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], kappa3.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = kappa3.rvs(a, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## scipy.stats.ksone

`scipy.stats.ksone` = <`scipy.stats._continuous_distns.ksone_gen` object>

Kolmogorov-Smirnov one-sided test statistic distribution.

This is the distribution of the one-sided Kolmogorov-Smirnov (KS) statistics  $D_n^+$  and  $D_n^-$  for a finite sample size  $n$  (the shape parameter).

As an instance of the `rv_continuous` class, `ksone` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`kstwobign`, `kstwo`, `kstest`

### Notes

$D_n^+$  and  $D_n^-$  are given by

$$D_n^+ = \sup_x (F_n(x) - F(x)),$$
$$D_n^- = \sup_x (F(x) - F_n(x)),$$

where  $F$  is a continuous CDF and  $F_n$  is an empirical CDF. `ksone` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to  $n$  i.i.d. random variates with CDF  $F$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ksone.pdf(x, n, loc, scale)` is identically equivalent to `ksone.pdf(y, n) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1]

### Examples

```
>>> from scipy.stats import ksone
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n = 1e+03
>>> mean, var, skew, kurt = ksone.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ksone.ppf(0.01, n),
... ksone.ppf(0.99, n), 100)
>>> ax.plot(x, ksone.pdf(x, n),
... 'r-', lw=5, alpha=0.6, label='ksone pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ksone(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ksone.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], ksone.cdf(vals, n))
True
```

Generate random numbers:

```
>>> r = ksone.rvs(n, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.kstwo**

`scipy.stats.kstwo = <scipy.stats._continuous_distns.kstwo_gen object>`

Kolmogorov-Smirnov two-sided test statistic distribution.

This is the distribution of the two-sided Kolmogorov-Smirnov (KS) statistic  $D_n$  for a finite sample size n (the shape parameter).

As an instance of the *rv\_continuous* class, *kstwo* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

$D_n$  is given by

$$D_n = \sup_x |F_n(x) - F(x)|$$

where  $F$  is a (continuous) CDF and  $F_n$  is an empirical CDF. `kstwo` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to  $n$  i.i.d. random variates with CDF  $F$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kstwo.pdf(x, n, loc, scale)` is identically equivalent to `kstwo.pdf(y, n) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import kstwo
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n = 10
>>> mean, var, skew, kurt = kstwo.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwo.ppf(0.01, n),
... kstwo.ppf(0.99, n), 100)
>>> ax.plot(x, kstwo.pdf(x, n),
... 'r-', lw=5, alpha=0.6, label='kstwo pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwo(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kstwo.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], kstwo.cdf(vals, n))
True
```

Generate random numbers:

```
>>> r = kstwo.rvs(n, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.kstwobign

`scipy.stats.kstwobign = <scipy.stats._continuous_distns.kstwobign_gen object>`

Limiting distribution of scaled Kolmogorov-Smirnov two-sided test statistic.

This is the asymptotic distribution of the two-sided Kolmogorov-Smirnov statistic  $\sqrt{n}D_n$  that measures the maximum absolute distance of the theoretical (continuous) CDF from the empirical CDF. (see *kstest*).

As an instance of the *rv\_continuous* class, *kstwobign* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[ksone](#), [kstwo](#), [kstest](#)

## Notes

$\sqrt{n}D_n$  is given by

$$D_n = \sup_x |F_n(x) - F(x)|$$

where  $F$  is a continuous CDF and  $F_n$  is an empirical CDF. *kstwobign* describes the asymptotic distribution (i.e. the limit of  $\sqrt{n}D_n$ ) under the null hypothesis of the KS test that the empirical CDF corresponds to i.i.d. random variates with CDF  $F$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kstwobign.pdf(x, loc, scale)` is identically equivalent to `kstwobign.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import kstwobign
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = kstwobign.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwobign.ppf(0.01),
... kstwobign.ppf(0.99), 100)
>>> ax.plot(x, kstwobign.pdf(x),
... 'r-', lw=5, alpha=0.6, label='kstwobign pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwobign()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kstwobign.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], kstwobign.cdf(vals))
True
```

Generate random numbers:

```
>>> r = kstwobign.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>var(loc=0, scale=1)</code>                                                               | Variance of the distribution.                                                                                                                |
| <code>std(loc=0, scale=1)</code>                                                               | Standard deviation of the distribution.                                                                                                      |
| <code>interval(alpha, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.laplace

`scipy.stats.laplace = <scipy.stats._continuous_distns.laplace_gen object>`

A Laplace continuous random variable.

As an instance of the *rv\_continuous* class, *laplace* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *laplace* is

$$f(x) = \frac{1}{2} \exp(-|x|)$$

for a real number *x*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `laplace.pdf(x, loc, scale)` is identically equivalent to `laplace.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace.ppf(0.01),
... laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x),
... 'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
True
```

Generate random numbers:

```
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.laplace\_asymmetric

`scipy.stats.laplace_asymmetric` = `<scipy.stats._continuous_distns.laplace_asymmetric_gen ob`

An asymmetric Laplace continuous random variable.

As an instance of the `rv_continuous` class, `laplace_asymmetric` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

### laplace

Laplace distribution

### Notes

The probability density function for `laplace_asymmetric` is

$$f(x, \kappa) = \frac{1}{\kappa + \kappa^{-1}} \exp(-x\kappa), \quad x \geq 0$$
$$= \frac{1}{\kappa + \kappa^{-1}} \exp(x/\kappa), \quad x < 0$$

for  $-\infty < x < \infty$ ,  $\kappa > 0$ .

`laplace_asymmetric` takes `kappa` as a shape parameter for  $\kappa$ . For  $\kappa = 1$ , it is identical to a Laplace distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `laplace_asymmetric.pdf(x, kappa, loc, scale)` is identically equivalent to `laplace_asymmetric.pdf(y, kappa) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1], [2]

### Examples

```
>>> from scipy.stats import laplace_asymmetric
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> kappa = 2
>>> mean, var, skew, kurt = laplace_asymmetric.stats(kappa, moments='mvsk
→')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace_asymmetric.ppf(0.01, kappa),
... laplace_asymmetric.ppf(0.99, kappa), 100)
>>> ax.plot(x, laplace_asymmetric.pdf(x, kappa),
... 'r-', lw=5, alpha=0.6, label='laplace_asymmetric pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace_asymmetric(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = laplace_asymmetric.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], laplace_asymmetric.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = laplace_asymmetric.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, kappa, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.levy

`scipy.stats.levy = <scipy.stats._continuous_distns.levy_gen object>`

A Levy continuous random variable.

As an instance of the *rv\_continuous* class, *levy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[levy\\_stable](#), [levy\\_1](#)

## Notes

The probability density function for *levy* is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{1}{2x}\right)$$

for  $x \geq 0$ .

This is the same as the Levy-stable distribution with  $a = 1/2$  and  $b = 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy.pdf(x, loc, scale)` is identically equivalent to `levy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy.ppf(0.01),
... levy.ppf(0.99), 100)
>>> ax.plot(x, levy.pdf(x),
... 'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.levy\_l

`scipy.stats.levy_l` = <`scipy.stats._continuous_distns.levy_l_gen` object>

A left-skewed Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[levy](#), [levy\\_stable](#)

### Notes

The probability density function for `levy_l` is:

$$f(x) = \frac{1}{|x|\sqrt{2\pi|x|}} \exp\left(-\frac{1}{2|x|}\right)$$

for  $x \leq 0$ .

This is the same as the Levy-stable distribution with  $a = 1/2$  and  $b = -1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_l.pdf(x, loc, scale)` is identically equivalent to `levy_l.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import levy_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = levy_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_l.ppf(0.01),
... levy_l.ppf(0.99), 100)
>>> ax.plot(x, levy_l.pdf(x),
... 'r-', lw=5, alpha=0.6, label='levy_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

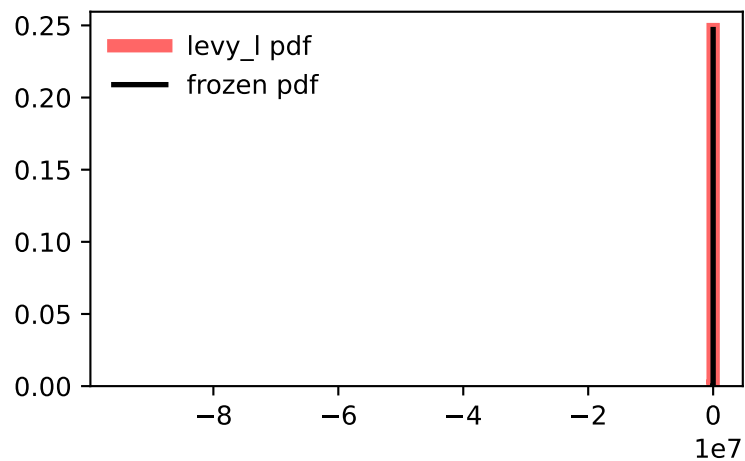

```
>>> vals = levy_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.levy\_stable

`scipy.stats.levy_stable = <scipy.stats._continuous_distns.levy_stable_gen object>`

A Levy-stable continuous random variable.

As an instance of the `rv_continuous` class, `levy_stable` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[levy](#), [levy\\_1](#)

## Notes

The distribution for `levy_stable` has characteristic function:

$$\varphi(t, \alpha, \beta, c, \mu) = e^{it\mu - |ct|^\alpha (1 - i\beta \operatorname{sign}(t)\Phi(\alpha, t))}$$

where:

$$\Phi = \begin{cases} \tan\left(\frac{\pi\alpha}{2}\right) & \alpha \neq 1 \\ -\frac{2}{\pi} \log|t| & \alpha = 1 \end{cases}$$

The probability density function for `levy_stable` is:

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \varphi(t) e^{-ixt} dt$$

where  $-\infty < t < \infty$ . This integral does not have a known closed form.

For evaluation of pdf we use either Zolotarev  $S_0$  parameterization with integration, direct integration of standard parameterization of characteristic function or FFT of characteristic function. If set to other than None and if number of points is greater than `levy_stable.pdf_fft_min_points_threshold` (defaults to None) we use FFT otherwise we use one of the other methods.

The default method is 'best' which uses Zolotarev's method if  $\alpha = 1$  and integration of characteristic function otherwise. The default method can be changed by setting `levy_stable.pdf_default_method` to either 'zolotarev', 'quadrature' or 'best'.

To increase accuracy of FFT calculation one can specify `levy_stable.pdf_fft_grid_spacing` (defaults to 0.001) and `pdf_fft_n_points_two_power` (defaults to a value that covers the input range \* 4). Setting `pdf_fft_n_points_two_power` to 16 should be sufficiently accurate in most cases at the expense of CPU time.

For evaluation of cdf we use Zolotarev  $S_0$  parameterization with integration or integral of the pdf FFT interpolated spline. The settings affecting FFT calculation are the same as for pdf calculation. Setting the threshold to None (default) will disable FFT. For cdf calculations the Zolotarev method is superior in accuracy, so FFT is disabled by default.

Fitting estimate uses quantile estimation method in [MC]. MLE estimation of parameters in fit method uses this quantile estimate initially. Note that MLE doesn't always converge if using FFT for pdf calculations; so it's best that `pdf_fft_min_points_threshold` is left unset.

**Warning:** For pdf calculations implementation of Zolotarev is unstable for values where  $\alpha = 1$  and  $\beta \neq 0$ . In this case the quadrature method is recommended. FFT calculation is also considered experimental.

For cdf calculations FFT calculation is considered experimental. Use Zolotarev's method instead (default).

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_stable.pdf(x, alpha, beta, loc, scale)` is identically equivalent to `levy_stable.pdf(y, alpha, beta) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import levy_stable
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> alpha, beta = 1.8, -0.5
>>> mean, var, skew, kurt = levy_stable.stats(alpha, beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_stable.ppf(0.01, alpha, beta),
... levy_stable.ppf(0.99, alpha, beta), 100)
>>> ax.plot(x, levy_stable.pdf(x, alpha, beta),
... 'r-', lw=5, alpha=0.6, label='levy_stable pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_stable(alpha, beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy_stable.ppf([0.001, 0.5, 0.999], alpha, beta)
>>> np.allclose([0.001, 0.5, 0.999], levy_stable.cdf(vals, alpha, beta))
True
```

Generate random numbers:

```
>>> r = levy_stable.rvs(alpha, beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>std(alpha, beta, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                                                                   |
| <code>interval(alpha, alpha, beta, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                     |

## scipy.stats.logistic

`scipy.stats.logistic = <scipy.stats._continuous_distns.logistic_gen object>`

A logistic (or Sech-squared) continuous random variable.

As an instance of the `rv_continuous` class, `logistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `logistic` is:

$$f(x) = \frac{\exp(-x)}{(1 + \exp(-x))^2}$$

`logistic` is a special case of `genlogistic` with  $c=1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `logistic.pdf(x, loc, scale)` is identically equivalent to `logistic.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(logistic.ppf(0.01),
... logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x),
... 'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = logistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.loggamma

`scipy.stats.loggamma` = <`scipy.stats._continuous_distns.loggamma_gen` object>

A log gamma continuous random variable.

As an instance of the `rv_continuous` class, `loggamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `loggamma` is:

$$f(x, c) = \frac{\exp(cx - \exp(x))}{\Gamma(c)}$$

for all  $x, c > 0$ . Here,  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`loggamma` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loggamma.pdf(x, c, loc, scale)` is identically equivalent to `loggamma.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loggamma.ppf(0.01, c),
... loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.loglaplace

`scipy.stats.loglaplace = <scipy.stats._continuous_distns.loglaplace_gen object>`

A log-Laplace continuous random variable.

As an instance of the `rv_continuous` class, `loglaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `loglaplace` is:

$$f(x, c) = \begin{cases} \frac{c}{2}x^{c-1} & \text{for } 0 < x < 1 \\ \frac{c}{2}x^{-c-1} & \text{for } x \geq 1 \end{cases}$$

for  $c > 0$ .

`loglaplace` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loglaplace.pdf(x, c, loc, scale)` is identically equivalent to `loglaplace.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

T.J. Kozubowski and K. Podgorski, “A log-Laplace growth rate model”, The Mathematical Scientist, vol. 28, pp. 49-60, 2003.

## Examples

```
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loglaplace.ppf(0.01, c),
... loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.lognorm

`scipy.stats.lognorm` = <`scipy.stats._continuous_distns.lognorm_gen` object>

A lognormal continuous random variable.

As an instance of the `rv_continuous` class, `lognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `lognorm` is:

$$f(x, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{\log^2(x)}{2s^2}\right)$$

for  $x > 0, s > 0$ .

`lognorm` takes  $s$  as a shape parameter for  $s$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lognorm.pdf(x, s, loc, scale)` is identically equivalent to `lognorm.pdf(y, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A common parametrization for a lognormal random variable  $Y$  is in terms of the mean,  $\mu$ , and standard deviation,  $\sigma$ , of the unique normally distributed random variable  $X$  such that  $\exp(X) = Y$ . This parametrization corresponds to setting  $s = \sigma$  and  $\text{scale} = \exp(\mu)$ .

### Examples

```
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lognorm.ppf(0.01, s),
... lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s),
... 'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```
>>> r = lognorm.rvs(s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.loguniform

`scipy.stats.loguniform = <scipy.stats._continuous_distns.reciprocal_gen object>`

A loguniform or reciprocal continuous random variable.

As an instance of the *rv\_continuous* class, *loguniform* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for this class is:

$$f(x, a, b) = \frac{1}{x \log(b/a)}$$

for  $a \leq x \leq b$ ,  $b > a > 0$ . This class takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `loguniform.pdf(x, a, b, loc, scale)` is identically equivalent to `loguniform.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import loguniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 0.01, 1.25
>>> mean, var, skew, kurt = loguniform.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loguniform.ppf(0.01, a, b),
... loguniform.ppf(0.99, a, b), 100)
>>> ax.plot(x, loguniform.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='loguniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loguniform(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loguniform.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], loguniform.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = loguniform.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

This doesn't show the equal probability of 0.01, 0.1 and 1. This is best when the x-axis is log-scaled:

```
>>> import numpy as np
>>> fig, ax = plt.subplots(1, 1)
>>> ax.hist(np.log10(r))
>>> ax.set_ylabel("Frequency")
>>> ax.set_xlabel("Value of random variable")
>>> ax.xaxis.set_major_locator(plt.FixedLocator([-2, -1, 0]))
>>> ticks = ["$10^{{{i}}}$".format(i) for i in [-2, -1, 0]]
>>> ax.set_xticklabels(ticks)
>>> plt.show()
```

This random variable will be log-uniform regardless of the base chosen for a and b. Let's specify with base 2 instead:

```
>>> rvs = loguniform(2**-2, 2**0).rvs(size=1000)
```

Values of  $1/4$ ,  $1/2$  and  $1$  are equally likely with this random variable. Here's the histogram:

```
>>> fig, ax = plt.subplots(1, 1)
>>> ax.hist(np.log2(rvs))
>>> ax.set_ylabel("Frequency")
>>> ax.set_xlabel("Value of random variable")
>>> ax.xaxis.set_major_locator(plt.FixedLocator([-2, -1, 0]))
>>> ticks = ["$2^{\{ \}}$".format(i) for i in [-2, -1, 0]]
>>> ax.set_xticklabels(ticks)
>>> plt.show()
```

## Methods

## scipy.stats.lomax

`scipy.stats.lomax = <scipy.stats._continuous_distns.lomax_gen object>`

A Lomax (Pareto of the second kind) continuous random variable.

As an instance of the *rv\_continuous* class, *lomax* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *lomax* is:

$$f(x, c) = \frac{c}{(1+x)^{c+1}}$$

for  $x \geq 0, c > 0$ .

*lomax* takes *c* as a shape parameter for *c*.

*lomax* is a special case of *pareto* with `loc=-1.0`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lomax.pdf(x, c, loc, scale)` is identically equivalent to `lomax.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of

a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lomax.ppf(0.01, c),
... lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='lomax pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = lomax.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.maxwell

`scipy.stats.maxwell` = <`scipy.stats._continuous_distns.maxwell_gen` object>

A Maxwell continuous random variable.

As an instance of the `rv_continuous` class, `maxwell` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

A special case of a `chi` distribution, with `df=3`, `loc=0.0`, and given `scale = a`, where `a` is the parameter used in the Mathworld description [1].

The probability density function for `maxwell` is:

$$f(x) = \sqrt{2/\pi} x^2 \exp(-x^2/2)$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1]

### Examples

```
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(maxwell.ppf(0.01),
... maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x),
... 'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True
```

Generate random numbers:

```
>>> r = maxwell.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.mielke

`scipy.stats.mielke = <scipy.stats._continuous_distns.mielke_gen object>`

A Mielke Beta-Kappa / Dagum continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `mielke` is:

$$f(x, k, s) = \frac{kx^{k-1}}{(1+x^s)^{1+k/s}}$$

for  $x > 0$  and  $k, s > 0$ . The distribution is sometimes called Dagum distribution ([2]). It was already defined in [3], called a Burr Type III distribution (`burr` with parameters  $c=s$  and  $d=k/s$ ).

`mielke` takes *k* and *s* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1], [2], [3]

## Examples

```
>>> from scipy.stats import mielke
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> k, s = 10.4, 4.6
>>> mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(mielke.ppf(0.01, k, s),
... mielke.ppf(0.99, k, s), 100)
>>> ax.plot(x, mielke.pdf(x, k, s),
... 'r-', lw=5, alpha=0.6, label='mielke pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = mielke(k, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
>>> np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
True
```

Generate random numbers:

```
>>> r = mielke.rvs(k, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.moyal

`scipy.stats.moyal` = <`scipy.stats._continuous_distns.moyal_gen` object>

A Moyal continuous random variable.

As an instance of the `rv_continuous` class, `moyal` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `moyal` is:

$$f(x) = \exp(-(x + \exp(-x))/2) / \sqrt{2\pi}$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `moyal.pdf(x, loc, scale)` is identically equivalent to `moyal.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

This distribution has utility in high-energy physics and radiation detection. It describes the energy loss of a charged relativistic particle due to ionization of the medium [1]. It also provides an approximation for the Landau distribution. For an in depth description see [2]. For additional description, see [3].

### References

New in version 1.1.0.

[1], [2], [3]

### Examples

```
>>> from scipy.stats import moyal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = moyal.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(moyal.ppf(0.01),
... moyal.ppf(0.99), 100)
>>> ax.plot(x, moyal.pdf(x),
... 'r-', lw=5, alpha=0.6, label='moyal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = moyal()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = moyal.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], moyal.cdf(vals))
True
```

Generate random numbers:

```
>>> r = moyal.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.nakagami

`scipy.stats.nakagami = <scipy.stats._continuous_distns.nakagami_gen object>`

A Nakagami continuous random variable.

As an instance of the *rv\_continuous* class, *nakagami* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *nakagami* is:

$$f(x, \nu) = \frac{2\nu^\nu}{\Gamma(\nu)} x^{2\nu-1} \exp(-\nu x^2)$$

for  $x \geq 0, \nu > 0$ .

*nakagami* takes *nu* as a shape parameter for  $\nu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `nakagami.pdf(x, nu, loc, scale)` is identically equivalent to `nakagami.pdf(y, nu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nakagami.ppf(0.01, nu),
... nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu),
... 'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.ncx2

`scipy.stats.ncx2` = <`scipy.stats._continuous_distns.ncx2_gen` object>

A non-central chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `ncx2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `ncx2` is:

$$f(x, k, \lambda) = \frac{1}{2} \exp(-(\lambda + x)/2) (x/\lambda)^{(k-2)/4} I_{(k-2)/2}(\sqrt{\lambda x})$$

for  $x \geq 0$  and  $k, \lambda > 0$ .  $k$  specifies the degrees of freedom (denoted `df` in the implementation) and  $\lambda$  is the non-centrality parameter (denoted `nc` in the implementation).  $I_\nu$  denotes the modified Bessel function of first order of degree  $\nu$  (`scipy.special.iv`).

`ncx2` takes `df` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncx2.pdf(x, df, nc, loc, scale)` is identically equivalent to `ncx2.pdf(y, df, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncx2.ppf(0.01, df, nc),
... ncx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc),
... 'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncx2.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncx2.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = ncx2.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.ncf**

`scipy.stats.ncf = <scipy.stats._continuous_distns.ncf_gen object>`

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

`scipy.stats.f`

Fisher distribution

## Notes

The probability density function for `ncf` is:

$$f(x, n_1, n_2, \lambda) = \exp\left(\frac{\lambda}{2} + \lambda n_1 \frac{x}{2(n_1 x + n_2)}\right) n_1^{n_1/2} n_2^{n_2/2} x^{n_1/2-1} \\ (n_2 + n_1 x)^{-(n_1+n_2)/2} \gamma(n_1/2) \gamma(1 + n_2/2) \\ \frac{L_{n_2/2}^{\frac{n_1}{2}-1}\left(-\lambda n_1 \frac{x}{2(n_1 x + n_2)}\right)}{B(n_1/2, n_2/2) \gamma\left(\frac{n_1+n_2}{2}\right)}$$

for  $n_1, n_2 > 0$ ,  $\lambda \geq 0$ . Here  $n_1$  is the degrees of freedom in the numerator,  $n_2$  the degrees of freedom in the denominator,  $\lambda$  the non-centrality parameter,  $\gamma$  is the logarithm of the Gamma function,  $L_n^k$  is a generalized Laguerre polynomial and  $B$  is the beta function.

