Most benchmarks are built using one or more types of
profile-driven feedback.  The types used are designated
by abbreviations in the notes:

+CFB: Code generation is optimized by the compiler, using
      feedback from a training run.  These commands are
      done before the first compile (in phase "fdo_pre0"):

           mkdir /tmp/pp
           rm -f /tmp/pp/${baseexe}*

      and these flags are added to the first and second compiles:

           PASS1_CFLAGS = -prof_gen_noopt -prof_dir /tmp/pp
           PASS2_CFLAGS = -prof_use       -prof_dir /tmp/pp

     (Peak builds use /tmp/pp above; base builds use /tmp/pb.)

+IFB: Icache usage is improved by the post-link-time optimizer
      Spike, using feedback from a training run.  These commands
      are used (in phase "fdo_postN"):

           mv ${baseexe} oldexe
```

Notes/Tuning Information (Continued)

```
            spike oldexe -feedback oldexe -o ${baseexe}

    +PFB: Prefetches are improved by the post-link-time optimizer
          Spike, using feedback from a training run.  These
          commands are used (in phase "fdo_post_makeN"):

               rm -f *Counts*
               mv ${baseexe} oldexe
               pixie -stats dstride oldexe 1>pixie.out 2>pixie.err
               mv oldexe.pixie ${baseexe}

          A training run is carried out (in phase "fdo_runN"), and
          then this command (in phase "fdo_postN"):

               spike oldexe -fb oldexe -stride_prefetch -o ${baseexe}

    When Spike is used for both Icache and Prefetch improvements,
    only one spike command is actually issued, with the Icache
    options followed by the Prefetch options.