`ncf` takes `df1`, `df2` and `nc` as shape parameters. If `nc=0`, the distribution becomes equivalent to the Fisher distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncf.pdf(x, dfn, dfd, nc, loc, scale)` is identically equivalent to `ncf.pdf(y, dfn, dfd, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc),
... ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc),
... 'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```

Generate random numbers:

```
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.nct

`scipy.stats.nct = <scipy.stats._continuous_distns.nct_gen object>`

A non-central Student's t continuous random variable.

As an instance of the `rv_continuous` class, `nct` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

If  $Y$  is a standard normal random variable and  $V$  is an independent chi-square random variable (*chi2*) with  $k$  degrees of freedom, then

$$X = \frac{Y + c}{\sqrt{V/k}}$$

has a non-central Student's t distribution on the real line. The degrees of freedom parameter  $k$  (denoted `df` in the implementation) satisfies  $k > 0$  and the noncentrality parameter  $c$  (denoted `nc` in the implementation) is a real number.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nct.pdf(x, df, nc, loc, scale)` is identically equivalent

to `nct.pdf(y, df, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df, nc = 14, 0.24
>>> mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nct.ppf(0.01, df, nc),
... nct.ppf(0.99, df, nc), 100)
>>> ax.plot(x, nct.pdf(x, df, nc),
... 'r-', lw=5, alpha=0.6, label='nct pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nct(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nct.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = nct.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.norm

`scipy.stats.norm` = <`scipy.stats._continuous_distns.norm_gen` object>

A normal continuous random variable.

The location (`loc`) keyword specifies the mean. The scale (`scale`) keyword specifies the standard deviation.

As an instance of the `rv_continuous` class, `norm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `norm` is:

$$f(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}}$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norm.pdf(x, loc, scale)` is identically equivalent to `norm.pdf(y) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norm.ppf(0.01),
... norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
... 'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = norm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.norminvgauss

`scipy.stats.norminvgauss` = <`scipy.stats._continuous_distns.norminvgauss_gen` object>

A Normal Inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `norminvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `norminvgauss` is:

$$f(x, a, b) = \frac{a K_1(a\sqrt{1+x^2})}{\pi\sqrt{1+x^2}} \exp(\sqrt{a^2 - b^2} + bx)$$

where *x* is a real number, the parameter *a* is the tail heaviness and *b* is the asymmetry parameter satisfying  $a > 0$  and  $|b| \leq a$ .  $K_1$  is the modified Bessel function of second kind (`scipy.special.k1`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norminvgauss.pdf(x, a, b, loc, scale)` is identically equivalent to `norminvgauss.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A normal inverse Gaussian random variable  $Y$  with parameters  $a$  and  $b$  can be expressed as a normal mean-variance mixture:  $Y = b * V + \text{sqr}(V) * X$  where  $X$  is  $\text{norm}(0,1)$  and  $V$  is  $\text{invgauss}(\text{mu}=1/\text{sqr}(a^{**2} - b^{**2}))$ . This representation is used to generate random variates.

## Examples

```
>>> from scipy.stats import norminvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 1.25, 0.5
>>> mean, var, skew, kurt = norminvgauss.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norminvgauss.ppf(0.01, a, b),
... norminvgauss.ppf(0.99, a, b), 100)
>>> ax.plot(x, norminvgauss.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='norminvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norminvgauss(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norminvgauss.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], norminvgauss.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = norminvgauss.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>var(a, b, loc=0, scale=1)</code>                                                              | Variance of the distribution.                                                                                                                |
| <code>std(a, b, loc=0, scale=1)</code>                                                              | Standard deviation of the distribution.                                                                                                      |
| <code>interval(alpha, a, b, loc=0, scale=1)</code>                                                  | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

**scipy.stats.pareto**

`scipy.stats.pareto` = <`scipy.stats._continuous_distns.pareto_gen` object>

A Pareto continuous random variable.

As an instance of the `rv_continuous` class, `pareto` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `pareto` is:

$$f(x, b) = \frac{b}{x^{b+1}}$$

for  $x \geq 1, b > 0$ .

`pareto` takes `b` as a shape parameter for  $b$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pareto.pdf(x, b, loc, scale)` is identically equivalent to `pareto.pdf(y, b) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pareto.ppf(0.01, b),
... pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='pareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.pearson3

`scipy.stats.pearson3` = <`scipy.stats._continuous_distns.pearson3_gen` object>

A pearson type III continuous random variable.

As an instance of the `rv_continuous` class, `pearson3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `pearson3` is:

$$f(x, \kappa) = \frac{|\beta|}{\Gamma(\alpha)} (\beta(x - \zeta))^{\alpha-1} \exp(-\beta(x - \zeta))$$

where:

$$\begin{aligned}\beta &= \frac{2}{\kappa} \\ \alpha &= \beta^2 = \frac{4}{\kappa^2} \\ \zeta &= -\frac{\alpha}{\beta} = -\beta\end{aligned}$$

$\Gamma$  is the gamma function (`scipy.special.gamma`). Pass the skew  $\kappa$  into `pearson3` as the shape parameter `skew`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pearson3.pdf(x, skew, loc, scale)` is identically equivalent to `pearson3.pdf(y, skew) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import pearson3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> skew = 0.1
>>> mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pearson3.ppf(0.01, skew),
... pearson3.ppf(0.99, skew), 100)
>>> ax.plot(x, pearson3.pdf(x, skew),
... 'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pearson3(skew)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True
```

Generate random numbers:

```
>>> r = pearson3.rvs(skew, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.powerlaw

`scipy.stats.powerlaw = <scipy.stats._continuous_distns.powerlaw_gen object>`

A power-function continuous random variable.

As an instance of the *rv\_continuous* class, *powerlaw* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *powerlaw* is:

$$f(x, a) = ax^{a-1}$$

for  $0 \leq x \leq 1, a > 0$ .

*powerlaw* takes *a* as a shape parameter for *a*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `powerlaw.pdf(x, a, loc, scale)` is identically equivalent to `powerlaw.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

`powerlaw` is a special case of `beta` with `b=1`.

## Examples

```
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlaw.ppf(0.01, a),
... powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='powerlaw pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = powerlaw.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.powerlognorm

`scipy.stats.powerlognorm` = <`scipy.stats._continuous_distns.powerlognorm_gen` object>  
 A power log-normal continuous random variable.

As an instance of the `rv_continuous` class, `powerlognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `powerlognorm` is:

$$f(x, c, s) = \frac{c}{xs} \phi(\log(x)/s) (\Phi(-\log(x)/s))^{c-1}$$

where  $\phi$  is the normal pdf, and  $\Phi$  is the normal cdf, and  $x > 0$ ,  $s, c > 0$ .

`powerlognorm` takes  $c$  and  $s$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlognorm.pdf(x, c, s, loc, scale)` is identically equivalent to `powerlognorm.pdf(y, c, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
... powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
... 'r-', lw=5, alpha=0.6, label='powerlognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```

Generate random numbers:

```
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.powernorm

`scipy.stats.powernorm = <scipy.stats._continuous_distns.powernorm_gen object>`

A power normal continuous random variable.

As an instance of the `rv_continuous` class, `powernorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `powernorm` is:

$$f(x, c) = c\phi(x)(\Phi(-x))^{c-1}$$

where  $\phi$  is the normal pdf, and  $\Phi$  is the normal cdf, and  $x \geq 0, c > 0$ .

`powernorm` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powernorm.pdf(x, c, loc, scale)` is identically equivalent to `powernorm.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powernorm.ppf(0.01, c),
... powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='powernorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = powernorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.rdist

`scipy.stats.rdist` = <`scipy.stats._continuous_distns.rdist_gen` object>

An R-distributed (symmetric beta) continuous random variable.

As an instance of the `rv_continuous` class, `rdist` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `rdist` is:

$$f(x, c) = \frac{(1 - x^2)^{c/2-1}}{B(1/2, c/2)}$$

for  $-1 \leq x \leq 1$ ,  $c > 0$ . `rdist` is also called the symmetric beta distribution: if `B` has a `beta` distribution with parameters  $(c/2, c/2)$ , then  $X = 2*B - 1$  follows a R-distribution with parameter  $c$ .

`rdist` takes  $c$  as a shape parameter for  $c$ .

This distribution includes the following distribution kernels as special cases:

|                     |                             |
|---------------------|-----------------------------|
| <code>c = 2:</code> | uniform                     |
| <code>c = 3:</code> | <code>`semicircular`</code> |
| <code>c = 4:</code> | Epanechnikov (parabolic)    |
| <code>c = 6:</code> | quartic (biweight)          |
| <code>c = 8:</code> | triweight                   |

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rdist.pdf(x, c, loc, scale)` is identically equivalent to `rdist.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.6
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rdist.ppf(0.01, c),
... rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and pdf:

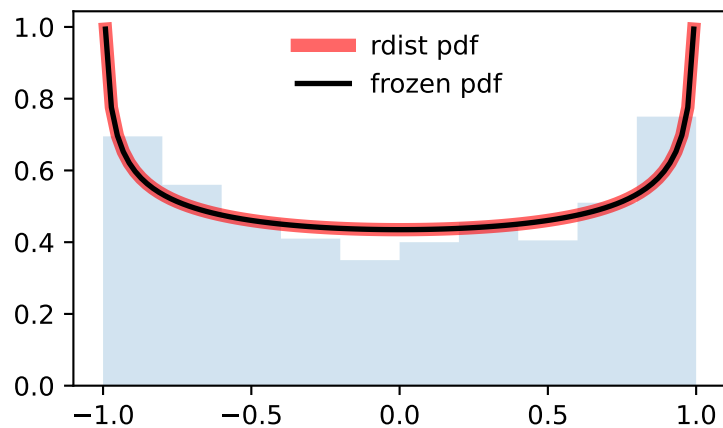

```
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.rayleigh

`scipy.stats.rayleigh = <scipy.stats._continuous_distns.rayleigh_gen object>`

A Rayleigh continuous random variable.

As an instance of the `rv_continuous` class, `rayleigh` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `rayleigh` is:

$$f(x) = x \exp(-x^2/2)$$

for  $x \geq 0$ .

`rayleigh` is a special case of `chi` with `df=2`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rayleigh.pdf(x, loc, scale)` is identically equivalent to `rayleigh.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rayleigh.ppf(0.01),
... rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x),
... 'r-', lw=5, alpha=0.6, label='rayleigh pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
True
```

Generate random numbers:

```
>>> r = rayleigh.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.rice**

`scipy.stats.rice` = <`scipy.stats._continuous_distns.rice_gen` object>

A Rice continuous random variable.

As an instance of the `rv_continuous` class, `rice` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `rice` is:

$$f(x, b) = x \exp\left(-\frac{x^2 + b^2}{2}\right) I_0(xb)$$

for  $x \geq 0, b > 0$ .  $I_0$  is the modified Bessel function of order zero (`scipy.special.i0`).

`rice` takes `b` as a shape parameter for  $b$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rice.pdf(x, b, loc, scale)` is identically equivalent to `rice.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The Rice distribution describes the length,  $r$ , of a 2-D vector with components  $(U + u, V + v)$ , where  $U, V$  are constant,  $u, v$  are independent Gaussian random variables with standard deviation  $s$ . Let  $R = \sqrt{U^2 + V^2}$ . Then the pdf of  $r$  is `rice.pdf(x, R/s, scale=s)`.

**Examples**

```
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rice.ppf(0.01, b),
... rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = rice.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.recipinvgauss

`scipy.stats.recipinvgauss` = <`scipy.stats._continuous_distns.recipinvgauss_gen` object>

A reciprocal inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `recipinvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `recipinvgauss` is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x}} \exp\left(\frac{-(1 - \mu x)^2}{2\mu^2 x}\right)$$

for  $x \geq 0$ .

`recipinvgauss` takes *mu* as a shape parameter for  $\mu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `recipinvgauss.pdf(x, mu, loc, scale)` is identically equivalent to `recipinvgauss.pdf(y, mu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu),
... recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu),
... 'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.semicircular

`scipy.stats.semicircular` = <`scipy.stats._continuous_distns.semicircular_gen` object>

A semicircular continuous random variable.

As an instance of the `rv_continuous` class, `semicircular` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`rdist`

### Notes

The probability density function for `semicircular` is:

$$f(x) = \frac{2}{\pi} \sqrt{1 - x^2}$$

for  $-1 \leq x \leq 1$ .

The distribution is a special case of `rdist` with  $c = 3$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `semicircular.pdf(x, loc, scale)` is identically equivalent to `semicircular.pdf(y) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1]

### Examples

```
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(semicircular.ppf(0.01),
... semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x),
... 'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = semicircular()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))
True
```

Generate random numbers:

```
>>> r = semicircular.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.skewcauchy

`scipy.stats.skewcauchy = <scipy.stats._continuous_distns.skewcauchy_gen object>`

A skewed Cauchy random variable.

As an instance of the *rv\_continuous* class, *skewcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

#### cauchy

Cauchy distribution

## Notes

The probability density function for *skewcauchy* is:

$$f(x) = \frac{1}{\pi \left( \frac{x^2}{(a \operatorname{sign}(x)+1)^2} + 1 \right)}$$

for a real number  $x$  and skewness parameter  $-1 < a < 1$ .

When  $a = 0$ , the distribution reduces to the usual Cauchy distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewcauchy.pdf(x, a, loc, scale)` is identically equivalent to `skewcauchy.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## References

[1]

## Examples

```
>>> from scipy.stats import skewcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 0.5
>>> mean, var, skew, kurt = skewcauchy.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(skewcauchy.ppf(0.01, a),
... skewcauchy.ppf(0.99, a), 100)
>>> ax.plot(x, skewcauchy.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='skewcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = skewcauchy(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

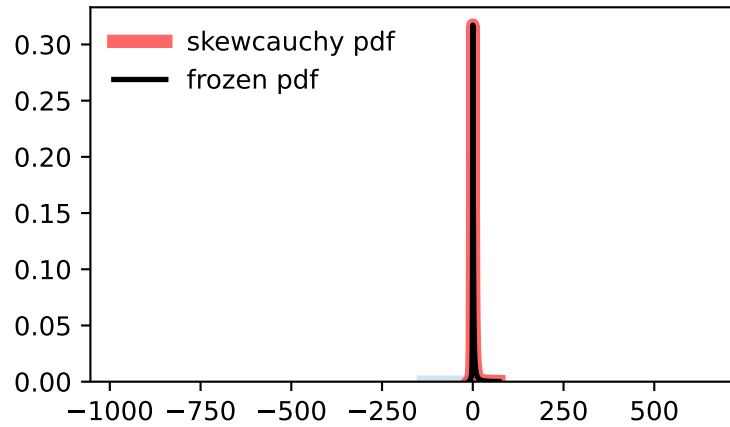

```
>>> vals = skewcauchy.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewcauchy.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = skewcauchy.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.skewnorm

`scipy.stats.skewnorm` = <`scipy.stats._continuous_distns.skew_norm_gen` object>

A skew-normal random variable.

As an instance of the `rv_continuous` class, `skewnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The pdf is:

$$\text{skewnorm.pdf}(x, a) = 2 * \text{norm.pdf}(x) * \text{norm.cdf}(a*x)$$

`skewnorm` takes a real number *a* as a skewness parameter. When *a* = 0 the distribution is identical to a normal distribution (`norm`). `rvs` implements the method of [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewnorm.pdf(x, a, loc, scale)` is identically equivalent to `skewnorm.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(skewnorm.ppf(0.01, a),
... skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>entropy(a, loc=0, scale=1)</code>                                                           | (Differential) entropy of the RV.                                                                                                            |
| <code>fit(data)</code>                                                                            | Parameter estimates for generic data. See <a href="#">scipy.stats.rv_continuous.fit</a> for detailed documentation of the keyword arguments. |
| <code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code> | Expected value of a function (of one argument) with respect to the distribution.                                                             |
| <code>median(a, loc=0, scale=1)</code>                                                            | Median of the distribution.                                                                                                                  |
| <code>mean(a, loc=0, scale=1)</code>                                                              | Mean of the distribution.                                                                                                                    |
| <code>var(a, loc=0, scale=1)</code>                                                               | Variance of the distribution.                                                                                                                |
| <code>std(a, loc=0, scale=1)</code>                                                               | Standard deviation of the distribution.                                                                                                      |
| <code>interval(alpha, a, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.studentized\_range

`scipy.stats.studentized_range` = <`scipy.stats._continuous_distns.studentized_range_gen` object>

A studentized range continuous random variable.

As an instance of the `rv_continuous` class, `studentized_range` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**t** Student's t distribution

### Notes

The probability density function for `studentized_range` is:

$$f(x; k, \nu) = \frac{k(k-1)\nu^{\nu/2}}{\Gamma(\nu/2)2^{\nu/2-1}} \int_0^\infty \int_{-\infty}^\infty s^\nu e^{-\nu s^2/2} \phi(z) \phi(sx+z) [\Phi(sx+z) - \Phi(z)]^{k-2} dz ds$$

for  $x \geq 0$ ,  $k > 1$ , and  $\nu > 0$ .

`studentized_range` takes `k` for  $k$  and `df` for  $\nu$  as shape parameters.

When  $\nu$  exceeds 100,000, an asymptotic approximation (infinite degrees of freedom) is used to compute the cumulative distribution function [4].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `studentized_range.pdf(x, k, df, loc, scale)` is identically equivalent to `studentized_range.pdf(y, k, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### References

[1], [2], [3], [4]

### Examples

```
>>> from scipy.stats import studentized_range
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> k, df = 3, 10
>>> mean, var, skew, kurt = studentized_range.stats(k, df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(studentized_range.ppf(0.01, k, df),
... studentized_range.ppf(0.99, k, df), 100)
>>> ax.plot(x, studentized_range.pdf(x, k, df),
... 'r-', lw=5, alpha=0.6, label='studentized_range pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = studentized_range(k, df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = studentized_range.ppf([0.001, 0.5, 0.999], k, df)
>>> np.allclose([0.001, 0.5, 0.999], studentized_range.cdf(vals, k, df))
True
```

Rather than using (`studentized_range.rvs`) to generate random variates, which is very slow for this distribution, we can approximate the inverse CDF using an interpolator, and then perform inverse transform sampling with this approximate inverse CDF.

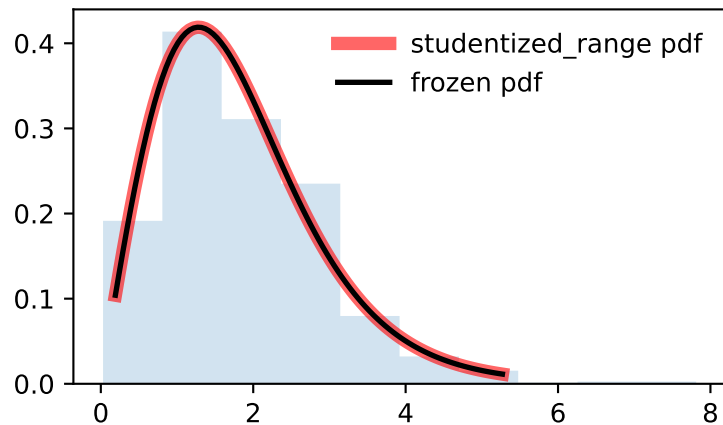

This distribution has an infinite but thin right tail, so we focus our attention on the leftmost 99.9 percent.

```
>>> a, b = studentized_range.ppf([0, .999], k, df)
>>> a, b
0, 7.41058083802274
```

```
>>> from scipy.interpolate import interp1d
>>> rng = np.random.default_rng()
>>> xs = np.linspace(a, b, 50)
>>> cdf = studentized_range.cdf(xs, k, df)
Create an interpolant of the inverse CDF
>>> ppf = interp1d(cdf, xs, fill_value='extrapolate')
Perform inverse transform sampling using the interpolant
>>> r = ppf(rng.uniform(size=1000))
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.t**

`scipy.stats.t` = <`scipy.stats._continuous_distns.t_gen` object>

A Student's t continuous random variable.

For the noncentral t distribution, see `nct`.

As an instance of the `rv_continuous` class, `t` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`nct`

**Notes**

The probability density function for `t` is:

$$f(x, \nu) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)} (1 + x^2/\nu)^{-(\nu+1)/2}$$

where  $x$  is a real number and the degrees of freedom parameter  $\nu$  (denoted `df` in the implementation) satisfies  $\nu > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `t.pdf(x, df, loc, scale)` is identically equivalent to `t.pdf(y, df) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(t.ppf(0.01, df),
... t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df),
... 'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.trapezoid

`scipy.stats.trapezoid = <scipy.stats._continuous_distns.trapezoid_gen object>`

A trapezoidal continuous random variable.

As an instance of the *rv\_continuous* class, *trapezoid* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The trapezoidal distribution can be represented with an up-sloping line from *loc* to  $(loc + c*scale)$ , then constant to  $(loc + d*scale)$  and then downsloping from  $(loc + d*scale)$  to  $(loc+scale)$ . This defines the trapezoid base from *loc* to  $(loc+scale)$  and the flat top from *c* to *d* proportional to the position along the base with  $0 \leq c \leq d \leq 1$ . When *c*=*d*, this is equivalent to *triang* with the same values for *loc*, *scale* and *c*. The method of [1] is used for computing moments.

*trapezoid* takes *c* and *d* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `trapezoid.pdf(x, c, d, loc, scale)` is identically equivalent to `trapezoid.pdf(y, c, d) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The standard form is in the range  $[0, 1]$  with  $c$  the mode. The location parameter shifts the start to  $loc$ . The scale parameter changes the width from 1 to  $scale$ .

## References

[1]

## Examples

```
>>> from scipy.stats import trapezoid
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapezoid.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(trapezoid.ppf(0.01, c, d),
... trapezoid.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapezoid.pdf(x, c, d),
... 'r-', lw=5, alpha=0.6, label='trapezoid pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = trapezoid(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = trapezoid.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapezoid.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = trapezoid.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.triang

`scipy.stats.triang` = <`scipy.stats._continuous_distns.triang_gen` object>

A triangular continuous random variable.

As an instance of the `rv_continuous` class, `triang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The triangular distribution can be represented with an up-sloping line from `loc` to `(loc + c*scale)` and then downsloping for `(loc + c*scale)` to `(loc + scale)`.

`triang` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `triang.pdf(x, c, loc, scale)` is identically equivalent to `triang.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The standard form is in the range `[0, 1]` with `c` the mode. The location parameter shifts the start to `loc`. The scale parameter changes the width from 1 to `scale`.

### Examples

```
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.158
>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(triang.ppf(0.01, c),
... triang.ppf(0.99, c), 100)
>>> ax.plot(x, triang.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='triang pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = triang(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.truncexpon

`scipy.stats.truncexpon = <scipy.stats._continuous_distns.truncexpon_gen object>`

A truncated exponential continuous random variable.

As an instance of the *rv\_continuous* class, *truncexpon* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *truncexpon* is:

$$f(x, b) = \frac{\exp(-x)}{1 - \exp(-b)}$$

for  $0 \leq x \leq b$ .

*truncexpon* takes *b* as a shape parameter for *b*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `truncexpon.pdf(x, b, loc, scale)` is identically equivalent to `truncexpon.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 4.69
>>> mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncexpon.ppf(0.01, b),
... truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.truncnorm**

`scipy.stats.truncnorm` = <`scipy.stats._continuous_distns.truncnorm_gen` object>  
 A truncated normal continuous random variable.

As an instance of the `rv_continuous` class, `truncnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The standard form of this distribution is a standard normal truncated to the range  $[a, b]$  — notice that  $a$  and  $b$  are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

```
a, b = (myclip_a - my_mean) / my_std, (myclip_b - my_mean) / my_std
```

`truncnorm` takes  $a$  and  $b$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncnorm.pdf(x, a, b, loc, scale)` is identically equivalent to `truncnorm.pdf(y, a, b) / scale` with  $y = (x - loc) / scale$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncnorm.ppf(0.01, a, b),
... truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = truncnorm.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.tukeylambda

`scipy.stats.tukeylambda = <scipy.stats._continuous_distns.tukeylambda_gen object>`

A Tukey-Lambda continuous random variable.

As an instance of the `rv_continuous` class, `tukeylambda` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy ( $\text{lambda} = -1$ )
- logistic ( $\text{lambda} = 0$ )
- approx Normal ( $\text{lambda} = 0.14$ )
- uniform from -1 to 1 ( $\text{lambda} = 1$ )

`tukeylambda` takes a real number *lambda* (denoted *lam* in the implementation) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `tukeylambda.pdf(x, lam, loc, scale)` is identically equivalent to `tukeylambda.pdf(y, lam) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that

shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import tukeylambda
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(tukeylambda.ppf(0.01, lam),
... tukeylambda.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambda.pdf(x, lam),
... 'r-', lw=5, alpha=0.6, label='tukeylambda pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = tukeylambda(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = tukeylambda.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambda.cdf(vals, lam))
True
```

Generate random numbers:

```
>>> r = tukeylambda.rvs(lam, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.uniform

`scipy.stats.uniform` = <`scipy.stats._continuous_distns.uniform_gen` object>

A uniform continuous random variable.

In the standard form, the distribution is uniform on  $[0, 1]$ . Using the parameters `loc` and `scale`, one obtains the uniform distribution on  $[loc, loc + scale]$ .

As an instance of the `rv_continuous` class, `uniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Examples

```
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(uniform.ppf(0.01),
... uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x),
... 'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
True
```

Generate random numbers:

```
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.vonmises

`scipy.stats.vonmises` = <`scipy.stats._continuous_distns.vonmises_gen` object>

A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `vonmises` and `vonmises_line` is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for  $-\pi \leq x \leq \pi$ ,  $\kappa > 0$ .  $I_0$  is the modified Bessel function of order zero (`scipy.special.i0`).

`vonmises` is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in `scipy`. The `cdf` is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

`vonmises_line` is the same distribution, defined on  $[-\pi, \pi]$  on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises.pdf(y, kappa) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

### Examples

```
>>> from scipy.stats import vonmises
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises.ppf(0.01, kappa),
... vonmises.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises.pdf(x, kappa),
... 'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.vonmises\_line

`scipy.stats.vonmises_line = <scipy.stats._continuous_distns.vonmises_gen object>`  
 A Von Mises continuous random variable.

As an instance of the *rv\_continuous* class, *vonmises\_line* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *vonmises* and *vonmises\_line* is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for  $-\pi \leq x \leq \pi$ ,  $\kappa > 0$ .  $I_0$  is the modified Bessel function of order zero (*scipy.special.i0*).

*vonmises* is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in *scipy*. The *cdf* is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

*vonmises\_line* is the same distribution, defined on  $[-\pi, \pi]$  on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises_line.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises_line.pdf(y, kappa) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises_line.ppf(0.01, kappa),
... vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa),
... 'r-', lw=5, alpha=0.6, label='vonmises_line pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises_line.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, kappa, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

**scipy.stats.wald**

`scipy.stats.wald` = <`scipy.stats._continuous_distns.wald_gen` object>

A Wald continuous random variable.

As an instance of the `rv_continuous` class, `wald` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `wald` is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x-1)^2}{2x}\right)$$

for  $x \geq 0$ .

`wald` is a special case of `invgauss` with `mu=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wald.pdf(x, loc, scale)` is identically equivalent to `wald.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

**Examples**

```
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wald.ppf(0.01),
... wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x),
... 'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
True
```

Generate random numbers:

```
>>> r = wald.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

| <code>interval(alpha, loc=0, scale=1)</code>                                                   | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution                                                        |

## scipy.stats.weibull\_min

`scipy.stats.weibull_min = <scipy.stats._continuous_distns.weibull_min_gen object>`  
 Weibull minimum continuous random variable.

The Weibull Minimum Extreme Value distribution, from extreme value theory (Fisher-Gnedenko theorem), is also often simply called the Weibull distribution. It arises as the limiting distribution of the rescaled minimum of iid random variables.

As an instance of the `rv_continuous` class, `weibull_min` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`weibull_max`, `numpy.random.Generator.weibull`, `exponweib`

## Notes

The probability density function for `weibull_min` is:

$$f(x, c) = cx^{c-1} \exp(-x^c)$$

for  $x > 0, c > 0$ .

`weibull_min` takes `c` as a shape parameter for  $c$ . (named  $k$  in Wikipedia article and  $a$  in `numpy.random.weibull`). Special shape values are  $c = 1$  and  $c = 2$  where Weibull distribution reduces to the `expon` and `rayleigh` distributions respectively.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_min.pdf(x, c, loc, scale)` is identically equivalent to `weibull_min.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_min.ppf(0.01, c),
... weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.weibull\_max

`scipy.stats.weibull_max = <scipy.stats._continuous_distns.weibull_max_gen object>`  
Weibull maximum continuous random variable.

The Weibull Maximum Extreme Value distribution, from extreme value theory (Fisher-Gnedenko theorem), is the limiting distribution of rescaled maximum of iid random variables. This is the distribution of  $-X$  if  $X$  is from the `weibull_min` function.

As an instance of the `rv_continuous` class, `weibull_max` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`weibull_min`

## Notes

The probability density function for `weibull_max` is:

$$f(x, c) = c(-x)^{c-1} \exp(-(-x)^c)$$

for  $x < 0$ ,  $c > 0$ .

`weibull_max` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_max.pdf(x, c, loc, scale)` is identically equivalent to `weibull_max.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

[https://en.wikipedia.org/wiki/Fisher-Tippett-Gnedenko\\_theorem](https://en.wikipedia.org/wiki/Fisher-Tippett-Gnedenko_theorem)

## Examples

```
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_max.ppf(0.01, c),
... weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_max.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.wrapcauchy

`scipy.stats.wrapcauchy = <scipy.stats._continuous_distns.wrapcauchy_gen object>`

A wrapped Cauchy continuous random variable.

As an instance of the *rv\_continuous* class, *wrapcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *wrapcauchy* is:

$$f(x, c) = \frac{1 - c^2}{2\pi(1 + c^2 - 2c \cos(x))}$$

for  $0 \leq x \leq 2\pi, 0 < c < 1$ .

*wrapcauchy* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `wrapcauchy.pdf(x, c, loc, scale)` is identically equivalent to `wrapcauchy.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ . Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

## Examples

```
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.0311
>>> mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wrapcauchy.ppf(0.01, c),
... wrapcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, wrapcauchy.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wrapcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = wrapcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

| <code>invwishart</code>             | An inverse Wishart random variable.            |
| <code>multinomial</code>            | A multinomial random variable.                 |
| <code>special_ortho_group</code>    | A matrix-valued SO(N) random variable.         |
| <code>ortho_group</code>            | A matrix-valued O(N) random variable.          |
| <code>unitary_group</code>          | A matrix-valued U(N) random variable.          |
| <code>random_correlation</code>     | A random correlation matrix.                   |
| <code>multivariate_t</code>         | A multivariate t-distributed random variable.  |
| <code>multivariate_hypergeom</code> | A multivariate hypergeometric random variable. |

### scipy.stats.multivariate\_normal

`scipy.stats.multivariate_normal = <scipy.stats._multivariate.multivariate_normal_gen object>`  
 A multivariate normal random variable.

The *mean* keyword specifies the mean. The *cov* keyword specifies the covariance matrix.

#### Parameters

- x** [array\_like] Quantiles, with the last axis of *x* denoting the components.
- mean** [array\_like, optional] Mean of the distribution (default zero)
- cov** [array\_like, optional] Covariance matrix of the distribution (default one)
- allow\_singular** [bool, optional] Whether to allow a singular covariance matrix. (Default: False)
- random\_state** [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]  
 If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used.  
 If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” multivariate normal random variable:

```
rv = multivariate_normal(mean=None, cov=1, allow_singular=False)
```

- Frozen object with the same methods but holding the given mean and covariance fixed.

#### Notes

##### Setting the parameter mean to None is equivalent to having mean

be the zero-vector. The parameter *cov* can be a scalar, in which case the covariance matrix is the identity times that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array\_like.

The covariance matrix *cov* must be a (symmetric) positive semi-definite matrix. The determinant and inverse of *cov* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *cov* does not need to have full rank.

The probability density function for `multivariate_normal` is

$$f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp\left(-\frac{1}{2}(x - \mu)^T \Sigma^{-1}(x - \mu)\right),$$

where  $\mu$  is the mean,  $\Sigma$  the covariance matrix, and  $k$  is the dimension of the space where  $x$  takes values.

New in version 0.14.0.

### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal
```

```
>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([0.00108914, 0.01033349, 0.05946514, 0.20755375, 0.43939129,
 0.56418958, 0.43939129, 0.20755375, 0.05946514, 0.01033349])
>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)
```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```
>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))
```

| <code>entropy()</code>                                                                                      | Compute the differential entropy of the multivariate normal. |

## scipy.stats.matrix\_normal

`scipy.stats.matrix_normal = <scipy.stats._multivariate.matrix_normal_gen object>`  
 A matrix normal random variable.

The *mean* keyword specifies the mean. The *rowcov* keyword specifies the among-row covariance matrix. The *colcov* keyword specifies the among-column covariance matrix.

### Parameters

**X** [array\_like] Quantiles, with the last two axes of *X* denoting the components.  
**mean** [array\_like, optional] Mean of the distribution (default: *None*)  
**rowcov** [array\_like, optional] Among-row covariance matrix of the distribution (default: *I*)  
**colcov** [array\_like, optional] Among-column covariance matrix of the distribution (default: *I*)  
**random\_state** [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]  
 If *seed* is *None* (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already

a `Generator` or `RandomState` instance then that instance is used.

**Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” matrix normal random variable:**

```
rv = matrix_normal(mean=None, rowcov=1, colcov=1)
```

- Frozen object with the same methods but holding the given mean and covariance fixed.

## Notes

*If mean is set to None then a matrix of zeros is used for the mean.*

The dimensions of this matrix are inferred from the shape of `rowcov` and `colcov`, if these are provided, or set to `1` if ambiguous.

`rowcov` and `colcov` can be two-dimensional array\_likes specifying the covariance matrices directly. Alternatively, a one-dimensional array will be interpreted as the entries of a diagonal matrix, and a scalar or zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by `rowcov` and `colcov` must be (symmetric) positive definite. If the samples in  $X$  are  $m \times n$ , then `rowcov` must be  $m \times m$  and `colcov` must be  $n \times n$ . `mean` must be the same shape as  $X$ .

The probability density function for `matrix_normal` is

$$f(X) = (2\pi)^{-\frac{mn}{2}} |U|^{-\frac{n}{2}} |V|^{-\frac{m}{2}} \exp\left(-\frac{1}{2} \text{Tr}[U^{-1}(X-M)V^{-1}(X-M)^T]\right),$$

where  $M$  is the mean,  $U$  the among-row covariance matrix,  $V$  the among-column covariance matrix.

The `allow_singular` behaviour of the `multivariate_normal` distribution is not currently supported. Covariance matrices must be full rank.

The `matrix_normal` distribution is closely related to the `multivariate_normal` distribution. Specifically,  $\text{Vec}(X)$  (the vector formed by concatenating the columns of  $X$ ) has a multivariate normal distribution with mean  $\text{Vec}(M)$  and covariance  $V \otimes U$  (where  $\otimes$  is the Kronecker product). Sampling and pdf evaluation are  $\mathcal{O}(m^3 + n^3 + m^2n + mn^2)$  for the matrix normal, but  $\mathcal{O}(m^3n^3)$  for the equivalent multivariate normal, making this equivalent form algorithmically inefficient.

New in version 0.17.0.

## Examples

```
>>> from scipy.stats import matrix_normal
```

```
>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
 [2, 3],
 [4, 5]])
>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
 [0, 2, 0],
 [0, 0, 3]])
>>> V = 0.3*np.identity(2); V
array([[0.3, 0.],
 [0. , 0.3]])
```

(continues on next page)

(continued from previous page)

```
>>> X = M + 0.1; X
array([[0.1, 1.1],
 [2.1, 3.1],
 [4.1, 5.1]])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054
```

```
>>> # Equivalent multivariate normal
>>> from scipy.stats import multivariate_normal
>>> vectorised_X = X.T.flatten()
>>> equiv_mean = M.T.flatten()
>>> equiv_cov = np.kron(V,U)
>>> multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
0.023410202050005054
```

| <code>logpdf(X, mean=None, rowcov=1, colcov=1)</code>                      | Log of the probability density function. |
| <code>rvs(mean=None, rowcov=1, colcov=1, size=1, random_state=None)</code> | Draw random samples.                     |

## scipy.stats.dirichlet

`scipy.stats.dirichlet` = <scipy.stats.\_multivariate.dirichlet\_gen object>  
A Dirichlet random variable.

The *alpha* keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

### Parameters

**x** [array\_like] Quantiles, with the last axis of *x* denoting the components.

**alpha** [array\_like] The concentration parameters. The number of entries determines the dimensionality of the distribution.

**random\_state** [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]  
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

**Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:**

```
rv = dirichlet(alpha)
```

- Frozen object with the same methods but holding the given concentration parameters fixed.

## Notes

Each  $\alpha$  entry must be positive. The distribution has only support on the simplex defined by

$$\sum_{i=1}^K x_i = 1$$

where  $0 < x_i < 1$ .

If the quantiles don't lie within the simplex, a `ValueError` is raised.

The probability density function for `dirichlet` is

$$f(x) = \frac{1}{B(\alpha)} \prod_{i=1}^K x_i^{\alpha_i - 1}$$

where

$$B(\alpha) = \frac{\prod_{i=1}^K \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^K \alpha_i)}$$

and  $\alpha = (\alpha_1, \dots, \alpha_K)$ , the concentration parameters and  $K$  is the dimension of the space where  $x$  takes values.

Note that the dirichlet interface is somewhat inconsistent. The array returned by the rvs function is transposed with respect to the format expected by the pdf and logpdf.

## Examples

```
>>> from scipy.stats import dirichlet
```

Generate a dirichlet random variable

```
>>> quantiles = np.array([0.2, 0.2, 0.6]) # specify quantiles
>>> alpha = np.array([0.4, 5, 15]) # specify concentration parameters
>>> dirichlet.pdf(quantiles, alpha)
0.2843831684937255
```

The same PDF but following a log scale

```
>>> dirichlet.logpdf(quantiles, alpha)
-1.2574327653159187
```

Once we specify the dirichlet distribution we can then calculate quantities of interest

```
>>> dirichlet.mean(alpha) # get the mean of the distribution
array([0.01960784, 0.24509804, 0.73529412])
>>> dirichlet.var(alpha) # get variance
array([0.00089829, 0.00864603, 0.00909517])
>>> dirichlet.entropy(alpha) # calculate the differential entropy
-4.3280162474082715
```

We can also return random samples from the distribution

```
>>> dirichlet.rvs(alpha, size=1, random_state=1)
array([[0.00766178, 0.24670518, 0.74563305]])
>>> dirichlet.rvs(alpha, size=2, random_state=2)
array([[0.01639427, 0.1292273 , 0.85437844],
 [0.00156917, 0.19033695, 0.80809388]])
```

## Methods

| <code>mean(alpha)</code>                           | The mean of the Dirichlet distribution                          |
| <code>var(alpha)</code>                            | The variance of the Dirichlet distribution                      |
| <code>entropy(alpha)</code>                        | Compute the differential entropy of the Dirichlet distribution. |

## scipy.stats.wishart

`scipy.stats.wishart` = <scipy.stats.\_multivariate.wishart\_gen object>

A Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix). These arguments must satisfy the relationship  $df > scale.ndim - 1$ , but see notes on using the *rvs* method with  $df < scale.ndim$ .

### Parameters

**x** [array\_like] Quantiles, with the last axis of *x* denoting the components.  
**df** [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix  
**scale** [array\_like] Symmetric positive definite scale matrix of the distribution  
**random\_state** [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]  
 If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used.  
 If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:

```
rv = wishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

[invwishart](#), [chi2](#)

## Notes

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

$$W_p(\nu, \Sigma)$$

where  $\nu$  is the degrees of freedom and  $\Sigma$  is the  $p \times p$  scale matrix.

The probability density function for *wishart* has support over positive definite matrices  $S$ ; if  $S \sim W_p(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|S|^{\frac{\nu-p-1}{2}}}{2^{\frac{\nu p}{2}} |\Sigma|^{\frac{\nu}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-tr(\Sigma^{-1}S)/2)$$

If  $S \sim W_p(\nu, \Sigma)$  (Wishart) then  $S^{-1} \sim W_p^{-1}(\nu, \Sigma^{-1})$  (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution  $W_1(\nu, 1)$  collapses to the  $\chi^2(\nu)$  distribution.

The algorithm [2] implemented by the *rvs* method may produce numerically singular matrices with  $p-1 < \nu < p$ ; the user may wish to check for this condition and generate replacement samples as necessary.

New in version 0.16.0.

## References

[1], [2]

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2
>>> x = np.linspace(1e-5, 8, 100)
>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
array([0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.1929669])
>>> c = chi2.pdf(x, 3); c[:5]
array([0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.1929669])
>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

## Methods

|                                                        |                                                               |
|--------------------------------------------------------|---------------------------------------------------------------|
| <code>pdf(x, df, scale)</code>                         | Probability density function.                                 |
| <code>logpdf(x, df, scale)</code>                      | Log of the probability density function.                      |
| <code>rvs(df, scale, size=1, random_state=None)</code> | Draw random samples from a Wishart distribution.              |
| <code>entropy()</code>                                 | Compute the differential entropy of the Wishart distribution. |

### scipy.stats.invwishart

`scipy.stats.invwishart` = <scipy.stats.\_multivariate.invwishart\_gen object>  
An inverse Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

#### Parameters

**x** [array\_like] Quantiles, with the last axis of *x* denoting the components.  
**df** [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix  
**scale** [array\_like] Symmetric positive definite scale matrix of the distribution  
**random\_state** [{None, int, `numpy.random.Generator`,  
`numpy.random.RandomState`}, optional  
 If *seed* is None (or `np.random`), the `numpy.random.RandomState` singleton is used.  
 If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

**Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:**

```
rv = invwishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

[wishart](#)

## Notes

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted

$$W_p^{-1}(\nu, \Psi)$$

where  $\nu$  is the degrees of freedom and  $\Psi$  is the  $p \times p$  scale matrix.

The probability density function for `invwishart` has support over positive definite matrices  $S$ ; if  $S \sim W_p^{-1}(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|\Sigma|^{\frac{\nu}{2}}}{2^{\frac{\nu p}{2}} |S|^{\frac{\nu+p+1}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-\text{tr}(\Sigma S^{-1})/2)$$

If  $S \sim W_p^{-1}(\nu, \Psi)$  (inverse Wishart) then  $S^{-1} \sim W_p(\nu, \Psi^{-1})$  (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution  $W_1(\nu, 1)$  collapses to the inverse Gamma distribution with parameters shape =  $\frac{\nu}{2}$  and scale =  $\frac{1}{2}$ .

New in version 0.16.0.

## References

[1], [2]

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import invwishart, invgamma
>>> x = np.linspace(0.01, 1, 100)
>>> iw = invwishart.pdf(x, df=6, scale=1)
>>> iw[:3]
array([1.20546865e-15, 5.42497807e-06, 4.45813929e-03])
>>> ig = invgamma.pdf(x, 6/2., scale=1./2)
>>> ig[:3]
array([1.20546865e-15, 5.42497807e-06, 4.45813929e-03])
>>> plt.plot(x, iw)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

## Methods

|                                                        |                                                           |
|--------------------------------------------------------|-----------------------------------------------------------|
| <code>pdf(x, df, scale)</code>                         | Probability density function.                             |
| <code>logpdf(x, df, scale)</code>                      | Log of the probability density function.                  |
| <code>rvs(df, scale, size=1, random_state=None)</code> | Draw random samples from an inverse Wishart distribution. |

### `scipy.stats.multinomial`

`scipy.stats.multinomial` = <`scipy.stats._multivariate.multinomial_gen` object>  
 A multinomial random variable.

#### *Parameters*

**x** [array\_like] Quantiles, with the last axis of  $x$  denoting the components.  
**n** [int] Number of trials  
**p** [array\_like] Probability of a trial falling into each category; should sum to 1  
**random\_state** [{None, int, `numpy.random.Generator`,] `numpy.random.RandomState`}, optional  
 If *seed* is None (or `np.random`), the `numpy.random.RandomState` singleton is used.  
 If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

**See also:**

#### `scipy.stats.binom`

The binomial distribution.

#### `numpy.random.Generator.multinomial`

Sampling from the multinomial distribution.

#### `scipy.stats.multivariate_hypergeom`

The multivariate hypergeometric distribution.

## Notes

$n$  should be a positive integer. Each element of  $p$  should be in the interval  $[0, 1]$  and the elements should sum to 1. If they do not sum to 1, the last element of the  $p$  array is not used and is replaced with the remaining probability left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the  $n$  and  $p$  parameters, returning a “frozen” multinomial random variable:

The probability mass function for *multinomial* is

$$f(x) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k},$$

supported on  $x = (x_1, \dots, x_k)$  where each  $x_i$  is a nonnegative integer and their sum is  $n$ .

New in version 0.19.0.

## Examples

```
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [0.3, 0.2, 0.5])
>>> rv.pmf([1, 3, 4])
0.0420000000000000072
```

The multinomial distribution for  $k = 2$  is identical to the corresponding binomial distribution (tiny numerical differences notwithstanding):

```
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[0.4, 0.6])
0.290303999999999973
>>> binom.pmf(3, 7, 0.4)
0.290304000000000012
```

The functions `pmf`, `logpmf`, `entropy`, and `cov` support broadcasting, under the convention that the vector parameters ( $x$  and  $p$ ) are interpreted as if each row along the last axis is a single object. For instance:

```
>>> multinomial.pmf([[3, 4], [3, 5]], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```

Here, `x.shape == (2, 2)`, `n.shape == (2,)`, and `p.shape == (2,)`, but following the rules mentioned above they behave as if the rows `[3, 4]` and `[3, 5]` in `x` and `[.3, .7]` in `p` were a single object, and as if we had `x.shape = (2,)`, `n.shape = (2,)`, and `p.shape = ()`. To obtain the individual elements without broadcasting, we would do this:

```
>>> multinomial.pmf([3, 4], n=7, p=[.3, .7])
0.2268945
>>> multinomial.pmf([3, 5], 8, p=[.3, .7])
0.25412184
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `p.shape[-1]`. For example:

```
>>> multinomial.cov([4, 5], [[.3, .7], [.4, .6]])
array([[[0.84, -0.84],
```

(continues on next page)

(continued from previous page)

```

 [-0.84, 0.84]],
 [[1.2 , -1.2],
 [-1.2 , 1.2]]])

```

In this example, `n.shape == (2,)` and `p.shape == (2, 2)`, and following the rules above, these broadcast as if `p.shape == (2,)`. Thus the result should also be of shape `(2,)`, but since each output is a  $2 \times 2$  matrix, the result in fact has shape `(2, 2, 2)`, where `result[0]` is equal to `multinomial.cov(n=4, p=[.3, .7])` and `result[1]` is equal to `multinomial.cov(n=5, p=[.4, .6])`.

## Methods

|                                                   |                                                                |
|---------------------------------------------------|----------------------------------------------------------------|
| <code>pmf(x, n, p)</code>                         | Probability mass function.                                     |
| <code>logpmf(x, n, p)</code>                      | Log of the probability mass function.                          |
| <code>rvs(n, p, size=1, random_state=None)</code> | Draw random samples from a multinomial distribution.           |
| <code>entropy(n, p)</code>                        | Compute the entropy of the multinomial distribution.           |
| <code>cov(n, p)</code>                            | Compute the covariance matrix of the multinomial distribution. |

## scipy.stats.special\_ortho\_group

`scipy.stats.special_ortho_group` = <`scipy.stats._multivariate.special_ortho_group_gen` object>  
A matrix-valued SO(N) random variable.

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)).

The `dim` keyword specifies the dimension N.

### Parameters

**dim** [scalar] Dimension of matrices

See also:

`ortho_group`, `scipy.spatial.transform.Rotation.random`

## Notes

This class is wrapping the `random_rot` code from the MDP Toolkit, <https://github.com/mdp-toolkit/mdp-toolkit>

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)). The algorithm is described in the paper Stewart, G.W., “The efficient generation of random orthogonal matrices with an application to condition estimators”, SIAM Journal on Numerical Analysis, 17(3), pp. 403-409, 1980. For more information see [https://en.wikipedia.org/wiki/Orthogonal\\_matrix#Randomization](https://en.wikipedia.org/wiki/Orthogonal_matrix#Randomization)

See also the similar `ortho_group`. For a random rotation in three dimensions, see `scipy.spatial.transform.Rotation.random`.

## Examples

```
>>> from scipy.stats import special_ortho_group
>>> x = special_ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
 [1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
 [-2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> scipy.linalg.det(x)
1.0
```

This generates one random matrix from SO(3). It is orthogonal and has a determinant of 1.

## Methods

|                                                       |                                 |
|-------------------------------------------------------|---------------------------------|
| <code>rvs(dim=None, size=1, random_state=None)</code> | Draw random samples from SO(N). |
|-------------------------------------------------------|---------------------------------|

## scipy.stats.ortho\_group

`scipy.stats.ortho_group` = <scipy.stats.\_multivariate.ortho\_group\_gen object>  
A matrix-valued O(N) random variable.

Return a random orthogonal matrix, drawn from the O(N) Haar distribution (the only uniform distribution on O(N)).

The *dim* keyword specifies the dimension N.

### Parameters

**dim** [scalar] Dimension of matrices

## Notes

This class is closely related to `special_ortho_group`.

Some care is taken to avoid numerical error, as per the paper by Mezzadri.

## References

[1]

## Examples

```
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
 [1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
 [-2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from  $O(3)$ . It is orthogonal and has a determinant of +1 or -1.

## Methods

|                                                       |                                   |
|-------------------------------------------------------|-----------------------------------|
| <code>rvs(dim=None, size=1, random_state=None)</code> | Draw random samples from $O(N)$ . |
|-------------------------------------------------------|-----------------------------------|

## scipy.stats.unitary\_group

`scipy.stats.unitary_group` = <scipy.stats.\_multivariate.unitary\_group\_gen object>  
A matrix-valued  $U(N)$  random variable.

Return a random unitary matrix.

The *dim* keyword specifies the dimension  $N$ .

### Parameters

**dim** [scalar] Dimension of matrices

## Notes

This class is similar to `ortho_group`.

## References

[1]

## Examples

```
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(3)
```

```
>>> np.dot(x, x.conj().T)
array([[1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
 [1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
 [-2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

This generates one random matrix from  $U(3)$ . The dot product confirms that it is unitary up to machine precision.

## Methods

|                                                       |                                   |
|-------------------------------------------------------|-----------------------------------|
| <code>rvs(dim=None, size=1, random_state=None)</code> | Draw random samples from $U(N)$ . |
|-------------------------------------------------------|-----------------------------------|

## scipy.stats.random\_correlation

`scipy.stats.random_correlation = <scipy.stats._multivariate.random_correlation_gen object>`  
 A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The *eigs* keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

### Parameters

**eigs** [1d ndarray] Eigenvalues of correlation matrix.

## Notes

Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single  $O(N)$  similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

## References

[1]

## Examples

```
>>> from scipy.stats import random_correlation
>>> rng = np.random.default_rng()
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5), random_state=rng)
>>> x
array([[1. , -0.07198934, -0.20411041, -0.24385796],
 [-0.07198934, 1. , 0.12968613, -0.29471382],
 [-0.20411041, 0.12968613, 1. , 0.2828693],
 [-0.24385796, -0.29471382, 0.2828693 , 1.]])
```

(continues on next page)

(continued from previous page)

```
>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([0.5, 0.8, 1.2, 1.5])
```

## Methods

```
``rvs(eigs=None, random_state=None)`` Draw random correlation matrices, all with eigenvalues eigs.
```

## scipy.stats.multivariate\_t

`scipy.stats.multivariate_t` = <`scipy.stats._multivariate.multivariate_t_gen` object>  
A multivariate t-distributed random variable.

The *loc* parameter specifies the location. The *shape* parameter specifies the positive semidefinite shape matrix. The *df* parameter specifies the degrees of freedom.

In addition to calling the methods below, the object itself may be called as a function to fix the location, shape matrix, and degrees of freedom parameters, returning a “frozen” multivariate t-distribution random.

### Parameters

**x** [array\_like] Quantiles, with the last axis of *x* denoting the components.  
**loc** [array\_like, optional] Location of the distribution. (default 0)  
**shape** [array\_like, optional] Positive semidefinite matrix of the distribution. (default 1)  
**df** [float, optional] Degrees of freedom of the distribution; must be greater than zero. If `np.inf` then results are multivariate normal. The default is 1.  
**allow\_singular** [bool, optional] Whether to allow a singular matrix. (default `False`)  
**random\_state** [{None, int, `numpy.random.Generator`, `numpy.random.RandomState`}, optional]  
 If *seed* is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

## Notes

Setting the parameter *loc* to `None` is equivalent to having *loc* be the zero-vector. The parameter *shape* can be a scalar, in which case the shape matrix is the identity times that value, a vector of diagonal entries for the shape matrix, or a two-dimensional array\_like. The matrix *shape* must be a (symmetric) positive semidefinite matrix. The determinant and inverse of *shape* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *shape* does not need to have full rank.

The probability density function for *multivariate\_t* is

$$f(x) = \frac{\Gamma(\nu + p)/2}{\Gamma(\nu/2)\nu^{p/2}\pi^{p/2}|\Sigma|^{1/2}} \exp \left[ 1 + \frac{1}{\nu}(\mathbf{x} - \boldsymbol{\mu})^\top \Sigma^{-1}(\mathbf{x} - \boldsymbol{\mu}) \right]^{-(\nu+p)/2},$$

where *p* is the dimension of **x**, **μ** is the *p*-dimensional location, **Σ** the *p* × *p*-dimensional shape matrix, and *ν* is the degrees of freedom.

New in version 1.6.0.

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_t
>>> x, y = np.mgrid[-1:3:.01, -2:1.5:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_t([1.0, -0.5], [[2.1, 0.3], [0.3, 1.5]], df=2)
>>> fig, ax = plt.subplots(1, 1)
>>> ax.set_aspect('equal')
>>> plt.contourf(x, y, rv.pdf(pos))
```

## Methods

|                                                                       |                                                         |
|-----------------------------------------------------------------------|---------------------------------------------------------|
| <code>pdf(x, loc=None, shape=1, df=1, allow_singular=False)</code>    | Probability density function.                           |
| <code>logpdf(x, loc=None, shape=1, df=1, allow_singular=False)</code> | Log of the probability density function.                |
| <code>rvs(loc=None, shape=1, df=1, size=1, random_state=None)</code>  | Draw random samples from a multivariate t-distribution. |

## scipy.stats.multivariate\_hypergeom

`scipy.stats.multivariate_hypergeom = <scipy.stats._multivariate.multivariate_hypergeom_gen`  
 A multivariate hypergeometric random variable.

### Parameters

- m** [array\_like] The number of each type of object in the population. That is,  $m[i]$  is the number of objects of type  $i$ .
- n** [array\_like] The number of samples taken from the population.
- random\_state** [{None, int, numpy.random.Generator,}]

`numpy.random.RandomState`}, optional  
 If `seed` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used.  
 If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

**See also:**

`scipy.stats.hypergeom`

The hypergeometric distribution.

`scipy.stats.multinomial`

The multinomial distribution.

## Notes

$m$  must be an array of positive integers. If the quantile  $i$  contains values out of the range  $[0, m_i]$  where  $m_i$  is the number of objects of type  $i$  in the population or if the parameters are inconsistent with one another (e.g. `x.sum() != n`), methods return the appropriate value (e.g. 0 for pmf). If  $m$  or  $n$  contain negative values, the result will contain `nan` there.

The probability mass function for `multivariate_hypergeom` is

$$P(X_1 = x_1, X_2 = x_2, \dots, X_k = x_k) = \frac{\binom{m_1}{x_1} \binom{m_2}{x_2} \dots \binom{m_k}{x_k}}{\binom{M}{n}},$$

$$(x_1, x_2, \dots, x_k) \in \mathbb{N}^k \text{ with } \sum_{i=1}^k x_i = n$$

where  $m_i$  are the number of objects of type  $i$ ,  $M$  is the total number of objects in the population (sum of all the  $m_i$ ), and  $n$  is the size of the sample to be taken from the population.

New in version 1.6.0.

## References

[1], [2]

## Examples

To evaluate the probability mass function of the multivariate hypergeometric distribution, with a dichotomous population of size 10 and 20, at a sample of size 12 with 8 objects of the first type and 4 objects of the second type, use:

```
>>> from scipy.stats import multivariate_hypergeom
>>> multivariate_hypergeom.pmf(x=[8, 4], m=[10, 20], n=12)
0.0025207176631464523
```

The `multivariate_hypergeom` distribution is identical to the corresponding `hypergeom` distribution (tiny numerical differences notwithstanding) when only two types (good and bad) of objects are present in the population as in the example above. Consider another example for a comparison with the hypergeometric distribution:

```
>>> from scipy.stats import hypergeom
>>> multivariate_hypergeom.pmf(x=[3, 1], m=[10, 5], n=4)
0.4395604395604395
>>> hypergeom.pmf(k=3, M=15, n=4, N=10)
0.43956043956044005
```

The functions `pmf`, `logpmf`, `mean`, `var`, `cov`, and `rvs` support broadcasting, under the convention that the vector parameters (`x`, `m`, and `n`) are interpreted as if each row along the last axis is a single object. For instance, we can combine the previous two calls to `multivariate_hypergeom` as

```
>>> multivariate_hypergeom.pmf(x=[[8, 4], [3, 1]], m=[[10, 20], [10, 5]],
... n=[12, 4])
array([0.00252072, 0.43956044])
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `m.shape[-1]`. For example:

```
>>> multivariate_hypergeom.cov(m=[[7, 9], [10, 15]], n=[8, 12])
array([[[1.05, -1.05],
 [-1.05, 1.05]],
 [[1.56, -1.56],
 [-1.56, 1.56]]])
```

That is, `result[0]` is equal to `multivariate_hypergeom.cov(m=[7, 9], n=8)` and `result[1]` is equal to `multivariate_hypergeom.cov(m=[10, 15], n=12)`.

Alternatively, the object may be called (as a function) to fix the `m` and `n` parameters, returning a “frozen” multivariate hypergeometric random variable.

```
>>> rv = multivariate_hypergeom(m=[10, 20], n=12)
>>> rv.pmf(x=[8, 4])
0.0025207176631464523
```

| <i>zipf</i>                  | A Zipf (Zeta) discrete random variable.                          |
| <i>zipfian</i>               | A Zipfian discrete random variable.                              |

## scipy.stats.bernoulli

`scipy.stats.bernoulli` = <`scipy.stats._discrete_distns.bernoulli_gen` object>  
 A Bernoulli discrete random variable.

As an instance of the *rv\_discrete* class, *bernoulli* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for *bernoulli* is:

$$f(k) = \begin{cases} 1 - p & \text{if } k = 0 \\ p & \text{if } k = 1 \end{cases}$$

for  $k$  in  $\{0, 1\}$ ,  $0 \leq p \leq 1$

*bernoulli* takes  $p$  as shape parameter, where  $p$  is the probability of a single success and  $1 - p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `bernoulli.pmf(k, p, loc)` is identically equivalent to `bernoulli.pmf(k - loc, p)`.

## Examples

```
>>> from scipy.stats import bernoulli
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p = 0.3
>>> mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(bernoulli.ppf(0.01, p),
... bernoulli.ppf(0.99, p))
>>> ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
>>> ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = bernoulli(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = bernoulli.cdf(x, p)
>>> np.allclose(x, bernoulli.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = bernoulli.rvs(p, size=1000)
```

## Methods

|                                                                                  |                                                                                                  |
|----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <code>rvs(p, loc=0, size=1, random_state=None)</code>                            | Random variates.                                                                                 |
| <code>pmf(k, p, loc=0)</code>                                                    | Probability mass function.                                                                       |
| <code>logpmf(k, p, loc=0)</code>                                                 | Log of the probability mass function.                                                            |
| <code>cdf(k, p, loc=0)</code>                                                    | Cumulative distribution function.                                                                |
| <code>logcdf(k, p, loc=0)</code>                                                 | Log of the cumulative distribution function.                                                     |
| <code>sf(k, p, loc=0)</code>                                                     | Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate). |
| <code>logsf(k, p, loc=0)</code>                                                  | Log of the survival function.                                                                    |
| <code>ppf(q, p, loc=0)</code>                                                    | Percent point function (inverse of <i>cdf</i> — percentiles).                                    |
| <code>isf(q, p, loc=0)</code>                                                    | Inverse survival function (inverse of <i>sf</i> ).                                               |
| <code>stats(p, loc=0, moments='mv')</code>                                       | Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').                                       |
| <code>entropy(p, loc=0)</code>                                                   | (Differential) entropy of the RV.                                                                |
| <code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code> | Expected value of a function (of one argument) with respect to the distribution.                 |
| <code>median(p, loc=0)</code>                                                    | Median of the distribution.                                                                      |
| <code>mean(p, loc=0)</code>                                                      | Mean of the distribution.                                                                        |
| <code>var(p, loc=0)</code>                                                       | Variance of the distribution.                                                                    |
| <code>std(p, loc=0)</code>                                                       | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, p, loc=0)</code>                                           | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution            |

## scipy.stats.betabinom

`scipy.stats.betabinom` = <scipy.stats.\_discrete\_distns.betabinom\_gen object>

A beta-binomial discrete random variable.

As an instance of the *rv\_discrete* class, *betabinom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[beta](#), [binom](#)

## Notes

The beta-binomial distribution is a binomial distribution with a probability of success *p* that follows a beta distribution.

The probability mass function for *betabinom* is:

$$f(k) = \binom{n}{k} \frac{B(k+a, n-k+b)}{B(a, b)}$$

for  $k \in \{0, 1, \dots, n\}$ ,  $n \geq 0$ ,  $a > 0$ ,  $b > 0$ , where  $B(a, b)$  is the beta function.

*betabinom* takes *n*, *a*, and *b* as shape parameters.

## References

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `betabinom.pmf(k, n, a, b, loc)` is identically equivalent to `betabinom.pmf(k - loc, n, a, b)`.

New in version 1.4.0.

[1]

## Examples

```
>>> from scipy.stats import betabinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n, a, b = 5, 2.3, 0.63
>>> mean, var, skew, kurt = betabinom.stats(n, a, b, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(betabinom.ppf(0.01, n, a, b),
... betabinom.ppf(0.99, n, a, b))
>>> ax.plot(x, betabinom.pmf(x, n, a, b), 'bo', ms=8, label='betabinom pmf
→')
>>> ax.vlines(x, 0, betabinom.pmf(x, n, a, b), colors='b', lw=5, alpha=0.
→5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = betabinom(n, a, b)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = betabinom.cdf(x, n, a, b)
>>> np.allclose(x, betabinom.ppf(prob, n, a, b))
True
```

Generate random numbers:

```
>>> r = betabinom.rvs(n, a, b, size=1000)
```

| <code>interval(alpha, n, a, b, loc=0)</code>                                          | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.binom

`scipy.stats.binom` = <`scipy.stats._discrete_distns.binom_gen` object>

A binomial discrete random variable.

As an instance of the `rv_discrete` class, `binom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[hypergeom](#), [nbinom](#), [nhypergeom](#)

### Notes

The probability mass function for `binom` is:

$$f(k) = \binom{n}{k} p^k (1-p)^{n-k}$$

for  $k \in \{0, 1, \dots, n\}$ ,  $0 \leq p \leq 1$

`binom` takes  $n$  and  $p$  as shape parameters, where  $p$  is the probability of a single success and  $1-p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `binom.pmf(k, n, p, loc)` is identically equivalent to `binom.pmf(k - loc, n, p)`.

### Examples

```
>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

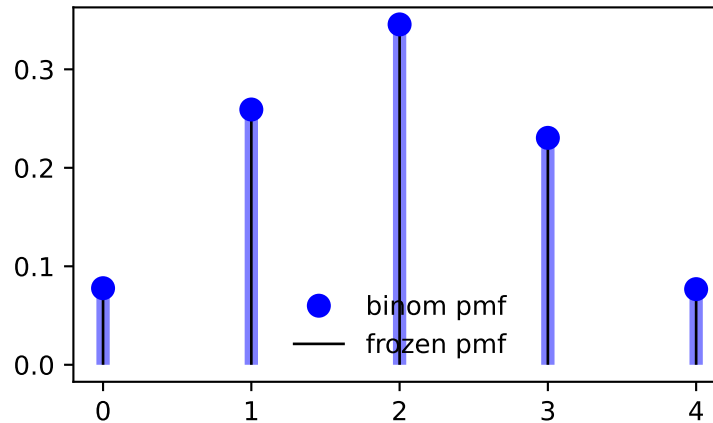

```
>>> x = np.arange(binom.ppf(0.01, n, p),
... binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='--', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of `cdf` and `ppf`:

```
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = binom.rvs(n, p, size=1000)
```

## Methods

| <code>interval(alpha, n, p, loc=0)</code>                                          | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.boltzmann

`scipy.stats.boltzmann` = <`scipy.stats._discrete_distns.boltzmann_gen` object>  
 A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the `rv_discrete` class, `boltzmann` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `boltzmann` is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k) / (1 - \exp(-\lambda N))$$

for  $k = 0, \dots, N - 1$ .

`boltzmann` takes  $\lambda > 0$  and  $N > 0$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `boltzmann.pmf(k, lambda_, N, loc)` is identically equivalent to `boltzmann.pmf(k - loc, lambda_, N)`.

### Examples

```
>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N),
... boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann_
→pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5,
→alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = boltzmann(lambda_, N)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = boltzmann.cdf(x, lambda_, N)
>>> np.allclose(x, boltzmann.ppf(prob, lambda_, N))
True
```

Generate random numbers:

```
>>> r = boltzmann.rvs(lambda_, N, size=1000)
```

## Methods

|                                                                                          |                                                                                                  |
|------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <code>rvs(lambda_, N, loc=0, size=1, random_state=None)</code>                           | Random variates.                                                                                 |
| <code>pmf(k, lambda_, N, loc=0)</code>                                                   | Probability mass function.                                                                       |
| <code>logpmf(k, lambda_, N, loc=0)</code>                                                | Log of the probability mass function.                                                            |
| <code>cdf(k, lambda_, N, loc=0)</code>                                                   | Cumulative distribution function.                                                                |
| <code>logcdf(k, lambda_, N, loc=0)</code>                                                | Log of the cumulative distribution function.                                                     |
| <code>sf(k, lambda_, N, loc=0)</code>                                                    | Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate). |
| <code>logsf(k, lambda_, N, loc=0)</code>                                                 | Log of the survival function.                                                                    |
| <code>ppf(q, lambda_, N, loc=0)</code>                                                   | Percent point function (inverse of <i>cdf</i> — percentiles).                                    |
| <code>isf(q, lambda_, N, loc=0)</code>                                                   | Inverse survival function (inverse of <i>sf</i> ).                                               |
| <code>stats(lambda_, N, loc=0, moments='mv')</code>                                      | Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').                                       |
| <code>entropy(lambda_, N, loc=0)</code>                                                  | (Differential) entropy of the RV.                                                                |
| <code>expect(func, args=(lambda_, N), loc=0, lb=None, ub=None, conditional=False)</code> | Expected value of a function (of one argument) with respect to the distribution.                 |
| <code>median(lambda_, N, loc=0)</code>                                                   | Median of the distribution.                                                                      |
| <code>mean(lambda_, N, loc=0)</code>                                                     | Mean of the distribution.                                                                        |
| <code>var(lambda_, N, loc=0)</code>                                                      | Variance of the distribution.                                                                    |
| <code>std(lambda_, N, loc=0)</code>                                                      | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, lambda_, N, loc=0)</code>                                          | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.dlaplace

`scipy.stats.dlaplace = <scipy.stats._discrete_distns.dlaplace_gen object>`

A Laplacian discrete random variable.

As an instance of the *rv\_discrete* class, *dlaplace* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *dlaplace* is:

$$f(k) = \tanh(a/2) \exp(-a|k|)$$

for integers  $k$  and  $a > 0$ .

*dlaplace* takes  $a$  as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `dlaplace.pmf(k, a, loc)` is identically equivalent to `dlaplace.pmf(k - loc, a)`.

## Examples

```
>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(dlaplace.ppf(0.01, a),
... dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = dlaplace.cdf(x, a)
>>> np.allclose(x, dlaplace.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = dlaplace.rvs(a, size=1000)
```

## Methods

|                                                                                  |                                                                                                  |

| <code>mean(a, loc=0)</code>                                                      | Mean of the distribution.                                                                        |
| <code>var(a, loc=0)</code>                                                       | Variance of the distribution.                                                                    |
| <code>std(a, loc=0)</code>                                                       | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, a, loc=0)</code>                                           | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.geom

`scipy.stats.geom` = <`scipy.stats._discrete_distns.geom_gen` object>

A geometric discrete random variable.

As an instance of the *rv\_discrete* class, *geom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[planck](#)

## Notes

The probability mass function for *geom* is:

$$f(k) = (1 - p)^{k-1}p$$

for  $k \geq 1, 0 < p \leq 1$

*geom* takes *p* as shape parameter, where *p* is the probability of a single success and  $1 - p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `geom.pmf(k, p, loc)` is identically equivalent to `geom.pmf(k - loc, p)`.

## Examples

```
>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(geom.ppf(0.01, p),
... geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='--', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = geom.rvs(p, size=1000)
```

## Methods

| <code>mean(p, loc=0)</code>                                                      | Mean of the distribution.                                                                        |
| <code>var(p, loc=0)</code>                                                       | Variance of the distribution.                                                                    |
| <code>std(p, loc=0)</code>                                                       | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, p, loc=0)</code>                                           | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.hypergeom

`scipy.stats.hypergeom` = <scipy.stats.\_discrete\_distns.hypergeom\_gen object>

A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin.  $M$  is the total number of objects,  $n$  is total number of Type I objects. The random variate represents the number of Type I objects in  $N$  drawn without replacement from the total population.

As an instance of the *rv\_discrete* class, *hypergeom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[nhypergeom](#), [binom](#), [nbinom](#)

## Notes

The symbols used to denote the shape parameters ( $M$ ,  $n$ , and  $N$ ) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$p(k, M, n, N) = \frac{\binom{n}{k} \binom{M-n}{N-k}}{\binom{M}{N}}$$

for  $k \in [\max(0, N - M + n), \min(n, N)]$ , where the binomial coefficients are defined as,

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `hypergeom.pmf(k, M, n, N, loc)` is identically equivalent to `hypergeom.pmf(k - loc, M, n, N)`.

## Examples

```
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```
>>> [M, n, N] = [20, 7, 12]
>>> rv = hypergeom(M, n, N)
>>> x = np.arange(0, n+1)
>>> pmf_dogs = rv.pmf(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group of chosen animals')
>>> ax.set_ylabel('hypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use `hypergeom` methods directly. To for example obtain the cumulative distribution function, use:

```
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```
>>> R = hypergeom.rvs(M, n, N, size=10)
```

## Methods

| <code>interval(alpha, M, n, N, loc=0)</code>                                          | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.logser

`scipy.stats.logser` = <`scipy.stats._discrete_distns.logser_gen` object>

A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the `rv_discrete` class, `logser` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for `logser` is:

$$f(k) = -\frac{p^k}{k \log(1-p)}$$

for  $k \geq 1, 0 < p < 1$

`logser` takes  $p$  as shape parameter, where  $p$  is the probability of a single success and  $1 - p$  is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

### Examples

```
>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(logser.ppf(0.01, p),
... logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = logser.rvs(p, size=1000)
```

## Methods

|                                                                                  |                                                                                                  |

| <code>interval(alpha, p, loc=0)</code>                                           | Endpoints of the range that contains fraction $\alpha$ [0, 1] of the distribution                |

## scipy.stats.nbinom

`scipy.stats.nbinom` = <`scipy.stats._discrete_distns.nbinom_gen` object>

A negative binomial discrete random variable.

As an instance of the `rv_discrete` class, `nbinom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[hypergeom](#), [binom](#), [nhypergeom](#)

### Notes

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for `nbinom` is:

$$f(k) = \binom{k+n-1}{n-1} p^n (1-p)^k$$

for  $k \geq 0, 0 < p \leq 1$

`nbinom` takes  $n$  and  $p$  as shape parameters where  $n$  is the number of successes,  $p$  is the probability of a single success, and  $1 - p$  is the probability of a single failure.

Another common parameterization of the negative binomial distribution is in terms of the mean number of failures  $\mu$  to achieve  $n$  successes. The mean  $\mu$  is related to the probability of success as

$$p = \frac{n}{n + \mu}$$

The number of successes  $n$  may also be specified in terms of a “dispersion”, “heterogeneity”, or “aggregation” parameter  $\alpha$ , which relates the mean  $\mu$  to the variance  $\sigma^2$ , e.g.  $\sigma^2 = \mu + \alpha\mu^2$ . Regardless of the convention used for  $\alpha$ ,

$$p = \frac{\mu}{\sigma^2}$$
$$n = \frac{\mu^2}{\sigma^2 - \mu}$$

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nbinom.pmf(k, n, p, loc)` is identically equivalent to `nbinom.pmf(k - loc, n, p)`.

### Examples

```
>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n, p = 5, 0.5
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(nbinom.ppf(0.01, n, p),
... nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = nbinom.rvs(n, p, size=1000)
```

## Methods

| <code>interval(alpha, n, p, loc=0)</code>                                          | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.nchypergeom\_fisher

`scipy.stats.nchypergeom_fisher = <scipy.stats._discrete_distns.nchypergeom_fisher_gen object>`

A Fisher's noncentral hypergeometric discrete random variable.

Fisher's noncentral hypergeometric distribution models drawing objects of two types from a bin.  $M$  is the total number of objects,  $n$  is the number of Type I objects, and *odds* is the odds ratio: the odds of selecting a Type I object rather than a Type II object when there is only one object of each type. The random variate represents the number of Type I objects drawn if we take a handful of objects from the bin at once and find out afterwards that we took  $N$  objects.

As an instance of the *rv\_discrete* class, *nchypergeom\_fisher* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

Let mathematical symbols  $N$ ,  $n$ , and  $M$  correspond with parameters  $N$ ,  $n$ , and  $M$  (respectively) as defined above.

The probability mass function is defined as

$$p(x; M, n, N, \omega) = \frac{\binom{n}{x} \binom{M-n}{N-x} \omega^x}{P_0},$$

for  $x \in [x_l, x_u]$ ,  $M \in \mathbb{N}$ ,  $n \in [0, M]$ ,  $N \in [0, M]$ ,  $\omega > 0$ , where  $x_l = \max(0, N - (M - n))$ ,  $x_u = \min(N, n)$ ,

$$P_0 = \sum_{y=x_l}^{x_u} \binom{n}{y} \binom{M-n}{N-y} \omega^y,$$

and the binomial coefficients are defined as

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

`nhypergeom_fisher` uses the BiasedUrn package by Agner Fog with permission for it to be distributed under SciPy's license.

The symbols used to denote the shape parameters ( $N$ ,  $n$ , and  $M$ ) are not universally accepted; they are chosen for consistency with `hypergeom`.

Note that Fisher's noncentral hypergeometric distribution is distinct from Wallenius' noncentral hypergeometric distribution, which models drawing a pre-determined  $N$  objects from a bin one by one. When the odds ratio is unity, however, both distributions reduce to the ordinary hypergeometric distribution.

The probability mass function above is defined in the "standardized" form. To shift distribution use the `loc` parameter. Specifically, `nhypergeom_fisher.pmf(k, M, n, N, odds, loc)` is identically equivalent to `nhypergeom_fisher.pmf(k - loc, M, n, N, odds)`.

## References

[1], [2]

## Examples

```
>>> from scipy.stats import nhypergeom_fisher
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> M, n, N, odds = 140, 80, 60, 0.5
>>> mean, var, skew, kurt = nhypergeom_fisher.stats(M, n, N, odds,
↳ moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(nhypergeom_fisher.ppf(0.01, M, n, N, odds),
... nhypergeom_fisher.ppf(0.99, M, n, N, odds))
>>> ax.plot(x, nhypergeom_fisher.pmf(x, M, n, N, odds), 'bo', ms=8,
↳ label='nhypergeom_fisher pmf')
>>> ax.vlines(x, 0, nhypergeom_fisher.pmf(x, M, n, N, odds), colors='b',
↳ lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = nhypergeom_fisher(M, n, N, odds)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = nchypergeom_fisher.cdf(x, M, n, N, odds)
>>> np.allclose(x, nchypergeom_fisher.ppf(prob, M, n, N, odds))
True
```

Generate random numbers:

```
>>> r = nchypergeom_fisher.rvs(M, n, N, odds, size=1000)
```

## Notes

Let mathematical symbols  $N$ ,  $n$ , and  $M$  correspond with parameters  $N$ ,  $n$ , and  $M$  (respectively) as defined above.

The probability mass function is defined as

$$p(x; N, n, M) = \binom{n}{x} \binom{M-n}{N-x} \int_0^1 (1-t^{\omega/D})^x (1-t^{1/D})^{N-x} dt$$

for  $x \in [x_l, x_u]$ ,  $M \in \mathbb{N}$ ,  $n \in [0, M]$ ,  $N \in [0, M]$ ,  $\omega > 0$ , where  $x_l = \max(0, N - (M - n))$ ,  $x_u = \min(N, n)$ ,

$$D = \omega(n - x) + ((M - n) - (N - x)),$$

and the binomial coefficients are defined as

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

`nchypergeom_wallenius` uses the BiasedUrn package by Agner Fog with permission for it to be distributed under SciPy's license.

The symbols used to denote the shape parameters ( $N$ ,  $n$ , and  $M$ ) are not universally accepted; they are chosen for consistency with `hypergeom`.

Note that Wallenius' noncentral hypergeometric distribution is distinct from Fisher's noncentral hypergeometric distribution, which models take a handful of objects from the bin at once, finding out afterwards that  $N$  objects were taken. When the odds ratio is unity, however, both distributions reduce to the ordinary hypergeometric distribution.

The probability mass function above is defined in the "standardized" form. To shift distribution use the `loc` parameter. Specifically, `nchypergeom_wallenius.pmf(k, M, n, N, odds, loc)` is identically equivalent to `nchypergeom_wallenius.pmf(k - loc, M, n, N, odds)`.

## scipy.stats.nhypergeom

`scipy.stats.nhypergeom = <scipy.stats._discrete_distns.nhypergeom_gen object>`

A negative hypergeometric discrete random variable.

Consider a box containing  $M$  balls:  $n$  red and  $M - n$  blue. We randomly sample balls from the box, one at a time and *without* replacement, until we have picked  $r$  blue balls. *nhypergeom* is the distribution of the number of red balls  $k$  we have picked.

As an instance of the *rv\_discrete* class, *nhypergeom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

[hypergeom](#), [binom](#), [nbinom](#)

## Notes

The symbols used to denote the shape parameters ( $M$ ,  $n$ , and  $r$ ) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$f(k; M, n, r) = \frac{\binom{k+r-1}{k} \binom{M-r-k}{n-k}}{\binom{M}{n}}$$

for  $k \in [0, n]$ ,  $n \in [0, M]$ ,  $r \in [0, M - n]$ , and the binomial coefficient is:

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

It is equivalent to observing  $k$  successes in  $k + r - 1$  samples with  $k + r$ 'th sample being a failure. The former can be modelled as a hypergeometric distribution. The probability of the latter is simply the number of failures remaining  $M - n - (r - 1)$  divided by the size of the remaining population  $M - (k + r - 1)$ . This relationship can be shown as:

$$NHG(k; M, n, r) = HG(k; M, n, k + r - 1) \frac{(M - n - (r - 1))}{(M - (k + r - 1))}$$

where  $NHG$  is probability mass function (PMF) of the negative hypergeometric distribution and  $HG$  is the PMF of the hypergeometric distribution.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nhypergeom.pmf(k, M, n, r, loc)` is identically equivalent to `nhypergeom.pmf(k - loc, M, n, r)`.

## References

[1], [2]

## Examples

```
>>> from scipy.stats import nhypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs (successes) in a sample with exactly 12 animals that aren't dogs (failures), we can initialize a frozen distribution and plot the probability mass function:

```
>>> M, n, r = [20, 7, 12]
>>> rv = nhypergeom(M, n, r)
>>> x = np.arange(0, n+2)
>>> pmf_dogs = rv.pmf(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group with given 12 failures')
>>> ax.set_ylabel('nhypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use `nhypergeom` methods directly. To for example obtain the probability mass function, use:

```
>>> prb = nhypergeom.pmf(x, M, n, r)
```

And to generate random numbers:

```
>>> R = nhypergeom.rvs(M, n, r, size=10)
```

To verify the relationship between *hypergeom* and *nhypergeom*, use:

```
>>> from scipy.stats import hypergeom, nhypergeom
>>> M, n, r = 45, 13, 8
>>> k = 6
>>> nhypergeom.pmf(k, M, n, r)
0.06180776620271643
>>> hypergeom.pmf(k, M, n, k+r-1) * (M - n - (r-1)) / (M - (k+r-1))
0.06180776620271644
```

| <code>interval(alpha, M, n, r, loc=0)</code>                                          | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.planck

`scipy.stats.planck = <scipy.stats._discrete_distns.planck_gen object>`

A Planck discrete exponential random variable.

As an instance of the *rv\_discrete* class, *planck* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

[geom](#)

## Notes

The probability mass function for *planck* is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k)$$

for  $k \geq 0$  and  $\lambda > 0$ .

*planck* takes  $\lambda$  as shape parameter. The Planck distribution can be written as a geometric distribution (*geom*) with  $p = 1 - \exp(-\lambda)$  shifted by  $\text{loc} = -1$ .

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `planck.pmf(k, lambda_, loc)` is identically equivalent to `planck.pmf(k - loc, lambda_)`.

## Examples

```
>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(planck.ppf(0.01, lambda_),
... planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))
True
```

Generate random numbers:

```
>>> r = planck.rvs(lambda_, size=1000)
```

## scipy.stats.poisson

`scipy.stats.poisson` = <scipy.stats.\_discrete\_distns.poisson\_gen object>

A Poisson discrete random variable.

As an instance of the *rv\_discrete* class, *poisson* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *poisson* is:

$$f(k) = \exp(-\mu) \frac{\mu^k}{k!}$$

for  $k \geq 0$ .

*poisson* takes  $\mu \geq 0$  as shape parameter. When  $\mu = 0$ , the *pmf* method returns 1.0 at quantile  $k = 0$ .

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `poisson.pmf(k, mu, loc)` is identically equivalent to `poisson.pmf(k - loc, mu)`.

## Examples

```
>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(poisson.ppf(0.01, mu),
... poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
>>> ax.vlines(x, 0, poisson.pmf(x, mu), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = poisson(mu)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='--', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:

```
>>> r = poisson.rvs(mu, size=1000)
```

## Methods

|                                                                                   |                                                                                                  |

## scipy.stats.randint

`scipy.stats.randint` = <`scipy.stats._discrete_distns.randint_gen` object>

A uniform discrete random variable.

As an instance of the *rv\_discrete* class, *randint* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *randint* is:

$$f(k) = \frac{1}{\text{high} - \text{low}}$$

for  $k \in \{\text{low}, \dots, \text{high} - 1\}$ .

*randint* takes *low* and *high* as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `randint.pmf(k, low, high, loc)` is identically equivalent to `randint.pmf(k - loc, low, high)`.

## Examples

```
>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> low, high = 7, 31
>>> mean, var, skew, kurt = randint.stats(low, high, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(randint.ppf(0.01, low, high),
... randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.
→5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = randint.cdf(x, low, high)
>>> np.allclose(x, randint.ppf(prob, low, high))
True
```

Generate random numbers:

```
>>> r = randint.rvs(low, high, size=1000)
```

## Methods

|                                                                                   |                                                                                                  |

## scipy.stats.skellam

`scipy.stats.skellam = <scipy.stats._discrete_distns.skellam_gen object>`

A Skellam discrete random variable.

As an instance of the *rv\_discrete* class, *skellam* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let  $k_1$  and  $k_2$  be two Poisson-distributed r.v. with expected values  $\lambda_1$  and  $\lambda_2$ . Then,  $k_1 - k_2$  follows a Skellam distribution with parameters  $\mu_1 = \lambda_1 - \rho\sqrt{\lambda_1\lambda_2}$  and  $\mu_2 = \lambda_2 - \rho\sqrt{\lambda_1\lambda_2}$ , where  $\rho$  is the correlation coefficient between  $k_1$  and  $k_2$ . If the two Poisson-distributed r.v. are independent then  $\rho = 0$ .

Parameters  $\mu_1$  and  $\mu_2$  must be strictly positive.

For details see: [https://en.wikipedia.org/wiki/Skellam\\_distribution](https://en.wikipedia.org/wiki/Skellam_distribution)

*skellam* takes  $\mu_1$  and  $\mu_2$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `skellam.pmf(k, mu1, mu2, loc)` is identically equivalent to `skellam.pmf(k - loc, mu1, mu2)`.

### Examples

```
>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2),
... skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

| <b>median(mu1, mu2, loc=0)</b>                                                   | Median of the distribution.                                                                      |
| <b>mean(mu1, mu2, loc=0)</b>                                                     | Mean of the distribution.                                                                        |
| <b>var(mu1, mu2, loc=0)</b>                                                      | Variance of the distribution.                                                                    |
| <b>std(mu1, mu2, loc=0)</b>                                                      | Standard deviation of the distribution.                                                          |
| <b>interval(alpha, mu1, mu2, loc=0)</b>                                          | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

## scipy.stats.yulesimon

`scipy.stats.yulesimon` = <`scipy.stats._discrete_distns.yulesimon_gen` object>

A Yule-Simon discrete random variable.

As an instance of the `rv_discrete` class, `yulesimon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability mass function for the `yulesimon` is:

$$f(k) = \alpha B(k, \alpha + 1)$$

for  $k = 1, 2, 3, \dots$ , where  $\alpha > 0$ . Here  $B$  refers to the `scipy.special.beta` function.

The sampling of random variates is based on pg 553, Section 6.3 of [1]. Our notation maps to the referenced logic via  $\alpha = a - 1$ .

For details see the wikipedia entry [2].

### References

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `yulesimon.pmf(k, alpha, loc)` is identically equivalent to `yulesimon.pmf(k - loc, alpha)`.

[1], [2]

### Examples

```
>>> from scipy.stats import yulesimon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> alpha = 11
>>> mean, var, skew, kurt = yulesimon.stats(alpha, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(yulesimon.ppf(0.01, alpha),
... yulesimon.ppf(0.99, alpha))
>>> ax.plot(x, yulesimon.pmf(x, alpha), 'bo', ms=8, label='yulesimon pmf')
>>> ax.vlines(x, 0, yulesimon.pmf(x, alpha), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = yulesimon(alpha)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = yulesimon.cdf(x, alpha)
>>> np.allclose(x, yulesimon.ppf(prob, alpha))
True
```

Generate random numbers:

```
>>> r = yulesimon.rvs(alpha, size=1000)
```

## Methods

|                                                                                      |                                                                                                  |

| <code>var(alpha, loc=0)</code>                                                       | Variance of the distribution.                                                                    |
| <code>std(alpha, loc=0)</code>                                                       | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, alpha, loc=0)</code>                                           | Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution            |

## scipy.stats.zipf

`scipy.stats.zipf = <scipy.stats._discrete_distns.zipf_gen object>`

A Zipf (Zeta) discrete random variable.

As an instance of the *rv\_discrete* class, *zipf* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[`zipfian`](#)

## Notes

The probability mass function for *zipf* is:

$$f(k, a) = \frac{1}{\zeta(a)k^a}$$

for  $k \geq 1, a > 1$ .

*zipf* takes  $a > 1$  as shape parameter.  $\zeta$  is the Riemann zeta function ([`scipy.special.zeta`](#))

The Zipf distribution is also known as the zeta distribution, which is a special case of the Zipfian distribution ([`zipfian`](#)).

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `zipf.pmf(k, a, loc)` is identically equivalent to `zipf.pmf(k - loc, a)`.

## References

[1]

## Examples

```
>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(zipf.ppf(0.01, a),
... zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = zipf.cdf(x, a)
>>> np.allclose(x, zipf.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = zipf.rvs(a, size=1000)
```

Confirm that *zipf* is the large *n* limit of *zipfian*.

```
>>> from scipy.stats import zipfian
>>> k = np.arange(11)
>>> np.allclose(zipf.pmf(k, a), zipfian.pmf(k, a, n=10000000))
True
```

## scipy.stats.zipfian

`scipy.stats.zipfian = <scipy.stats._discrete_distns.zipfian_gen object>`

A Zipfian discrete random variable.

As an instance of the *rv\_discrete* class, *zipfian* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[zipf](#)

## Notes

The probability mass function for *zipfian* is:

$$f(k, a, n) = \frac{1}{H_{n,a} k^a}$$

for  $k \in \{1, 2, \dots, n-1, n\}$ ,  $a \geq 0$ ,  $n \in \{1, 2, 3, \dots\}$ .

*zipfian* takes *a* and *n* as shape parameters.  $H_{n,a}$  is the  $n^{\text{th}}$  generalized harmonic number of order *a*.

The Zipfian distribution reduces to the Zipf (zeta) distribution as  $n \rightarrow \infty$ .

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `zipfian.pmf(k, a, n, loc)` is identically equivalent to `zipfian.pmf(k - loc, a, n)`.

## References

[1], [2]

## Examples

```
>>> from scipy.stats import zipfian
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, n = 1.25, 10
>>> mean, var, skew, kurt = zipfian.stats(a, n, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(zipfian.ppf(0.01, a, n),
... zipfian.ppf(0.99, a, n))
>>> ax.plot(x, zipfian.pmf(x, a, n), 'bo', ms=8, label='zipfian pmf')
>>> ax.vlines(x, 0, zipfian.pmf(x, a, n), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = zipfian(a, n)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = zipfian.cdf(x, a, n)
>>> np.allclose(x, zipfian.ppf(prob, a, n))
True
```

Generate random numbers:

```
>>> r = zipfian.rvs(a, n, size=1000)
```

Confirm that *zipfian* reduces to *zipf* for large  $n$ ,  $a > 1$ .

```
>>> from scipy.stats import zipf
>>> k = np.arange(11)
>>> np.allclose(zipfian.pmf(k, a=3.5, n=10000000), zipf.pmf(k, a=3.5))
True
```

## Methods

|                                                                                    |                                                                                                  |
|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <code>rvs(a, n, loc=0, size=1, random_state=None)</code>                           | Random variates.                                                                                 |
| <code>pmf(k, a, n, loc=0)</code>                                                   | Probability mass function.                                                                       |
| <code>logpmf(k, a, n, loc=0)</code>                                                | Log of the probability mass function.                                                            |
| <code>cdf(k, a, n, loc=0)</code>                                                   | Cumulative distribution function.                                                                |
| <code>logcdf(k, a, n, loc=0)</code>                                                | Log of the cumulative distribution function.                                                     |
| <code>sf(k, a, n, loc=0)</code>                                                    | Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate). |
| <code>logsf(k, a, n, loc=0)</code>                                                 | Log of the survival function.                                                                    |
| <code>ppf(q, a, n, loc=0)</code>                                                   | Percent point function (inverse of <i>cdf</i> — percentiles).                                    |
| <code>isf(q, a, n, loc=0)</code>                                                   | Inverse survival function (inverse of <i>sf</i> ).                                               |
| <code>stats(a, n, loc=0, moments='mv')</code>                                      | Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').                                       |
| <code>entropy(a, n, loc=0)</code>                                                  | (Differential) entropy of the RV.                                                                |
| <code>expect(func, args=(a, n), loc=0, lb=None, ub=None, conditional=False)</code> | Expected value of a function (of one argument) with respect to the distribution.                 |
| <code>median(a, n, loc=0)</code>                                                   | Median of the distribution.                                                                      |
| <code>mean(a, n, loc=0)</code>                                                     | Mean of the distribution.                                                                        |
| <code>var(a, n, loc=0)</code>                                                      | Variance of the distribution.                                                                    |
| <code>std(a, n, loc=0)</code>                                                      | Standard deviation of the distribution.                                                          |
| <code>interval(alpha, a, n, loc=0)</code>                                          | Endpoints of the range that contains fraction alpha [0, 1] of the distribution                   |

An overview of statistical functions is given below. Many of these functions have a similar version in `scipy.stats`. `mstats` which work for masked arrays.

## Summary statistics

|                                                            |                                                                       |
|------------------------------------------------------------|-----------------------------------------------------------------------|
| <code>describe(a[, axis, ddof, bias, nan_policy])</code>   | Compute several descriptive statistics of the passed array.           |
| <code>gmean(a[, axis, dtype, weights])</code>              | Compute the geometric mean along the specified axis.                  |
| <code>hmean(a[, axis, dtype])</code>                       | Calculate the harmonic mean along the specified axis.                 |
| <code>kurtosis(a[, axis, fisher, bias, nan_policy])</code> | Compute the kurtosis (Fisher or Pearson) of a dataset.                |
| <code>mode(a[, axis, nan_policy])</code>                   | Return an array of the modal (most common) value in the passed array. |
| <code>moment(a[, moment, axis, nan_policy])</code>         | Calculate the nth moment about the mean for a sample.                 |
| <code>skew(a[, axis, bias, nan_policy])</code>             | Compute the sample skewness of a data set.                            |
| <code>kstat(data[, n])</code>                              | Return the nth k-statistic ( $1 \leq n \leq 4$ so far).               |
| <code>kstatvar(data[, n])</code>                           | Return an unbiased estimator of the variance of the k-statistic.      |
| <code>tmean(a[, limits, inclusive, axis])</code>           | Compute the trimmed mean.                                             |
| <code>tvar(a[, limits, inclusive, axis, ddof])</code>      | Compute the trimmed variance.                                         |
| <code>tmin(a[, lowerlimit, axis, inclusive, ...])</code>   | Compute the trimmed minimum.                                          |
| <code>tmax(a[, upperlimit, axis, inclusive, ...])</code>   | Compute the trimmed maximum.                                          |
| <code>tstd(a[, limits, inclusive, axis, ddof])</code>      | Compute the trimmed sample standard deviation.                        |
| <code>tsem(a[, limits, inclusive, axis, ddof])</code>      | Compute the trimmed standard error of the mean.                       |
| <code>variation(a[, axis, nan_policy, ddof])</code>        | Compute the coefficient of variation.                                 |
| <code>find_repeats(arr)</code>                             | Find repeats and repeat counts.                                       |
| <code>trim_mean(a, proportiontocut[, axis])</code>         | Return mean of array after trimming distribution from both tails.     |

|                                                               |                                                                                                      |
|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>gstd(a[, axis, ddof])</code>                            | Calculate the geometric standard deviation of an array.                                              |
| <code>iqr(x[, axis, rng, scale, nan_policy, ...])</code>      | Compute the interquartile range of the data along the specified axis.                                |
| <code>sem(a[, axis, ddof, nan_policy])</code>                 | Compute standard error of the mean.                                                                  |
| <code>bayes_mvs(data[, alpha])</code>                         | Bayesian confidence intervals for the mean, var, and std.                                            |
| <code>mvstdist(data)</code>                                   | ‘Frozen’ distributions for mean, variance, and standard deviation of data.                           |
| <code>entropy(pk[, qk, base, axis])</code>                    | Calculate the entropy of a distribution for given probability values.                                |
| <code>differential_entropy(values, *[, ...])</code>           | Given a sample of a distribution, estimate the differential entropy.                                 |
| <code>median_absolute_deviation(*args, **kwargs)</code>       | <code>median_absolute_deviation</code> is deprecated, use <code>median_abs_deviation</code> instead! |
| <code>median_abs_deviation(x[, axis, center, ...])</code>     | Compute the median absolute deviation of the data along the given axis.                              |
| <code>bootstrap(data, statistic, *[, vectorized, ...])</code> | Compute a two-sided bootstrap confidence interval of a statistic.                                    |

**scipy.stats.describe**

`scipy.stats.describe` (*a*, *axis*=0, *ddof*=1, *bias*=True, *nan\_policy*='propagate')

Compute several descriptive statistics of the passed array.

**Parameters**

- a** [array\_like] Input data.
- axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees of freedom (only for variance). Default is 1.
- bias** [bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.
- nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

**Returns**

- nobs** [int or ndarray of ints] Number of observations (length of data along *axis*). When 'omit' is chosen as *nan\_policy*, the length along each axis slice is counted separately.
- minmax: tuple of ndarrays or floats** Minimum and maximum value of *a* along the given axis.
- mean** [ndarray or float] Arithmetic mean of *a* along the given axis.
- variance** [ndarray or float] Unbiased variance of *a* along the given axis; denominator is number of observations minus one.
- skewness** [ndarray or float] Skewness of *a* along the given axis, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.
- kurtosis** [ndarray or float] Kurtosis (Fisher) of *a* along the given axis. The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

See also:

[skew, kurtosis](#)

## Examples

```

>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5,
 variance=9.166666666666666, skewness=0.0,
 kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
 mean=array([2., 3.]), variance=array([2., 2.]),
 skewness=array([0., 0.]), kurtosis=array([-2., -2.]))

```

**scipy.stats.gmean**

`scipy.stats.gmean(a, axis=0, dtype=None, weights=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is:  $n$ -th root of  $(x_1 * x_2 * \dots * x_n)$

**Parameters**

- a** [array\_like] Input array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.
- weights** [array\_like, optional] The weights array can either be 1-D (in which case its length must be the size of *a* along the given *axis*) or of the same shape as *a*. Default is None, which gives each value a weight of 1.0.

**Returns**

- gmean** [ndarray] See *dtype* parameter above.

See also:

**numpy.mean**

Arithmetic average

**numpy.average**

Weighted average

**hmean**

Harmonic mean

## Notes

The geometric average is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. `float64` intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

## References

[1]

## Examples

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

## scipy.stats.hmean

`scipy.stats.hmean(a, axis=0, dtype=None)`

Calculate the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

### Parameters

- a** [array\_like] Input array, masked array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

### Returns

- hmean** [ndarray] See *dtype* parameter above.

See also:

`numpy.mean`

Arithmetic average

`numpy.average`

Weighted average

`gmean`

Geometric mean

## Notes

The harmonic mean is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

## Examples

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

## `scipy.stats.kurtosis`

`scipy.stats.kurtosis` (*a*, *axis=0*, *fisher=True*, *bias=True*, *nan\_policy='propagate'*)

Compute the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If `bias` is `False` then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

### Parameters

- a** [array] Data for which the kurtosis is calculated.
- axis** [int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array *a*.
- fisher** [bool, optional] If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
- bias** [bool, optional] If False, then the calculations are corrected for statistical bias.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

- kurtosis** [array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.

## References

[1]

## Examples

In Fisher's definition, the kurtosis of the normal distribution is zero. In the following example, the kurtosis is close to zero, because it was calculated from the dataset, not from the continuous distribution.

```
>>> from scipy.stats import norm, kurtosis
>>> data = norm.rvs(size=1000, random_state=3)
>>> kurtosis(data)
-0.06928694200380558
```

The distribution with a higher kurtosis has a heavier tail. The zero valued kurtosis of the normal distribution in Fisher's definition can serve as a reference point.

```
>>> import matplotlib.pyplot as plt
>>> import scipy.stats as stats
>>> from scipy.stats import kurtosis
```

```
>>> x = np.linspace(-5, 5, 100)
>>> ax = plt.subplot()
>>> distnames = ['laplace', 'norm', 'uniform']
```

```
>>> for distname in distnames:
... if distname == 'uniform':
... dist = getattr(stats, distname)(loc=-2, scale=4)
... else:
... dist = getattr(stats, distname)
... data = dist.rvs(size=1000)
... kur = kurtosis(data, fisher=True)
... y = dist.pdf(x)
... ax.plot(x, y, label="{}, {}".format(distname, round(kur, 3)))
... ax.legend()
```

The Laplace distribution has a heavier tail than the normal distribution. The uniform distribution (which has negative kurtosis) has the thinnest tail.

## scipy.stats.mode

`scipy.stats.mode` (*a*, *axis*=0, *nan\_policy*='propagate')

Return an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

### Parameters

- a** [array\_like] n-dimensional array of which to find mode(s).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is "propagate"):
  - "propagate": returns nan

- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

#### Returns

**mode** [ndarray] Array of modal values.  
**count** [ndarray] Array of counts for each mode.

#### Examples

```
>>> a = np.array([[6, 8, 3, 0],
... [3, 2, 1, 7],
... [8, 1, 8, 4],
... [5, 3, 0, 5],
... [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
ModeResult(mode=array([[3, 1, 0, 0]]), count=array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify `axis=None`:

```
>>> stats.mode(a, axis=None)
ModeResult(mode=array([3]), count=array([3]))
```

#### scipy.stats.moment

`scipy.stats.moment` (*a*, *moment=1*, *axis=0*, *nan\_policy='propagate'*)

Calculate the *n*th moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

#### Parameters

**a** [array\_like] Input array.  
**moment** [int or array\_like of ints, optional] Order of central moment that is returned. Default is 1.

**axis** [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.

**nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

### Returns

#### n-th central moment

[ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

See also:

[kurtosis](#), [skew](#), [describe](#)

### Notes

The k-th central moment of a data sample is:

$$m_k = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^k$$

Where n is the number of samples and x-bar is the mean. This function uses exponentiation by squares [1] for efficiency.

### References

[1]

### Examples

```
>>> from scipy.stats import moment
>>> moment([1, 2, 3, 4, 5], moment=1)
0.0
>>> moment([1, 2, 3, 4, 5], moment=2)
2.0
```

### scipy.stats.skew

`scipy.stats.skew` (*a*, *axis=0*, *bias=True*, *nan\_policy='propagate'*)

Compute the sample skewness of a data set.

For normally distributed data, the skewness should be about zero. For unimodal continuous distributions, a skewness value greater than zero means that there is more weight in the right tail of the distribution. The function *skewtest* can be used to determine if the skewness value is close enough to zero, statistically speaking.

#### Parameters

**a** [ndarray] Input array.

**axis** [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.

**bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

**nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

**Returns**

**skewness** [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

**Notes**

The sample skewness is computed as the Fisher-Pearson coefficient of skewness, i.e.

$$g_1 = \frac{m_3}{m_2^{3/2}}$$

where

$$m_i = \frac{1}{N} \sum_{n=1}^N (x[n] - \bar{x})^i$$

is the biased sample *i*th central moment, and  $\bar{x}$  is the sample mean. If `bias` is False, the calculations are corrected for bias and the value computed is the adjusted Fisher-Pearson standardized moment coefficient, i.e.

$$G_1 = \frac{k_3}{k_2^{3/2}} = \frac{\sqrt{N(N-1)}}{N-2} \frac{m_3}{m_2^{3/2}}$$

**References**

[1]

**Examples**

```
>>> from scipy.stats import skew
>>> skew([1, 2, 3, 4, 5])
0.0
>>> skew([2, 8, 0, 4, 1, 9, 9, 0])
0.2650554122698573
```

**scipy.stats.kstat**

`scipy.stats.kstat` (*data*, *n=2*)  
Return the nth k-statistic (1<=n<=4 so far).

The nth k-statistic `k_n` is the unique symmetric unbiased estimator of the nth cumulant `kappa_n`.

**Parameters**

**data** [array\_like] Input array. Note that n-D input gets flattened.

**n** [int, {1, 2, 3, 4}, optional] Default is equal to 2.

**Returns****kstat** [float] The nth k-statistic.**See also:****kstatvar**

Returns an unbiased estimator of the variance of the k-statistic.

**moment**

Returns the n-th central moment about the mean for a sample.

**Notes**

For a sample size n, the first few k-statistics are given by:

$$k_1 = \mu k_2 = \frac{n}{n-1} m_2 k_3 = \frac{n^2}{(n-1)(n-2)} m_3 k_4 = \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)}$$

where  $\mu$  is the sample mean,  $m_2$  is the sample variance, and  $m_i$  is the i-th sample central moment.**References**<http://mathworld.wolfram.com/k-Statistic.html><http://mathworld.wolfram.com/Cumulant.html>**Examples**

```
>>> from scipy import stats
>>> from numpy.random import default_rng
>>> rng = default_rng()
```

As sample size increases, n-th moment and n-th k-statistic converge to the same number (although they aren't identical). In the case of the normal distribution, they converge to zero.

```
>>> for n in [2, 3, 4, 5, 6, 7]:
... x = rng.normal(size=10**n)
... m, k = stats.moment(x, 3), stats.kstat(x, 3)
... print("%.3g %.3g %.3g" % (m, k, m-k))
-0.631 -0.651 0.0194 # random
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```

### scipy.stats.kstatvar

`scipy.stats.kstatvar` (*data*, *n*=2)

Return an unbiased estimator of the variance of the k-statistic.

See `kstat` for more details of the k-statistic.

#### Parameters

**data** [array\_like] Input array. Note that n-D input gets flattened.  
**n** [int, {1, 2}, optional] Default is equal to 2.

#### Returns

**kstatvar** [float] The nth k-statistic variance.

See also:

#### `kstat`

Returns the n-th k-statistic.

#### `moment`

Returns the n-th central moment about the mean for a sample.

### Notes

The variances of the first few k-statistics are given by:

$$\text{var}(k_1) = \frac{\kappa^2}{n} \text{var}(k_2) = \frac{\kappa^4}{n} + \frac{2\kappa_2^2}{n-1} \text{var}(k_3) = \frac{\kappa^6}{n} + \frac{9\kappa_2\kappa_4}{n-1} + \frac{9\kappa_3^2}{n-1} + \frac{6n\kappa_2^3}{(n-1)(n-2)} \text{var}(k_4) = \frac{\kappa^8}{n} + \frac{16\kappa_2\kappa_6}{n-1} + \frac{48\kappa_3\kappa_5}{n-1}$$

### scipy.stats.tmean

`scipy.stats.tmean` (*a*, *limits*=None, *inclusive*=(True, True), *axis*=None)

Compute the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given *limits*.

#### Parameters

**a** [array\_like] Array of values.  
**limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.  
**inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).  
**axis** [int or None, optional] Axis along which to compute test. Default is None.

#### Returns

**tmean** [float] Trimmed mean.

See also:

#### `trim_mean`

Returns mean after trimming a proportion from both tails.

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3,17))
10.0
```

## scipy.stats.tvar

`scipy.stats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed variance.

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

### Parameters

- a** [array\_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is *None*, then all values are used. Either of the limit values in the tuple can also be *None* representing a half-open interval. The default value is *None*.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If *None*, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees of freedom. Default is 1.

### Returns

- tvar** [float] Trimmed variance.

## Notes

*tvar* computes the unbiased sample variance, i.e. it uses a correction factor  $n / (n - 1)$ .

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3,17))
20.0
```

### scipy.stats.tmin

`scipy.stats.tmin` (*a*, *lowerlimit=None*, *axis=0*, *inclusive=True*, *nan\_policy='propagate'*)

Compute the trimmed minimum.

This function finds the minimum value of an array *a* along the specified axis, but only considering values greater than a specified lower limit.

#### Parameters

- a** [array\_like] Array of values.
- lowerlimit** [None or float, optional] Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

#### Returns

- tmin** [float, int or ndarray] Trimmed minimum.

### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0
```

```
>>> stats.tmin(x, 13)
13
```

```
>>> stats.tmin(x, 13, inclusive=False)
14
```

### scipy.stats.tmax

`scipy.stats.tmax` (*a*, *upperlimit=None*, *axis=0*, *inclusive=True*, *nan\_policy='propagate'*)

Compute the trimmed maximum.

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

#### Parameters

- a** [array\_like] Array of values.
- upperlimit** [None or float, optional] Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

**Returns**

**tmax** [float, int or ndarray] Trimmed maximum.

### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19
```

```
>>> stats.tmax(x, 13)
13
```

```
>>> stats.tmax(x, 13, inclusive=False)
12
```

### scipy.stats.tstd

`scipy.stats.tstd(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed sample standard deviation.

This function finds the sample standard deviation of given values, ignoring values outside the given *limits*.

**Parameters**

**a** [array\_like] Array of values.

**limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** [int, optional] Delta degrees of freedom. Default is 1.

**Returns**

**tstd** [float] Trimmed sample standard deviation.

## Notes

`tstd` computes the unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161
>>> stats.tstd(x, (3,17))
4.4721359549995796
```

## scipy.stats.tsem

`scipy.stats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

### Parameters

- |                  |                                                                                                                                                                                                                                                                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>a</b>         | [array_like] Array of values.                                                                                                                                                                                                                                                                                                                           |
| <b>limits</b>    | [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When <i>limits</i> is <i>None</i> , then all values are used. Either of the limit values in the tuple can also be <i>None</i> representing a half-open interval. The default value is <i>None</i> . |
| <b>inclusive</b> | [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).                                                                                                                                           |
| <b>axis</b>      | [int or None, optional] Axis along which to operate. Default is 0. If <i>None</i> , compute over the whole array <i>a</i> .                                                                                                                                                                                                                             |
| <b>ddof</b>      | [int, optional] Delta degrees of freedom. Default is 1.                                                                                                                                                                                                                                                                                                 |

### Returns

- |             |                                             |
|-------------|---------------------------------------------|
| <b>tsem</b> | [float] Trimmed standard error of the mean. |
|-------------|---------------------------------------------|

## Notes

`tsem` uses unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3,17))
1.1547005383792515
```

## scipy.stats.variation

`scipy.stats.variation(a, axis=0, nan_policy='propagate', ddof=0)`

Compute the coefficient of variation.

The coefficient of variation is the standard deviation divided by the mean. This function is equivalent to:

```
np.std(x, axis=axis, ddof=ddof) / np.mean(x)
```

The default for `ddof` is 0, but many definitions of the coefficient of variation use the square root of the unbiased sample variance for the sample standard deviation, which corresponds to `ddof=1`.

### Parameters

- a** [array\_like] Input array.
- axis** [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values
- ddof** [int, optional] Delta degrees of freedom. Default is 0.

### Returns

- variation** [ndarray] The calculated variation along the requested axis.

## References

[1]

## Examples

```
>>> from scipy.stats import variation
>>> variation([1, 2, 3, 4, 5])
0.47140452079103173
```

## scipy.stats.find\_repeats

`scipy.stats.find_repeats(arr)`

Find repeats and repeat counts.

### Parameters

- arr** [array\_like] Input array. This is cast to float64.

### Returns

- values** [ndarray] The unique values from the (flattened) input that are repeated.
- counts** [ndarray] Number of times the corresponding 'value' is repeated.

## Notes

In numpy >= 1.9 `numpy.unique` provides similar functionality. The main difference is that `find_repeats` only returns repeated values.

## Examples

```
>>> from scipy import stats
>>> stats.find_repeats([2, 1, 2, 3, 2, 2, 5])
RepeatedResults(values=array([2.]), counts=array([4]))
```

```
>>> stats.find_repeats([[10, 20, 1, 2], [5, 5, 4, 4]])
RepeatedResults(values=array([4., 5.]), counts=array([2, 2]))
```

## scipy.stats.trim\_mean

`scipy.stats.trim_mean(a, proportiontocut, axis=0)`

Return mean of array after trimming distribution from both tails.

If `proportiontocut = 0.1`, slices off ‘leftmost’ and ‘rightmost’ 10% of scores. The input is sorted before slicing. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off `proportiontocut`).

### Parameters

- a** [array\_like] Input array.
- proportiontocut** [float] Fraction to cut off of both tails of the distribution.
- axis** [int or None, optional] Axis along which the trimmed means are computed. Default is 0. If None, compute over the whole array *a*.

### Returns

- trim\_mean** [ndarray] Mean of trimmed array.

See also:

`trimboth`

`tmean`

Compute the trimmed mean ignoring values outside given *limits*.

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.trim_mean(x, 0.1)
9.5
>>> x2 = x.reshape(5, 4)
>>> x2
array([[0, 1, 2, 3],
 [4, 5, 6, 7],
 [8, 9, 10, 11],
 [12, 13, 14, 15],
```

(continues on next page)

(continued from previous page)

```
[16, 17, 18, 19]])
>>> stats.trim_mean(x2, 0.25)
array([8., 9., 10., 11.])
>>> stats.trim_mean(x2, 0.25, axis=1)
array([1.5, 5.5, 9.5, 13.5, 17.5])
```

### scipy.stats.gstd

`scipy.stats.gstd(a, axis=0, ddof=1)`

Calculate the geometric standard deviation of an array.

The geometric standard deviation describes the spread of a set of numbers where the geometric mean is preferred. It is a multiplicative factor, and so a dimensionless quantity.

It is defined as the exponent of the standard deviation of  $\log(a)$ . Mathematically the population geometric standard deviation can be evaluated as:

```
gstd = exp(std(log(a)))
```

New in version 1.3.0.

#### Parameters

- a** [array\_like] An array like object containing the sample data.
- axis** [int, tuple or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Degree of freedom correction in the calculation of the geometric standard deviation. Default is 1.

#### Returns

##### ndarray or float

An array of the geometric standard deviation. If *axis* is None or *a* is a 1d array a float is returned.

#### Notes

As the calculation requires the use of logarithms the geometric standard deviation only supports strictly positive values. Any non-positive or infinite values will raise a *ValueError*. The geometric standard deviation is sometimes confused with the exponent of the standard deviation,  $\exp(\text{std}(a))$ . Instead the geometric standard deviation is  $\exp(\text{std}(\log(a)))$ . The default value for *ddof* is different to the default value (0) used by other *ddof* containing functions, such as `np.std` and `np.nanstd`.

#### Examples

Find the geometric standard deviation of a log-normally distributed sample. Note that the standard deviation of the distribution is one, on a log scale this evaluates to approximately  $\exp(1)$ .

```
>>> from scipy.stats import gstd
>>> rng = np.random.default_rng()
>>> sample = rng.lognormal(mean=0, sigma=1, size=1000)
>>> gstd(sample)
2.810010162475324
```

Compute the geometric standard deviation of a multidimensional array and of a given axis.

```

>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> gstd(a, axis=None)
2.2944076136018947
>>> gstd(a, axis=2)
array([[1.82424757, 1.22436866, 1.13183117],
 [1.09348306, 1.07244798, 1.05914985]])
>>> gstd(a, axis=(1,2))
array([2.12939215, 1.22120169])

```

The geometric standard deviation further handles masked arrays.

```

>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> ma = np.ma.masked_where(a > 16, a)
>>> ma
masked_array(
 data=[[1, 2, 3, 4],
 [5, 6, 7, 8],
 [9, 10, 11, 12]],
 mask=[[False, False, False, False],
 [False, False, False, False],
 [False, False, False, False]],
 fill_value=999999)
>>> gstd(ma, axis=2)
masked_array(
 data=[[1.8242475707663655, 1.2243686572447428, 1.1318311657788478],
 [1.0934830582350938, --, --]],
 mask=[[False, False, False],
 [False, True, True]],
 fill_value=999999)

```

### scipy.stats.iqr

`scipy.stats.iqr(x, axis=None, rng=(25, 75), scale=1.0, nan_policy='propagate', interpolation='linear', keepdims=False)`

Compute the interquartile range of the data along the specified axis.

The interquartile range (IQR) is the difference between the 75th and 25th percentile of the data. It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers [2].

The `rng` parameter allows this function to compute other percentile ranges than the actual IQR. For example, setting `rng=(0, 100)` is equivalent to `numpy.ptp`.

The IQR of an empty array is `np.nan`.

New in version 0.18.0.

#### Parameters

- x** [array\_like] Input array or object that can be converted to an array.
- axis** [int or sequence of int, optional] Axis along which the range is computed. The default is to compute the IQR for the entire array.

- rng** [Two-element sequence containing floats in range of [0,100] optional] Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important.
- scale** [scalar or str, optional] The numerical value of scale will be divided out of the final result. The following string values are recognized:
- ‘raw’: No scaling, just return the raw IQR. **Deprecated!** Use `scale=1` instead.
  - ‘normal’: Scale by  $2\sqrt{2}erf^{-1}(\frac{1}{2}) \approx 1.349$ .
- The default is 1.0. The use of `scale='raw'` is deprecated. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that `out / scale` is a valid operation. The output dimensions depend on the input array, `x`, the `axis` argument, and the `keepdims` flag.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
- ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values
- interpolation** [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}, optional] Specifies the interpolation method to use when the percentile boundaries lie between two data points `i` and `j`. The following options are available (default is ‘linear’):
- ‘linear’:  $i + (j - i) * fraction$ , where `fraction` is the fractional part of the index surrounded by `i` and `j`.
  - ‘lower’: `i`.
  - ‘higher’: `j`.
  - ‘nearest’: `i` or `j` whichever is nearest.
  - ‘midpoint’:  $(i + j) / 2$ .
- keepdims** [bool, optional] If this is set to `True`, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array `x`.
- Returns**
- iqr** [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

`numpy.std`, `numpy.var`

## Notes

This function is heavily dependent on the version of `numpy` that is installed. Versions greater than 1.11.0b3 are highly recommended, as they include a number of enhancements and fixes to `numpy.percentile` and `numpy.nanpercentile` that affect the operation of this function. The following modifications apply:

### Below 1.10.0

[`nan_policy` is poorly defined.] The default behavior of `numpy.percentile` is used for ‘propagate’. This is a hybrid of ‘omit’ and ‘propagate’ that mostly yields a skewed version of ‘omit’ since NaNs are sorted to the end of the data. A warning is raised if there are NaNs in the data.

### Below 1.9.0: `numpy.nanpercentile` does not exist.

This means that `numpy.percentile` is used regardless of `nan_policy` and a warning is issued. See previous item for a description of the behavior.

**Below 1.9.0: keepdims and interpolation are not supported.**

The keywords get ignored with a warning if supplied with non-default values. However, multiple axes are still supported.

## References

[1], [2], [3]

## Examples

```
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
 [3, 2, 1]])
>>> iqr(x)
4.0
>>> iqr(x, axis=0)
array([3.5, 2.5, 1.5])
>>> iqr(x, axis=1)
array([3., 1.])
>>> iqr(x, axis=1, keepdims=True)
array([[3.],
 [1.]])
```

## scipy.stats.sem

`scipy.stats.sem(a, axis=0, ddof=1, nan_policy='propagate')`

Compute standard error of the mean.

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

### Parameters

- a** [array\_like] An array containing the values for which the standard error is returned.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.
- nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is "propagate"):
  - "propagate": returns nan
  - "raise": throws an error
  - "omit": performs the calculations ignoring nan values

### Returns

- s** [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

## Notes

The default value for *ddof* is different to the default (0) used by other *ddof* containing routines, such as `np.std` and `np.nanstd`.

## Examples

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> stats.sem(a)
array([2.8284, 2.8284, 2.8284, 2.8284])
```

Find standard error across the whole array, using *n* degrees of freedom:

```
>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628
```

## scipy.stats.bayes\_mvs

`scipy.stats.bayes_mvs` (*data*, *alpha*=0.9)

Bayesian confidence intervals for the mean, var, and std.

### Parameters

- data** [array\_like] Input data, if multi-dimensional it is flattened to 1-D by *bayes\_mvs*. Requires 2 or more data points.
- alpha** [float, optional] Probability that the returned confidence interval contains the true parameter.

### Returns

**mean\_cntr, var\_cntr, std\_cntr**

[tuple] The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

```
(center, (lower, upper))
```

with *center* the mean of the conditional pdf of the value given the data, and (*lower*, *upper*) a confidence interval, centered on the median, containing the estimate to a probability *alpha*.

See also:

`mvstdist`

## Notes

Each tuple of mean, variance, and standard deviation estimates represent the (*center*, (*lower*, *upper*)) with *center* the mean of the conditional pdf of the value given the data and (*lower*, *upper*) is a confidence interval centered on the median, containing the estimate to a probability *alpha*.

Converts data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey's prior for variance and std.

Equivalent to `tuple((x.mean(), x.interval(alpha)) for x in mvstdist(dat))`

## References

T.E. Oliphant, “A Bayesian perspective on estimating mean, variance, and standard-deviation from data”, <https://scholarsarchive.byu.edu/facpub/278>, 2006.

## Examples

First a basic example to demonstrate the outputs:

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.103650222612533, 10.896349777387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.7823367265645143, 4.
→945614605014631))
```

Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)
```

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.hist(data, bins=100, density=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated_
→mean')
>>> ax.axvspan(res_mean.minmax[0], res_mean.minmax[1], facecolor='r',
... alpha=0.2, label=r'Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated_
→scale')
>>> ax.axvspan(res_std.minmax[0], res_std.minmax[1], facecolor='g',
→alpha=0.2,
... label=r'Estimated scale (95% limits)')
```

```
>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()
```

### scipy.stats.mvstdist

`scipy.stats.mvstdist` (*data*)

'Frozen' distributions for mean, variance, and standard deviation of data.

#### Parameters

**data** [array\_like] Input array. Converted to 1-D using `ravel`. Requires 2 or more data-points.

#### Returns

**mdist** ["frozen" distribution object] Distribution object representing the mean of the data.

**vdist** ["frozen" distribution object] Distribution object representing the variance of the data.

**sdist** ["frozen" distribution object] Distribution object representing the standard deviation of the data.

#### See also:

[bayes\\_mvs](#)

#### Notes

The return values from `bayes_mvs` (*data*) is equivalent to `tuple((x.mean(), x.interval(0.90)) for x in mvstdist(data))`.

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from `bayes_mvs`.

## References

T.E. Oliphant, “A Bayesian perspective on estimating mean, variance, and standard-deviation from data”, <https://scholarsarchive.byu.edu/facpub/278>, 2006.

## Examples

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvstdist(data)
```

We now have frozen distribution objects “mean”, “var” and “std” that we can examine:

```
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

## scipy.stats.entropy

`scipy.stats.entropy(pk, qk=None, base=None, axis=0)`

Calculate the entropy of a distribution for given probability values.

If only probabilities  $pk$  are given, the entropy is calculated as  $S = -\sum(pk * \log(pk), axis=axis)$ .

If  $qk$  is not None, then compute the Kullback-Leibler divergence  $S = \sum(pk * \log(pk / qk), axis=axis)$ .

This routine will normalize  $pk$  and  $qk$  if they don’t sum to 1.

### Parameters

- pk** [sequence] Defines the (discrete) distribution.  $pk[i]$  is the (possibly unnormalized) probability of event  $i$ .
- qk** [sequence, optional] Sequence against which the relative entropy is computed. Should be in the same format as  $pk$ .
- base** [float, optional] The logarithmic base to use, defaults to  $e$  (natural logarithm).
- axis: int, optional** The axis along which the entropy is calculated. Default is 0.

### Returns

- S** [float] The calculated entropy.

## Examples

```
>>> from scipy.stats import entropy
```

Bernoulli trial with different  $p$ . The outcome of a fair coin is the most uncertain:

```
>>> entropy([1/2, 1/2], base=2)
1.0
```

The outcome of a biased coin is less uncertain:

```
>>> entropy([9/10, 1/10], base=2)
0.46899559358928117
```

Relative entropy:

```
>>> entropy([1/2, 1/2], qk=[9/10, 1/10])
0.5108256237659907
```

### scipy.stats.differential\_entropy

`scipy.stats.differential_entropy` (*values*, \*, *window\_length=None*, *base=None*, *axis=0*, *method='auto'*)

Given a sample of a distribution, estimate the differential entropy.

Several estimation methods are available using the *method* parameter. By default, a method is selected based the size of the sample.

#### Parameters

**values** [sequence] Sample from a continuous distribution.

**window\_length** [int, optional] Window length for computing Vasicek estimate. Must be an integer between 1 and half of the sample size. If `None` (the default), it uses the heuristic value

$$\lfloor \sqrt{n} + 0.5 \rfloor$$

where  $n$  is the sample size. This heuristic was originally proposed in [2] and has become common in the literature.

**base** [float, optional] The logarithmic base to use, defaults to  $e$  (natural logarithm).

**axis** [int, optional] The axis along which the differential entropy is calculated. Default is 0.

**method** [{'vasicek', 'van es', 'ebrahimi', 'correa', 'auto'}, optional] The method used to estimate the differential entropy from the sample. Default is 'auto'. See Notes for more information.

#### Returns

**entropy** [float] The calculated differential entropy.

### Notes

This function will converge to the true differential entropy in the limit

$$n \rightarrow \infty, \quad m \rightarrow \infty, \quad \frac{m}{n} \rightarrow 0$$

The optimal choice of `window_length` for a given sample size depends on the (unknown) distribution. Typically, the smoother the density of the distribution, the larger the optimal value of `window_length` [1].

The following options are available for the *method* parameter.

- 'vasicek' uses the estimator presented in [1]. This is one of the first and most influential estimators of differential entropy.
- 'van es' uses the bias-corrected estimator presented in [3], which is not only consistent but, under some conditions, asymptotically normal.
- 'ebrahimi' uses an estimator presented in [4], which was shown in simulation to have smaller bias and mean squared error than the Vasicek estimator.
- 'correa' uses the estimator presented in [5] based on local linear regression. In a simulation study, it had consistently smaller mean square error than the Vasicek estimator, but it is more expensive to compute.

- 'auto' selects the method automatically (default). Currently, this selects 'van es' for very small samples (<10), 'ebrahimi' for moderate sample sizes (11-1000), and 'vasicek' for larger samples, but this behavior is subject to change in future versions.

All estimators are implemented as described in [6].

## References

[1], [2], [3], [4], [5], [6]

## Examples

```
>>> from scipy.stats import differential_entropy, norm
```

Entropy of a standard normal distribution:

```
>>> rng = np.random.default_rng()
>>> values = rng.standard_normal(100)
>>> differential_entropy(values)
1.3407817436640392
```

Compare with the true entropy:

```
>>> float(norm.entropy())
1.4189385332046727
```

For several sample sizes between 5 and 1000, compare the accuracy of the 'vasicek', 'van es', and 'ebrahimi' methods. Specifically, compare the root mean squared error (over 1000 trials) between the estimate and the true differential entropy of the distribution.

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>>
>>>
>>> def rmse(res, expected):
... '''Root mean squared error'''
... return np.sqrt(np.mean((res - expected)**2))
>>>
>>>
>>> a, b = np.log10(5), np.log10(1000)
>>> ns = np.round(np.logspace(a, b, 10)).astype(int)
>>> reps = 1000 # number of repetitions for each sample size
>>> expected = stats.expon.entropy()
>>>
>>> method_errors = {'vasicek': [], 'van es': [], 'ebrahimi': []}
>>> for method in method_errors:
... for n in ns:
... rvs = stats.expon.rvs(size=(reps, n), random_state=rng)
... res = stats.differential_entropy(rvs, method=method, axis=-1)
... error = rmse(res, expected)
... method_errors[method].append(error)
>>>
```

(continues on next page)

(continued from previous page)

```

>>> for method, errors in method_errors.items():
... plt.loglog(ns, errors, label=method)
>>>
>>> plt.legend()
>>> plt.xlabel('sample size')
>>> plt.ylabel('RMSE (1000 trials)')
>>> plt.title('Entropy Estimator Error (Exponential Distribution)')

```

### scipy.stats.median\_absolute\_deviation

`scipy.stats.median_absolute_deviation(*args, **kwargs)`

`median_absolute_deviation` is deprecated, use `median_abs_deviation` instead!

To preserve the existing default behavior, use `scipy.stats.median_abs_deviation(..., scale=1/1.4826)`. The value 1.4826 is not numerically precise for scaling with a normal distribution. For a numerically precise value, use `scipy.stats.median_abs_deviation(..., scale='normal')`.

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation but more robust to outliers [2].

The MAD of an empty array is `np.nan`.

New in version 1.3.0.

#### Parameters

- x** [array\_like] Input array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.
- center** [callable, optional] A function that will return the central value. The default is to use `np.median`. Any user defined function used will need to have the function signature `func(arr, axis)`.
- scale** [int, optional] The scaling factor applied to the MAD. The default scale (1.4826) ensures consistency with the standard deviation for normally distributed data.

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

**Returns**

**mad** [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

**See also:**

`numpy.std`, `numpy.var`, `numpy.median`, `scipy.stats.iqr`, `scipy.stats.tmean`  
`scipy.stats.tstd`, `scipy.stats.tvar`

**Notes**

The `center` argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=np.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

**References**

[1], [2]

**Examples**

When comparing the behavior of `median_absolute_deviation` with `np.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_absolute_deviation(x)
1.2280762773108278
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_absolute_deviation(x)
1.2340335571164334
```

**Axis handling example:**

```
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
 [3, 2, 1]])
>>> stats.median_absolute_deviation(x)
```

(continues on next page)

(continued from previous page)

```
array([5.1891, 3.7065, 2.2239])
>>> stats.median_absolute_deviation(x, axis=None)
2.9652
```

**scipy.stats.median\_abs\_deviation**

`scipy.stats.median_abs_deviation(x, axis=0, center=<function median>, scale=1.0, nan_policy='propagate')`

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation but more robust to outliers [2].

The MAD of an empty array is `np.nan`.

New in version 1.5.0.

**Parameters**

- x** [array\_like] Input array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.
- center** [callable, optional] A function that will return the central value. The default is to use `np.median`. Any user defined function used will need to have the function signature `func(arr, axis)`.
- scale** [scalar or str, optional] The numerical value of scale will be divided out of the final result. The default is 1.0. The string “normal” is also accepted, and results in *scale* being the inverse of the standard normal quantile function at 0.75, which is approximately 0.67449. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that `out / scale` is a valid operation. The output dimensions depend on the input array, *x*, and the *axis* argument.
- nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
  - ‘propagate’: returns nan
  - ‘raise’: throws an error
  - ‘omit’: performs the calculations ignoring nan values

**Returns**

- mad** [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

See also:

`numpy.std`, `numpy.var`, `numpy.median`, `scipy.stats.iqr`, `scipy.stats.tmean`  
`scipy.stats.tstd`, `scipy.stats.tvar`

## Notes

The *center* argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=np.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

The input array may contain *inf*, but if *center* returns *inf*, the corresponding MAD for that data will be *nan*.

## References

[1], [2]

## Examples

When comparing the behavior of *median\_abs\_deviation* with `np.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_abs_deviation(x)
0.82832610097857
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_abs_deviation(x)
0.8323442311590675
```

Axis handling example:

```
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
 [3, 2, 1]])
>>> stats.median_abs_deviation(x)
array([3.5, 2.5, 1.5])
>>> stats.median_abs_deviation(x, axis=None)
2.0
```

Scale normal example:

```
>>> x = stats.norm.rvs(size=1000000, scale=2, random_state=123456)
>>> stats.median_abs_deviation(x)
1.3487398527041636
>>> stats.median_abs_deviation(x, scale='normal')
1.9996446978061115
```

**scipy.stats.bootstrap**

`scipy.stats.bootstrap` (*data*, *statistic*, \*, *vectorized=True*, *paired=False*, *axis=0*, *confidence\_level=0.95*, *n\_resamples=9999*, *batch=None*, *method='BCa'*, *random\_state=None*)

Compute a two-sided bootstrap confidence interval of a statistic.

When *method* is 'percentile', a bootstrap confidence interval is computed according to the following procedure.

1. Resample the data: for each sample in *data* and for each of *n\_resamples*, take a random sample of the original sample (with replacement) of the same size as the original sample.
2. Compute the bootstrap distribution of the statistic: for each set of resamples, compute the test statistic.
3. Determine the confidence interval: find the interval of the bootstrap distribution that is
  - symmetric about the median and
  - contains *confidence\_level* of the resampled statistic values.

While the 'percentile' method is the most intuitive, it is rarely used in practice. Two more common methods are available, 'basic' ('reverse percentile') and 'BCa' ('bias-corrected and accelerated'); they differ in how step 3 is performed.

If the samples in *data* are taken at random from their respective distributions *n* times, the confidence interval returned by *bootstrap* will contain the true value of the statistic for those distributions approximately *confidence\_level*  $\times$  *n* times.

**Parameters**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>data</b>             | [sequence of array-like] Each element of data is a sample from an underlying distribution.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>statistic</b>        | [callable] Statistic for which the confidence interval is to be calculated. <i>statistic</i> must be a callable that accepts <code>len(data)</code> samples as separate arguments and returns the resulting statistic. If <i>vectorized</i> is set <code>True</code> , <i>statistic</i> must also accept a keyword argument <i>axis</i> and be vectorized to compute the statistic along the provided <i>axis</i> .                                                                                                                    |
| <b>vectorized</b>       | [bool, default: <code>True</code> ] If <i>vectorized</i> is set <code>False</code> , <i>statistic</i> will not be passed keyword argument <i>axis</i> , and is assumed to calculate the statistic only for 1D samples.                                                                                                                                                                                                                                                                                                                 |
| <b>paired</b>           | [bool, default: <code>False</code> ] Whether the statistic treats corresponding elements of the samples in <i>data</i> as paired.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>axis</b>             | [int, default: 0] The axis of the samples in <i>data</i> along which the <i>statistic</i> is calculated.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>confidence_level</b> | [float, default: 0.95] The confidence level of the confidence interval.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>n_resamples</b>      | [int, default: 9999] The number of resamples performed to form the bootstrap distribution of the statistic.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>batch</b>            | [int, optional] The number of resamples to process in each vectorized call to <i>statistic</i> . Memory usage is $O(\text{batch} * n)$ , where <i>n</i> is the sample size. Default is <code>None</code> , in which case <code>batch = n_resamples</code> (or <code>batch = max(n_resamples, n)</code> for <code>method='BCa'</code> ).                                                                                                                                                                                                |
| <b>method</b>           | [{'percentile', 'basic', 'bca'}, default: 'BCa'] Whether to return the 'percentile' bootstrap confidence interval ('percentile'), the 'reverse' or the bias-corrected and accelerated bootstrap confidence interval ('BCa'). Note that only 'percentile' and 'basic' support multi-sample statistics at this time.                                                                                                                                                                                                                     |
| <b>random_state</b>     | [{None, int, <code>numpy.random.Generator</code> ,<br><code>numpy.random.RandomState</code> }, optional]<br>If <i>seed</i> is <code>None</code> (or <code>np.random</code> ), the <code>numpy.random.RandomState</code> singleton is used. If <i>seed</i> is an int, a new <code>RandomState</code> instance is used, seeded with <i>seed</i> . If <i>seed</i> is already a <code>Generator</code> or <code>RandomState</code> instance then that instance is used.<br>Pseudorandom number generator state used to generate resamples. |

**Returns**

**res** [BootstrapResult] An object with attributes:

- confidence\_interval** [ConfidenceInterval] The bootstrap confidence interval as an instance of `collections.namedtuple` with attributes *low* and *high*.
- standard\_error** [float or ndarray] The bootstrap standard error, that is, the sample standard deviation of the bootstrap distribution

**References**

[1], [2], [3]

**Examples**

Suppose we have sampled data from an unknown distribution.

```
>>> import numpy as np
>>> rng = np.random.default_rng()
>>> from scipy.stats import norm
>>> dist = norm(loc=2, scale=4) # our "unknown" distribution
>>> data = dist.rvs(size=100, random_state=rng)
```

We are interested in the standard deviation of the distribution.

```
>>> std_true = dist.std() # the true value of the statistic
>>> print(std_true)
4.0
>>> std_sample = np.std(data) # the sample statistic
>>> print(std_sample)
3.9460644295563863
```

We can calculate a 90% confidence interval of the statistic using *bootstrap*.

```
>>> from scipy.stats import bootstrap
>>> data = (data,) # samples must be in a sequence
>>> res = bootstrap(data, np.std, confidence_level=0.9,
... random_state=rng)
>>> print(res.confidence_interval)
ConfidenceInterval(low=3.57655333533867, high=4.382043696342881)
```

If we sample from the distribution 1000 times and form a bootstrap confidence interval for each sample, the confidence interval contains the true value of the statistic approximately 900 times.

```
>>> n_trials = 1000
>>> ci_contains_true_std = 0
>>> for i in range(n_trials):
... data = (dist.rvs(size=100, random_state=rng),)
... ci = bootstrap(data, np.std, confidence_level=0.9, n_
→resamples=1000,
... random_state=rng).confidence_interval
... if ci[0] < std_true < ci[1]:
```

(continues on next page)

(continued from previous page)

```
... ci_contains_true_std += 1
>>> print(ci_contains_true_std)
875
```

Rather than writing a loop, we can also determine the confidence intervals for all 1000 samples at once.

```
>>> data = (dist.rvs(size=(n_trials, 100), random_state=rng),)
>>> res = bootstrap(data, np.std, axis=-1, confidence_level=0.9,
... n_resamples=1000, random_state=rng)
>>> ci_l, ci_u = res.confidence_interval
```

Here, *ci\_l* and *ci\_u* contain the confidence interval for each of the `n_trials = 1000` samples.

```
>>> print(ci_l[995:])
[3.77729695 3.75090233 3.45829131 3.34078217 3.48072829]
>>> print(ci_u[995:])
[4.88316666 4.86924034 4.32032996 4.2822427 4.59360598]
```

And again, approximately 90% contain the true value, `std_true = 4`.

```
>>> print(np.sum((ci_l < std_true) & (std_true < ci_u)))
900
```

*bootstrap* can also be used to estimate confidence intervals of multi-sample statistics, including those calculated by hypothesis tests. *scipy.stats.mood* performs Mood's test for equal scale parameters, and it returns two outputs: a statistic, and a p-value. To get a confidence interval for the test statistic, we first wrap *scipy.stats.mood* in a function that accepts two sample arguments, accepts an *axis* keyword argument, and returns only the statistic.

```
>>> from scipy.stats import mood
>>> def my_statistic(sample1, sample2, axis):
... statistic, _ = mood(sample1, sample2, axis=-1)
... return statistic
```

Here, we use the 'percentile' method with the default 95% confidence level.

```
>>> sample1 = norm.rvs(scale=1, size=100, random_state=rng)
>>> sample2 = norm.rvs(scale=2, size=100, random_state=rng)
>>> data = (sample1, sample2)
>>> res = bootstrap(data, my_statistic, method='basic', random_state=rng)
>>> print(mood(sample1, sample2)[0]) # element 0 is the statistic
-5.521109549096542
>>> print(res.confidence_interval)
ConfidenceInterval(low=-7.255994487314675, high=-4.016202624747605)
```

The bootstrap estimate of the standard error is also available.

```
>>> print(res.standard_error)
0.8344963846318795
```

Paired-sample statistics work, too. For example, consider the Pearson correlation coefficient.

```
>>> from scipy.stats import pearsonr
>>> n = 100
>>> x = np.linspace(0, 10, n)
>>> y = x + rng.uniform(size=n)
>>> print(pearsonr(x, y)[0]) # element 0 is the statistic
0.9962357936065914
```

We wrap `pearsonr` so that it returns only the statistic.

```
>>> def my_statistic(x, y):
... return pearsonr(x, y)[0]
```

We call `bootstrap` using `paired=True`. Also, since `my_statistic` isn't vectorized to calculate the statistic along a given axis, we pass in `vectorized=False`.

```
>>> res = bootstrap((x, y), my_statistic, vectorized=False, paired=True,
... random_state=rng)
>>> print(res.confidence_interval)
ConfidenceInterval(low=0.9950085825848624, high=0.9971212407917498)
```

## Frequency statistics

|                                                                |                                                                                                                   |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>cumfreq(a[, numbins, defaultreallimits, weights])</code> | Return a cumulative frequency histogram, using the histogram function.                                            |
| <code>itemfreq(*args, **kwargs)</code>                         | <code>itemfreq</code> is deprecated! <code>itemfreq</code> is deprecated and will be removed in a future version. |
| <code>percentileofscore(a, score[, kind])</code>               | Compute the percentile rank of a score relative to a list of scores.                                              |
| <code>scoreatpercentile(a, per[, limit, ...])</code>           | Calculate the score at a given percentile of the input sequence.                                                  |
| <code>relfreq(a[, numbins, defaultreallimits, weights])</code> | Return a relative frequency histogram, using the histogram function.                                              |

### scipy.stats.cumfreq

`scipy.stats.cumfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a cumulative frequency histogram, using the histogram function.

A cumulative histogram is a mapping that counts the cumulative number of observations in all of the bins up to the specified bin.

#### Parameters

- a** [array\_like] Input array.
- numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\text{min}() - s, a.\text{max}() + s)$ , where  $s = (1/2)(a.\text{max}() - a.\text{min}()) / (\text{numbins} - 1)$ .
- weights** [array\_like, optional] The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

#### Returns

**cumcount** [ndarray] Binned values of cumulative frequency.  
**lowerlimit** [float] Lower real limit  
**binsize** [float] Width of each bin.  
**extrapoints** [int] Extra points.

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from numpy.random import default_rng
>>> from scipy import stats
>>> rng = default_rng()
>>> x = [1, 4, 2, 1, 3, 1]
>>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
>>> res.cumcount
array([1., 2., 3., 3.])
>>> res.extrapoints
3
```

Create a normal distribution with 1000 random values

```
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate cumulative frequencies

```
>>> res = stats.cumfreq(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size,
... res.cumcount.size)
```

Plot histogram and cumulative histogram

```
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

### scipy.stats.itemfreq

`scipy.stats.itemfreq(*args, **kwargs)`

*itemfreq* is deprecated! *itemfreq* is deprecated and will be removed in a future version. Use instead `np.unique(..., return_counts=True)`

Return a 2-D array of item frequencies.

#### Parameters

**a** [(N,) array\_like] Input array.

#### Returns

**itemfreq** [(K, 2) ndarray] A 2-D frequency table. Column 1 contains sorted, unique values from *a*, column 2 contains their respective counts.

### Examples

```
>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
array([[0., 2.],
 [1., 4.],
 [2., 2.],
 [4., 1.],
 [5., 1.]])
>>> np.bincount(a)
array([2, 4, 2, 0, 1, 1])
```

```
>>> stats.itemfreq(a/10.)
array([[0. , 2.],
 [0.1, 4.],
 [0.2, 2.],
 [0.4, 1.],
 [0.5, 1.]])
```

### scipy.stats.percentileofscore

`scipy.stats.percentileofscore` (*a*, *score*, *kind*='rank')

Compute the percentile rank of a score relative to a list of scores.

A *percentileofscore* of, for example, 80% means that 80% of the scores in *a* are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, *kind*.

#### Parameters

- |              |                                                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>a</b>     | [array_like] Array of scores to which <i>score</i> is compared.                                                                                              |
| <b>score</b> | [int or float] Score that is compared to the elements in <i>a</i> .                                                                                          |
| <b>kind</b>  | [{'rank', 'weak', 'strict', 'mean'}, optional] Specifies the interpretation of the resulting score. The following options are available (default is 'rank'): |
- 'rank': Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores.
  - 'weak': This kind corresponds to the definition of a cumulative distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score.
  - 'strict': Similar to "weak", except that only values that are strictly less than the given score are counted.
  - 'mean': The average of the "weak" and "strict" scores, often used in testing. See [https://en.wikipedia.org/wiki/Percentile\\_rank](https://en.wikipedia.org/wiki/Percentile_rank)

#### Returns

- |             |                                                                     |
|-------------|---------------------------------------------------------------------|
| <b>pcos</b> | [float] Percentile-position of score (0-100) relative to <i>a</i> . |
|-------------|---------------------------------------------------------------------|

See also:

[\*numpy.percentile\*](#)

### Examples

Three-quarters of the given values lie below a given score:

```
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='strict')
40.0
```

But 4/5 values are less than or equal to 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='mean')
60.0
```

### scipy.stats.scoreatpercentile

`scipy.stats.scoreatpercentile` (*a*, *per*, *limit*=(), *interpolation\_method*='fraction', *axis*=None)

Calculate the score at a given percentile of the input sequence.

For example, the score at *per*=50 is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of *interpolation*. If the parameter *limit* is provided, it should be a tuple (lower, upper) of two values.

#### Parameters

- a** [array\_like] A 1-D array of values from which to extract score.
- per** [array\_like] Percentile(s) at which to extract score. Values should be in range [0,100].
- limit** [tuple, optional] Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of *a* outside this (closed) interval will be ignored.
- interpolation\_method** [{"fraction", "lower", "higher"}, optional] Specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*. The following options are available (default is "fraction"):
  - "fraction":  $i + (j - i) * \text{fraction}$  where *fraction* is the fractional part of the index surrounded by *i* and *j*
  - "lower": *i*
  - "higher": *j*
- axis** [int, optional] Axis along which the percentiles are computed. Default is None. If None, compute over the whole array *a*.

#### Returns

- score** [float or ndarray] Score at percentile(s).

[percentileofscore](#), [numpy.percentile](#)

### Notes

This function will become obsolete in the future. For NumPy 1.9 and higher, `numpy.percentile` provides all the functionality that `scoreatpercentile` provides. And it's significantly faster. Therefore it's recommended to use `numpy.percentile` for users that have `numpy >= 1.9`.

### Examples

```
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```

**scipy.stats.relfreq**

`scipy.stats.relfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.

**Parameters**

- a** [array\_like] Input array.
- numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\min() - s, a.\max() + s)$ , where  $s = (1/2)(a.\max() - a.\min()) / (\text{numbins} - 1)$ .
- weights** [array\_like, optional] The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

**Returns**

- frequency** [ndarray] Binned values of relative frequency.
- lowerlimit** [float] Lower real limit.
- binsize** [float] Width of each bin.
- extrapoints** [int] Extra points.

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from numpy.random import default_rng
>>> from scipy import stats
>>> rng = default_rng()
>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfreq(a, numbins=4)
>>> res.frequency
array([0.16666667, 0.5 , 0.16666667, 0.16666667])
>>> np.sum(res.frequency) # relative frequencies should add up to 1
1.0
```

Create a normal distribution with 1000 random values

```
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate relative frequencies

```
>>> res = stats.relfreq(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size,
... res.frequency.size)
```

Plot relative frequency histogram

```
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.binsize)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

|                                                            |                                                                        |
|------------------------------------------------------------|------------------------------------------------------------------------|
| <code>binned_statistic(x, values[, statistic, ...])</code> | Compute a binned statistic for one or more sets of data.               |
| <code>binned_statistic_2d(x, y, values[, ...])</code>      | Compute a bidimensional binned statistic for one or more sets of data. |

### scipy.stats.binned\_statistic

`scipy.stats.binned_statistic(x, values, statistic='mean', bins=10, range=None)`

Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

#### Parameters

- x** [(N,) array\_like] A sequence of values to be binned.
- values** [(N,) array\_like or list of (N,) array\_like] The data on which the statistic will be computed. This must be the same shape as *x*, or a set of sequences - each the same shape as *x*. If *values*

is a set of sequences, the statistic will be computed on each independently.

**statistic** [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:

- 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- 'std': compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`.
- 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.
- 'count': compute the count of points within each bin. This is identical to an unweighted histogram. `values` array is not referenced.
- 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.
- 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.

**bins** [int or sequence of scalars, optional] If `bins` is an int, it defines the number of equal-width bins in the given range (10 by default). If `bins` is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in `x` that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to `bins[-1]`. If the bin edges are specified, the number of bins will be,  $(n_x = \text{len}(\text{bins}) - 1)$ .

**range** [(float, float) or [(float, float)], optional] The lower and upper range of the bins. If not provided, range is simply  $(x.\text{min}(), x.\text{max}())$ . Values outside the range are ignored.

**Returns**

**statistic** [array] The values of the selected statistic in each bin.

**bin\_edges** [array of dtype float] Return the bin edges  $(\text{length}(\text{statistic}) + 1)$ .

**binnumber: 1-D ndarray of ints**  
Indices of the bins (corresponding to `bin_edges`) in which each value of `x` belongs. Same length as `values`. A binnumber of `i` means the corresponding value is between  $(\text{bin\_edges}[i - 1], \text{bin\_edges}[i])$ .

**See also:**

`numpy.digitize`, `numpy.histogram`, `binned_statistic_2d`, `binned_statistic_dd`

**Notes**

All but the last (righthand-most) bin is half-open. In other words, if `bins` is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which includes 4.

New in version 0.11.0.

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

First some basic examples:

Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```
>>> values = [1.0, 1.0, 2.0, 1.5, 3.0]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
BinnedStatisticResult(statistic=array([4. , 4.5]),
 bin_edges=array([1., 4., 7.]), binnumber=array([1, 1, 1, 2, 2]))
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```
>>> values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
BinnedStatisticResult(statistic=array([[4. , 4.5],
 [8. , 9.]]), bin_edges=array([1., 4., 7.]),
 binnumber=array([1, 1, 1, 2, 2]))
```

```
>>> stats.binned_statistic([1, 2, 1, 2, 4], np.arange(5), statistic='mean',
↳',
... bins=3)
BinnedStatisticResult(statistic=array([1., 2., 4.]),
 bin_edges=array([1., 2., 3., 4.]),
 binnumber=array([1, 2, 1, 2, 3]))
```

As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```
>>> rng = np.random.default_rng()
>>> windspeed = 8 * rng.random(500)
>>> boatspeed = .3 * windspeed**.5 + .2 * rng.random(500)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed,
... boatspeed, statistic='median', bins=[1,2,3,4,5,6,7])
>>> plt.figure()
>>> plt.plot(windspeed, boatspeed, 'b.', label='raw data')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=5,
... label='binned statistic of data')
>>> plt.legend()
```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

```
>>> low_boatspeed = boatspeed[binnumber == 0]
```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```
>>> x = np.linspace(0, 5, num=500)
>>> x_pdf = stats.maxwell.pdf(x)
>>> samples = stats.maxwell.rvs(size=10000)
```

```
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf,
... statistic='mean', bins=25)
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2
```

```
>>> plt.figure()
>>> plt.hist(samples, bins=50, density=True, histtype='stepfilled',
... alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
... label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()
```

**scipy.stats.binned\_statistic\_2d**

`scipy.stats.binned_statistic_2d(x, y, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)`

Compute a bidimensional binned statistic for one or more sets of data.

This is a generalization of a `histogram2d` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters**

- x** [(N,) array\_like] A sequence of values to be binned along the first dimension.
- y** [(N,) array\_like] A sequence of values to be binned along the second dimension.
- values** [(N,) array\_like or list of (N,) array\_like] The data on which the statistic will be computed. This must be the same shape as *x*, or a list of sequences - each with the same shape as *x*. If *values* is such a list, the statistic will be computed on each independently.
- statistic** [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
- 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - 'std': compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`.
  - 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - 'count': compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
  - 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.
- bins** [int or [int, int] or array\_like or [array, array], optional] The bin specification:
- the number of bins for the two dimensions (`nx = ny = bins`),
  - the number of bins in each dimension (`nx, ny = bins`),
  - the bin edges for the two dimensions (`x_edge = y_edge = bins`),
  - the bin edges in each dimension (`x_edge, y_edge = bins`).
- If the bin edges are specified, the number of bins will be, (`nx = len(x_edge)-1`, `ny = len(y_edge)-1`).
- range** [(2,2) array\_like, optional] The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the *bins* parameters): `[[xmin, xmax], [ymin, ymax]]`. All values outside of this range will be considered outliers and not tallied in the histogram.
- expand\_binnumbers** [bool, optional] 'False' (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. 'True': the returned *binnumber* is 'unraveled' into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section.
- New in version 0.17.0.
- Returns**
- statistic** [(nx, ny) ndarray] The values of the selected statistic in each two-dimensional bin.
- x\_edge** [(nx + 1) ndarray] The bin edges along the first dimension.

**y\_edge** [(ny + 1) ndarray] The bin edges along the second dimension.

**binnumber** [(N,) array of ints or (2,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

**See also:**

`numpy.digitize`, `numpy.histogram2d`, `binned_statistic`, `binned_statistic_dd`

## Notes

**Binedges:** All but the last (righthand-most) bin is half-open. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which *includes* 4.

**binnumber:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (D\_edge[i-1], D\_edge[i]), where 'D' is either 'x' or 'y'.

New in version 0.11.0.

## Examples

```
>>> from scipy import stats
```

Calculate the counts with explicit bin-edges:

```
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,
↳biny])
>>> ret.statistic
array([[2., 1.],
 [1., 0.]])
```

The bin in which each sample is placed is given by the *binnumber* returned parameter. By default, these are the linearized bin indices:

```
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the *expand\_binnumbers* parameter:

```
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,
↳biny],
... expand_binnumbers=True)
```

(continues on next page)

```
>>> ret.binnumber
array([[1, 1, 1, 2],
 [1, 2, 1, 1]])
```

Which shows that the first three elements belong in the xbin 1, and the fourth into xbin 2; and so on for y.

### scipy.stats.binned\_statistic\_dd

`scipy.stats.binned_statistic_dd`(*sample*, *values*, *statistic*='mean', *bins*=10, *range*=None, *expand\_binnumbers*=False, *binned\_statistic\_result*=None)

Compute a multidimensional binned statistic for a set of data.

This is a generalization of a histogramdd function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

#### Parameters

- |                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sample</b>            | [array_like] Data to histogram passed as a sequence of N arrays of length D, or as an (N,D) array.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>values</b>            | [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as <i>sample</i> , or a list of sequences - each with the same shape as <i>sample</i> . If <i>values</i> is such a list, the statistic will be computed on each independently.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>statistic</b>         | [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available: <ul style="list-style-type: none"> <li>• 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'count': compute the count of points within each bin. This is identical to an unweighted histogram. <i>values</i> array is not referenced.</li> <li>• 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.</li> <li>• 'std': compute the standard deviation within each bin. This is implicitly calculated with <code>ddof=0</code>. If the number of values within a given bin is 0 or 1, the computed standard deviation value will be 0 for the bin.</li> <li>• 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.</li> <li>• function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by <code>function([])</code>, or NaN if this returns an error.</li> </ul> |
| <b>bins</b>              | [sequence or positive int, optional] The bin specification must be in one of the following forms: <ul style="list-style-type: none"> <li>• A sequence of arrays describing the bin edges along each dimension.</li> <li>• The number of bins for each dimension (<code>nx, ny, ... = bins</code>).</li> <li>• The number of bins for all dimensions (<code>nx = ny = ... = bins</code>).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>range</b>             | [sequence, optional] A sequence of lower and upper bin edges to be used if the edges are not given explicitly in <i>bins</i> . Defaults to the minimum and maximum values along each dimension.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>expand_binnumbers</b> | [bool, optional] 'False' (default): the returned <i>binnumber</i> is a shape (N,) array of linearized bin indices. 'True': the returned <i>binnumber</i> is 'unraveled' into a shape (D,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the <i>binnumber</i> returned value, and the <i>Examples</i> section of <code>binned_statistic_2d</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**binned\_statistic\_result**

[`binnedStatisticddResult`] Result of a previous call to the function in order to reuse bin edges and bin numbers with new values and/or a different statistic. To reuse bin numbers, `expand_binnumbers` must have been set to `False` (the default)  
New in version 0.17.0.

**Returns**

**statistic** [ndarray, shape(nx1, nx2, nx3,...)] The values of the selected statistic in each two-dimensional bin.  
**bin\_edges** [list of ndarrays] A list of  $D$  arrays describing the  $(n_x + 1)$  bin edges for each dimension.  
**binnumber** [(N,) array of ints or (D,N) ndarray of ints] This assigns to each element of `sample` an integer that represents the bin in which this observation falls. The representation depends on the `expand_binnumbers` argument. See *Notes* for details.

**See also:**

`numpy.digitize`, `numpy.histogramdd`, `binned_statistic`, `binned_statistic_2d`

**Notes**

**Binedges:** All but the last (righthand-most) bin is half-open in each dimension. In other words, if `bins` is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which *includes* 4.

**binnumber:** This returned argument assigns to each element of `sample` an integer that represents the bin in which it belongs. The representation depends on the `expand_binnumbers` argument. If `'False'` (default): The returned `binnumber` is a shape  $(N,)$  array of linearized indices mapping each element of `sample` to its corresponding bin (using row-major ordering). If `'True'`: The returned `binnumber` is a shape  $(D,N)$  ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of  $i$  means the corresponding value is between `(bin_edges[D][i-1], bin_edges[D][i])`, for each dimension 'D'.

New in version 0.11.0.

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D
```

Take an array of 600  $(x, y)$  coordinates as an example. `binned_statistic_dd` can handle arrays of higher dimension  $D$ . But a plot of dimension  $D+1$  is required.

```
>>> mu = np.array([0., 1.])
>>> sigma = np.array([[1., -0.5], [-0.5, 1.5]])
>>> multinormal = stats.multivariate_normal(mu, sigma)
>>> data = multinormal.rvs(size=600, random_state=235412)
>>> data.shape
(600, 2)
```

Create bins and count how many arrays fall in each bin:

```

>>> N = 60
>>> x = np.linspace(-3, 3, N)
>>> y = np.linspace(-3, 4, N)
>>> ret = stats.binned_statistic_dd(data, np.arange(600), bins=[x, y],
... statistic='count')
>>> bincounts = ret.statistic

```

Set the volume and the location of bars:

```

>>> dx = x[1] - x[0]
>>> dy = y[1] - y[0]
>>> x, y = np.meshgrid(x[:-1]+dx/2, y[:-1]+dy/2)
>>> z = 0

```

```

>>> bincounts = bincounts.ravel()
>>> x = x.ravel()
>>> y = y.ravel()

```

```

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> with np.errstate(divide='ignore'): # silence random axes3d warning
... ax.bar3d(x, y, z, dx, dy, bincounts)

```

Reuse bin numbers and bin edges with new values:

```

>>> ret2 = stats.binned_statistic_dd(data, -np.arange(600),
... binned_statistic_result=ret,
... statistic='mean')

```

## Correlation functions

## scipy.stats.f\_oneway

`scipy.stats.f_oneway(*args, axis=0)`  
Perform one-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The test is applied to samples from two or more groups, possibly with differing sizes.

### Parameters

#### sample1, sample2, ...

[array\_like] The sample measurements for each group. There must be at least two arguments. If the arrays are multidimensional, then all the dimensions of the array must be the same except for *axis*.

**axis** [int, optional] Axis of the input arrays along which the test is applied. Default is 0.

### Returns

**statistic** [float] The computed F statistic of the test.

**pvalue** [float] The associated p-value from the F distribution.

### Warns

#### F\_onewayConstantInputWarning

Raised if each of the input arrays is constant array. In this case the F statistic is either infinite or isn't defined, so `np.inf` or `np.nan` is returned.

#### F\_onewayBadInputSizesWarning

Raised if the length of any input array is 0, or if all the input arrays have length 1. `np.nan` is returned for the F statistic and the p-value in these cases.

## Notes

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test (`scipy.stats.kruskal`) or the Alexander-Govern test (`scipy.stats.alexandergovern`) although with some loss of power.

The length of each group must be at least one, and there must be at least one group with length greater than one. If these conditions are not satisfied, a warning is generated and `(np.nan, np.nan)` is returned.

If each group contains constant values, and there exist at least two groups with different values, the function generates a warning and returns `(np.inf, 0)`.

If all values in all groups are the same, function generates a warning and returns `(np.nan, np.nan)`.

The algorithm is from Heiman [2], pp.394-7.

## Examples

```
>>> from scipy.stats import f_oneway
```

Here are some data [3] on a shell measurement (the length of the anterior adductor muscle scar, standardized by dividing by length) in the mussel *Mytilus trossulus* from five locations: Tillamook, Oregon; Newport, Oregon; Petersburg, Alaska; Magadan, Russia; and Tvarminne, Finland, taken from a much larger data set used in McDonald et al. (1991).

```
>>> tillamook = [0.0571, 0.0813, 0.0831, 0.0976, 0.0817, 0.0859, 0.0735,
... 0.0659, 0.0923, 0.0836]
>>> newport = [0.0873, 0.0662, 0.0672, 0.0819, 0.0749, 0.0649, 0.0835,
... 0.0725]
>>> petersburg = [0.0974, 0.1352, 0.0817, 0.1016, 0.0968, 0.1064, 0.105]
>>> magadan = [0.1033, 0.0915, 0.0781, 0.0685, 0.0677, 0.0697, 0.0764,
... 0.0689]
>>> tvarminne = [0.0703, 0.1026, 0.0956, 0.0973, 0.1039, 0.1045]
>>> f_oneway(tillamook, newport, petersburg, magadan, tvarminne)
F_onewayResult(statistic=7.121019471642447, pvalue=0.0002812242314534544)
```

`f_oneway` accepts multidimensional input arrays. When the inputs are multidimensional and `axis` is not given, the test is performed along the first axis of the input arrays. For the following data, the test is performed three times, once for each column.

```
>>> a = np.array([[9.87, 9.03, 6.81],
... [7.18, 8.35, 7.00],
... [8.39, 7.58, 7.68],
... [7.45, 6.33, 9.35],
```

(continues on next page)

(continued from previous page)

```

... [6.41, 7.10, 9.33],
... [8.00, 8.24, 8.44]])
>>> b = np.array([[6.35, 7.30, 7.16],
... [6.65, 6.68, 7.63],
... [5.72, 7.73, 6.72],
... [7.01, 9.19, 7.41],
... [7.75, 7.87, 8.30],
... [6.90, 7.97, 6.97]])
>>> c = np.array([[3.31, 8.77, 1.01],
... [8.25, 3.24, 3.62],
... [6.32, 8.81, 5.19],
... [7.48, 8.83, 8.91],
... [8.59, 6.01, 6.07],
... [3.07, 9.72, 7.48]])
>>> F, p = f_oneway(a, b, c)
>>> F
array([1.75676344, 0.03701228, 3.76439349])
>>> p
array([0.20630784, 0.96375203, 0.04733157])

```

### scipy.stats.alexandergovern

`scipy.stats.alexandergovern(*args, nan_policy='propagate')`

Performs the Alexander Govern test.

The Alexander-Govern approximation tests the equality of  $k$  independent means in the face of heterogeneity of variance. The test is applied to samples from two or more groups, possibly with differing sizes.

#### Parameters

**sample1, sample2, ...**

[array\_like] The sample measurements for each group. There must be at least two samples.

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

#### Returns

**statistic** [float] The computed A statistic of the test.

**pvalue** [float] The associated p-value from the chi-squared distribution.

#### Warns

**AlexanderGovernConstantInputWarning**

Raised if an input is a constant array. The statistic is not defined in this case, so `np.nan` is returned.

See also:

[f\\_oneway](#)

one-way ANOVA

## Notes

The use of this test relies on several assumptions.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. Unlike `f_oneway`, this test does not assume on homoscedasticity, instead relaxing the assumption of equal variances.

Input samples must be finite, one dimensional, and with size greater than one.

## References

[1]

## Examples

```
>>> from scipy.stats import alexandergovern
```

Here are some data on annual percentage rate of interest charged on new car loans at nine of the largest banks in four American cities taken from the National Institute of Standards and Technology's ANOVA dataset.

We use `alexandergovern` to test the null hypothesis that all cities have the same mean APR against the alternative that the cities do not all have the same mean APR. We decide that a significance level of 5% is required to reject the null hypothesis in favor of the alternative.

```
>>> atlanta = [13.75, 13.75, 13.5, 13.5, 13.0, 13.0, 13.0, 12.75, 12.5]
>>> chicago = [14.25, 13.0, 12.75, 12.5, 12.5, 12.4, 12.3, 11.9, 11.9]
>>> houston = [14.0, 14.0, 13.51, 13.5, 13.5, 13.25, 13.0, 12.5, 12.5]
>>> memphis = [15.0, 14.0, 13.75, 13.59, 13.25, 12.97, 12.5, 12.25,
... 11.89]
>>> alexandergovern(atlanta, chicago, houston, memphis)
AlexanderGovernResult(statistic=4.65087071883494,
 pvalue=0.19922132490385214)
```

The p-value is 0.1992, indicating a nearly 20% chance of observing such an extreme value of the test statistic under the null hypothesis. This exceeds 5%, so we do not reject the null hypothesis in favor of the alternative.

## scipy.stats.pearsonr

`scipy.stats.pearsonr(x, y)`

Pearson correlation coefficient and p-value for testing non-correlation.

The Pearson correlation coefficient [1] measures the linear relationship between two datasets. The calculation of the p-value relies on the assumption that each dataset is normally distributed. (See Kowalski [3] for a discussion of the effects of non-normality of the input on the distribution of the correlation coefficient.) Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as x increases, so does y. Negative correlations imply that as x increases, y decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets.

### *Parameters*

**x** [(N,) array\_like] Input array.  
**y** [(N,) array\_like] Input array.

**Returns**

**r** [float] Pearson's correlation coefficient.  
**p-value** [float] Two-tailed p-value.

**Warns****PearsonRConstantInputWarning**

Raised if an input is a constant array. The correlation coefficient is not defined in this case, so `np.nan` is returned.

**PearsonRNearConstantInputWarning**

Raised if an input is "nearly" constant. The array `x` is considered nearly constant if `norm(x - mean(x)) < 1e-13 * abs(mean(x))`. Numerical errors in the calculation `x - mean(x)` in this case might result in an inaccurate calculation of `r`.

**See also:****[spearmanr](#)**

Spearman rank-order correlation coefficient.

**[kendalltau](#)**

Kendall's tau, a correlation measure for ordinal data.

**Notes**

The correlation coefficient is calculated as follows:

$$r = \frac{\sum(x - m_x)(y - m_y)}{\sqrt{\sum(x - m_x)^2 \sum(y - m_y)^2}}$$

where  $m_x$  is the mean of the vector  $x$  and  $m_y$  is the mean of the vector  $y$ .

Under the assumption that  $x$  and  $m_y$  are drawn from independent normal distributions (so the population correlation coefficient is 0), the probability density function of the sample correlation coefficient  $r$  is ([1], [2]):

$$f(r) = \frac{(1 - r^2)^{n/2-2}}{B(\frac{1}{2}, \frac{n}{2} - 1)}$$

where  $n$  is the number of samples, and  $B$  is the beta function. This is sometimes referred to as the exact distribution of  $r$ . This is the distribution that is used in `pearsonr` to compute the p-value. The distribution is a beta distribution on the interval  $[-1, 1]$ , with equal shape parameters  $a = b = n/2 - 1$ . In terms of SciPy's implementation of the beta distribution, the distribution of  $r$  is:

```
dist = scipy.stats.beta(n/2 - 1, n/2 - 1, loc=-1, scale=2)
```

The p-value returned by `pearsonr` is a two-sided p-value. For a given sample with correlation coefficient  $r$ , the p-value is the probability that  $\text{abs}(r')$  of a random sample  $x'$  and  $y'$  drawn from the population with zero correlation would be greater than or equal to  $\text{abs}(r)$ . In terms of the object `dist` shown above, the p-value for a given  $r$  and length  $n$  can be computed as:

```
p = 2*dist.cdf(-abs(r))
```

When  $n$  is 2, the above continuous distribution is not well-defined. One can interpret the limit of the beta distribution as the shape parameters  $a$  and  $b$  approach  $a = b = 0$  as a discrete distribution with equal probability masses at  $r = 1$  and  $r = -1$ . More directly, one can observe that, given the data  $x = [x_1, x_2]$  and  $y = [y_1, y_2]$ , and assuming  $x_1 \neq x_2$  and  $y_1 \neq y_2$ , the only possible values for  $r$  are 1 and -1. Because  $\text{abs}(r')$  for any sample  $x'$  and  $y'$  with length 2 will be 1, the two-sided p-value for a sample of length 2 is always 1.

## Examples

```
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pearsonr(a, b)
(0.8660254037844386, 0.011724811003954649)
```

```
>>> stats.pearsonr([1, 2, 3, 4, 5], [10, 9, 2.5, 6, 4])
(-0.7426106572325057, 0.1505558088534455)
```

## scipy.stats.spearmanr

`scipy.stats.spearmanr` (*a*, *b=None*, *axis=0*, *nan\_policy='propagate'*, *alternative='two-sided'*)

Calculate a Spearman correlation coefficient with associated p-value.

The Spearman rank-order correlation coefficient is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

### Parameters

- a, b** [1D or 2D array\_like, *b* is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under `axis`, below. Both arrays need to have the same length in the `axis` dimension.
- axis** [int or None, optional] If `axis=0` (default), then each column represents a variable, with observations in the rows. If `axis=1`, the relationship is transposed: each row represents a variable, while the columns contain observations. If `axis=None`, then both arrays will be raveled.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
  - 'propagate': returns nan
  - 'raise': throws an error
  - 'omit': performs the calculations ignoring nan values

**alternative**

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available:

- 'two-sided': the correlation is nonzero
- 'less': the correlation is negative (less than zero)
- 'greater': the correlation is positive (greater than zero)

New in version 1.7.0.

**Returns****correlation**

[float or ndarray (2-D square)] Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters. Correlation matrix is square with length equal to total number of variables (columns or rows) in *a* and *b* combined.

**pvalue**

[float] The p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated. See *alternative* above for alternative hypotheses. *pvalue* has the same shape as *correlation*.

```

### scipy.stats.pointbiserialr

`scipy.stats.pointbiserialr(x, y)`

Calculate a point biserial correlation coefficient and its p-value.

The point biserial correlation is used to measure the relationship between a binary variable,  $x$ , and a continuous variable,  $y$ . Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a determinative relationship.

This function uses a shortcut formula but produces the same result as `pearsonr`.

#### Parameters

**x** [array\_like of bools] Input array.  
**y** [array\_like] Input array.

#### Returns

**correlation** [float] R value.  
**pvalue** [float] Two-sided p-value.

### Notes

`pointbiserialr` uses a t-test with  $n-1$  degrees of freedom. It is equivalent to `pearsonr`.

The value of the point-biserial correlation can be calculated from:

$$r_{pb} = \frac{\bar{Y}_1 - \bar{Y}_0}{s_y} \sqrt{\frac{N_1 N_2}{N(N-1)}}$$

Where  $Y_0$  and  $Y_1$  are means of the metric observations coded 0 and 1 respectively;  $N_0$  and  $N_1$  are number of observations coded 0 and 1 respectively;  $N$  is the total number of observations and  $s_y$  is the standard deviation of all the metric observations.

A value of  $r_{pb}$  that is significantly different from zero is completely equivalent to a significant difference in means between the two groups. Thus, an independent groups t Test with  $N - 2$  degrees of freedom may be used to test whether  $r_{pb}$  is nonzero. The relation between the t-statistic for comparing two independent groups and  $r_{pb}$  is given by:

$$t = \sqrt{N-2} \frac{r_{pb}}{\sqrt{1-r_{pb}^2}}$$

## Examples

```
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pointbiserialr(a, b)
(0.8660254037844386, 0.011724811003954652)
>>> stats.pearsonr(a, b)
(0.86602540378443871, 0.011724811003954626)
>>> np.corrcoef(a, b)
array([[1. , 0.8660254],
 [0.8660254, 1.]])
```

### scipy.stats.kendalltau

`scipy.stats.kendalltau(x, y, initial_lexsort=None, nan_policy='propagate', method='auto', variant='b')`

Calculate Kendall's tau, a correlation measure for ordinal data.

Kendall's tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, and values close to -1 indicate strong disagreement. This implements two variants of Kendall's tau: tau-b (the default) and tau-c (also known as Stuart's tau-c). These differ only in how they are normalized to lie within the range -1 to 1; the hypothesis tests (their p-values) are identical. Kendall's original tau-a is not implemented separately because both tau-b and tau-c reduce to tau-a in the absence of ties.

#### Parameters

- x, y** [array\_like] Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.
- initial\_lexsort** [bool, optional] Unused (deprecated).
- nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is "propagate"):
  - "propagate": returns nan
  - "raise": throws an error
  - "omit": performs the calculations ignoring nan values
- method** [{"auto", "asymptotic", "exact"}, optional] Defines which method is used to calculate the p-value [5]. The following options are available (default is "auto"):
  - "auto": selects the appropriate method based on a trade-off between speed and accuracy
  - "asymptotic": uses a normal approximation valid for large samples
  - "exact": computes the exact p-value, but can only be used if no ties are present. As the sample size increases, the "exact" computation time may grow and the result may lose some precision.
- variant: {'b', 'c'}, optional** Defines which variant of Kendall's tau is returned. Default is 'b'.

#### Returns

- correlation** [float] The tau statistic.

**pvalue** [float] The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association,  $\tau = 0$ .
